**Compound operations for numbers**

You can configure compound numeric expressions. For example, the following expression returns a numeric value that is the sum of an HTTP header length and a URL length:

`http.req.header.length + http.req.url.length`

The following tables describes operators that you can use to configure compound expressions for numeric data.

<table>
<thead>
<tr>
<th>Arithmetic operations</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>num + num</code></td>
<td>Add the value of the expression on the left of the operator to the value of the expression on the right. Following is an example: <code>http.req.content_length + http.req.url.length</code></td>
</tr>
<tr>
<td><code>num – num</code></td>
<td>Subtract the value of the expression on the right of the operator from the value of the expression on the left.</td>
</tr>
<tr>
<td><code>num * num</code></td>
<td>Multiply the value of the expression on the left of the operator with the value of the expression on the right. Following is an example: <code>client.interface.rxthroughput * 9</code></td>
</tr>
<tr>
<td><code>num / num</code></td>
<td>Divide the value of the expression on the left of the operator by the value of the expression on the right.</td>
</tr>
<tr>
<td>Arithmetic operations on numbers</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>num % num</td>
<td>Calculate the modulo, or the numeric remainder on a division of the value of the expression on the left of the operator by the value of the expression on the right. For example, the values “15 mod 4” equals 3, and “12 mod 4” equals 0.</td>
</tr>
<tr>
<td>~number</td>
<td>Returns a number after applying a bitwise logical negation of the number. The following example assumes that numeric.expression returns 12 (binary 1100): ~numeric.expression. The result of applying the ~ operator is -11 (a binary 1110011, 32 bits total with all ones to the left). Note that all returned values of less than 32 bits before applying the operator implicitly have zeros to the left to make them 32 bits wide.</td>

</tr>
</tbody>
</table>

**Functions for data types in the policy infrastructure**

The NetScaler policy infrastructure supports the following numeric data types:

- Integer (32 bits)
- Unsigned long (64 bits)
- Double (64 bits)

Simple expressions can return all of these data types. Therefore, you can create compound expressions that use arithmetic operators and logical operators to evaluate or return values of these data types. Additionally, you can use all of these values in policy expressions. Literal constants of type unsigned long can be specified by appending the string ul to the number. Literal constants of type double contain a period (.), an exponent, or both.

**Arithmetic Operators, Logical Operators, and Type Promotion**

In compound expressions, the following standard arithmetic and logical operators can be used for the double and unsigned long data types:

- +, -, *, and /
All of these operators have the same meaning as in the C programming language.

In all cases of mixed operations between operands of type integer, unsigned long, and double, type promotion is performed so that the operation can be performed on operands of the same type. A type of lower precedence is automatically promoted to the type of the operand with the highest precedence involved in the operation. The order of precedence (higher to lower) is as follows:

- Double
- Unsigned long
- Integer

Therefore, an operation that returns a numeric result returns a result of the highest type involved in the operation.

For example, if the operands are of type integer and unsigned long, the integer operand is automatically converted to type unsigned long. This type conversion is performed even in simple expressions in which the type of data identified by the expression prefix does not match the type of data that is passed as the argument to the function. To illustrate such an example, in the operation HTTP.REQ.CONTENT_LENGTH.DIV(3ul), the integer returned by the prefix HTTP.REQ.CONTENT_LENGTH is automatically converted to unsigned long (the type of the data passed as the argument to the DIV() function), and an unsigned long division is performed. Similarly, the argument can be promoted in an expression. For example, HTTP.REQ.HEADER("myHeader").TYPECAST_DOUBLE_AT.DIV(5) promotes the integer 5 to type double and performs double-precision division.

For information about expressions for casting data of one type to data of another type, see Typecasting data.

Specify the character set in expressions

September 24, 2018

The policy infrastructure on the Citrix® NetScaler® appliance supports the ASCII and UTF-8 character sets. The default character set is ASCII. If the traffic for which you are configuring an expression consists of only ASCII characters, you need not specify the character set in the expression. However, you must specify the character set in every simple expression that is meant for UTF-8 traffic. To specify the
UTF-8 character set in a simple expression, you must include the SET_CHAR_SET(<charset>) function, with <charset> specified as UTF_8, as shown in the following examples:

```plaintext
1 HTTP.REQ.BODY(10).SET_CHAR_SET(UTF_8).CONTAINS("ß")
2 HTTP.RES.BODY(100).SET_CHAR_SET(UTF_8).BEFORE_STR("Bücher").AFTER_STR("Wörterbuch")
```

In an expression, the SET_CHAR_SET() function must be introduced at the point in the expression after which data processing must be carried out in the specified character set. For example, in the expression HTTP.REQ.BODY(1000).AFTER_REGEX(re/following example/).BEFORE_REGEX(re/In the preceding example/).CONTAINS_ANY("Greek_ alphabet"), if the strings stored in the pattern set “Greek_alphabet” are in UTF-8, you must include the SET_CHAR_SET(UTF_8) function immediately before the CONTAINS_ANY("<strings>") function, as follows:

```plaintext
HTTP.REQ.BODY(1000).AFTER_REGEX(re/following example/).BEFORE_REGEX(re/In the preceding example/).SET_CHAR_SET(UTF_8).CONTAINS_ANY("Greek_ alphabet")
```

The SET_CHAR_SET() function sets the character set for all further processing (that is, for all subsequent functions) in the expression unless it is overridden later in the expression by another SET_CHAR_SET() function that changes the character set. Therefore, if all the functions in a given simple expression are intended for UTF-8, you can include the SET_CHAR_SET(UTF_8) function immediately after functions that identify text (for example, the HEADER("<name>") or BODY(<int>) functions). In the second example that follows the first paragraph above, if the ASCII arguments passed to the AFTER_REGEX() and BEFORE_REGEX() functions are changed to UTF-8 strings, you can include the SET_CHAR_SET(UTF_8) function immediately after the BODY(1000) function, as follows:

```plaintext
HTTP.REQ.BODY(1000).SET_CHAR_SET(UTF_8).AFTER_REGEX(re/ Bücher/).BEFORE_REGEX(re/Wörterbuch/).CONTAINS_ANY("Greek_alphabet")
```

The UTF-8 character set is a superset of the ASCII character set, so expressions configured for the ASCII character set continue to work as expected if you change the character set to UTF-8.

**Compound expressions with different character sets**

In a compound expression, if one subset of expressions is configured to work with data in the ASCII character set and the rest of the expressions are configured to work with data in the UTF-8 character set, the character set specified for each individual expression is considered when the expressions are evaluated individually. However, when processing the compound expression, just before processing the operators, the appliance promotes the character set of the returned ASCII values to UTF-8. For example, in the following compound expression, the first simple expression evaluates data in the ASCII character set while the second simple expression evaluates data in the UTF-8 character set:

```plaintext
HTTP.REQ.HEADER("MyHeader") == HTTP.REQ.BODY(10).SET_CHAR_SET(UTF_8)
```
However, when processing the compound expression, just before evaluating the “is equal to” Boolean operator, the NetScaler appliance promotes the character set of the value returned by HTTP.REQ.HEADER("MyHeader") to UTF-8.

The first simple expression in the following example evaluates data in the ASCII character set. However, when the NetScaler appliance processes the compound expression, just before concatenating the results of the two simple expressions, the appliance promotes the character set of the value returned by HTTP.REQ.BODY(10) to UTF-8.

HTTP.REQ.BODY(10)+ HTTP.REQ.HEADER("MyHeader").SET_CHAR_SET(UTF_8)

Consequently, the compound expression returns data in the UTF-8 character set.

**Specify the character set based on the character set of traffic**

You can set the character set to UTF-8 on the basis of traffic characteristics. If you are not sure whether the character set of the traffic being evaluated is UTF-8, you can configure a compound expression in which the first expression checks for UTF-8 traffic and subsequent expressions set the character set to UTF-8. Following is an example of a compound expression that first checks the value of “charset” in the request’s Content-Type header for “UTF-8” before checking whether the first 1000 bytes in the request contain the UTF-8 string Bücher:

HTTP.REQ.HEADER("Content-Type").SET_TEXT_MODE(IGNORECASE).TYPECAST_NVLIST_T("=",";";""").VALUE("charset").EQ("UTF-8") & HTTP.REQ.BODY(1000).SET_CHAR_SET(UTF_8).CONTAINS("Bücher")

If you are sure that the character set of the traffic being evaluated is UTF-8, the second expression in the example is sufficient.

**Character and string literals in expressions**

During expression evaluation, even if the current character set is ASCII, character literals and string literals, which are enclosed in single quotation marks (’’) and quotation marks (""), respectively, are considered to be literals in the UTF-8 character set. In a given expression, if a function is operating on character or string literals in the ASCII character set and you include a non-ASCII character in the literal, an error is returned.

**Values in hexadecimal and octal formats**

When configuring an expression, you can enter values in octal and hexadecimal formats. However, each hexadecimal or octal byte is considered a UTF-8 byte. Invalid UTF-8 bytes result in errors regardless of whether the value is entered manually or pasted from the clipboard. For example, “\xce\x20” is
an invalid UTF-8 character because “c8” cannot be followed by “20” (each byte in a multi-byte UTF-8 string must have the high bit set). Another example of an invalid UTF-8 character is “\xe \xa9,” since the hexadecimal characters are separated by a white-space character.

**Functions that return UTF-8 strings**

Only the

`<text>.XPATH` and

`<text>.XPATH_JSON` functions always return UTF-8 strings. The following MYSQL routines determine at runtime which character set to return, depending on the data in the protocol:

- `MYSQL_CLIENT_T.USER`
- `MYSQL_CLIENT_T.DATABASE`
- `MYSQL_REQ_QUERY_T.COMMAND`
- `MYSQL_REQ_QUERY_T.TEXT`
- `MYSQL_REQ_QUERY_T.TEXT(<unsigned int>)`
- `MYSQL_RES_ERROR_T.SQLSTATE`
- `MYSQL_RES_ERROR_T.MESSAGE`
- `MYSQL_RES_FIELD_T.CATALOG`
- `MYSQL_RES_FIELD_T.DB`
- `MYSQL_RES_FIELD_T.TTABLE`
- `MYSQL_RES_FIELD_T.ORIGINAL_TABLE`
- `MYSQL_RES_FIELD_T.NAME`
- `MYSQL_RES_FIELD_T.ORIGINAL_NAME`
- `MYSQL_RES_OK_T.MESSAGE`
- `MYSQL_RES_ROW_T.TEXT_ELEM(<unsigned int>)`

**Terminal connection settings for UTF-8**

When you set up a connection to the NetScaler appliance by using a terminal connection (by using PuTTY, for example), you must set the character set for transmission of data to UTF-8.

**Classic expressions in advanced policy expressions**

September 24, 2018

**Warning**

Classic policy expressions are no longer supported from NetScaler 12.0 build 56.20 onwards and as an alternative, Citrix recommends you to use Advanced policies. For more information, see
Configure advanced policy expressions: Get started.

Classic expressions describe basic characteristics of traffic. In some cases, you may want to use a classic expression in an Advanced policy expression are no longer supported from NetScaler 12.0 build 56.20 onwards and as an alternative, Citrix recommends you to use Advanced policies. For more information, see Advanced Policies topic. You can do so with the Advanced policy expression configuration tool. This can be helpful when manually migrating the older classic expressions to the Advanced policy.

Note that when you upgrade the NetScaler to version 9.0 or higher, Integrated Caching policies are automatically upgraded to Advanced policies, and the expressions in these policies are upgraded to the Advanced policies.

The following is the syntax for all Advanced policy expressions that use a classic expression:

SYS.EVAL_CLASSIC_EXPR(“expression”)

Note

The syntax and the metadata for the SYS.EVAL_CLASSIC_EXPR expression is getting deprecated. You can manually convert or use nspepi tool to convert the Classic expression to advanced expression.

Following are examples of the SYS.EVAL_CLASSIC_EXPR(“expression”) expression:

```
1 sys.eval_classic_expr("req.ssl.client.cipher.bits > 1000")
2 sys.eval_classic_expr("url contains abc")
3 sys.eval_classic_expr("req.ip.sourceip == 10.102.1.61 -netmask 255.255.255.255")
4 sys.eval_classic_expr("time >= *:30:00GMT")
5 sys.eval_classic_expr("e1 || e2")
6 sys.eval_classic_expr("req.http.urllen > 50")
7 sys.eval_classic_expr("dayofweek == wedGMT")
```

Configure advanced policy expressions in a policy

September 24, 2018

You can configure an Advanced policy expression of up to 1,499 characters in a policy. The user interface for Advanced policy expressions depends to some extent on the feature for which you are configuring the expression, and on whether you are configuring an expression for a policy or for another use.

When configuring expressions on the command line, you delimit the expression by using quotation marks (‘...’ or ‘.”). Within an expression, you escape additional quotation marks by using a
NetScaler 12.0

back-slash (). For example, the following are standard methods for escaping quotation marks in an expression:

"\"abc\\"
\"abc\"

You must also use a backslash to escape question marks and other backslashes on the command line. For example, the expression http.req.url.contains("?") requires a backslash so that the question mark is parsed. Note that the backslash character will not appear on the command line after you type the question mark. On the other hand, if you escape a backslash (for example, in the expression ‘http.req.url.contains("\http")’), the escape characters are echoed on the command line.

To make an entry more readable, you can escape the quotation marks for an entire expression. At the start of the expression you enter the escape sequence “q” plus one of the following special characters: /{<

You enter only the special character at the end of the expression, as follows:

1 q@http.req.url.contains("sometext") && http.req.cookie.exists@
2 q~http.req.url.contains("sometext") && http.req.cookie.exists~

Note that an expression that uses the { delimiter is closed with }.

For some features (for example, Integrated Caching and Responder), the policy configuration dialog box provides a secondary dialog box for configuring expressions. This dialog enables you to choose from drop-down lists that show the available choices at each point during expression configuration. You cannot use arithmetic operators when using these configuration dialogs, but most other advanced policy expression features are available. To use arithmetic operators, write your expressions in free-form format.

**Configure an Advanced policy syntax rule by using the CLI**

**Note:**
Default syntax policy is now renamed as Advanced policy.

At the command prompt, type the following commands to configure a default syntax rule and verify the configuration:

1. add cache|dns|rewrite|cs policy policyName **-rule** expression featureSpecificParameters **-action**
2. `show cache|dns|rewrite|cs policy policyName`

   Following is an example of configuring a caching policy:

   **Example:**

   ```
   > add cache policy pol-cache -rule http.req.content_length.le(5) - 
   > action INVAL
   Done

   > show cache policy pol-cache
   Name: pol-cache
   Rule: http.req.content_length.le(5)
   CacheAction: INVAL
   Invalidate groups: DEFAULT
   UndefAction: Use Global
   Hits: 0
   Undef Hits: 0
   Done
   ```

   **Configure a default syntax policy expression by using the GUI**

   1. In the navigation pane, click the name of the feature where you want to configure a policy, for example, you can select Integrated Caching, Responder, DNS, Rewrite, or Content Switching, and then click **Policies**.

   2. Click **Add**.

   3. For most features, click in the **Expression** field. For content switching, click **Configure**.

   4. Click the **Prefix** icon (the house) and select the first expression prefix from the drop-down list. For example, in Responder, the options are HTTP, SYS, and CLIENT. The next set of applicable options appear in a drop-down list.

   5. Double-click the next option to select it, and then type a period (.) Again, a set of applicable options appears in another drop-down list.

   6. Continue selecting options until an entry field (signalled by parentheses) appears. When you see an entry field, enter an appropriate value in the parentheses. For example, if you select `GT(int)` (greater-than, integer format), you specify an integer in the parentheses. Text strings are delimited by quotation marks. Following is an example:

   ```
   HTTP.REQ.BODY(1000).BETWEEN("this","that")
   ```
To insert an operator between two parts of a compound expression, click the Operators icon (the sigma), and select the operator type. Following is an example of a configured expression with a Boolean OR (signalled by double vertical bars,):

```
7. HTTP.REQ.URL.EQ("www.mycompany.com") || HTTP.REQ.BODY(1000).BETWEEN("this", "that")
```

8. To insert a named expression, click the down arrow next to the Add icon (the plus sign) and select a named expression.

9. To configure an expression using drop-down menus, and to insert built-in expressions, click the Add icon (the plus sign). The Add Expression dialog box works in a similar way to the main dialog box, but it provides drop-down lists for selecting options, and it provides text fields for data entry instead of parentheses. This dialog box also provides a Frequently Used Expressions drop-down list that inserts commonly used expressions. When you are done adding the expression, click OK.

10. When finished, click Create. A message in the status bar indicates that the policy expression is configured successfully.

**Test a default syntax expression by using the GUI**

1. In the navigation pane, click the name of the feature for which you want to configure a policy (for example, you can select Integrated Caching, Responder, DNS, Rewrite, or Content Switching), and then click Policies.
2. Select a policy and click Open.
3. To test the expression, click the Evaluate icon (the check mark).
4. In the expression evaluator dialog box, select the Flow Type that matches the expression.
5. In the HTTP Request Data or HTTP Response Data field, paste the HTTP request or response that you want to parse with the expression, and click Evaluate. Note that you must supply a complete HTTP request or response, and the header and body should be separated by blank line. Some programs that trap HTTP headers do not also trap the response. If you are copying and pasting only the header, insert a blank line at the end of the header to form a complete HTTP request or response.
6. Click **Close** to close this dialog box.

## Configure named advanced policy expressions

**September 24, 2018**

Instead of retyping the same expression multiple times in multiple policies, you can configure a named expression and refer to the name any time you want to use the expression in a policy. For example, you could create the following named expressions:

- **ThisExpression:**
  
  ```
  http.req.body(100).contains("this")
  ```

- **ThatExpression:**
  
  ```
  http.req.body(100).contains("that")
  ```

You can then use these named expressions in a policy expression. For example, the following is a legal expression based on the preceding examples:

<table>
<thead>
<tr>
<th>ThisExpression</th>
<th>ThatExpression</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

You can use the name of an advanced policy expression as the prefix to a function. The named expression can be either a simple expression or a compound expression. The function must be one that can operate on the type of data that is returned by the named expression.

### Example 1: Simple Named Expression as a Prefix

The following simple named expression, which identifies a text string, can be used as a prefix to the `AFTER_STR(<string>)` function, which works with text data:

```
HTTP.REQ.BODY(1000)
```

If the name of the expression is `top1KB`, you can use `top1KB.AFTER_STR("username")` instead of `HTTP.REQ.BODY(1000).AFTER_STR("username")`.

### Example 2: Compound named expression as a prefix

You can create a compound named expression called `basic_header_value` to concatenate the user name in a request, a colon (:), and the user’s password, as follows:
add policy expression basic_header_value "HTTP.REQ.USER.NAME + ":" + HTTP.REQ.USER.PASSWD"

You can then use the name of the expression in a rewrite action, as shown in the following example:

add rewrite action insert_b64encoded_authorization insert_http_header authorization '"Basic " + basic_header_value.b64encode'-bypassSafetyCheck YES

In the example, in the expression that is used to construct the value of the custom header, the B64 encoding algorithm is applied to the string returned by the compound named expression. You can also use a named expression (either by itself or as a prefix to a function) to create the text expression for the replacement target in a rewrite.

**Configure a named default syntax expression by using the CLI**

At the command prompt, type the following commands to configure a named expression and verify the configuration:

```
1 - add policy expression \<name\>\<value\>
2 - show policy expression \<name\>
```

**Example:**

```
1 > add policy expression myExp "http.req.body(100).contains("the other ")"
2  Done
3
4 > show policy expression myExp
5  1) Name: myExp  Expr: "http.req.body(100).contains("the other"
6       )"  Hits: 0  Type : ADVANCED
7  Done
```

The expression can be up to 1,499 characters.

**Configure a named expression by using the GUI**

1. In the navigation pane, expand **AppExpert**, and then click **Expressions**.
2. Click **Advanced Expressions**.
3. Click **Add**.
4. Enter a name and a description for the expression.
5. Configure the expression by using the process described in Configure advanced policy expression. A message in the status bar indicates that the policy expression is configured successfully.

Configure advanced policy expressions outside the context of a policy

September 24, 2018

A number of functions, including the following, can require an advanced policy expression that is not part of a policy:

- **Integrated Caching selectors:**
  You define multiple non-compound expressions (selectlets) in the definition of the selector. Each selectlet is in an implicit logical AND relationship with the others.

- **Load Balancing:**
  You configure an expression for the TOKEN method of load balancing for a load balancing virtual server.

- **Rewrite actions:**
  Expressions define the location of the rewrite action and the type of rewriting to be performed, depending on the type of rewrite action that you are configuring. For example, a DELETE action only uses a target expression. A REPLACE action uses a target expression and an expression to configure the replacement text.

- **Rate-based policies:**
  You use advanced policy expressions to configure Limit Selectors. You can use these selectors when configuring policies to throttle the rate of traffic to various servers. You define up to five non-compound expressions (selectlets) in the definition of the selector. Each selectlet is in an implicit logical AND with the others.

Configure an advanced policy expression outside a policy by using the CLI (cache selector example)

At the command prompt, type the following commands to configure an advanced policy expression outside a policy and verify the configuration:

```bash
1 - add cache selector \<selectorName\> \<rule\>
2 - show cache selector \<selectorName\>
```

Example:
Following is an equivalent command that uses the more readable q delimiter, as described in Configure advanced policy expressions in a policy:

```
1   > add cache selector mainpageSelector2 q=http.req.cookie.value("ABC_def")~
2       q=http.req.url.query.value("_ghi")~selector "mainpageSelector2"
3       added
4   Done
5   > show cache selector mainpageSelector2
6       Name: mainpageSelector2
7       Expressions:
8           1) http.req.cookie.value("ABC_def")
9           2) http.req.url.query.value("_ghi")
10      Done
```

**Advanced policy expressions: evaluating text**

September 24, 2018

You can configure a policy with an advanced policy expression that evaluates text in a request or response. Advanced policy text expressions can range from simple expressions that perform string matching in HTTP headers to complex expressions that encode and decode text. You can configure text expressions to be case sensitive or case insensitive and to use or ignore spaces. You can also configure complex text expressions by combining text expressions with Boolean operators.

You can use expression prefixes and operators for evaluating HTTP requests, HTTP responses, and VPN and Clientless VPN data. However, text expression prefixes are not restricted to evaluating these elements of your traffic.
About text expressions

December 7, 2018

You can configure various expressions for working with text that flows through the NetScaler appliance. Following are some examples of how you can parse text by using a default syntax expression:

- Determine that a particular HTTP header exists.
  
  For example, you may want to identify HTTP requests that contains a particular Accept-Language header for the purpose of directing the request to a particular server.

- Determine that a particular HTTP URL contains a particular string.
  
  For example, you may want to block requests for particular URLs. Note that the string can occur at the beginning, middle, or end of another string.

- Identify a POST request that is directed to a particular application.
  
  For example, you may want to identify all POST requests that are directed to a database application for the purpose of refreshing cached application data.

Note that there are specialized tools for viewing the data stream for HTTP requests and responses.

About operations on text

A text-based expression consists of at least one prefix to identify an element of data and usually (although not always) an operation on that prefix. Text-based operations can apply to any part of a request or a response. Basic operations on text include various types of string matches.

For example, the following expression compares a header value with a string:

```plaintext
http.req.header("myHeader").contains("some-text")
```

Following expressions are examples of matching a file type in a request:

```plaintext
http.req.url.suffix.contains("jpeg")
http.req.url.suffix.eq("jpeg")
```

In the preceding examples, the contains operator permits a partial match and the eq operator looks for an exact match.

Other operations are available to format the string before evaluating it. For example, you can use text operations to strip out quotes and white spaces, to convert the string to all lowercase, or to concatenate strings.

**Note:** Complex operations are available to perform matching based on patterns or to convert one type of text format to another type.
For more information, see the following topics:

- Pattern sets and data sets.
- Regular expressions.
- Typcasting data.

**Compounding and precedence in text expressions**

You can apply various operators to combine text prefixes or expressions. For example, the following expression concatenates the returned values of each prefix:

```plaintext
http.req.hostname + http.req.url
```

Following is an example of a compound text expression that uses a logical AND. Both components of this expression must be TRUE for a request to match the expression:

```plaintext
http.req.method.eq(post) & http.req.body(1024).startswith("destination=")
```

**Note:** For more information on operators for compounding, see Compound default syntax expressions.

**Categories of text expressions**

The primary categories of text expressions that you can configure are:

- Information in HTTP headers, HTTP URLs, and the POST body in HTTP requests.
  
  For more information, see Expression prefixes for text in HTTP requests and responses.

- Information regarding a VPN or a clientless VPN.
  
  For more information, see Expression prefixes for VPNs and clientless VPNs.

- TCP payload information.
  
  For more information about TCP payload expressions, see Default syntax expressions: Parsing HTTP, TCP, and UDP data.

- Text in a Secure Sockets Layer (SSL) certificate.
  
  For information about text expressions for SSL and SSL certificate data, see Default syntax expressions: Parsing SSL certificates and Expressions for SSL certificate dates.

**Note:** Parsing a document body, such as the body of a POST request, can affect performance. You may want to test the performance impact of policies that evaluate a document body.
Guidelines for text expressions

From a performance standpoint, it typically is best to use protocol-aware functions in an expression. For example, the following expression makes use of a protocol-aware function:

```
HTTP.REQ.URL.QUERY
```

The previous expression performs better than the following equivalent expression, which is based on string parsing:

```
HTTP.REQ.URL.AFTER_STR("?")
```

In the first case, the expression looks specifically at the URL query. In the second case, the expression scans the data for the first occurrence of a question mark.

There is also a performance benefit from structured parsing of text, as in the following expression:

```
HTTP.REQ.HEADER("Example").TYPECAST_LIST_T(',').GET(1)
```

(For more information on typecasting, see Typecasting data. The typecasting expression, which collects comma-delimited data and structures it into a list, typically would perform better than the following unstructured equivalent:

```
HTTP.REQ.HEADER("Example").AFTER_STR(""," ").BEFORE_STR(""," ")
```

Finally, unstructured text expressions typically have better performance than regular expressions. For example, the following is an unstructured text expression:

```
HTTP.REQ.HEADER("Example").AFTER_STR("more")
```

The previous expression would generally provide better performance than the following equivalent, which uses a regular expression:

```
HTTP.REQ.HEADER("Example").AFTER_REGEX(re/more/)
```

For more information on regular expressions, see Regular expressions.

Expression prefixes for text in HTTP requests and responses

January 6, 2019

An HTTP request or response typically contains text, such as in the form of headers, header values, URLs, and POST body text. You can configure expressions to operate on one or more of these text-based items in an HTTP request or response.

Refer to the Expression Prefix table for information on how to configure and extract text from different parts of an HTTP request or response.
Expression prefixes for VPNs and clientless VPNs

November 13, 2018

The Advanced policy engine provides prefixes that are specific to parsing VPN or Clientless VPN data. This data includes the following:

- Host names, domains, and URLs in VPN traffic.
- Protocols in the VPN traffic.
- Queries in the VPN traffic.

These text elements are often URLs and components of URLs. In addition to applying the text-based operations on these elements, you can parse these elements by using operations that are specific to parsing URLs. For more information, see Expressions for extracting segments of URLs.

The following table describes the expression prefixes for this type of data.

<table>
<thead>
<tr>
<th>VPN and Clientless VPN Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPN.BASEURL.CVPN_DECOD</td>
<td>Extracts the original URL from a clientless VPN URL.</td>
</tr>
<tr>
<td>VPN.BASEURL.CVPN_ENCODE</td>
<td>Converts a URL to clientless VPN format.</td>
</tr>
<tr>
<td>VPN.BASEURL.HOSTNAME</td>
<td>Extracts the HTTP host name from the host name in the URL. This prefix cannot be used in bidirectional policies.</td>
</tr>
<tr>
<td>VPN.BASEURL.HOSTNAME.DOMAIN</td>
<td>Extracts the domain name from the host name. For example, if the host name is <a href="http://www.mycompany.com">www.mycompany.com</a> or <a href="http://www.mycompany.com:8080">www.mycompany.com:8080</a>, this prefix extracts mycompany.com. This prefix returns incorrect results if the host name is an IP address. For information on expressions for IP addresses, see “Default Syntax Expressions: IP and MAC Addresses, Throughput, VLAN IDs.” All text operations after this prefix are case insensitive.</td>
</tr>
</tbody>
</table>
## VPN and Clientless VPN Expression Description

<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>VPN.BASEURL.HOSTNAME.EQ</strong> (&lt;hostname &gt;)</td>
<td>Returns a Boolean TRUE if the host name matches &lt;hostname&gt;. The comparison is case insensitive. For example, if the host name is <a href="http://www.mycompany.com">www.mycompany.com</a>, the following returns TRUE: vpn.baseurl.hostname.eq(&quot;www.mycompany.com&quot;). If the text mode is URLENCODED, the host name is decoded before comparison. For more information, see “Operations for HTTP, HTML, and XML Encoding and “Safe” Characters.”</td>
</tr>
<tr>
<td><strong>VPN.BASEURL.HOSTNAME.SERVER</strong></td>
<td>Evaluates the server portion of the host name. For example, if the host name is <a href="http://www.mycompany.com">www.mycompany.com</a> or <a href="http://www.mycompany.com:8080">www.mycompany.com:8080</a>, the server is <a href="http://www.mycompany.com">www.mycompany.com</a>. All text operations after this prefix are case insensitive.</td>
</tr>
<tr>
<td><strong>VPN.BASEURL.PATH</strong></td>
<td>Extracts a slash- (/) separated list from the path component of the URL. For example, this prefix extracts /a/b/c/mypage.html from the following URL: <a href="http://www.mycompany.com/a/b/c/mypage.html?a=1">http://www.mycompany.com/a/b/c/mypage.html?a=1</a>. The following expression selects just the “a”: http.req.url.path.get(1). For more information on the GET operation, see “Expressions for Extracting Segments of URLs.”</td>
</tr>
</tbody>
</table>
### VPN and Clientless VPN Expression Description

<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPN.BASEURL.PATH.IGNORE_EMPTY_ELEMENTS</td>
<td>This prefix ignores the elements in a list. For example, the following comma-separated list has an empty element after “a=10”: a=10,,b=11,,c=89. The element following b=11 contains a space, and by default, is not considered an empty element. Consider the following HTTP header: Cust_Header : 123,,15. The following expression returns a count of 4 when evaluating this header: http.req.header(“Cust_Header”).typecase_list_t(‘,’).ignore_empty_elements.count. The following expression returns a count of 5 when evaluating this header: http.req.header(“Cust_Header”).typecase_list_t(‘,’).count.</td>
</tr>
<tr>
<td>VPN.BASEURL.PATH_AND_QUERY</td>
<td>Evaluates the text in the URL that follows the host name. For example, if the URL is <a href="http://www.mycompany.com/a/b/c/mypage.html?a=1">http://www.mycompany.com/a/b/c/mypage.html?a=1</a>, this prefix evaluates /a/b/c/mypage.html?a=1.</td>
</tr>
<tr>
<td>VPN.BASEURL.PROTOCOL</td>
<td>Evaluates the protocol in the URL. Do not use this prefix in bidirectional policies.</td>
</tr>
<tr>
<td>VPN.BASEURL.QUERY</td>
<td>Extracts a name-value list, using the “=” and “&amp;” delimiters from the query string in a URL.</td>
</tr>
<tr>
<td>VPN.BASEURL.QUERY.IGNORE_EMPTY_ELEMENTSThis method ignores the empty elements in a name-value list. For example, in the following name-value list, there is an empty element following “a=10”: a=10;;b=11; ;c=89. The element following b=11 contains a space and is not considered an empty element. Consider the following HTTP header: Cust_Header : a=1;;b=2; ;c=3. The following expression produces a count of 4 after evaluating this header: http.req.header(“Cust_Header”).typecast_nvlist_t(‘=’,’;’).ignore_empty_elements.count. The following expression produces a count of 5 after evaluating the header: http.req.header(“Cust_Header”).typecast_nvlist_t(‘=’,’;’).count.</td>
<td></td>
</tr>
<tr>
<td>VPN and Clientless VPN Expression</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>VPN.BASEURL.SUFFIX</td>
<td>Evaluates the file name suffix in a URL. For example, if the path is /a/b/c/my.page.html, this operation selects “html.”</td>
</tr>
<tr>
<td>VPN.CLIENTLESS_BASEURL</td>
<td>Evaluates the clientless VPN base URL.</td>
</tr>
<tr>
<td>VPN.CLIENTLESS_BASEURL.CVPN_DECODE</td>
<td>Extracts the original URL from the clientless VPN formatted URL.</td>
</tr>
<tr>
<td>VPN.CLIENTLESS_BASEURL.CVPN_ENCODE</td>
<td>Converts a URL to the clientless VPN format.</td>
</tr>
<tr>
<td>VPN.CLIENTLESS_BASEURL.HOSTNAME</td>
<td>Evaluates the host name in the URL. Do not use this prefix in bidirectional policies.</td>
</tr>
<tr>
<td>VPN.CLIENTLESS_BASEURL.HOSTNAME.DOMAIN</td>
<td>Evaluates the domain name part of the host name. For example, if the host name is <a href="http://www.mycompany.com">www.mycompany.com</a> or <a href="http://www.mycompany.com:8080">www.mycompany.com:8080</a>, the domain is mycompany.com. This operation returns incorrect results if the host name is an IP address. For information on expressions for IP addresses, see “Default Syntax Expressions: IP and MAC Addresses, Throughput, VLAN IDs..” All text operations after this prefix are case insensitive.</td>
</tr>
<tr>
<td>VPN.CLIENTLESS_BASEURL.HOSTNAME.EQ(&lt;hostname&gt;)</td>
<td>Returns a Boolean TRUE if the host name matches &lt;hostname&gt;. For example, if the host name is <a href="http://www.mycompany.com">www.mycompany.com</a> or <a href="http://www.mycompany.com:8080">www.mycompany.com:8080</a>, the following is true: vpn.clientless_baseurl.hostname.eq(&quot;www.mycompany.com&quot;) The comparison is case insensitive. If the textmode is URLENCODED, the host name is decoded before comparison. For more information, see “Operations for HTTP, HTML, and XML Encoding and “Safe” Characters.”</td>
</tr>
<tr>
<td>VPN and Clientless VPN Expression</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td><strong>VPN.CLIENTLESS_BASEURL.HOSTNAME.SERVER</strong></td>
<td>Evaluates the server part of a host name. For example, if the host name is <a href="http://www.mycompany.com">www.mycompany.com</a> or <a href="http://www.mycompany.com:8080">www.mycompany.com:8080</a>, the server is <a href="http://www.mycompany.com">www.mycompany.com</a>. All text operations after this prefix are case insensitive.</td>
</tr>
<tr>
<td><strong>VPN.CLIENTLESS_BASEURL.PATH</strong></td>
<td>Evaluates a slash- (/) separated list in the URL path. For example, this prefix selects /a/b/c/mypage.html from the following URL: <a href="http://www.mycompany.com/a/b/c/mypage.html?a=1">http://www.mycompany.com/a/b/c/mypage.html?a=1</a>. The following expression selects “a” from the preceding URL: http.req.url.path.get(1). For more information on the GET operation, see “Expressions for Extracting Segments of URLs.”</td>
</tr>
<tr>
<td><strong>VPN.CLIENTLESS_BASEURL.PATH.IGNORE_EMPTY_ELEMENTS</strong></td>
<td>Ignores empty elements in a list. For example, if the list delimiter is a comma (,) the following list has an empty element following “a=10”: a=10,b=11, ,c=89. The element following b=11 contains a space and is not considered an empty element. Consider the following HTTP header: Cust_Header : 123,24, ,15. The following expression returns a value of 4 after evaluating this header: http.req.header(“Cust_Header”).typecast_list_t(‘,’).ignore_empty_elements.count. The following expression returns a value of 5 after evaluating this header: http.req.header(“Cust_Header”).typecast_list_t(‘,’).</td>
</tr>
<tr>
<td><strong>VPN.CLIENTLESS_BASEURL.PATH_AND_QUERY</strong></td>
<td>Evaluates the text following the host name in a URL. For example, this prefix selects /a/b/c/mypage.html?a=1 from the following URL: <a href="http://www.mycompany.com/a/b/c/mypage.html?a=1">http://www.mycompany.com/a/b/c/mypage.html?a=1</a></td>
</tr>
<tr>
<td><strong>VPN.CLIENTLESS_BASEURL.PROTOCOL</strong></td>
<td>Evaluates the protocol in the URL. Do not use this prefix in bidirectional policies.</td>
</tr>
</tbody>
</table>
### VPN and Clientless VPN Expression

<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>VPN.CLIENTLESS_BASEURL.QUERY</strong></td>
<td>Extracts a name-value list that uses the delimiters “=” and “&amp;” from a URL query string.</td>
</tr>
<tr>
<td><strong>VPN.CLIENTLESS_BASEURL.QUERY.IGNORE_EMPTY_ELEMENTS</strong></td>
<td>Ignores empty elements in a name-value list. For example, the following list contains an empty element after “a=10”: a=10;;b=11; c=89. The element following b=11 contains a space and is not considered an empty element. As another example, consider the following http header: Cust_Header: a=1;b=2;c=3. The following expression returns a value of 4 after evaluating the preceding header: http.req.header(&quot;Cust_Header&quot;).typecast_nvlist_t(=,';').ignore_empty_elements.count. The following expression returns a value of 5 after evaluating the preceding header: http.req.header(&quot;Cust_Header&quot;).typecast_nvlist_t(=,';').ignore_empty_elements.count.</td>
</tr>
<tr>
<td><strong>VPN.CLIENTLESS_BASEURL.SUFFIX</strong></td>
<td>Evaluates the file suffix in a URL. For example, if the URL path is /a/b/c/mypage.html then this operation selects html.</td>
</tr>
<tr>
<td><strong>VPN.CLIENTLESS_HOSTURL</strong></td>
<td>Selects the clientless VPN host URL.</td>
</tr>
<tr>
<td><strong>VPN.CLIENTLESS_HOSTURL.CVPN_DECODE</strong></td>
<td>Selects the original URL from the clientless VPN formatted URL.</td>
</tr>
<tr>
<td><strong>VPN.CLIENTLESS_HOSTURL.CVPN_ENCODE</strong></td>
<td>Converts a URL to clientless VPN format.</td>
</tr>
<tr>
<td><strong>VPN.CLIENTLESS_HOSTURL.HOSTNAME</strong></td>
<td>Extracts the host name in the URL. Do not use this prefix in bidirectional policies.</td>
</tr>
<tr>
<td><strong>VPN.CLIENTLESS_HOSTURL.HOSTNAME.DOMAIN</strong></td>
<td>Extracts the domain name from the host name. For example, if the host name is <a href="http://www.mycompany.com">www.mycompany.com</a> or <a href="http://www.mycompany.com:8080">www.mycompany.com:8080</a>, the domain is mycompany.com. This operation returns incorrect results if the host name contains an IP address. For information on expressions for IP addresses, see “Default Syntax Expressions: IP and MAC Addresses, Throughput, VLAN IDs.” All text operations after this prefix are case insensitive.</td>
</tr>
</tbody>
</table>
### VPN and Clientless VPN Expression

<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPN.CLIENTLESS_HOSTURL.HOSTNAME.EQ(&lt;hostname&gt;)</td>
<td>Results in Boolean TRUE if the host name matches the &lt;hostname&gt; argument. The comparison is case insensitive. For example, if the host name is <a href="http://www.mycompany.com">www.mycompany.com</a> or <a href="http://www.mycompany.com">www.mycompany.com</a>, the following expression returns TRUE: vpn.clientless_hosturl.hostname.eq(&quot;www.mycompany.com&quot;). If the text mode is URLENCODED, the host name is decoded before comparison. For more information, see “Operations for HTTP, HTML, and XML Encoding and “Safe” Characters.”</td>
</tr>
<tr>
<td>VPN.CLIENTLESS_HOSTURL.HOSTNAME.SERVER</td>
<td>Evaluates the server part of the host name. For example, if the host name is <a href="http://www.mycompany.com">www.mycompany.com</a> or <a href="http://www.mycompany.com:8080">www.mycompany.com:8080</a>, the server is <a href="http://www.mycompany.com">www.mycompany.com</a>. The comparison is case insensitive, and all text operations after this method are case insensitive.</td>
</tr>
<tr>
<td>VPN.CLIENTLESS_HOSTURL.PATH</td>
<td>Evaluates a slash-/() separated list on the path component of the URL. For example, consider the following URL: <a href="http://www.mycompany.com/a/b/c/mypage.html?a=1">http://www.mycompany.com/a/b/c/mypage.html?a=1</a>. This prefix selects /a/b/c/mypage.html from the preceding URL.</td>
</tr>
</tbody>
</table>

### VPN and Clientless VPN Expression

<table>
<thead>
<tr>
<th>VPN and Clientless VPN Expression</th>
<th>Description</th>
</tr>
</thead>
</table>
| VPN.CLIENTLESS_HOSTURL.PATH.IGNORE_EMPTY_ELEMENTS | Ignores the empty elements in a list. For example, if the delimiter in a list is ",," the following list contains an empty element after the entry "a=10": a=10,b=11, ,c=89. The element following b=11 contains a space and is not considered an empty element. Consider the following header: Cust_Header : 123,24, ,15. The following expression returns a value of 4 for this header: http.req.header("Cust_Header").typecast_list_t(,).ignore_empty_elements.count. The following expression returns a value of 5 for the same header: http.req.header("Cust_Header").typecast_list_t(,).

<p>| VPN.CLIENTLESS_HOSTURL.PATH_AND_QUERY | Evaluates the portion of the URL that follows the host name. For example, consider the following URL: <a href="http://www.mycompany.com/a/b/c/mypage.html?a=1">http://www.mycompany.com/a/b/c/mypage.html?a=1</a>. This prefix returns /a/b/c/mypage.html?a=1 from the preceding URL. |
| VPN.CLIENTLESS_HOSTURL.PROTOCOL | Evaluates the protocol in the URL. Do not use this prefix in bidirectional policies. |
| VPN.CLIENTLESS_HOSTURL.QUERY | Extracts a name-value list, using the “=” and “&amp;” delimiters from a URL query string. |</p>
<table>
<thead>
<tr>
<th>VPN and Clientless VPN Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPN.CLIENTLESS_HOSTURL.QUERY.IGNOREEMPTY_ELEMENTS</td>
<td>Ignores empty elements in a name-value list. For example, the following list uses a semicolon (;) delimiter. This list contains an empty element after “a=10”: a=10; b=11; c=89. In the preceding example, the element following b=11 is not considered an empty element. Consider the following header: Cust_Header : a=1; b=2; c=3. The following expression returns a value of 4 after evaluating this header: http.req.header(&quot;Cust_Header&quot;).typecast_nvlist_t(’=’, ’;’).ignore_empty_elements.count. The following expression returns a value of 5 after evaluating the same header: http.req.header(&quot;Cust_Header&quot;).typecast_nvlist_t(’=’, ’;’).</td>
</tr>
<tr>
<td>VPN.CLIENTLESS_HOSTURL.SUFFIX</td>
<td>Extracts a file name suffix in a URL. For example, if the path is /a/b/c/my.page.html, this prefix selects html.</td>
</tr>
<tr>
<td>VPN.HOST.DOMAIN</td>
<td>Extracts the domain name part of the host name. For example, if the host name is <a href="http://www.mycompany.com">www.mycompany.com</a> or <a href="http://www.mycompany.com:8080">www.mycompany.com:8080</a>, the domain is mycompany.com. This prefix returns incorrect results if the host name contains an IP address. For information on expressions for IP addresses, see “Default Syntax Expressions: IP and MAC Addresses, Throughput, VLAN IDs.” All text operations after this prefix case insensitive.</td>
</tr>
</tbody>
</table>
VPN and Clientless VPN Expression | Description
---|---
VPN.HOST.EQ(<hostname>) | Returns a Boolean TRUE value if the host name matches the <hostname>. The comparison is case insensitive. For example, if the host name is www.mycompany.com or www.mycompany.com:8080, the following returns TRUE: vpn.host.eq(“www.mycompany.com”). If the text mode is URLENCODED the host name is decoded before comparison. For more information, see “Operations for HTTP, HTML, and XML Encoding and “Safe” Characters.”
VPN.HOST.SERVER | Extracts the server name part of the host name. For example, if the host name is www.mycompany.com or www.mycompany.com:8080, the server is www.mycompany.com. All text operations after this prefix are case insensitive.

Basic operations on text

September 24, 2018

Basic operations on text include operations for string matching, calculating the length of a string, and controlling case sensitivity. You can include white space in a string that is passed as an argument to an expression, but the string cannot exceed 255 characters.

String comparison functions

The following table lists basic string matching operations in which the functions return a Boolean TRUE or FALSE.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;text&gt;.CONTAINS(&lt;string&gt;)</td>
<td>Returns a Boolean TRUE value if the target contains &lt;string&gt;. Example: http.req.url.contains(” .jpeg”)</td>
</tr>
</tbody>
</table>
### NetScaler 12.0

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;text&gt;.EQ(&lt;string&gt;)</code></td>
<td>Returns a Boolean TRUE value if the target is an exact match with <code>&lt;string&gt;</code>. For example, the following expression returns a Boolean TRUE for a URL with a host name of “myhostabc”: <code>http.req.url.hostname.eq(&quot;myhostabc&quot;)</code></td>
</tr>
<tr>
<td><code>&lt;text&gt;.STARTSWITH(&lt;string&gt;)</code></td>
<td>Returns a Boolean TRUE value if the target begins with <code>&lt;string&gt;</code>. For example, the following expression returns a Boolean TRUE for a URL with a host name of “myhostabc”: <code>http.req.url.hostname.startswith(&quot;myhost&quot;)</code></td>
</tr>
<tr>
<td><code>&lt;text&gt;.ENDSWITH(&lt;string&gt;)</code></td>
<td>Returns a Boolean TRUE value if the target ends with <code>&lt;string&gt;</code>. For example, the following expression returns a Boolean TRUE for a URL with a host name of “myhostabc”: <code>http.req.url.hostname.endswith(&quot;abc&quot;)</code></td>
</tr>
<tr>
<td><code>&lt;text&gt;.NE(&lt;string&gt;)</code></td>
<td>Returns a Boolean TRUE value if the prefix is not equal to the string argument. If the prefix returns a non-string value, the function argument is compared to the string representation of the value returned by the prefix. You can use the functions with <code>SET_TEXT_MODE(IGNORECASE)</code> or <code>SET_TEXT_MODE(NOIGNORECASE)</code>, and with both ASCII and UTF-8 character sets.</td>
</tr>
<tr>
<td><code>&lt;text&gt;.GT(&lt;string&gt;)</code></td>
<td>Returns a Boolean TRUE value if the prefix is alphabetically greater than the string argument. If the prefix returns a non-string value, the function argument is compared to the string representation of the value returned by the prefix. You can use the functions with <code>SET_TEXT_MODE(IGNORECASE)</code> or <code>SET_TEXT_MODE(NOIGNORECASE)</code>, and with both ASCII and UTF-8 character sets.</td>
</tr>
</tbody>
</table>
### Function Description

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;text&gt;.GE(&lt;string&gt;)</code></td>
<td>Returns a Boolean TRUE value if the prefix is alphabetically greater than or equal to the string argument. If the prefix returns a non-string value, the function argument is compared to the string representation of the value returned by the prefix. You can use the functions with <code>SET_TEXT_MODE(IGNORECASE)</code> or <code>SET_TEXT_MODE(NOIGNORECASE)</code>, and with both ASCII and UTF-8 character sets.</td>
</tr>
<tr>
<td><code>&lt;text&gt;.LT(&lt;string&gt;)</code></td>
<td>Returns a Boolean TRUE value if the prefix is alphabetically lesser than the string argument. If the prefix returns a non-string value, the function argument is compared to the string representation of the value returned by the prefix. You can use the functions with <code>SET_TEXT_MODE(IGNORECASE)</code> or <code>SET_TEXT_MODE(NOIGNORECASE)</code>, and with both ASCII and UTF-8 character sets.</td>
</tr>
<tr>
<td><code>&lt;text&gt;.LE(&lt;string&gt;)</code></td>
<td>Returns a Boolean TRUE value if the prefix is alphabetically lesser than or equal to the string argument. If the prefix returns a non-string value, the function argument is compared to the string representation of the value returned by the prefix. You can use the functions with <code>SET_TEXT_MODE(IGNORECASE)</code> or <code>SET_TEXT_MODE(NOIGNORECASE)</code>, and with both ASCII and UTF-8 character sets.</td>
</tr>
</tbody>
</table>

### Calculate the length of a string

The `<text>.LENGTH` operation returns a numeric value that is equal to the number of characters (not bytes) in a string:

```plaintext```
<text>.LENGTH
```

For example, you may want to identify request URLs that exceed a particular length. Following is an expression that implements this example:
HTTP.REQ.URL.LENGTH < 500

After taking a count of the characters or elements in a string, you can apply numeric operations to them. For more information, see Default Syntax Expressions: Working with Dates, Times, and Numbers.

Consider, ignore, and change text case

The following functions operate on the case (upper-case or lower-case) of the characters in the string.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;text&gt;.SET_TEXT_MODE(IGNORECASE)</td>
<td>This function turns case sensitivity on or off for all text operations.</td>
</tr>
<tr>
<td>&lt;text&gt;.TO_LOWER</td>
<td>Converts the target to lowercase for a text block of up to 2 kilobyte (KB). Returns UNDEF if the target exceeds 2 KB. For example, the string “ABCd:” is converted to “abcd:”.</td>
</tr>
<tr>
<td>&lt;text&gt;.TO_UPPER</td>
<td>Converts the target to uppercase. Returns UNDEF if the target exceeds 2 KB. For example, the string “abcD:” is converted to “ABCD:”.</td>
</tr>
</tbody>
</table>

Strip specific characters from a string

You can use the STRIP_CHARS(<string>) function to remove specific characters from the text that is returned by a default syntax expression prefix (the input string). All instances of the characters that you specify in the argument are stripped from the input string. You can use any text method on the resulting string, including the methods used for matching the string with a pattern set.

For example, in the expression CLIENT.UDP.DNS.DOMAIN.STRIP_CHARS(“.-.”), the STRIP_CHARS(<string>) function strips all periods (.), hyphens (-), and underscores (_) from the domain name returned by the prefix CLIENT.UDP.DNS.DOMAIN. If the domain name that is returned is “a.dom_ai_n-name”, the function returns the string “adomainname”.

© 1999-2018 Citrix Systems, Inc. All rights reserved. 1153
In the following example, the resulting string is compared with a pattern set called “listofdomains”:

```
CLIENT.UDP.DNS.DOMAIN.STRIPE_CHARS("-.").CONTAINS_ANY("listofdomains")
```

**Note:** You cannot perform a rewrite on the string that is returned by the STRIP_CHARS(<string>) function.

The following functions strip matching characters from the beginning and end of a given string input.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;text&gt;.STRIP_START_CHARS(s)</code></td>
<td>Strips matching characters from the beginning of the input string until the first non-matching character is found and returns the remainder of the string. You must specify the characters that you want to strip as a single string within quotation marks. For example, if the name of a header is TestLang and ://en_us:is its value, HTTP.RES.HEADER(&quot;TestLang&quot;).STRIP_START_CHARS(&quot;://&quot;) strips the specified characters from the beginning of the value of the header until the first non-matching character e is found and returns en_us: as a string.</td>
</tr>
<tr>
<td><code>&lt;text&gt;.STRIP_END_CHARS(s)</code></td>
<td>Strips matching characters from the end of the input string to the first non-matching character is found and returns the remainder of the string. You must specify the characters that you want to strip as a single string within quotation marks. For example, if the name of a header is TestLang and ://en_us:is its value, HTTP.RES.HEADER(&quot;TestLang&quot;).STRIP_START_CHARS(&quot;://&quot;) strips the specified characters from the end of the value of the header until the first non-matching character s is found and returns://_en_us as a string.</td>
</tr>
</tbody>
</table>

**Append a string to another string**

You can use the APPEND() function to append the string representation of the argument to the string representation of the value returned by the preceding function. The preceding function can be one that returns a number, unsigned long, double, time value, IPv4 address, or IPv6 address. The argu-
ment can be a text string, number, unsigned long, double, time value, IPv4 address, or IPv6 address. The resulting string value is the same string value that is obtained by using the + operator.

Complex operations on text

January 6, 2019

In addition to performing simple string matching, you can configure expressions that examine more complex aspects of text, including examining the length of a string and looking within a text block for patterns rather than specific strings.

Be aware of the following for any text-based operation:

- For any operation that takes a string argument, the string cannot exceed 255 characters.
- You can include white space when you specify a string in an expression.

Operations on the length of a string

The following operations extract strings on the basis of a character count.

<table>
<thead>
<tr>
<th>Character Count Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;text&gt;.TRUNCATE(&lt;count&gt;)</code></td>
<td>Returns a string after truncating the end of the target by the number of characters in <code>&lt;count&gt;</code>. If the entire string is shorter than <code>&lt;count&gt;</code>, nothing is returned.</td>
</tr>
<tr>
<td><code>&lt;text&gt;.TRUNCATE(&lt;character&gt;, &lt;count&gt;)</code></td>
<td>Returns a string after truncating the text after <code>&lt;character&gt;</code> by the number of characters specified in <code>&lt;count&gt;</code>.</td>
</tr>
<tr>
<td><code>&lt;text&gt;.PREFIX(&lt;character&gt;, &lt;count&gt;)</code></td>
<td>Selects the longest prefix in the target that has at most <code>&lt;count&gt;</code> occurrences of <code>&lt;character&gt;</code>.</td>
</tr>
<tr>
<td><code>&lt;text&gt;.SUFFIX(&lt;character&gt;, &lt;count&gt;)</code></td>
<td>Selects the longest suffix in the target that has at most <code>&lt;count&gt;</code> occurrences of <code>&lt;character&gt;</code>. For example, consider the following response body: JLEwx. The following expression returns a value of “JLEwx”: http.res.body(100).suffix('L',1) The following expression returns “LLEwx”: http.res.body(100).suffix('L',2)</td>
</tr>
</tbody>
</table>
Operations on a portion of a string

Refer to the String operations table to know how to extract a subset of a larger string by using one of the operations.

Operations for comparing the alphanumeric order of two strings

The COMPARE operation examines the first nonmatching character of two different strings. This operation is based on lexicographic order, which is the method used when ordering terms in dictionaries.

This operation returns the arithmetic difference between the ASCII values of the first nonmatching characters in the compared strings. The following differences are examples:

- The difference between “abc” and “abd” is -1 (based on the third pair-wise character comparison).
- The difference between “@” and “abc” is -33.
- The difference between “1” and “abc” is -47.

Following is the syntax for the COMPARE operation.

<text>.COMPARE(<string>)

Extract an integer from a string of bytes that represent text

Refer to the Integer extraction table to know how to treat a string of bytes that represent text as a sequence of bytes, extract 8, 16, or 32 bits from the sequence, and then convert the extracted bits to an integer.
**Convert text to a hash value**

You can convert a text string to a hash value by using the HASH function. This function returns a 31-bit positive integer as a result of the operation. Following is the format of the expression:

`<text>.HASH`

This function ignores case and white spaces. For example, after the operation, the two strings `Ab c` and `a bc` would produce the same hash value.

**Encode and decode text by applying the Base64 encoding algorithm**

The following two functions encode and decode a text string by applying the Base64 encoding algorithm.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>text.B64ENCODE</td>
<td>Encodes the text string (designated by text) by applying the Base64 encoding algorithm.</td>
</tr>
<tr>
<td>text.B64DECODE</td>
<td>Decodes the Base64-encoded string (designated by text) by applying the Base64 decoding algorithm. The operation raises an UNDEF if text is not in B64-encoded format.</td>
</tr>
</tbody>
</table>

**Refine the search in a rewrite action by using the EXTEND function**

The EXTEND function is used in rewrite actions that specify patterns or pattern sets and target the bodies of HTTP packets. When a pattern match is found, the EXTEND function extends the scope of the search by a predefined number of bytes on both sides of the matching string. A regular expression can then be used to perform a rewrite on matches in this extended region. Rewrite actions that are configured with the EXTEND function perform rewrites faster than rewrite actions that evaluate entire HTTP bodies using only regular expressions.

The format of the EXTEND function is `EXTEND(m,n)`, where m and n are the number of bytes by which the scope of the search is extended before and after the matching pattern, respectively. When a match is found, the new search scope comprises m bytes that immediately precede the matching string, the string itself, and the n bytes that follow the string. A regular expression can then be used to perform a rewrite on a portion of this new string.

The EXTEND function can be used only if the rewrite action in which it is used fulfills the following requirements:
The search is performed by using patterns or patterns sets (not regular expressions) and the rewrite action evaluates only the bodies of HTTP packets.

Additionally, the EXTEND function can be used only with the following types of rewrite actions:

- replace_all
- insert_after_all
- delete_all
- insert_before_all

For example, you might want to delete all instances of "<http://exampleurl.com/>" and "<http://exampleurl.au/>" in the first 1000 bytes of the body. To do this, you can configure a rewrite action to search for all instances of the string exampleurl, extend the scope of the search on both sides of the string when a match is found, and then use a regular expression to perform the rewrite in the extended region. The following example extends the scope of the search by 20 bytes to the left and 50 bytes to the right of the matching string:

```
add rewrite action delurl_example delete_all 'HTTP.REQ.BODY(1000)'-pattern exampleurl -refineSearch 'extend(20,50).regex_select(re##http://exampleurl.(com|au)#)#')
```

### Convert text to hexadecimal format

The following function converts text to hexadecimal format and extracts the resulting string:

```
<text>.BLOB_TO_HEX(<string>)
```

For example, this function converts the byte string “abc” to “61:62:63”.

### Encrypt and decrypt text

In default syntax expressions, you can use the ENCRYPT and DECRYPT functions to encrypt and decrypt text. Data encrypted by the ENCRYPT function on a given NetScaler appliance or high availability (HA) pair is intended for decryption by the DECRYPT function on the same NetScaler appliance or HA pair. The appliance supports the RC4, DES3, AES128, AES192, and AES256 encryption methods. The key value that is required for encryption is not user-specifiable. When an encryption method is set, the appliance automatically generates a random key value that is appropriate for the specified method. The default method is AES256 encryption, which is the most secure encryption method and the one that Citrix recommends.

You do not need to configure encryption unless you want to change the encryption method or you want the appliance to generate a new key value for the current encryption method.

**Note:** You can also encrypt and decrypt XML payloads. For information about the functions for encrypting and decrypting XML payloads, see Encrypt and decrypt XML payloads.
Configure encryption

During startup, the appliance runs the set ns encryptionParams command with, by default, the AES256 encryption method, and uses a randomly generated key value that is appropriate for AES256 encryption. The appliance also encrypts the key value and saves the command, with the encrypted key value, to the NetScaler configuration file. Consequently, the AES256 encryption method is enabled for the ENCRYPT and DECRYPT functions by default. The key value that is saved in the configuration file persists across reboots even though the appliance runs the command each time you restart it.

You can run the set ns encryptionParams command manually, or use the GUI, if you want to change the encryption method or if you want the appliance to generate a new key value for the current encryption method. To use the CLI to change the encryption method, set only the method parameter, as shown in “Example 1: Changing the Encryption Method.” If you want the appliance to generate a new key value for the current encryption method, set the method parameter to the current encryption method and the keyValue parameter to an empty string (“”), as shown in “Example 2: Generating a New Key Value for the Current Encryption Method.” After you generate a new key value, you must save the configuration. If you do not save the configuration, the appliance uses the newly generated key value only until the next restart, after which it reverts to the key value in the saved configuration.

Configure encryption by using the GUI

1. Navigate to **System > Settings**.
2. In the Settings area, click **Change Encryption parameters**.
3. In the **Change Encryption Parameters** dialog box, do one of the following:
   - To change the encryption method, in the Method list, select the encryption method that you want.
   - To generate a new key value for the current encryption method, click **Generate a new key** for the selected method.
4. Click **OK**.

Use the ENCRYPT and DECRYPT functions

You can use the ENCRYPT and DECRYPT functions with any expression prefix that returns text. For example, you can use the ENCRYPT and DECRIPT functions in rewrite policies for cookie encryption. In the following example, the rewrite actions encrypt a cookie named MyCookie, which is set by a back-end service, and decrypt the same cookie when it is returned by a client:

```bash
add rewrite action my-cookie-encrypt-action replace "$HTTP.RES.SET_COOKIE.COOKIE("MyCookie")\n.VALUE(0)\n" HTTP.RES.SET_COOKIE.COOKIE("MyCookie")\n.VALUE(0).ENCRYPT -bypassSafetyCheck YES
```
After you configure policies for encryption and decryption, save the configuration to bring the policies into effect.

**Configure encryption key for third-party encryption**

In default syntax expressions, you can use ENCRYPT and DECRYPT functions for encrypting and decrypting text in a request or response. The data encrypted by the ENCRYPT function on an appliance (standalone, high availability or cluster) is intended to be decrypted by the DECRYPT function by the same appliance. The appliance supports RC4, DES, Triple-DES, AES92, and AES256 encryption methods and each of these methods use a secret key for both encryption and decryption of data. You can use any of these methods to encrypt and decrypt data in two ways - self-encryption and third-party encryption.

The self-encryption feature in an appliance (standalone, high availability or cluster) encrypts and then decrypts data by evaluating the header value. One example to understand this is the HTTP Cookie encryption. The expression evaluates the header, encrypts the HTTP cookie value in the Set-Cookie header in the outgoing response and then decrypts the cookie value when it is returned in the cookie header of a subsequent incoming request from the client. The key value is not user configurable, instead when an encryption method is configured in the set ns encryptionParams command, the appliance automatically generates a random key value for the configured method. By default, the command uses the AES256 encryption method, which is the highly secured method and Citrix recommends this method.

The third-party encryption feature encrypts or decrypts data with a third-party application. For example, a client may encrypt data in a request and the appliance decrypts the data before sending it the back-end server or vice versa. To perform this, the appliance and the third-party application must share a secret key. On the appliance, you can directly configure the secret key using an encryption key object and key value is automatically generated by the appliance for a stronger encryption. The same key is manually configured on the third-party appliance so that both appliance and third-party application can use the same key for encrypting and decryption data.

**Note:**

Using third-party encryption, you can also encrypt and decrypt XML payloads. For information about the functions for encrypting and decrypting XML payloads, see “Encrypting and Decrypting XML Payloads.”
Cipher methods

A cipher method provides two functions: an encryption function that transforms a plaintext byte sequence into a ciphertext byte sequence, and a decryption function that transforms the ciphertext back to the plaintext. Cipher methods use byte sequences called keys to perform encryption and decryption. Cipher methods that use the same key for encryption and decryption are called symmetric. Cipher methods that use different keys for encryption and decryption are asymmetric. The most notable examples of asymmetric ciphers are in public key cryptography, which uses a public key available to anyone for encryption and a private key known only to the decryptor.

A good cipher method makes it infeasible to decrypt (“crack”) ciphertext if you don’t possess the key. “Infeasible” really means that cracking the ciphertext would take more time and computing resources than it is worth. As computers become more powerful and cheaper, ciphers that were formerly infeasible to crack become more feasible. Also, over time, flaws are found in cipher methods (or their implementations), making cracking easier. Newer cipher methods are therefore preferred over older ones. In general, longer length keys provide better security than shorter keys, at the cost of longer encryption and decryption times.

A cipher method can use stream ciphers or block ciphers. RC4 is the mostly secured stream ciphers and it is used only for legacy application. Block ciphers can include padding.

Stream ciphers

A stream cipher method operates on individual bytes. Only one stream cipher is available on NetScaler appliances: RC4, which uses a 128 bit (16 byte) key length. For a given key, RC4 generates a pseudo-random sequence of bytes, call a keystream, which is X-ORed with the plaintext to produce the ciphertext. RC4 is no longer considered secure and should be used only if required by legacy applications.

Block ciphers

A block cipher method operates on a fixed block of bytes. A NetScaler appliance provides two block ciphers: Data Encryption Standard (DES) and the Advanced Encryption Standard (AES). DES uses a block size of 8 bytes and (on a NetScaler appliance) two choices for key length: 64 bits (8 bytes), of which 56 bits are data and 8 bits are parity, and Triple-DES, a 192 bit (24 byte) key length. AES has a block size of 16 bytes and (on NetScaler) three choices for key length: 128 bits (16 bytes), 192 bits (24 bytes) and 256 bits (32 bytes).
Padding

If the plaintext for a block cipher is not an integral number of blocks, padding with additional bytes might be required. For example, suppose the plaintext is “xyzzy” (hex 78797a7a79). For an 8-byte Triple-DES block, this value would have to be padded to create 8 bytes. The padding scheme must allow the decryption function to determine the length of the original plaintext after decryption. Following are some padding schemes currently in use (n is the number of bytes added):

- **PKCS7**: Adds n bytes of value n each. For example, 78797a7a79030303. This is the padding scheme used by OpenSSL and ENCRYPT() policy function. The PKCS5 padding scheme is the same as PKCS7.
- **ANSI X.923**: Adds n-1 zero bytes and a final byte of value n. For example, 78797a7a79000003.
- **ISO 10126**: Adds n-1 random bytes and a final byte of value n. For example, 78797a7a79xxxx03, where xx can be any byte value. The DECRYPT() policy function accepts this padding scheme, which also allows it to accept the PKCS7 and ANSI X.923 schemes.
- **ISO/IEC 7816-4**: Adds a 0x80 byte and n-1 zero bytes. For example, 78797a7a79800000. This is also call OneAndZeros padding.
- **Zero**: Adds n zero bytes. Example: 78797a7a79000000. This can only be used with plaintext that does not include NUL bytes.

If padding is used and the plaintext is an integral number of blocks, an additional block is typically added so that the decryption function can unambiguously determine the original plaintext length. For PCKS7 and 8 byte block, this would be 0808080808080808.

Modes of operation

There are a number of different modes of operation for block ciphers, which specify how multiple blocks of plaintext are encrypted. Some modes use an initialization vector (IV), a block of data apart from the plaintext that is used to start the encryption process. It is a good practice to use a different IV for each encryption, so that the same plaintext produces different ciphertext. The IV does not need to be secret, and so is usually prepended to the ciphertext. Modes include:

- **Electronic Codebook (ECB)**: Each block of plaintext is encrypted independently. An IV is not used. Padding is required if the plaintext is not a multiple of the cipher block size. The same plaintext and key always produces the same ciphertext. Because of this, ECB is considered less secure than other modes and should only be used for legacy applications.
- **Cipher Block Chaining (CBC)**: Each block of plaintext is XORed with the previous ciphertext block, or the IV for the first block, before being encrypted. Padding is required if the plaintext is not a multiple of the cipher block size. This is the mode used with the NetScaler encryptionParams method.
- **Cipher Feedback (CFB)**: The previous ciphertext block, or the IV for the first block, is encrypted and the output is XORed with the current plaintext block to create the current ciphertext block.
The feedback can be 1 bit, 8 bits, or 128 bits. Since the plaintext is XORed with the cipher text, padding is not required.

- Output Feedback (OFB): A keystream is generated by applying the cipher successively to the IV and XORing the keystream blocks with the plaintext. Padding is not required.

**Configure encryption keys for third-party encryption**

Following are the configuration tasks performed in configuring encryption key.

1. Adding an encryption key. Configures an encryption key for a specified cipher method with a specified key value.
2. Modifying an encryption key. You can edit parameters for a configured encryption key.
3. Unsetting an encryption key. Sets parameters for a configured encryption key to their default values. An encryption key value with the name must exist. Sets padding to DEFAULT (determined by the method), Deletes an existing IV, which causes ENCRYPT() to generate a random IV. Deletes an existing comment. The method and key value cannot be reset.
4. Removing an encryption key. Deletes a configured encryption key. The key cannot have any references.
5. Show an encryption key. Displays parameters for the configured encryption key or all configured keys. If the name is omitted, the key value is not displayed.

**Add an encryption key by using the CLI**

At the command prompt, type:

```
add ns encryptionKey <name> -method <method> [-keyValue <hexstring>][-padding (OFF | ON)] [-iv <hexstring>] [-comment <string>]
```

Where,

```
1 <method> = ( NONE | RC4 | DES3 | AES128 | AES192 | AES256 | DES | DES-CBC | DES-CFB | DES-OFB | DES-ECB | DES3-CBC | DES3-CFB | DES3-OFB | DES3-ECB | AES128-CBC | AES128-CFB | AES128-OFB | AES128-ECB | AES192-CBC | AES192-CFB | AES192-OFB | AES192-ECB | AES256-CBC | AES256-CFB | AES256-OFB | AES256-ECB ) <hexstring> = hex-encoded byte sequence
```

The above encryption methods specify the operation mode with CBC as the default mode of operation. Therefore, DES, DES2, AES128, AES192, and AES256 methods are equivalent to DES-CBC, DES3-CBC, AES128-CBC, AES192-CBC, and AES256-CBC methods.

**Modify an encryption key by using the CLI**
At the command prompt, type:

```text
set ns encryptionKey <name> [-method <method>] [-keyValue <hexstring>] [-padding ( OFF | ON )] [-iv <string>] [-comment <string>]
```

**Unset an encryption key by using the CLI**

At the command prompt, type:

```text
unset ns encryptionKey <name> [-padding] [-iv] [-comment]
```

**Remove an encryption key by using the CLI**

At the command prompt, type:

```text
rm ns encryptionKey <name>
```

**Show an encryption key by using the CLI**

At the command prompt, type:

```text
Example:
```

```
1 show ns encryptionKey [<name>]  
2  
3 add ns encryptionKey my_key -method aes256 -keyValue 26 ea5537b7e0746089476e5658f9327c0b10c3b4778c673a5b38cee182874711 -iv c2bf0b2e15c15004d6b14bcde7e5e365  
4  
5 set ns encryptionKey my_key -keyValue b8742b163abcdef62d639837b3ee3ce9f543842d8200dfe6548831d2bd1d93476  
6  
7 unset ns encryptionKey my_key -iv  
8 rm ns encryptionKey my_key  
9 show ns encryptionKey my_key  
10 Name: my_key  
11 Method: AES256  
12 Padding: DEFAULT  
13 Key Value: (not disclosed)
```

**Add an encryption key by using the GUI**

Navigate to **System > Encryption Keys** and click **Add** to create an encryption key.

**Modify an encryption key by using the GUI**

Navigate to **System > Encryption Keys** and click **Edit** to modify parameters for a configured encryption key.
Remove an encryption key by using the GUI

Navigate to System > Encryption keys and click Delete.

**encrypt and decrypt functions for third-party encryption**

Following is the **encrypt** function used for third-party encryption.

\[
\text{encrypt} \left( \text{encryptionKey}, \text{out\_encoding} \right)
\]

Where,

- **Input data for the appliance** is the text to be encrypted
- **encryptionKey**: An optional string parameter that specifies the configured encryption key object to provide the encryption method, secret key value and other encryption parameters. If omitted, the method uses the automatically generated key value associated with the set ns encryptionParamS command.
- **out\_encoding**: This value specifies how the output is encoded. If omitted, BASE64 encoding is used.

**Input:**

<table>
<thead>
<tr>
<th>No.</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>BASE64: original PEM base64-encoding: 6 bits (0..63) encoded as one ASCII character:</td>
</tr>
<tr>
<td></td>
<td>0..23 = 'A'..'Z', 24..51 = 'a'..'z', 52..61 = '0'..'9'</td>
</tr>
<tr>
<td></td>
<td>62 = '+', 63 = '/', '=' = pad byte.</td>
</tr>
<tr>
<td>2</td>
<td>BASE64URL: URL and Filename safe base64-encoding: same as BASE64 except 62 = '-', 63 = '_'</td>
</tr>
<tr>
<td>3</td>
<td>HEX_UPPER: Hexadecimal with 0..9 = '0'..'9' and 10..15 = 'A'..'F'</td>
</tr>
<tr>
<td>4</td>
<td>HEX_LOWER: Hexadecimal with 0..9 = '0'..'9' and 10..15 = 'a'..'f'</td>
</tr>
<tr>
<td>5</td>
<td>HEX_COLONS: Hexadecimal with 0..9 = '0'..'9' and 10..15 = 'A'..'F'</td>
</tr>
<tr>
<td></td>
<td>';' between each hex byte. Matches BLOB_TO_HEX() output format</td>
</tr>
<tr>
<td>6</td>
<td>HEX: For input, accepts HEX_UPPER, HEX_LOWER, and HEX_COLONS format. For output, produces HEX_LOWER format</td>
</tr>
</tbody>
</table>

**Output:** The output is a text encrypted using the specified method and key and encoded using a specified output encoding. It inserts a generated IV before the encrypted text for block methods and modes that require an IV, and either no IV is specified for the encryptionKey or the encryptionKey is omitted.

Following is the **decrypt** function used for third-party decryption.

\[
\text{decrypt} \left( \text{encryptionKey}, \text{in\_encoding} \right)
\]

Where,
NetScaler 12.0

Input data is an encrypted text using the specified method and key encoded using the specified input encoding. This text is expected to include a generated IV before the encrypted text for block methods and modes that require an IV, and either no IV is specified for the encryptionKey or the encryptionKey is omitted.

cryptKey—An optional string parameter that specifies the configured encryptionKey object to provide the encryption method, secret key and other encryption parameters. If omitted, the method and automatically generated key associated with the encryptionParams setting will be used.

in_encoding—An optional enumeration parameter that specifies how the input is expected to be encoded. The values are the same as the out_encoding of ENCRYPT. If omitted, BASE64 encoding will be expected.

The output data is an unencoded decrypted text.

**Variants and optional parameters**

Following are the variants of these functions with the optional parameters:

<table>
<thead>
<tr>
<th>Variant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENCRYPT</td>
<td>Use encryptionParams command and BASE64 output encoding parameter.</td>
</tr>
<tr>
<td>ENCRYPT(out_encoding)</td>
<td>Use encryptionParams and specified output encoding parameter.</td>
</tr>
<tr>
<td>ENCRYPT(encryptionKey)</td>
<td>Use the specified encryptionKey and BASE64 output encoding parameter.</td>
</tr>
<tr>
<td>ENCRYPT(encryptionKey, out_encoding)</td>
<td>Use the specified encryptionKey and output encoding parameter.</td>
</tr>
<tr>
<td>DECRYPT</td>
<td>Use encryptionParams command and BASE64 input encoding parameter.</td>
</tr>
<tr>
<td>DECRYPT(out_encoding)</td>
<td>Use encryptionParams command and the specified input encoding parameter.</td>
</tr>
<tr>
<td>DECRYPT(encryptionKey)</td>
<td>Use the specified encryptionKey and BASE64 input encoding parameter.</td>
</tr>
<tr>
<td>DECRYPT(encryptionKey, out_encoding)</td>
<td>Use the specified encryptionKey and input encoding parameter.</td>
</tr>
</tbody>
</table>
Configure HMAC keys

NetScaler appliances support a Hashed Message Authentication Code (HMAC) function that calculates a digest method or hash of input text by using a secret key shared between a message sender and message receiver. The digest method (derived from an RFC 2104 technique) authenticates the sender and verifies that the message content has not been altered. For example, when a client sends a message with the shared HMAC key to a NetScaler appliance, advanced (PI) policy expressions use the HMAC function to compute the hash-based code on the selected text. Then, when the receiver receives the message with the secret key, it recomputes the HMAC by comparing it with the original HMAC to determine whether the message has been altered. The HMAC function is supported by standalone appliances and by appliances in a high availability configuration or in a cluster. Using it is similar to configuring an encryption key.

The add ns hmackey and set ns hmackey commands include a parameter that specifies the digest method and the shared secret key to use for the HMAC computation.

To configure a HMAC key, you must perform the following:

1. Adding an HMAC key. Configures an HMAC key with a specified key value.
2. Modifying an HMAC key. Modifies parameters for a configured HMAC key. The digest method can be changed without changing the key value, since the key value length is not determined by the digest. However, it is advisable to specify a new key when changing the digest.
3. Unsetting an HMAC key. Sets parameters for a configured HMAC key to their default values. An hmacKey object with the name must exist. The only parameter that can be unset is the comment, which is deleted.
4. Removing an HMAC key. Deletes a configured key. The key cannot have any references.
5. Show an HMAC key. Displays parameters for the configured HMAC ac key or all configured keys. If the name is omitted, the key value is not displayed.

Add an HMAC key by using the CLI

At the command prompt, type:

```
add ns hmacKey <name> -digest <digest> -keyValue <hexstring> [-comment <string>]
```

Where,

```
<digest> = (MD2 | MD4 | MD5 | SHA1 | SHA224 | SHA256 | SHA384 | SHA512)
```

This command configures a key for the HMAC () function with the specified digest and key value and also validates the following:

- Name syntax is correct and does not duplicate the name of an existing key.
NetScaler 12.0

- Key value is valid hex. As specified by RFC 2104, the key can any length. On a NetScaler appliance, the key value can range from 0 to 255 bytes (0 to 510 hex characters). If the key is shorter than the digest block size, a warning is issued and the key is padded with zeroes. If the key is longer than the block size, it is run through the digest to produce an effective key that is the same length as the block.

Example:

```
add ns hmacKey my_hmac_key -digest sha1 -keyValue 0c753c6c5ef859189cacdf95b506d02c1797
```

The above encryption methods specify the operation mode with CBC as the default mode of operation. Therefore, DES, DES2, AES128, AES192, and AES256 methods are equivalent to DES-CBC, DES3-CBC, AES128-CBC, AES192-CBC, and AES256-CBC methods.

Modify an HMAC key by using the CLI

This command modifies the parameters configured for a HMAC key. You can change the digest without changing the key value, since the key value length is not determined by the digest. However, it is advisable to specify a new key when changing the digest. At the command prompt, type:

```
set ns hmacKey <name> [-digest <digest>] [-keyValue <hexvalue>] [-comment <string>]
```

Unset an HMAC key by using the CLI

This command sets parameters configured for a HMAC key with their default values. An hmacKey object with the name must exist. The only parameter that you can unset is the comment option, which is deleted. At the command prompt, type:

```
unset ns hmacKey <name> -comment
```

Remove an HMAC key by using the CLI

This command deletes the configured hmac key. The key cannot have references. At the command prompt, type:

```
rmi ns hmacKey <name>
```

Show an HMAC key by using the CLI

At the command prompt, type:
Advanced policy expressions: working with dates, times, and numbers

September 24, 2018

Most numeric data that the NetScaler appliance processes consists of dates and times. In addition to working with dates and times, the appliance processes other numeric data, such as the lengths of HTTP requests and responses. To process this data, you can configure advanced policy expressions that process numbers.

A numeric expression consists of an expression prefix that returns a number and sometimes, but not always, an operator that can perform an operation on the number. Examples of expression prefixes that return numbers are SYS.TIME.DAY, HTTP.REQ.CONTENT_LENGTH, and HTTP.RES.BODY.LENGTH. Numeric operators can work with any prefix expression that returns data in numeric format. The GT(<int>) operator, for example, can be used with any prefix expression, such as HTTP.REQ.CONTENT_LENGTH, that returns an integer. Numeric expression prefixes and operators are also covered in Advanced Policy Expressions: Parsing HTTP, TCP, and UDP Data.

Format of dates and times in an expression

September 24, 2018

When configuring an advanced policy expression in a policy that works with dates and times (for example, the NetScaler system time or a date in an SSL certificate), you specify a time format as follows:

GMT|LOCAL [<yyyy>] [<month>] [<d>] [<h>] [<m>] [<s>]

Where:

- <yyyy> is a four-digit year after GMT or LOCAL.
• <month> is a three-character abbreviation for the month, for example, Jan, Dec.

• <d> is a day of the week or an integer for the date.

You cannot specify the day as Monday, Tuesday, and so on. You specify either an integer for a specific day of the month, or you specify a date as the first, second, third weekday of the month, and so on. Following are examples of specifying a day of the week:

– Sun_1 is the first Sunday of the month.
– Sun_3 is the third Sunday of the month.
– Wed_3 is the third Wednesday of the month.
– 30 is an example of an exact date in a month.

• <h> is the hour, for example, 10h.

• <s> is the number of seconds, for example, 30s.

The following example expression is true if the date is between 2008 Jan and 2009 Jan, based on GMT:

```
http.req.date.between(GMT 2008 Jan, GMT 2009 Jan)
```

The following example expression is true for March and all months that follow March in the calendar year, based on GMT:

```
sys.time.ge(GMT 2008 Mar)
```

When you specify a date and time, note that the format is case sensitive and must preserve the exact number of blank spaces between entries.

```
1 **Note:**
2 In an expression that requires two time values, both must use GMT or both must use LOCAL. You cannot mix the two in an expression.
3
4 Unlike when you use the SYS.TIME prefix in an advanced policy expression, if you specify SYS.TIME in a rewrite action, the NetScaler returns a string in conventional date format (for example, Sun, 06 Nov 1994 08:49:37 GMT). For example, the following rewrite action replaces the http.res.date header with the NetScaler system time in a conventional date format:
5
6 add rewrite action sync_date replace http.res.date sys.time
```

### Expressions for the NetScaler system time

September 24, 2018
The SYS. TIME expression prefix extracts the NetScaler system time. You can configure expressions that establish whether a particular event occurred at a particular time or within a particular time range according to the NetScaler system time.

The following table describes the expressions that you can create by using the SYS.TIME prefix.

- **SYS.TIME.BETWEEN(<time1>, <time2>):**
  
  Returns a Boolean TRUE if the returned value is later than <time1> and earlier than <time2>.

  You format the <time1>, <time2> arguments as follows:
  - They must both be GMT or both LOCAL.
  - <time2> must be later than <time1>.

  For example, if the current time is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month, you can specify the following:
  - sys.time.between(GMT 2004, GMT 2006)
  - sys.time.between(GMT 2004 Jan, GMT 2006 Nov)
  - sys.time.between(GMT 2004 Jan, GMT 2006)
  - sys.time.between(GMT 2005 May Sun_1, GMT 2005 May Sun_3)
  - sys.time.between(GMT 2005 May 1, GMT May 2005 1)
  - sys.time.between(LOCAL 2005 May 1, LOCAL May 2005 1)

- **SYS.TIME.DAY:**
  
  Returns the current day of the month as a number from 1 through 31.

- **SYS.TIME.EQ(<time>):**
  
  Returns a Boolean TRUE if the current time is equal to the <time> argument.

  For example, if the current time is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month, you can specify the following (evaluation results are shown in parentheses):
  - sys.time.eq(GMT 2005) (TRUE in this example.)
  - sys.time.eq(GMT 2005 Dec) (FALSE in this example.)
  - sys.time.eq(LOCAL 2005 May) (Evaluates to TRUE or FALSE in this example, depending on the current time zone.)
  - sys.time.eq(GMT 10h) (TRUE in this example.)
  - sys.time.eq(GMT 10h 30s) (TRUE in this example.)
  - sys.time.eq(GMT May 10h) (TRUE in this example.)
  - sys.time.eq(GMT Sun) (TRUE in this example.)
  - sys.time.eq(GMT May Sun_1) (TRUE in this example.)

- **SYS.TIME.NE(<time>):**
  
  Returns a Boolean TRUE if the current time is not equal to the <time> argument.
**SYS.TIME.GE(<time>):**

Returns a Boolean TRUE if the current time is later than or equal to <time>.

For example, if the current time is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month, you can specify the following (evaluation results are shown in parentheses):

- `sys.time.ge(GMT 2004)` (TRUE in this example.)
- `sys.time.ge(GMT 2005 Jan)` (TRUE in this example.)
- `sys.time.ge(LOCAL 2005 May)` (TRUE or FALSE in this example, depending on the current time zone.)
- `sys.time.ge(GMT 8h)` (TRUE in this example.)
- `sys.time.ge(GMT 30m)` (FALSE in this example.)
- `sys.time.ge(GMT May 10h)` (TRUE in this example.)
- `sys.time.ge(GMT May 10h 0m)` (TRUE in this example.)
- `sys.time.ge(GMT Sun)` (TRUE in this example.)
- `sys.time.ge(GMT May Sun_1)` (TRUE in this example.)

**SYS.TIME.GT(<time>):**

Returns a Boolean TRUE if the time value is later than the <time> argument.

For example, if the current time is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month, you can specify the following (evaluation results are shown in parentheses):

- `sys.time.gt(GMT 2004)` (TRUE in this example.)
- `sys.time.gt(GMT 2005 Jan)` (TRUE in this example.)
- `sys.time.gt(LOCAL 2005 May)` (TRUE or FALSE, depending on the current time zone.)
- `sys.time.gt(GMT 8h)` (TRUE in this example.)
- `sys.time.gt(GMT 30m)` (FALSE in this example.)
- `sys.time.gt(GMT May 10h)` (FALSE in this example.)
- `sys.time.gt(GMT May 10h 0m)` (TRUE in this example.)
- `sys.time.gt(GMT Sun)` (FALSE in this example.)
- `sys.time.gt(GMT May Sun_1)` (FALSE in this example.)

**SYS.TIME.HOURS:**

Returns the current hour as an integer from 0 to 23.

**SYS.TIME.LE(<time>):**

Returns a Boolean TRUE if the current time value precedes or is equal to the <time> argument.

For example, if the current time is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month, you can specify the following (evaluation results are shown in parentheses):

- `sys.time.le(GMT 2006)` (TRUE in this example.)
- `sys.time.le(GMT 2005 Dec)` (TRUE in this example.)
- `sys.time.le(LOCAL 2005 May)` (TRUE or FALSE depending on the current timezone.)
- `sys.time.le(GMT 8h)` (FALSE in this example.)
- `sys.time.le(GMT 30m)` (TRUE in this example.)
- `sys.time.le(GMT May 10h)` (TRUE in this example.)
- `sys.time.le(GMT Jun 11h)` (TRUE in this example.)
- `sys.time.le(GMT Wed)` (TRUE in this example.)
- `sys.time.le(GMT May Sun_1)` (TRUE in this example.)

**SYS.TIME.LT(<time>):**

Returns a Boolean TRUE if the current time value precedes the `<time>` argument.

For example, if the current time is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month, you can specify the following (evaluation results are shown in parentheses):

- `sys.time.lt(GMT 2006)` (TRUE in this example.)
- `sys.time.lt.time.lt(GMT 2005 Dec)` (TRUE in this example.)
- `sys.time.lt(LOCAL 2005 May)` (TRUE or FALSE depending on the current time zone.)
- `sys.time.lt(GMT 8h)` (FALSE in this example.)
- `sys.time.lt(GMT 30m)` (TRUE in this example.)
- `sys.time.lt(GMT May 10h)` (FALSE in this example.)
- `sys.time.lt(GMT Jun 11h)` (TRUE in this example.)
- `sys.time.lt(GMT Wed)` (TRUE in this example.)
- `sys.time.lt(GMT May Sun_1)` (FALSE in this example.)

**SYS.TIME.MINUTES:**

Returns the current minute as an integer from 0 to 59.

**SYS.TIME.MONTH:**

Extracts the current month and returns an integer from 1 (January) to 12 (December).

**SYS.TIME.RELATIVE_BOOT:**

Calculates the number of seconds to the closest previous or scheduled reboot, and returns an integer.

If the closest boot time is in the past, the integer is negative. If it is in the future, the integer is positive.

**SYS.TIME.RELATIVE_NOW:**

Calculates the number of seconds between the current NetScaler system time and the specified time, and returns an integer showing the difference.

If the designated time is in the past, the integer is negative; if it is in the future, the integer is positive.
• **SYS.TIME.SECONDS:**

Extracts the seconds from the current NetScaler system time, and returns that value as an integer from 0 to 59.

• **SYS.TIME.WEEKDAY:**

Returns the current weekday as a value from 0 (Sunday) to 6 (Saturday).

• **SYS.TIME.WITHIN (<time1>, <time2>):**

If you omit an element of time in <time1>, for example, the day or hour, it is assumed to have the lowest value in its range. If you omit an element in <time2>, it is assumed to have the highest value of its range.

The ranges for the elements of time are as follows: month 1-12, day 1-31, weekday 0-6, hour 0-23, minutes 0-59 and seconds 0-59. If you specify the year, you must do so in both <time1> and <time2>.

For example, if the time is GMT 2005 May 10 10h 15m 30s, and it is the second Tuesday of the month, you can specify the following (evaluation results are shown in parentheses):

- sys.time.within(GMT 2004, GMT 2006) (TRUE in this example.)
- sys.time.within(GMT 2004 Jan, GMT 2006 Mar) (FALSE, May is not in the range of January to March.)
- sys.time.within(GMT Feb, GMT) (TRUE, May is in the range of February to December.)
- sys.time.within(GMT Sun_1, GMT Sun_3) (TRUE, the second Tuesday is between the first Sunday and the third Sunday.)
- sys.time.within(GMT 2005 May 1 10h, GMT May 2005 1 17h) (TRUE in this example.)
- sys.time.within(LOCAL 2005 May 1, LOCAL May 2005 1) (TRUE or FALSE, depending on the NetScaler system time zone.)

• **SYS.TIME.YEAR:**

Extracts the year from the current system time and returns that value as a four-digit integer.

**Expressions for SSL certificate dates**

September 24, 2018

You can determine the validity period for SSL certificates by configuring an expression that contains the following prefix:

`CLIENT.SSL.CLIENT_CERT`

The following example expression matches a particular time for expiration with the information in the certificate:
The following table describes time-based operations on SSL certificates. To obtain the expression you want, replace certificate in the expression in the first column with the prefix expression, “CLIENT.SSL.CLIENT_CERT”.

- **<certificate>.VALID_NOT_AFTER:**
  Returns the last day before certificate expiration. The return format is the number of seconds since GMT January 1, 1970 (0 hours, 0 minutes, 0 seconds).

- **<certificate>.VALID_NOT_AFTER.BETWEEN(<time1>, <time2>):**
  Returns a Boolean TRUE value if the certificate validity is between the <time1> and <time2> arguments. Both <time1> and <time2> must be fully specified. Following are examples:
  - GMT 1995 Jan is fully specified.
  - GMT Jan is not fully specified
  - GMT 1995 20 is not fully specified.
  - GMT Jan Mon_2 is not fully specified.
  The <time1> and <time2> arguments must be both GMT or both LOCAL, and <time2> must be greater than <time1>.
  For example, if it is GMT 2005 May 1 10h 15m 30s, and the first Sunday of the month, you can specify the following (evaluation results are in parentheses).
    - . . .between(GMT 2004, GMT 2006) (TRUE)
    - . . .between(GMT 2004 Jan, GMT 2006 Nov) (TRUE)
    - . . .between(GMT 2004 Jan, GMT 2006) (TRUE)
    - . . .between(GMT 2005 May Sun_1, GMT 2005 May Sun_3) (TRUE)
    - . . .between(GMT 2005 May 1, GMT May 2005 1) (TRUE)
    - . . .between(LOCAL 2005 May 1, LOCAL May 2005 1) (TRUE or FALSE, depending on the NetScaler system time zone.)

- **<certificate>.VALID_NOT_AFTER.DAY:**
  Extracts the last day of the month that the certificate is valid, and returns a number from 1 through 31, as appropriate for the date.

- **<certificate>.VALID_NOT_AFTER.EQ(<time>):**
  Returns a Boolean TRUE if the time is equal to the <time> argument.
  For example, if the current time is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month, you can specify the following (evaluation results for this example are in parentheses):
    - . . .eq(GMT 2005) (TRUE)
- . . .eq(GMT 2005 Dec) (FALSE)
- . . .eq(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone)
- . . .eq(GMT 10h) (TRUE)
- . . .eq(GMT 10h 30s) (TRUE)
- . . .eq(GMT May 10h) (TRUE)
- . . .eq(GMT Sun) (TRUE)
- . . .eq(GMT May Sun_1) (TRUE)

• <certificate>.VALID_NOT_AFTER.GE(<time>):

Returns a Boolean TRUE if the time value is greater than or equal to the argument <time>.

For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results for this example are in parentheses):

- . . .ge(GMT 2004) (TRUE)
- . . .ge(GMT 2005 Jan) (TRUE)
- . . .ge(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.)
- . . .ge(GMT 8h) (TRUE)
- . . .ge(GMT 30m) (FALSE)
- . . .ge(GMT May 10h) (TRUE)
- . . .ge(GMT May 10h 0m) (TRUE)
- . . .ge(GMT Sun) (TRUE)
- . . .ge(GMT May Sun_1) (TRUE)

• <certificate>.VALID_NOT_AFTER.GT(<time>):

Returns a Boolean TRUE if the time value is greater than the argument <time>.

For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results for this example are in parentheses):

- . . .gt(GMT 2004) (TRUE)
- . . .gt(GMT 2005 Jan) (TRUE)
- . . .gt(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.)
- . . .gt(GMT 8h) (TRUE)
- . . .gt(GMT 30m) (FALSE)
- . . .gt(GMT May 10h) (FALSE)
- . . .gt(GMT Sun) (FALSE)
- . . .gt(GMT May Sun_1) (FALSE)

• <certificate>.VALID_NOT_AFTER.HOURS:

Extracts the last hour that the certificate is valid and returns that value as an integer from 0 to
23.

- `<certificate>.VALID_NOT_AFTER.LE(<time>):`

  Returns a Boolean TRUE if the time precedes or is equal to the `<time>` argument.

  For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results for this example are in parentheses):

  - . . .le(GMT 2006) (TRUE)
  - . . .le(GMT 2005 Dec) (TRUE)
  - . . .le(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.)
  - . . .le(GMT 8h) (FALSE)
  - . . .le(GMT 30m) (TRUE)
  - . . .le(GMT May 10h) (TRUE)
  - . . .le(GMT Jun 11h) (TRUE)
  - . . .le(GMT Wed) (TRUE)
  - . . .le(GMT May Sun_1) (TRUE)

- `<certificate>.VALID_NOT_AFTER.LT(<time>):`

  Returns a Boolean TRUE if the time precedes the `<time>` argument.

  For example, if the current time is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month, you can specify the following:

  - . . .lt(GMT 2006) (TRUE)
  - . . .lt(GMT 2005 Dec) (TRUE)
  - . . .lt(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.)
  - . . .lt(GMT 8h) (FALSE)
  - . . .lt(GMT 30m) (TRUE)
  - . . .lt(GMT May 10h) (FALSE)
  - . . .lt(GMT Jun 11h) (TRUE)
  - . . .lt(GMT Wed) (TRUE)
  - . . .lt(GMT May Sun_1) (FALSE)

- `<certificate>.VALID_NOT_AFTER.MINUTES:`

  Extracts the last minute that the certificate is valid and returns that value as an integer from 0 to 59.

- `<certificate>.VALID_NOT_AFTER.MONTH:`

  Extracts the last month that the certificate is valid and returns that value as an integer from 1 (January) to 12 (December).

- `<certificate>.VALID_NOT_AFTER.RELATIVE_BOOT:`
Calculates the number of seconds to the closest previous or scheduled reboot and returns an integer. If the closest boot time is in the past, the integer is negative. If it is in the future, the integer is positive.

- `<certificate>.VALID_NOT_AFTER.RELATIVE_NOW;`

Calculates the number of seconds between the current system time and the specified time and returns an integer. If the time is in the past, the integer is negative; if it is in the future, the integer is positive.

- `<certificate>.VALID_NOT_AFTER.SECONDS;`

Extracts the last second that the certificate is valid and returns that value as an integer from 0 to 59.

- `<certificate>.VALID_NOT_AFTER.WEEKDAY;`

Extracts the last weekday that the certificate is valid. Returns a number between 0 (Sunday) and 6 (Saturday) to give the weekday in the time value.

- `<certificate>.VALID_NOT_AFTER.WITHIN(<time1>,<time2>);`

Returns a Boolean TRUE if the time lies within all the ranges defined by the elements in `<time1>` and `<time2>`.

If you omit an element of time from `<time1>`, it is assumed to have the lowest value in its range. If you omit an element from `<time2>`, it is assumed to have the highest value of its range. If you specify a year in `<time1>`, you must specify it in `<time2>`.

The ranges for elements of time are as follows: month 1-12, day 1-31, weekday 0-6, hour 0-23, minutes 0-59 and seconds 0-59. For the result to be TRUE, each element in the time must exist in the corresponding range that you specify in `<time1>`, `<time2>`.

For example, if time is GMT 2005 May 10 10h 15m 30s, and it is the second Tuesday of the month, you can specify the following (evaluation results are in parentheses):

- . . .within(GMT 2004, GMT 2006) (TRUE)
- . . .within(GMT 2004 Jan, GMT 2006 Mar) (FALSE, May is not in the range of January to March.)
- . . .within(GMT Feb, GMT) (TRUE, May is in the range for February to December)
- . . .within(GMT Sun_1, GMT Sun_3) (TRUE, the second Tuesday lies within the range of the first Sunday through the third Sunday)
- . . .within(GMT 2005 May 1 10h, GMT May 2005 1 17h) (TRUE)
- . . .within(LOCAL 2005 May 1, LOCAL May 2005 1) (TRUE or FALSE, depending on the NetScaler system time zone)

- `<certificate>.VALID_NOT_AFTER.YEAR;`

Extracts the last year that the certificate is valid and returns a four-digit integer.
• `<certificate>.VALID_NOT_BEFORE`:

Returns the date that the client certificate becomes valid.

The return format is the number of seconds since GMT January 1, 1970 (0 hours, 0 minutes, 0 seconds).

• `<certificate>.VALID_NOT_BEFORE.BETWEEN(<time1>, <time2>)`:

Returns a Boolean TRUE if the time value is between the two time arguments. Both `<time1>` and `<time2>` arguments must be fully specified.

Following are examples:

- GMT 1995 Jan is fully specified.
- GMT Jan is not fully specified.
- GMT 1995 20 is not fully specified.
- GMT Jan Mon_2 is not fully specified.

The time arguments must be both GMT or both LOCAL, and `<time2>` must be greater than `<time1>`.

For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results for this example are in parentheses):

- . . .between(GMT 2004, GMT 2006) (TRUE)
- . . .between(GMT 2004 Jan, GMT 2006 Nov) (TRUE)
- . . .between(GMT 2004 Jan, GMT 2006) (TRUE)
- . . .between(GMT 2005 May Sun_1, GMT 2005 May Sun_3) (TRUE)
- . . .between(GMT 2005 May 1, GMT May 2005 1) (TRUE)
- . . .between(LOCAL 2005 May 1, LOCAL May 2005 1) (TRUE or FALSE, depending on the NetScaler system time zone.)

• `<certificate>.VALID_NOT_BEFORE.DAY`:

Extracts the last day of the month that the certificate is valid and returns that value as a number from 1 through 31 representing that day.

• `<certificate>.VALID_NOT_BEFORE.EQ(<time>)`:

Returns a Boolean TRUE if the time is equal to the `<time>` argument.

For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results for this example are in parentheses):

- . . .eq(GMT 2005) (TRUE)
- . . .eq(GMT 2005 Dec) (FALSE)
- . . .eq(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.)
NetScaler 12.0

- . . .eq(GMT 10h) (TRUE)
- . . .eq(GMT 10h 30s) (TRUE)
- . . .eq(GMT May 10h) (TRUE)
- . . .eq(GMT Sun) (TRUE)
- . . .eq(GMT May Sun_1) (TRUE)

• **<certificate>.VALID_NOT_BEFORE.GE(<time>):**

Returns a Boolean TRUE if the time is greater than (after) or equal to the <time> argument.

For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results are in parentheses):

- . . .ge(GMT 2004) (TRUE)
- . . .ge(GMT 2005 Jan) (TRUE)
- . . .ge(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.)
- . . .ge(GMT 8h) (TRUE)
- . . .ge(GMT 30m) (FALSE)
- . . .ge(GMT May 10h) (TRUE)
- . . .ge(GMT May 10h 0m) (TRUE)
- . . .ge(GMT Sun) (TRUE)
- . . .ge(GMT May Sun_1) (TRUE)

• **<certificate>.VALID_NOT_BEFORE.GT(<time>):**

Returns a Boolean TRUE if the time occurs after the <time> argument.

For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results are in parentheses):

- . . .gt(GMT 2004) (TRUE)
- . . .gt(GMT 2005 Jan) (TRUE)
- . . .gt(LOCAL 2005 May) (TRUE or FALSE, depending on the current time zone.)
- . . .gt(GMT 8h) (TRUE)
- . . .gt(GMT 30m) (FALSE)
- . . .gt(GMT May 10h) (FALSE)
- . . .gt(GMT May 10h 0m) (TRUE)
- . . .gt(GMT Sun) (FALSE)
- . . .gt(GMT May Sun_1) (FALSE)

• **<certificate>.VALID_NOT_BEFORE.HOURS:**

Extracts the last hour that the certificate is valid and returns that value as an integer from 0 to 23.

- **<certificate>.VALID_NOT_BEFORE.LE(<time>)**
Returns a Boolean TRUE if the time precedes or is equal to the <time> argument.

For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results for this example are in parentheses):

- \( \leq \text{GMT 2006} \) (TRUE)
- \( \leq \text{GMT 2005 Dec} \) (TRUE)
- \( \leq \text{LOCAL 2005 May} \) (TRUE or FALSE, depending on the current time zone.)
- \( \leq \text{GMT 8h} \) (FALSE)
- \( \leq \text{GMT 30m} \) (TRUE)
- \( \leq \text{GMT May 10h} \) (TRUE)
- \( \leq \text{GMT Jun 11h} \) (TRUE)
- \( \leq \text{GMT Wed} \) (TRUE)
- \( \leq \text{GMT May Sun_1} \) (TRUE)

- <certificate>.VALID_NOT_BEFORE.LT(<time>):

Returns a Boolean TRUE if the time precedes the <time> argument.

For example, if the time value is GMT 2005 May 1 10h 15m 30s, and it is the first Sunday of the month of May in 2005, you can specify the following (evaluation results for this example are in parentheses):

- \( \lt \text{GMT 2006} \) (TRUE)
- \( \lt \text{GMT 2005 Dec} \) (TRUE)
- \( \lt \text{LOCAL 2005 May} \) (TRUE or FALSE, depending on the current time zone.)
- \( \lt \text{GMT 8h} \) (FALSE)
- \( \lt \text{GMT 30m} \) (TRUE)
- \( \lt \text{GMT May 10h} \) (FALSE)
- \( \lt \text{GMT Jun 11h} \) (TRUE)
- \( \lt \text{GMT Wed} \) (TRUE)
- \( \lt \text{GMT May Sun_1} \) (FALSE)

- <certificate>.VALID_NOT_BEFORE.MINUTES:

Extracts the last minute that the certificate is valid. Returns the current minute as an integer from 0 to 59.

- <certificate>.VALID_NOT_BEFORE.MONTH:

Extracts the last month that the certificate is valid. Returns the current month as an integer from 1 (January) to 12 (December).

- <certificate>.VALID_NOT_BEFORE.RELATIVE_BOOT:

Calculates the number of seconds to the closest previous or scheduled NetScaler reboot and
returns an integer. If the closest boot time is in the past, the integer is negative; if it is in the
future, the integer is positive.

• <certificate>.VALID_NOT_BEFORE.RELATIVE_NOW:
  Returns the number of seconds between the current NetScaler system time and the specified
time as an integer. If the designated time is in the past, the integer is negative. If it is in the
future, the integer is positive.

• <certificate>.VALID_NOT_BEFORE.SECONDS:
  Extracts the last second that the certificate is valid. Returns the current second as an integer
from 0 to 59.

• <certificate>.VALID_NOT_BEFORE.WEEKDAY:
  Extracts the last weekday that the certificate is valid. Returns the weekday as a number between
0 (Sunday) and 6 (Saturday).

• <certificate>.VALID_NOT_BEFORE.WITHIN(<time1>, <time2>):
  Returns a Boolean TRUE if each element of time exists within the range defined in the <time1>,
<time2> arguments.

  If you omit an element of time from <time1>, it is assumed to have the lowest value in its range.
  If you omit an element of time from <time2>, it is assumed to have the highest value in its range.
  If you specify a year in <time1>, it must be specified in <time2>. The ranges for elements of time
  are as follows: month 1-12, day 1-31, weekday 0-6, hour 0-23, minutes 0-59 and seconds 0-59.

  For example, if the time is GMT 2005 May 10 10h 15m 30s, and it is the second Tuesday of the
  month, you can specify the following (evaluation results are in parentheses):

  - . . .within(GMT 2004, GMT 2006) (TRUE)
  - . . .within(GMT 2004 Jan, GMT 2006 Mar) (FALSE, May is not in the range of January to
    March.)
  - . . .within(GMT Feb, GMT) (TRUE, May is in the range of February to December.)
  - . . .within(GMT Sun_1, GMT Sun_3) (TRUE, the second Tuesday is between the first Sunday
    and the third Sunday.)
  - . . .within(GMT 2005 May 1 10h, GMT May 2005 1 17h) (TRUE)
  - . . .within(LOCAL 2005 May 1, LOCAL May 2005 1) (TRUE or FALSE, depending on the
    NetScaler system time zone)

• <certificate>.VALID_NOT_BEFORE.YEAR:
  Extracts the last year that the certificate is valid. Returns the current year as a four-digit integer.
Expressions for HTTP request and response dates

September 24, 2018

The following expression prefixes return the contents of the HTTP Date header as text or as a date object. These values can be evaluated as follows:

- As a number. The numeric value of an HTTP Date header is returned in the form of the number of seconds since Jan 1, 1970.

  For example, the expression `http.req.date.mod(86400)` returns the number of seconds since the beginning of the day. These values can be evaluated using the same operations as other non-date-related numeric data. For more information, see Expression prefixes for numeric data other than date and time.

- As an HTTP header. Date headers can be evaluated using the same operations as other HTTP headers.

  For more information, see Default syntax expressions: Parsing HTTP, TCP, and UDP data.

- As text. Date headers can be evaluated using the same operations as other strings.

  For more information, see Advanced Policy Expressions: Evaluating Text.

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HTTP.REQ.DATE</td>
<td>Returns the contents of the HTTP Date header as text or as a date object. The date formats recognized are: RFC822. Sun, 06 Jan 1980 08:49:37 GMT, RFC850. Sunday, 06-Jan-80 09:49:37 GMT, and ASCTIME. Sun Jan 6 08:49:37 1980.</td>
</tr>
<tr>
<td>HTTP.RES.DATE</td>
<td>Returns the contents of the HTTP Date header as text or as a date object. The date formats recognized are: RFC822. Sun, 06 Jan 1980 8:49:37 GMT, RFC850. Sunday, 06-Jan-80 9:49:37 GMT, and ASCTIME. Sun Jan 6 08:49:37 1980.</td>
</tr>
</tbody>
</table>

Generate the day of the week, as a string, in short and long formats

September 24, 2018
The functions, WEEKDAY_STRING_SHORT and WEEKDAY_STRING, generate the day of the week, as a string, in short and long formats, respectively. The strings that are returned are always in English. The prefix used with these functions must return the day of the week in integer format and the acceptable range for the value returned by the prefix is 0-6. Therefore, you can use any prefix that returns an integer in the acceptable range. An UNDEF condition is raised if the returned value is not in this range or if memory allocation fails.

Following are the descriptions of the functions:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;prefix&gt;.WEEKDAY_STRING_SHORT</td>
<td>Returns the day of the week in short format. The short form is always 3 characters long with an initial capital and the remaining characters in lower case. For example, SYS.TIME.WEEKDAY.WEEKDAY_STRING_SHORT returns Sun if the value returned by the WEEKDAY function is 0 and Sat if the value returned by the prefix is 6.</td>
</tr>
<tr>
<td>&lt;prefix&gt;.WEEKDAY_STRING</td>
<td>Returns the day of the week in long format. The long form always has an initial capital, with the remaining characters in lower case. For example, SYS.TIME.WEEKDAY.WEEKDAY_STRING returns Sunday if the value returned by the WEEKDAY function is 0 and Saturday if the value returned by the prefix is 6.</td>
</tr>
</tbody>
</table>

Expression prefixes for numeric data other than date and time

September 24, 2018

In addition to configuring expressions that operate on time, you can configure expressions for the following types of numeric data:

- The length of HTTP requests, the number of HTTP headers in a request, and so on.
  
  For more information, see [Expressions for numeric HTTP payload data other than dates](#).

- IP and MAC addresses.
  
  For more information, see [Expressions for IP addresses and IP subnets](#).
• Client and server data in regard to interface IDs and transaction throughput rate.
  For more information, see Expressions for numeric client and server data.

• Numeric data in client certificates other than dates.
  For information on these prefixes, including the number of days until certificate expiration and the encryption key size, see Prefixes for numeric data in SSL certificates.

Converting numbers to text

September 24, 2018

The following functions produce binary strings from a number returned by an expression prefix. These functions are particularly useful in the TCP rewrite feature as replacement strings for binary data. For more information about the TCP rewrite feature, see Rewrite.

All the functions return a value of type text. The endianness that some of the functions accept as a parameter is either LITTLE_ENDIAN or BIG_ENDIAN.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;number&gt;.SIGNED8_STRING</td>
<td>Produces an 8-bit signed binary string representing the number. If the value is out of range, an undef condition is raised. Example: HTTP.REQ.BODY(100).GET_SIGNED8(16).SUB(3).SIGNED8_STRING</td>
</tr>
<tr>
<td>&lt;number&gt;.UNSIGNED8_STRING</td>
<td>Produces an 8-bit unsigned binary string representing the number. If the value is out of range, an undef condition is raised. Example: HTTP.REQ.BODY(100).GET_UNSIGNED8(31).ADD(3).UNSIGNED8_STRING</td>
</tr>
<tr>
<td>&lt;number&gt;.SIGNED16_STRING(&lt;endianness&gt;)</td>
<td>Produces a 16-bit signed binary string representing the number. If the value is out of range, an undef condition is raised. Example: HTTP.REQ.BODY(100).SKIP(12).GET_SIGNED16(0, BIG_ENDIAN).SUB(4).SIGNED16_STRING(BIG_ENDIAN)</td>
</tr>
<tr>
<td>&lt;number&gt;.UNSIGNED16_STRING(&lt;endianness&gt;)</td>
<td>Produces a 16-bit unsigned binary string representing the number. If the value is out of range, an undef condition is raised. Example: HTTP.REQ.BODY(100).GET_UNSIGNED16(47, LITTLE_ENDIAN).ADD(7).UNSIGNED16_STRING(LITTLE_ENDIAN)</td>
</tr>
</tbody>
</table>
### NetScaler 12.0

#### Function Description

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;number&gt;.SIGNED32_STRING(&lt;endianness&gt;)</code></td>
<td>Produces a 32-bit signed binary string representing the number. Example: HTTP.REQ.BODY(100).AFTER_STR(“delim”).GET_SIGNED32(BIG_ENDIAN).SUB(1).SIGNED32_STRING(BIG_ENDIAN)</td>
</tr>
<tr>
<td><code>&lt;unsigned_long_number&gt;.UNSIGNED8_STRING</code></td>
<td>Produces an 8-bit unsigned binary string representing the number. If the value is out of range, an undef condition is raised. Example: HTTP.REQ.BODY(100).GET_UNSIGNED8(24).TYPECAST_UNSIGNED_LONG_AT.ADD(12).UNSIGNED8_STRING</td>
</tr>
<tr>
<td><code>&lt;unsigned_long_number&gt;.UNSIGNED16_STRING(&lt;endianness&gt;)</code></td>
<td>Produces a 16-bit unsigned binary string representing the number. If the value is out of range, an undef condition is raised. Example: HTTP.REQ.BODY(100).GET_UNSIGNED16(23,LITTLE_ENDIAN).TYPECAST UNSIGNED_LONG_AT.ADD(10).UNSIGNED16_STRING(LITTLE_ENDIAN)</td>
</tr>
<tr>
<td><code>&lt;unsigned_long_number&gt;.UNSIGNED32_STRING(&lt;endianness&gt;)</code></td>
<td>Produces a 32-bit unsigned binary string representing the number. If the value is out of range, an undef condition is raised. Example: HTTP.REQ.BODY(100).AFTER_STR(“delim2”).GET_UNSIGNED32(0,BIG_ENDIAN).ADD(2).UNSIGNED32_STRING(BIG_ENDIAN)</td>
</tr>
</tbody>
</table>

### Virtual server based expressions

September 24, 2018

The `SYS.VSERVER("<vserver-name>")` expression prefix enables you to identify a virtual server. You can use the following functions with this prefix to retrieve information related to the specified virtual server:

- **THROUGHPUT.** Returns the throughput of the virtual server in Mbps (Megabits per second). The value returned is an unsigned long number.
  
  **Usage:** `SYS.VSERVER("vserver").THROUGHPUT`

- **CONNECTIONS.** Returns the number of connections being managed by the virtual server. The value returned is an unsigned long number.
  
  **Usage:** `SYS.VSERVER("vserver").CONNECTIONS`

- **STATE.** Returns the state of the virtual server. The value returned is `UP`, `DOWN`, or `"\"undetermined\"\"`.
  
  **Usage:** `SYS.VSERVER("vserver").STATE`
OUT_OFSERVICE. One of these values can therefore be passed as an argument to the
EQ() operator to perform a comparison that results in a Boolean TRUE or FALSE.

**Usage:** SYS.VSERVER(“vserver”).STATE

- **HEALTH.** Returns the percentage of services in an UP state for the specified virtual server. The
  value returned is an integer.

  **Usage:** SYS.VSERVER(“vserver”).HEALTH

- **RESPTIME.** Returns the response time as an integer representing the number of microseconds. Response
time is the average TTFB (Time To First Byte) from all the services bound to the virtual
server.

  **Usage:** SYS.VSERVER(“vserver”).RESPTIME

- **SURGECOUNT.** Returns the number of requests in the surge queue of the virtual server. The
  value returned is an integer.

  **Usage:** SYS.VSERVER(“vserver”).SURGECOUNT

**Example 1:**
The following rewrite policy aborts rewrite processing if the number of connections at the load bal-
ancing virtual server LBvserver exceeds 10000:

```
add rewrite policy norewrite_pol sys.vserver("LBvserver").connections.gt (10000) norewrite
```

**Example 2:**
The following rewrite action inserts a custom header, TP, whose value is the throughout at the virtual
server LBvserver:

```
add rewrite action tp_header insert_http_header TP SYS.VSERVER("LBvserver").THROUGHPUT
```

**Example 3:**
The following audit log message action writes the average TTFB of the services bound to a virtual
server, to the newnslog log file:

```
add audit message action log_vserver_resptime_act INFORMATIONAL \"\"NS Response Time to Servers:\" + sys.vserver("sslbyb").resptime + \" millisec \"-logtoNewnslog YES -bypassSafetyCheck YES
```

**Advanced policy expressions: Parsing HTTP, TCP, and UDP data**
You can configure Advanced policy expressions to evaluate and process the payload in HTTP requests and responses. The payload associated with an HTTP connection includes the various HTTP headers (both standard and custom headers), the body, and other connection information such as the URL. Additionally, you can evaluate and process the payload in a TCP or UDP packet. For HTTP connections, for example, you can check whether a particular HTTP header is present or if the URL includes a particular query parameter.

You can configure expressions to transform the URL encoding and apply HTML or XML “safe” coding for subsequent evaluation. You can also use XPATH and JSON prefixes to evaluate date in XML and JSON files, respectively.

You can also use text-based and numeric Advanced policy expressions to evaluate HTTP request and response data. For more information, see Advanced policy expressions: Evaluating text and Default Syntax Expressions: Working with Dates, Times, and Numbers.

About evaluating HTTP and TCP payload

September 24, 2018

The payload of an HTTP request or response consists of HTTP protocol information such as headers, a URL, body content, and version and status information. When you configure a default syntax expression to evaluate HTTP payload, you use a default syntax expression prefix and, if necessary, an operator.

For example, you use the following expression, which includes the http.req.header("<header_name>“) prefix and the exists operator, if you want to determine whether an HTTP connection includes a custom header named “myHeader”:

```plaintext
http.req.header("myHeader").exists
```

You can also combine multiple Advanced policy expressions with Boolean and arithmetic operators. For example, the following compound expression could be useful with various NetScaler features, such as Integrated Caching, Rewrite, and Responder. This expression first uses the && Boolean operator to determine whether an HTTP connection includes the Content-Type header with a value of “text/html.” If that operation returns a value of FALSE, the expression determines whether the HTTP connection includes a “Transfer-Encoding” or “Content-Length” header.

```plaintext
(http.req.header("Content-Type").exists && http.req.header("Content-Type") .eq("text/html") || (http.req.header("Transfer-Encoding").exists) || (http. req.header("Content-Length").exists)
```

The payload of a TCP or UDP packet is the data portion of the packet. You can configure Advanced policy expressions to examine features of a TCP or UDP packet, including the following:

- Source and destination domains
- Source and destination ports
- The text in the payload
- Record types

The following expression prefixes extract text from the body of the payload:

- **HTTP.REQ.BODY(integer)**. Returns the body of an HTTP request as a multiline text object, up to the character position designated in the integer argument. If there are fewer characters in the body than is specified in the argument, the entire body is returned.
- **HTTP.RES.BODY(integer)**. Returns a portion of the HTTP response body. The length of the returned text is equal to the number in the integer argument. If there are fewer characters in the body than is specified in integer, the entire body is returned.
- **CLIENT.TCP.PAYLOAD(integer)**. Returns TCP payload data as a string, starting with the first character in the payload and continuing for the number of characters in the integer argument.

Following is an example that evaluates to TRUE if a response body of 1024 bytes contains the string “https”, and this string occurs after the string “start string” and before the string “end string”:

```
http.res.body(1024).after_str("start_string").before_str("end_string").contains("https")
```

**Note:** You can apply any text operation to the payload body. For information on operations that you can apply to text, see Advanced policy expressions: Evaluating text.

### Expressions for identifying the protocol in an incoming IP packet

**September 24, 2018**

The following table lists the expressions that you can use to identify the protocol in an incoming packet.

<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLIENT.IP.PROTOCOL</td>
<td>Identifies the protocol in IPv4 packets sent by clients.</td>
</tr>
<tr>
<td>CLIENT.IPV6.PROTOCOL</td>
<td>Identifies the protocol in IPv6 packets sent by clients.</td>
</tr>
<tr>
<td>SERVER.IP.PROTOCOL</td>
<td>Identifies the protocol in IPv4 packets sent by servers.</td>
</tr>
<tr>
<td>SERVER.IPV6.PROTOCOL</td>
<td>Identifies the protocol in IPv6 packets sent by servers.</td>
</tr>
</tbody>
</table>
Arguments to the PROTOCOL function

You can pass the Internet Assigned Numbers Authority (IANA) protocol number to the PROTOCOL function. For example, if you want to determine whether the protocol in an incoming packet is TCP, you can use CLIENT.IP.PROTOCOL.EQ(6), where 6 is the IANA-assigned protocol number for TCP. For some protocols, you can pass an enumeration value instead of the protocol number. For example, instead of CLIENT.IP.PROTOCOL.EQ(6), you can use CLIENT.IP.PROTOCOL.EQ(TCP). The following table lists the protocols for which you can use enumeration values, and the corresponding enumeration values for use with the PROTOCOL function.

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Enumeration value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Transmission Control Protocol (TCP)</td>
<td>TCP</td>
</tr>
<tr>
<td>User Datagram Protocol (UDP)</td>
<td>UDP</td>
</tr>
<tr>
<td>Internet Control Message Protocol (ICMP)</td>
<td>ICMP</td>
</tr>
<tr>
<td>IP Authentication Header (AH), for providing authentication services in IPv4 and IPv6</td>
<td>AH</td>
</tr>
<tr>
<td>Encapsulating Security Payload (ESP) protocol</td>
<td>ESP</td>
</tr>
<tr>
<td>General Routing Encapsulation (GRE)</td>
<td>GRE</td>
</tr>
<tr>
<td>IP-within-IP Encapsulation Protocol</td>
<td>IPIP</td>
</tr>
<tr>
<td>Internet Control Message Protocol for IPv6 (ICMPv6)</td>
<td>ICMPv6</td>
</tr>
<tr>
<td>Fragment Header for IPv6</td>
<td>FRAGMENT</td>
</tr>
</tbody>
</table>

Use case scenarios

The protocol expressions can be used in both request-based and response-based policies. You can use the expressions in various NetScaler features, such as load balancing, WAN optimization, content switching, rewrite, and listen policies. You can use the expressions with functions such as EQ() and NE(), to identify the protocol in a policy and perform an action.

Following are some use cases for the expressions:

- In Branch Repeater load balancing configurations, you can use the expressions in a listen policy for the wildcard virtual server. For example, you can configure the wildcard virtual server with the listen policy CLIENT.IP.PROTOCOL.EQ(TCP) so that the virtual server processes only TCP traffic and simply bridges all non-TCP traffic. Even though you can use an Access Control List instead of the listen policy, the listen policy provides better control over what traffic is processed.
• For content switching virtual servers of type ANY, you can configure content switching policies that switch requests on the basis of the protocol in incoming packets. For example, you can configure content switching policies to direct all TCP traffic to one load balancing virtual server and all non-TCP traffic to another load balancing virtual server.
• You can use the client-based expressions to configure persistence based on the protocol. For example, you can use CLIENT.IP.PROTOCOL to configure persistence on the basis of the protocols in incoming IPv4 packets.

Expressions for HTTP and cache-control headers

September 24, 2018

One common method of evaluating HTTP traffic is to examine the headers in a request or a response. A header can perform a number of functions, including the following:

• Provide cookies that contain data about the sender.
• Identify the type of data that is being transmitted.
• Identify the route that the data has traveled (the Via header).

Note

If an operation is used to evaluate both header and text data, the header-based operation always overrides the text-based operation. For example, the AFTER_STR operation, when applied to a header, overrides text-based AFTER_STR operations for all instances of the current header type.

Prefixes for HTTP headers

The following table describes expression prefixes that extract HTTP headers.
<table>
<thead>
<tr>
<th>HTTP Header Prefix</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HTTP:REQ:HEADER(&quot;&quot;)</td>
<td>Returns the contents of the HTTP header specified by the argument. The header name cannot exceed 32 characters. Note that this prefix returns the value from the Host header by default. To use this value as a hostname you need to typecast it as follows: <code>http.req.header(&quot;host&quot;).typecast_http_hostname_t</code>. For more information on typecasting, see <a href="/en-us/netscaler/12/appexpert/policies-and-expressions/ns-typecasting-data-wrapper-con.html">Typecasting data</a>.</td>
</tr>
<tr>
<td>HTTP:REQ:FULL_HEADER</td>
<td>Returns the contents of the complete set of HTTP header fields including the request line (for example, “GET /brochures/index.html HTTP/1.1”) and the terminating \r\n\r\n sequence.</td>
</tr>
<tr>
<td>HTTP Header Prefix</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>HTTP.REQ.DATE</td>
<td>Returns the contents of the HTTP Date header. The following date formats are recognized: RFC822. Sun, 06 Jan 1980 8:49:37 GMT, RFC850. Sunday, 06-Jan-80 9:49:37 GMT, ASCII TIME. Sun Jan 6 08:49:37 1980. To evaluate a Date header as a date object, see Default Syntax Expressions: Working with Dates, Times, and Numbers.</td>
</tr>
<tr>
<td>HTTP.REQ.COOKIE</td>
<td>(Name/Value List) Returns the contents of the HTTP Cookie header.</td>
</tr>
<tr>
<td>HTTP.REQ.TXID</td>
<td>Returns the HTTP transaction ID. The value is a function of an internal transaction number, system boot time and system MAC address.</td>
</tr>
<tr>
<td>HTTP.RES.HEADER(&quot;&quot;)</td>
<td>Returns the contents of the HTTP header specified by the argument. The header name cannot exceed 32 characters.</td>
</tr>
<tr>
<td>HTTP Header Prefix</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>HTTP.RES.FULL_HEADER</td>
<td>Returns the contents of the complete set of HTTP header fields including the status line (for example, “HTTP/1.1 200 OK”) and the terminating \r\n sequence.</td>
</tr>
<tr>
<td>HTTP.RES.SET_COOKIE or HTTP.RES.SET_COOKIE2</td>
<td>Set-Cookie header object in a response.</td>
</tr>
<tr>
<td>HTTP.RES.SET_COOKIE(&lt;name&gt;) or HTTP.RES.SET_COOKIE2(&lt;name&gt;)</td>
<td>Returns the cookie of the specified name if it is present. If it is not present, returns a text object of length 0. Returns UNDEF if more than 15 Set-Cookie headers are present and the specified cookie was not found in these headers.</td>
</tr>
<tr>
<td>HTTP Header Prefix</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>HTTP.RES.SET_COOKIE(name).DOMAIN</td>
<td>Returns the first Domain field in the cookie. For example, if the cookie is Set-Cookie: Customer = “ABC”; DOMAIN=”.abc.com”; DOMAIN=”.xyz.com”, the following expression returns .abc.com: http.res.set_cookie.cookie(“customer”).domain. A string of zero length is returned if the Domain field or its value is absent.</td>
</tr>
<tr>
<td>HTTP.RES.SET_COOKIE.EXISTS(name)</td>
<td>Returns a Boolean TRUE if a Cookie with the name specified in the &lt;name&gt; argument exists in the Set-Cookie header. This prefix returns UNDEF if more than 15 Set-Cookie headers are present and the named cookie is not in the first 15 headers.</td>
</tr>
<tr>
<td>HTTP Header Prefix</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>HTTP.RES.SET_COOKIE.COOKIE(&lt;name&gt;).EXPIRES</td>
<td>Returns the Expires field of the cookie. This is a date string that can be evaluated as a number, as a time object, or as text. If multiple Expires fields are present, the first one is returned. If the Expires field is absent, a text object of length zero is returned. To evaluate the returned value as a time object, see Default Syntax Expressions: Working with Dates, Times, and Numbers.</td>
</tr>
<tr>
<td>HTTP.RES.SET_COOKIE_PATH.GET(n)</td>
<td></td>
</tr>
<tr>
<td>HTTP Header Prefix</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>HTTP.RES.SET_COOKIE2.COOKIE(&lt;name&gt;).PATH</td>
<td>Returns the value of Path field of the cookie as a slash- (&quot;/&quot;) separated list. Multiple instances of a slash are treated as single slash. If multiple Path fields are present, the value of the first instance is returned. For example, the following is a cookie with two path fields: Set-Cookie: Customer = &quot;ABC&quot;; PATH=&quot;/a//b/c&quot;; PATH=&quot;/x/y/z&quot;. The following expression returns /a//b/c from this cookie: http.res.set_cookie.cookie(“Customer”).path. The following expression returns b: http.res.set_cookie.cookie(“Customer”).path.get(2). Quotes are stripped from the returned value. A string of zero length is returned if the Path field or its value is absent.</td>
</tr>
<tr>
<td>HTTP Header Prefix</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>HTTP.RES.SET_COOKIE</td>
<td>Ignores the empty elements in the list. For example, in the list a=10, b=11, , c=89, the element delimiter in the list is , and the list has an empty element following a=10. The element following b=11 is not considered an empty element. As another example, in the following expression, if a request contains Cust_Header : 123,,15, the following expression returns a value of 4: http.req.header(&quot;Cust_Header&quot;).typecast_list_t(', ').ignore_empty_elements.count. The following expression returns a value of 5: http.req.header(&quot;Cust_Header&quot;).count</td>
</tr>
</tbody>

<tr>
<td>HTTP .RES.SET_COOKIE.COOKIE(&lt;name&gt;, &lt;integer&gt;).DOMAIN</td>
<td>Returns the value of the Domain field of the first cookie with the specified name. For example, the following expression returns a value of abc.com from the cookie Set-Cookie: Customer = “ABC”; DOMAIN=“.abc.com”; DOMAIN=.xyz.com: http.res.set_cookie.cookie(“CUSTOMER”).domain. A string of zero length is returned if the Domain field or its value is absent.</td>
</tr>
<tr>
<td>HTTP .RES.SET_COOKIE.COOKIE(&lt;name&gt;, &lt;integer&gt;).EXPIRES</td>
<td>Returns the nth instance (0-based) of the Expires field of the cookie with the specified name as a date string. The value can be operated upon as a time object that supports a number of date formats. If the Expires attribute is absent a string of length zero is returned.</td>
</tr>
<tr>
<td>HTTP Header Prefix</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>HTTP.RES.SET_COOKIE.COOKIE(&lt;name&gt;,&lt;integer&gt;).PATH</td>
<td>Returns the value of the Path field of the nth cookie, as a ‘/’ separated list. Multiple /s are treated as a single /. For example, the following expression returns /a//b/c from the cookie Set-Cookie: Customer = “ABC”; PATH=”/a//b/c”; PATH= ”/x/y/z”: http.res.set_cookie.cookie(“CUSTOMER”).path. The following returns b: http.res.set_cookie.cookie(“CUSTOMER”).path.get(2). A string of zero length is returned if the Path field or its value is absent.</td>
</tr>
<tr>
<td>HTTP Header Prefix</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| HTTP.RES.SET_COOKIE.<integer>).PATH.IGNORE_EMPTY_ELEMENTS or HTTP.RES.SET_COOKIE2.<integer>).PATH.IGNORE_EMPTY_ELEMENTS | Ignores the empty elements in the list. For example, in the list a=10,b=11, ,c=89, the element delimiter in the list is , and the list has an empty element following a=10. The element following b=11 is not considered an empty element. As another example, in the following expression, if a request contains Cust_Header : 123,24, ,15 the following expression returns a value of 4: http.req.header("Cust_Header").typecast_list_t(', ').ignore_empty_elements.count. The following expression returns a value of 5: http.req.header("Cust_Header").typecast_list_t(', ').count.
HTTP Header Prefix | Description
--- | ---
HTTP.RES.SET_COOKIE.COOKIE(<name>, <integer>).PORT or HTTP.RES.SET_COOKIE2.COOKIE(<name>, <integer>).PORT | Returns the value or values of the Port field of the named cookie as a ',' separated list. For example, the following expression returns 80, 2580 from the cookie Set-Cookie: Customer = “ABC”; PATH=/a/b/c”; PORT= “80, 2580”; http.res.set_cookie.cookie(“ABC”).port. A string of zero length is returned if the Port field or its value is absent.

### HTTP Header Prefix Description

<table>
<thead>
<tr>
<th>HTTP Header Prefix</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HTTP.RES.TXID</td>
<td>Returns the HTTP transaction ID. The value is a function of an internal transaction number, system boot time and system MAC address.</td>
</tr>
</tbody>
</table>

### Operations for HTTP headers

The following table describes operations that you can specify with the prefixes for HTTP headers.

<table>
<thead>
<tr>
<th>HTTP Header Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>http header .EXISTS</td>
<td>Returns a Boolean TRUE if an instance of the specified header type exists. Following is an example: http.req.header(&quot;Cache-Control&quot;).exists</td>
</tr>
<tr>
<td>http header.CONTAINS &quot; http header.CONTAINS(&lt;string&gt;)&quot;</td>
<td>Returns a Boolean TRUE if the &lt;string&gt; argument appears in any instance of the header value. Note: This operation overrides any text-based Contains operations on all instances of the current header type.</td>
</tr>
<tr>
<td>http header .COUNT</td>
<td>Returns the number of headers in a request or response, to a maximum of 15 headers of the same type. The result is undefined if there are more than 15 instances of the header.</td>
</tr>
<tr>
<td>http header.AFTER_STR(&lt;string&gt;)</td>
<td>Extracts the text that follows the first occurrence of the &lt;string&gt; argument. The headers are evaluated from the last instance to the first.</td>
</tr>
<tr>
<td>http header.BEFORE_STR(&lt;string&gt;)</td>
<td>Extracts the text that appears prior to the first occurrence of the input &lt;string&gt; argument. The headers are evaluated from the last instance to the first.</td>
</tr>
</tbody>
</table>
HTTP Header Operation | Description
--- | ---
http header.INSTANCE(<instance number>) | An HTTP header can occur multiple times in a request or a response. This operation returns the header that occurs <instance number> of places before the final instance. For example, instance(0) selects the last instance of the current type, instance(1) selects the next-to-last instance, and so on. This prefix cannot be used in bidirectional policies.

http header.SUBSTR(<string>) | Extracts the text that matches the <string> argument. The headers are evaluated from the last instance to the first.

http header.VALUE(<instance number>) | An HTTP header can occur multiple times in a request or a response. VALUE(0) selects the value in the last instance, VALUE(1) selects the value in the next-to-last instance, and so on. The <instance number> argument cannot exceed 14.

Prefixes for cache-control headers

The following prefixes apply specifically to Cache-Control headers.

HTTP Header Prefix | Description
--- | ---
HTTP.REQ.CACHE_CONTROL | Returns a Cache-Control header in an HTTP request.
HTTP.RES.CACHE_CONTROL | Returns a Cache-Control header in an HTTP response.

Operations for cache-control headers

You can apply any of the operations for HTTP headers to Cache-Control headers. For more information, see Operations for HTTP headers.

In addition, the following operations identify specific types of Cache-Control headers. See RFC 2616 for information about these header types.
<table>
<thead>
<tr>
<th>HTTP Header Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cache-Control header.NAME(&lt;integer&gt;)</td>
<td>Returns as a text value the name of the Cache-Control header that corresponds to the nth component in a name-value list, as specified by &lt;integer&gt;. The index of the name-value component is 0-based. If the &lt;integer&gt; that is specified by the integer argument is greater than the number of components in the list, a zero-length text object is returned. Following is an example: http.req.cache_control.name(3).contains(&quot;some_text&quot;)</td>
</tr>
<tr>
<td>Cache-Control header.IS_INVALID</td>
<td>Returns a Boolean TRUE if the Cache-Control header is not present in the request or response. Following is an example: http.req.cache_control.is_invalid</td>
</tr>
<tr>
<td>Cache-Control header.IS_PRIVATE</td>
<td>Returns a Boolean TRUE if the Cache-Control header has the value Private. Following is an example: http.req.cache_control.is_private</td>
</tr>
<tr>
<td>Cache-Control header.IS_PUBLIC</td>
<td>Returns a Boolean TRUE if the Cache-Control header has the value Private. Following is an example: http.req.cache_control.is_public</td>
</tr>
<tr>
<td>Cache-Control header.IS_NO_STORE</td>
<td>Returns a Boolean TRUE if the Cache-Control header has the value No-Store. Following is an example: http.req.cache_control.is_no_store</td>
</tr>
<tr>
<td>Cache-Control header.IS_NO_CACHE</td>
<td>Returns a Boolean TRUE if the Cache-Control header has the value No-Cache. Following is an example: http.req.cache_control.is_no_cache</td>
</tr>
<tr>
<td>Cache-Control header.IS_MAX_AGE</td>
<td>Returns a Boolean TRUE if the Cache-Control header has the value Max-Age. Following is an example: http.req.cache_control.is_max_age</td>
</tr>
<tr>
<td>Cache-Control header.IS_MIN_FRESH</td>
<td>Returns a Boolean TRUE if the Cache-Control header has the value Min-Fresh. Following is an example: http.req.cache_control.is_min_fresh</td>
</tr>
<tr>
<td>Cache-Control header.IS_MAX_STALE</td>
<td>Returns a Boolean TRUE if the Cache-Control header has the value Max-Stale. Following is an example: http.req.cache_control.is_max_stale</td>
</tr>
<tr>
<td>HTTP Header Operation</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>Cache-Control header.IS_MUST_REVALIDATE</td>
<td>Returns a Boolean TRUE if the Cache-Control header has the value Must-Revalidate. Following is an example: http.req.cache_control.is_must_revalidate</td>
</tr>
<tr>
<td>Cache-Control header.IS_NO_TRANSFORM</td>
<td>Returns a Boolean TRUE if the Cache-Control header has the value No-Transform. Following is an example: http.req.cache_control.is_no_transform</td>
</tr>
<tr>
<td>Cache-Control header.IS_ONLY_IF_CACHED</td>
<td>Returns a Boolean TRUE if the Cache-Control header has the value Only-If-Cached. Following is an example: http.req.cache_control.is_only_if_cached</td>
</tr>
<tr>
<td>Cache-Control header.IS_PROXY_REVALIDATE</td>
<td>Returns a Boolean TRUE if the Cache-Control header has the value Proxy-Revalidate. Following is an example: http.req.cache_control.is_proxy_revalidate</td>
</tr>
<tr>
<td>Cache-Control header.IS_S_MAXAGE</td>
<td>Returns a Boolean TRUE if the Cache-Control header has the value S-Maxage. Following is an example: http.req.cache_control.is_s_maxage</td>
</tr>
<tr>
<td>Cache-Control header.IS_UNKNOWN</td>
<td>Returns a Boolean TRUE if the Cache-Control header is of an unknown type. Following is an example: http.req.cache_control.is_unknown</td>
</tr>
<tr>
<td>Cache-Control header.MAX_AGE</td>
<td>Returns the value of the Cache-Control header Max-Age. If this header is absent or invalid, 0 is returned. Following is an example: http.req.cache_control.max_age.le(3)</td>
</tr>
<tr>
<td>Cache-Control header.MAX_STALE</td>
<td>Returns the value of the Cache-Control header Max-Stale. If this header is absent or invalid, 0 is returned. Following is an example: http.req.cache_control.max_stale.le(3)</td>
</tr>
<tr>
<td>Cache-Control header.MIN_FRESH</td>
<td>Returns the value of the Cache-Control header Min-Fresh. If this header is absent or invalid, 0 is returned. Following is an example: http.req.cache_control.min_fresh.le(3)</td>
</tr>
</tbody>
</table>
HTTP Header Operation | Description
--- | ---
Cache-Control header.S_MAXAGE | Returns the value of the Cache-Control header S-Maxage. If this header is absent or invalid, 0 is returned. Following is an example: http.req.cache_control.s_maxage.eq(2)

### Expressions for extracting segments of URLs

November 5, 2018

You can extract URLs and portions of URLs, such as the host name, or a segment of the URL path. For example, the following expression identifies HTTP requests for image files by extracting image file suffixes from the URL:

```
http.req.url.suffix.eq("jpeg") || http.req.url.suffix.eq("gif")
```

Most expressions for URLs operate on text and are described in Expression Prefixes for Text in HTTP Requests and Responses. This section discusses the GET operation. The GET operation extracts text when used with the following prefixes:

- HTTP.REQ.URL.PATH
- VPN.BASEURL.PATH
- VPN.CLIENTLESS_BASEURL.PATH

The following table describes prefixes for HTTP URLs.

<table>
<thead>
<tr>
<th>URL Prefix</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HTTP.REQ.URL.PATH.GET(&lt;n&gt;)</td>
<td>Returns a slash- (“/”) separated list from the URL path. For example, consider the following URL: <a href="http://www.mycompany.com/dir1/dir2/dir3/index.html?a=1">http://www.mycompany.com/dir1/dir2/dir3/index.html?a=1</a>. The following expression returns dir1 from this URL: &lt;http.req.url.path.get(1)&gt;; The following expression returns dir2: http.req.url.path.get(2)</td>
</tr>
</tbody>
</table>
Expressions for HTTP status codes and numeric HTTP payload data other than dates

September 24, 2018

The following table describes prefixes for numeric values in HTTP data other than dates.

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HTTP.REQ.CONTENT_LENGTH</td>
<td>Returns the length of an HTTP request as a number. Following is an example: http.req.content_length &lt; 500</td>
</tr>
<tr>
<td>HTTP.RES.CONTENT_LENGTH</td>
<td>Returns the length of the HTTP response as a number. Following is an example: http.res.content_length &lt;= 1000</td>
</tr>
<tr>
<td>HTTP.RES.STATUS</td>
<td>Returns the response status code</td>
</tr>
<tr>
<td>HTTP.RES.IS_REDIRECT</td>
<td>Returns a Boolean TRUE if the response code is associated with a redirect. Following are the redirect response codes: 300 (Multiple Choices), 301 (Moved Permanently), 302 (Found), 303 (See Other), 305 (Use Proxy), and 307 (Temporary Redirect). Note: Status code 304 is not considered a redirect HTTP response status code. Status code 306 is unused.</td>
</tr>
</tbody>
</table>
SIP expressions

September 24, 2018

The NetScaler Advanced policy expressions language contains a number of expressions that operate on Session Initiation Protocol (SIP) connections. These expressions are intended to be used in policies for any supported protocol that operates on a request/response basis. These expressions can be used in content switching, rate limiting, responder, and rewrite policies.

Certain limitations apply to SIP expressions used with responder policies. Only the DROP, NOOP or RESPONDWITH actions are allowed on a SIP load balancing virtual server. Responder policies can be bound to a load balancing virtual server, an override global bind point, a default global bind point, or a sip_udp policy label.

The header format used by the SIP protocol is similar to that used by the HTTP protocol, so many of the new expressions look and function much like their HTTP analogs. Each SIP header consists of a line that includes the SIP method, the URL, and the version, followed by a series of name-value pairs that look like HTTP headers.

Following is a sample SIP header that is referred to in the expressions tables beneath it:

```
INVITE sip:16@www.sip.com:5060;transport=udp SIP/2.0
Record-Route: <sip:200.200.100.22;lr=on>
Via: SIP/2.0/UDP 200.200.100.22;branch=z9hG4bK444b.c8e103d1.0;rport=5060;
     received=10.102.84.18
Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;
     received=10.102.84.160
From: "12" <sip:12@sip_example.com>;tag=00127f54ec85a6d90cc14f45-53cc0185
To: "16" <sip:16@sip_example.com>;tag=00127f54ec85a6d90cc14f45-53cc0185
Call-ID: 00127f54-ec850017-e46f5b9-5ec149c2@10.102.84.180
Max-Forwards: 69
CSeq: 101 INVITE
User-Agent: Cisco-CP7940G/8.0
Contact: <sip:12@10.102.84.180:5060;transport=udp>
Expires: 180
Accept: application/sdp
Allow: ACK,BYE,CANCEL,INVITE,NOTIFY,OPTIONS,REFER,REGISTER,UPDATE
Supported: replaces,join,norefersub
Content-Length: 277
Content-Type: application/sdp
Content-Disposition: session;handling=optional
```
**SIP reference tables**

The following tables contain lists of expressions that operate on SIP headers. The first table contains expressions that apply to request headers. Most response-based expressions are nearly the same as the corresponding request-based expressions. To create a response expression from the corresponding request expression, you change the first two sections of the expression from SIP.REQ to SIP.RES, and make other obvious adjustments. The second table contains those response expressions that are unique to responses and have no request equivalents. You can use any element in the following tables as a complete expression on its own, or you can use various operators to combine these expression elements with others to form more complex expressions.

### SIP request expressions

<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIP.REQ.METHOD</td>
<td>Operates on the method of the SIP request. The supported SIP request methods are ACK, BYE, CANCEL, INFO, INVITE, MESSAGE, NOTIFY, OPTIONS, PRACK, PUBLISH, REFER, REGISTER, SUBSCRIBE, and UPDATE. This expression is a derivative of the text class, so all operations that are applicable to text are applicable to this method. For example, for a SIP request of INVITE sip:16@10.102.84.181:5060;transport=udp SIP/2.0, this expression returns INVITE.</td>
</tr>
<tr>
<td>SIP.REQ.URL</td>
<td>Operates on the SIP request URL. This expression is a derivative of the text class, so all operations that are applicable to text are applicable to this method. For example, for a SIP request of INVITE sip:16@10.102.84.181:5060;transport=udp SIP/2.0, this expression returns sip:16@10.102.84.181:5060;transport=udp.</td>
</tr>
<tr>
<td>SIP.REQ.URL.PROTOCOL</td>
<td>Returns the URL protocol. For example, for a SIP URL ofsip:<a href="mailto:16@www.sip.com">16@www.sip.com</a>:5060;transport=udp, this expression returns sip.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIP.REQ.URL.HOSTNAME</td>
<td>Returns the hostname portion of the SIP URL. For example, for a SIP URL ofsip:<a href="mailto:16@www.sip.com">16@www.sip.com</a>:5060;transport=udp, this expression returns <a href="http://www.sip.com:5060">www.sip.com:5060</a>.</td>
</tr>
<tr>
<td>SIP.REQ.URL.HOSTNAME.PORT</td>
<td>Returns the port portion of the SIP URL hostname. If no port is specified, this expression returns the default SIP port, 5060. For example, for a SIP hostname of <a href="http://www.sip.com:5060">www.sip.com:5060</a>, this expression returns 5060.</td>
</tr>
<tr>
<td>SIP.REQ.URL.HOSTNAME.DOMAIN</td>
<td>Returns the domain name portion of the SIP URL hostname. If the host is an IP address, then this expression returns an incorrect result. For example, for a SIP hostname of <a href="http://www.sip.com:5060">www.sip.com:5060</a>, this expression returns sip.com. For a SIP hostname of 192.168.43.15:5060, this expression returns an error.</td>
</tr>
<tr>
<td>SIP.REQ.URL.HOSTNAME.SERVER</td>
<td>Returns the server portion of the host. For example, for a SIP hostname of <a href="http://www.sip.com:5060">www.sip.com:5060</a>, this expression returns www.</td>
</tr>
<tr>
<td>SIP.REQ.URL.USERNAME</td>
<td>Returns the username that precedes the @ character. For example, for a SIP URL of sip:<a href="mailto:16@www.sip.com">16@www.sip.com</a>:5060;transport=udp, this expression returns 16.</td>
</tr>
<tr>
<td>SIP.REQ.VERSION</td>
<td>Returns the SIP version number in the request. For example, for a SIP request of INVITE sip:16@10.102.84.181:5060;transport=udp SIP/2.0, this expression returns SIP/2.0.</td>
</tr>
<tr>
<td>SIP.REQ.VERSION.MAJOR</td>
<td>Returns the major version number (the number to the left of the period). For example, for a SIP version number of SIP/2.0, this expression returns 2.</td>
</tr>
<tr>
<td>Expression</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SIP.REQ.VERSION.MINOR</td>
<td>Returns the minor version number (the number to the right of the period). For example, for a SIP version number of SIP/2.0, this expression returns 0.</td>
</tr>
<tr>
<td>SIP.REQ.CONTENT_LENGTH</td>
<td>Returns the contents of the Content-Length header. This expression is a derivative of the sip_header_t class, so all operations that are available for SIP headers can be used. For example, for a SIP Content-Length header of Content-Length: 277, this expression returns 277.</td>
</tr>
<tr>
<td>SIP.REQ.TO</td>
<td>Returns the contents of the To header. For example, for a SIP To header of To: “16” <a href="">sip:16@sip_example.com</a>;tag=00127f54ec85a6d90cc14f45-53cc0185, this expression returns “16” <a href="">sip:16@sip_example.com</a>;tag=00127f54ec85a6d90cc14f45-53cc0185.</td>
</tr>
<tr>
<td>SIP.REQ.TO.ADDRESS</td>
<td>Returns the SIP URI, which is found in the sip_url object. All operations that are available for SIP URIs can be used. For example, for a SIP To header of To: “16” <a href="">sip:16@sip_example.com</a>;tag=00127f54ec85a6d90cc14f45-53cc0185, this expression returns sip:<a href="mailto:16@sip_example.com">16@sip_example.com</a>.</td>
</tr>
<tr>
<td>SIP.REQ.TO.DISPLAY_NAME</td>
<td>Returns the display name portion of the To header. For example, for a SIP To header of To: “16” <a href="">sip:16@sip_example.com</a>;tag=00127f54ec85a6d90cc14f45-53cc0185, this expression returns 16.</td>
</tr>
<tr>
<td>SIP.REQ.TO.TAG</td>
<td>Returns the “tag” value from the “tag” name value pair in the TO header. For example, for a SIP To header of To: “16” <a href="">sip:16@sip_example.com</a>;tag=00127f54ec85a6d90cc14f45-53cc0185, this expression returns 00127f54ec85a6d90cc14f45-53cc0185.</td>
</tr>
<tr>
<td>Expression</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SIP.REQ.FROM</td>
<td>Returns the contents of the From header. For example, for a SIP From header of From: “12”<a href="">sip:12@sip_example.com</a>;tag=00127f54ec85a6d90cc14f45-53cc0185, this expression returns sip:<a href="mailto:12@sip_example.com">12@sip_example.com</a>.</td>
</tr>
<tr>
<td>SIP.REQ.FROM.ADDRESS</td>
<td>Returns the SIP URI, which is found in the sip_url object. All operations that are available for SIP URIs can be used. For example, for a SIP From header of From: “12”<a href="">sip:12@sip_example.com</a>;tag=00127f54ec85a6d90cc14f45-53cc0185, this expression returns sip:<a href="mailto:12@sip_example.com">12@sip_example.com</a>.</td>
</tr>
<tr>
<td>SIP.REQ.FROM.DISPLAY_NAME</td>
<td>Returns the display name portion of the To header. For example, for a SIP From header of From: “12”<a href="">sip:12@sip_example.com</a>;tag=00127f54ec85a6d90cc14f45-53cc0185, this expression returns 12.</td>
</tr>
<tr>
<td>SIP.REQ.FROM.TAG</td>
<td>Returns the “tag” value from the “tag” name/value pair in the TO header. For example, for a SIP From header of From: “12”<a href="">sip:12@sip_example.com</a>;tag=00127f54ec85a6d90cc14f45-53cc0185, this expression returns 00127f54ec85a6d90cc14f45-53cc0185.</td>
</tr>
<tr>
<td>SIP.REQ.VIA</td>
<td>Returns the complete Via header. If there are multiple Via headers in the request, returns the last Via header. For example, for the two Via headers in the sample SIP header, this expression returns Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;re...</td>
</tr>
<tr>
<td>SIP.REQ.VIA.SENTBY_ADDRESS</td>
<td>Returns the address that sent the request. For example, for the Via header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;re... this expression returns 10.102.84.180.</td>
</tr>
<tr>
<td>Expression</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SIP.REQ.VIA.SENTBY_PORT</td>
<td>Returns the port that sent the request. For example, for the Via header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, this expression returns 5060.</td>
</tr>
<tr>
<td>SIP.REQ.VIA.RPORT</td>
<td>Returns the value from the rport name/value pair. For example, for the Via header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, this expression returns 5060.</td>
</tr>
<tr>
<td>SIP.REQ.VIA.BRANCH</td>
<td>Returns the value from the branch name/value pair. For example, for the Via header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, this expression returns z9hG4bK03e76d0b.</td>
</tr>
<tr>
<td>SIP.REQ.VIA.RECEIVED</td>
<td>Returns the value from the received name/value pair. For example, for the Via header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, this expression returns 10.102.84.160.</td>
</tr>
<tr>
<td>SIP.REQ.CALLID</td>
<td>Returns the contents of the Callid header. This expression is a derivative of the sip_header_t class, so all operations that are available for SIP headers can be used. For example, for a SIP Callid header of Call-ID: 00127f54-ec850017-0e46f5b9-5ec149c2@10.102.84.180, this expression returns 00127f54-ec850017-0e46f5b9-5ec149c2@10.102.84.180.</td>
</tr>
<tr>
<td>SIP.REQ.CSEQ</td>
<td>Returns the CSEQ number from the CSEQ, as an integer. For example, for a SIP CSEQ header of CSeq: 101 INVITE, this expression returns 101.</td>
</tr>
<tr>
<td>SIP.REQ.HEADER(&lt;header_name&gt;)</td>
<td>Returns the specified SIP header. For example, to return the SIP From header, you would type SIP.REQ.HEADER(&quot;From&quot;).</td>
</tr>
<tr>
<td>Expression</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SIP.REQ.HEADER(&lt;header_name&gt;).INSTANCE()</td>
<td>Returns the specified instance of the specified SIP header. Multiple instances of the same SIP header can occur. Where you want a specific instance of such a SIP header (for example, a specific Via header), you can specify that header by typing a number as the . Header instances are matched from last (0) to first. In other words, SIP.REQ.HEADER(&quot;Via&quot;).INSTANCE(0) returns the last instance of the Via header, while SIP.REQ.HEADER(&quot;Via&quot;).INSTANCE(1) returns the last instance but one of the Via header, and so on. For example, if used on the example SIP header, SIP.REQ.HEADER(&quot;Via&quot;).INSTANCE(1) returns Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060.</td>
</tr>
<tr>
<td>SIP.REQ.HEADER(&lt;header_name&gt;).VALUE()</td>
<td>Returns the contents of the specified instance of the specified SIP header. The usage is nearly the same as the previous expression. For example, if used on the SIP header example in the preceding table entry, SIP.REQ.HEADER(“Via”).VALUE(1) returns SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060.</td>
</tr>
<tr>
<td>SIP.REQ.HEADER(&lt;header_name&gt;).COUNT</td>
<td>Returns the number of instances of a particular header as an integer. For example, if used on the SIP header example above, SIP.REQ.HEADER(“Via”).COUNT returns 2.</td>
</tr>
<tr>
<td>Expression</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-------------</td>
</tr>
<tr>
<td><strong>SIP.REQ.HEADER(&lt;header_name&gt;).EXISTS</strong></td>
<td>Returns a boolean value of true or false, depending upon whether the specified header exists or not. For example, if used on the SIP header example above, SIP.REQ.HEADER(&quot;Expires&quot;).EXISTS returns true, while SIP.REQ.HEADER(&quot;Caller-ID&quot;).EXISTS returns false.</td>
</tr>
<tr>
<td><strong>SIP.REQ.HEADER(&lt;header_name&gt;).LIST</strong></td>
<td>Returns the comma-separated parameter list in the specified header. For example, if used on the SIP header example above, SIP.REQ.HEADER(&quot;Allow&quot;).LIST returns &quot;ACK,BYE,CANCEL,INVITE,NOTIFY,OPTIONS,REFER,REGISTER,UPDATE&quot;. You can append the string .GET(0) to select a specific list item. For example, to get the first item (ACK) from the above list, you would type SIP.REQ.HEADER(&quot;Allow&quot;).LIST.GET(0). To extract the second item (BYE), you would type SIP.REQ.HEADER(&quot;Allow&quot;).LIST.GET(1). Note: If the specified header contains a list of name/value pairs, the entire name/value pair is returned.</td>
</tr>
<tr>
<td><strong>SIP.REQ.HEADER(&lt;header_name&gt;).TYPECAST_SIP_HEADER_T(&quot;&quot;)</strong></td>
<td>Typecasts to . Any text can be typecasted to the sip_header_t class, after which all header-based operations can be used. After you perform this operation, you can apply all operations that can be used with . For example, the expression SIP.REQ.CONTENT_LENGTH.TYPECAST_SIP_HEADER_T typecasts all instances of the Content-Length header. After you perform this operation, you can apply all header operations to all instances of the specified header.</td>
</tr>
<tr>
<td>Expression</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SIP.REQ.HEADER(&lt;header_name&gt;).CONTAINS(&lt;string&gt;)</td>
<td>Returns boolean true if the specified text string is present in any instance of the specified header. Operates on all the instances of the specified header. Header instances are matched from last (0) to first.</td>
</tr>
<tr>
<td>SIP.REQ.HEADER(&lt;header_name&gt;).EQUALS_ANY(&lt;patset&gt;)</td>
<td>Returns boolean true if any pattern associated with &lt;patset&gt; matches any content in any instance of the specified header. Operates on all the instances of the specified header. Header instances are matched from last (0) to first.</td>
</tr>
<tr>
<td>SIP.REQ.HEADER(&lt;header_name&gt;).CONTAINS_ANY(&lt;patset&gt;)</td>
<td>Returns boolean true if any pattern associated with &lt;patset&gt; matches any content in any instance of the specified header. Operates on all the instances of the specified header. Header instances are matched from last (0) to first.</td>
</tr>
<tr>
<td>SIP.REQ.HEADER(&lt;header_name&gt;).CONTAINS_INDEX(&lt;patset&gt;)</td>
<td>Returns the index of the matching pattern associated with &lt;patset&gt; if that pattern matches any content in any instance of the specified header. Operates on all the instances of the specified header. Header instances are matched from last (0) to first.</td>
</tr>
<tr>
<td>SIP.REQ.HEADER(&lt;header_name&gt;).EQUALS_INDEX(&lt;patset&gt;)</td>
<td>Returns the index of the matching pattern associated with &lt;patset&gt; if that pattern matches any instance of the specified header. Operates on all the instances of the specified header. Header instances are matched from last (0) to first.</td>
</tr>
<tr>
<td>Expression</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-------------</td>
</tr>
<tr>
<td>SIP.REQ.HEADER(&lt;header_name&gt;).SUBSTR(&lt;string&gt;)</td>
<td>If the specified string is present in any instance of the specified header, this expression returns that string. For example, for the SIP header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;returns “rport=5060”. SIP.REQ.HEADER(“Via”).SUBSTR(“rport=5060”) returns an empty string.</td>
</tr>
<tr>
<td>SIP.REQ.HEADER(&lt;header_name&gt;).AFTER_STR(&lt;string&gt;)</td>
<td>If the specified string is present in any instance of the specified header, this expression returns the string immediately after that string. For example, for the SIP header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, the expression SIP.REQ.HEADER(“Via”).AFTER_STR(“rport=” returns 5060.</td>
</tr>
<tr>
<td>Expression</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-------------</td>
</tr>
<tr>
<td>SIP.REQ.HEADER(&lt;header_name&gt;).REGEX_MATCH(&lt;regex&gt;)</td>
<td>Returns boolean true if the specified regular expression (regex) matches any instance of the specified header. You must specify the regular expression in the following format: re&lt;delimiter&gt;regular expression&lt;same delimiter&gt;. The regular expression cannot be larger than 1499 characters in length. It must conform to the PCRE regular expression library. See <a href="http://www.pcre.org/pcre.txt">http://www.pcre.org/pcre.txt</a> for documentation on PCRE regular expression syntax. The pcrepattern man page also has useful information on specifying patterns by using PCRE regular expressions. The regular expression syntax supported in this expression has some differences from PCRE. Back references are not allowed. You should avoid recursive regular expressions; although some work, many do not. The dot (.) metacharacter matches newlines. Unicode is not supported. SET_TEXT_MODE(IGNORECASE) overrides the (?i) internal option specified in the regular expression.</td>
</tr>
<tr>
<td>SIP.REQ.HEADER(&lt;header_name&gt;).REGEX_SELECT(&lt;regex&gt;)</td>
<td>If the specified regex matches any text in any instance of the specified header, this expression returns the text. For example, for the SIP header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, the expression SIP.REQ.HEADER(“Via”).REGEX_SELECT(“received=[0-9]{1,3}.[0-9]{1,3}.[0-9]{1,3}.[0-9]{1,3}”) returns received=10.102.84.160.</td>
</tr>
<tr>
<td>Expression</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-------------</td>
</tr>
<tr>
<td>SIP.REQ.HEADER(&lt;header_name&gt;).AFTER_REGEX(&lt;regex&gt;)</td>
<td>If the specified regex matches any text in any instance of the specified header, this expression returns the string immediately after that text. For example, for the SIP header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, the expression SIP.REQ.HEADER(“Via”).AFTER_REGEX(“received=”)) returns 10.102.84.160.</td>
</tr>
<tr>
<td>SIP.REQ.HEADER(&lt;header_name&gt;).BEFORE_REGEX(&lt;regex&gt;)</td>
<td>If the specified regex matches any text in any instance of the specified header, this expression returns the string immediately before that text. For example, for the SIP header Via: SIP/2.0/UDP 10.102.84.180:5060;branch=z9hG4bK03e76d0b;rport=5060;received=10.102.84.160, the expression SIP.REQ.HEADER(“Via”).BEFORE_REGEX(“[0-9]{1,3}.[0-9]{1,3}.[0-9]{1,3}.”) returns received=.</td>
</tr>
<tr>
<td>SIP.REQ.FULL_HEADER</td>
<td>Returns the entire SIP header, including the terminating CR/LF.</td>
</tr>
<tr>
<td>SIP.REQ.IS_VALID</td>
<td>Returns boolean true if the request format is valid.</td>
</tr>
<tr>
<td>SIP.REQ.BODY(&lt;length&gt;)</td>
<td>Returns the request body, up to the specified length. If the specified length is greater than the length of the request body, this expression returns the entire request body.</td>
</tr>
<tr>
<td>SIP.REQ.LB_VSERVER</td>
<td>Returns the name of the load balancing virtual server (LB vserver) that is serving the current request.</td>
</tr>
<tr>
<td>SIP.REQ.CS_VSERVER</td>
<td>Returns the name of the content switching virtual server (CS vserver) that is serving the current request.</td>
</tr>
</tbody>
</table>

**SIP response expressions**

<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIP.RES.STATUS</td>
<td>Returns the SIP response status code. For example, if the first line of the response is SIP/2.0 100 Trying, this expression returns 100.</td>
</tr>
<tr>
<td>SIP.RES.STATUS_MSG</td>
<td>Returns the SIP response status message. For example, if the first line of the response is SIP/2.0 100 Trying, this expression returns Trying.</td>
</tr>
<tr>
<td>SIP.RES.IS_REDIRECT</td>
<td>Returns boolean true if the response code is a redirect.</td>
</tr>
<tr>
<td>SIP.RES.METHOD</td>
<td>Returns the response method extracted from the request method string in the CSeq header.</td>
</tr>
</tbody>
</table>

**Operations for HTTP, HTML, and XML encoding and “safe” characters**

September 24, 2018

The following operations work with the encoding of HTML data in a request or response and XML data in a POST body.

- `<text>.HTML_XML_SAFE:`
  Transforms special characters into XML safe format, as in the following examples:
  
  A left-pointing angle bracket (<) is converted to `<
  A right-pointing angle bracket (>) is converted to `>
  An ampersand (&) is converted to `&
  This operation safeguards against cross-site scripting attacks. Maximum length of the transformed text is 2048 bytes. This is a read-only operation.
  
  After applying the transformation, additional operators that you specify in the expression are applied to the selected text. Following is an example:
  
  `http.req.url.query.html_xml_safe. contains("myQueryString")`

- `<text>.HTTP_HEADER_SAFE:`
  Converts all new line (`\n`) characters in the input text to ‘%0A’ to enable the input to be used safely in HTTP headers.
  
  This operation safeguards against response-splitting attacks.
  
  The maximum length of the transformed text is 2048 bytes. This is a read-only operation.
• `<text>.HTTP_URL_SAFE:
  Converts unsafe URL characters to '%xx' values, where “xx” is a hex-based representation of the
  input character. For example, the ampersand (&) is represented as %26 in URL-safe encoding.
  The maximum length of the transformed text is 2048 bytes. This is a read-only operation.
  Following are URL safe characters. All others are unsafe:
  - Alpha-numeric characters: a-z, A-Z, 0-9
  - Asterix: "*"
  - Ampersand: "&"
  - At-sign: "@"
  - Colon: ";"
  - Comma: ";"
  - Dollar: "$"
  - Dot: ".
  - Equals: "="
  - Exclamation mark: "!"
  - Hyphen: "-"
  - Open and close parentheses: "(, )"
  - Percent: "%"
  - Plus: "+
  - Semicolon: ";"
  - Single quote: "'
  - Slash: "/"
  - Question mark: "?"
  - Tilde: "~"
  - Underscore: "_"

• `<text>.MARK_SAFE:
  Marks the text as safe without applying any type of data transformation.

• `<text>.SET_TEXT_MODE(URLENCODED|NOURLENCODED):
  Transforms all %HH encoding in the byte stream. This operation works with characters (not
  bytes). By default, a single byte represents a character in ASCII encoding. However, if you specify
  URLENCODED mode, three bytes can represent a character.
  In the following example, a PREFIX(3) operation selects the first 3 characters in a target.
  http.req.url.hostname.prefix(3)
  In the following example, the NetScaler can select up to 9 bytes from the target:
  http.req.url.hostname.set_text_mode(urllencoded).prefix(3)

• `<text>.SET_TEXT_MODE(PLUS_AS_SPACE|NO_PLUS_AS_SPACE):
  Specifies how to treat the plus character (+). The PLUS_AS_SPACE option replaces a plus
character with white space. For example, the text “hello+world” becomes “hello world.” The NO_PLUS_AS_SPACE option leaves plus characters as they are.

- `<text>.SET_TEXT_MODE(BACKSLASH_ENCODED|NO_BACKSLASH_ENCODED):`
  Specifies whether or not backslash decoding is performed on the text object represented by `<text>`. If BACKSLASH_ENCODED is specified, the SET_TEXT_MODE operator performs the following operations on the text object:
  - All occurrences of “\XXX” will be replaced with the character “Y” (where XXX represents a number in the octal system and Y represents the ASCII equivalent of XXX). The valid range of octal values for this type of encoding is 0 to 377. For example, the encoded text “http\72//” and http\072//” will both be decoded to http://, where the colon (:) is the ASCII equivalent of the octal value “72”.
  - All occurrences of “\xHH” will be replaced with the character “Y” (HH represents a number in the hexadecimal system and Y denotes the ASCII equivalent of HH. For example, the encoded text “http\x3a//” will be decoded to http://, where the colon (:) is the ASCII equivalent of the hexadecimal value “3a”.
  - All occurrences of “\uWWXX” will be replaced with the character sequence “YZ” (Where WW and XX represent two distinct hexadecimal values and Y and Z represent their ASCII equivalents of WW and XX respectively. For example, the encoded text “http%u3a2f//” and “http%u003a//” will both be decoded to http://, where “3a” and “2f” are two hexadecimal values and the colon (:) and forward slash (“/”) represent their ASCII equivalents respectively.
  - All occurrences of “\b”, “\n”, “\t”, “\f”, and “\r” are replaced with the corresponding ASCII characters.
    If NO_BACKSLASH_ENCODED is specified, backslash decoding is not performed on the text object.

- `<text>.SET_TEXT_MODE(BAD_ENCODE_RAISE_UNDEF|NO_BAD_ENCODE_RAISE_UNDEF):`
  Performs the associated undefined action if either the URLENCODED or the BACKSLASH_ENCODED mode is set and bad encoding corresponding to the specified encoding mode is encountered in the text object represented by `<text>`. If NO_BAD_ENCODE_RAISE_UNDEF is specified, the associated undefined action will not be performed when bad encoding is encountered in the text object represented by `<text>`.

**Expressions for TCP, UDP, and VLAN data**

September 24, 2018
TCP and UDP data take the form of a string or a number. For expression prefixes that return string values for TCP and UDP data, you can apply any text-based operations. For more information, see Advanced policy expressions: Evaluating text.

For expression prefixes that return numeric value, such as a source port, you can apply an arithmetic operation. For more information, see Basic operations on expression prefixes and Compound operations for numbers.

The following table describes prefixes that extract TCP and UDP data.

<table>
<thead>
<tr>
<th>GET Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLIENT.TCP.PAYLOAD(&lt;integer&gt;)</td>
<td>Returns TCP payload data as a string, starting with the first character in the payload and continuing for the number of characters in the &lt;integer&gt; argument. You can apply any text-based operation to this prefix.</td>
</tr>
<tr>
<td>CLIENT.TCP.SRCPORT</td>
<td>Returns the ID of the current packet's source port as a number.</td>
</tr>
<tr>
<td>CLIENT.TCP.DSTPORT</td>
<td>Returns the ID of the current packet's destination port as a number.</td>
</tr>
<tr>
<td>CLIENT.TCP.OPTIONS</td>
<td>Returns the TCP options set by the client. Examples of TCP options are Maximum Segment Size (MSS), Window Scale, Selective Acknowledgements (SACK), and Time Stamp Option. The COUNT, TYPE(&lt;type&gt;), and TYPE_NAME(&lt;m&gt;) operators can be used with this prefix. For the TCP options set by the server, see the SERVER.TCP.OPTIONS prefix.</td>
</tr>
<tr>
<td>CLIENT.TCP.OPTIONS.COUNT</td>
<td>Returns the number of TCP options that the client has set.</td>
</tr>
<tr>
<td>CLIENT.TCP.OPTIONS.TYPE(&lt;type&gt;)</td>
<td>Returns the value of the TCP option whose type (or option kind) is specified as the argument. The value is returned as a string of bytes in big endian format (or network byte order). Parameters: type - Type value</td>
</tr>
</tbody>
</table>
### GET Operation Description

<table>
<thead>
<tr>
<th>GET Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLIENT.TCP.OPTIONS.TYPE_NAME(&lt;m&gt;)</td>
<td>Returns the value of the TCP option whose enumeration constant is specified as the argument. The enumeration constants that you can pass as the argument are REPEATER, TIMESTAMP, SACK_PERMITTED, WINDOW, and MAXSEG. To specify the TCP option kind instead of these enumeration constants, use CLIENT.TCP.OPTIONS.TYPE(&lt;type&gt;). For other TCP options, you must use CLIENT.TCP.OPTIONS.TYPE(&lt;type&gt;). Parameters: m - TCP option enumeration constant</td>
</tr>
<tr>
<td>CLIENT.TCP.REPEATER_OPTION.EXISTS</td>
<td>Returns a Boolean TRUE if Repeater TCP options exist.</td>
</tr>
<tr>
<td>CLIENT.TCP.REPEATER_OPTION.IP</td>
<td>Returns the branch repeater's IPv4 address from the Repeater TCP options.</td>
</tr>
<tr>
<td>CLIENT.TCP.REPEATER_OPTION.MAC</td>
<td>Returns the branch repeater's MAC address from the Repeater TCP options.</td>
</tr>
<tr>
<td>CLIENT.UDP.DNS.DOMAIN</td>
<td>Returns the DNS domain name.</td>
</tr>
<tr>
<td>CLIENT.UDP.DNS.DOMAIN.EQ(&quot;&lt;hostname&gt;&quot;)</td>
<td>Returns a Boolean TRUE if the domain name matches the &lt;hostname&gt; argument. The comparison is case insensitive. Following is an example: client.udp.dns.domain.eq(&quot;www.mycompany.com&quot;)</td>
</tr>
<tr>
<td>CLIENT.UDP.DNS.IS_AAAAREC</td>
<td>Returns a Boolean TRUE if the record type is AAAA. These types of records indicate an IPv6 address in forward lookups.</td>
</tr>
<tr>
<td>CLIENT.UDP.DNS.IS_ANYREC</td>
<td>Returns a Boolean TRUE if it is of any record type.</td>
</tr>
<tr>
<td>CLIENT.UDP.DNS.IS_AREC</td>
<td>Returns a Boolean TRUE if the record is type A. Type A records provide the host address.</td>
</tr>
<tr>
<td>GET Operation</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>CLIENT.UDP.DNS.IS_CNAMEREC</td>
<td>Returns a Boolean TRUE if the record is of type CNAME. In systems that use multiple names to identify a resource, there is one canonical name and a number of aliases. The CNAME provides the canonical name.</td>
</tr>
<tr>
<td>CLIENT.UDP.DNS.IS_MXREC</td>
<td>Returns a Boolean TRUE if the record is of type MX (mail exchanger). This DNS record describes a priority and a host name. The MX records for the same domain name specify the email servers in the domain and the priority for each server.</td>
</tr>
<tr>
<td>CLIENT.UDP.DNS.IS_NSREC</td>
<td>Returns a Boolean TRUE if the record is of type NS. This is a name server record that includes a host name with an associated A record. This enables locating the domain name that is associated with the NS record.</td>
</tr>
<tr>
<td>CLIENT.UDP.DNS.IS_PTRREC</td>
<td>Returns a Boolean TRUE if the record is of type PTR. This is a domain name pointer and is often used to associate a domain name with an IPv4 address.</td>
</tr>
<tr>
<td>CLIENT.UDP.DNS.IS_SOAREC</td>
<td>Returns a Boolean TRUE if the record is of type SOA. This is a start of authority record.</td>
</tr>
<tr>
<td>CLIENT.UDP.DNS.IS_SRVREC</td>
<td>Returns a Boolean TRUE if the record is of type SRV. This is a more general version of the MX record.</td>
</tr>
<tr>
<td>CLIENT.UDP.DSTPORT</td>
<td>Returns the numeric ID of the current packet’s UDP destination port.</td>
</tr>
<tr>
<td>CLIENT.UDP.SRCPORT</td>
<td>Returns the numeric ID of the current packet’s UDP source port.</td>
</tr>
<tr>
<td>CLIENT.UDP.RADIUS</td>
<td>Returns RADIUS data for the current packet.</td>
</tr>
<tr>
<td>CLIENT.UDP.RADIUS.ATTR_TYPE(&lt;type&gt;)</td>
<td>Returns the value for the attribute type specified as the argument.</td>
</tr>
<tr>
<td>CLIENT.UDP.RADIUS.USERNAME</td>
<td>Returns the RADIUS user name.</td>
</tr>
<tr>
<td>CLIENT.TCP.MSS</td>
<td>Returns the maximum segment size (MSS) for the current connection as a number.</td>
</tr>
<tr>
<td>GET Operation</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>CLIENT.VLAN.ID</td>
<td>Returns the numeric ID of the VLAN through which the current packet entered the NetScaler.</td>
</tr>
<tr>
<td>SERVER.TCP.DSTPORT</td>
<td>Returns the numeric ID of the current packet’s destination port.</td>
</tr>
<tr>
<td>SERVER.TCP.SRCPORT</td>
<td>Returns the numeric ID of the current packet’s source port.</td>
</tr>
<tr>
<td>SERVER.TCP.OPTIONS</td>
<td>Returns the TCP options set by the server. Examples of TCP options are Maximum Segment Size (MSS), Window Scale, Selective Acknowledgements (SACK), and Time Stamp Option. The COUNT, TYPE(&lt;type&gt;), and TYPE_NAME(&lt;m&gt;) operators can be used with this prefix. For the TCP options set by the client, see the CLIENT.TCP.OPTIONS prefix.</td>
</tr>
<tr>
<td>SERVER.TCP.OPTIONS.COUNT</td>
<td>Returns the number of TCP options that the server has set.</td>
</tr>
<tr>
<td>SERVER.TCP.OPTIONS.TYPE(&lt;type&gt;)</td>
<td>Returns the value of the TCP option whose type (or option kind) is specified as the argument. The value is returned as a string of bytes in big endian format (or network byte order). Parameters: type - Type value</td>
</tr>
<tr>
<td>SERVER.TCP.OPTIONS.TYPE_NAME(&lt;m&gt;)</td>
<td>Returns the value of the TCP option whose enumeration constant is specified as the argument. The enumeration constants that you can pass as the argument are REPEATER, TIMESTAMP, SACK_PERMITTED, WINDOW, and MAXSEG. To specify the TCP option kind instead of these enumeration constants, use CLIENT.TCP.OPTIONS.TYPE(&lt;type&gt;). For other TCP options, you must use CLIENT.TCP.OPTIONS.TYPE(&lt;type&gt;). Parameters: m - TCP option enumeration constant</td>
</tr>
<tr>
<td>SERVER.VLAN</td>
<td>Operates on the VLAN through which the current packet entered the NetScaler.</td>
</tr>
</tbody>
</table>
GET Operation | Description
--- | ---
SERVER.VLAN.ID | Returns the numeric ID of the VLAN through which the current packet entered the NetScaler.

Expressions for evaluating a DNS message and identifying its carrier protocol

September 24, 2018

You can evaluate DNS requests and responses by using expressions that begin with DNS.REQ and DNS.RES, respectively. You can also identify the transport layer protocol that is being used to send the DNS messages.

The following functions return the contents of a DNS query.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DNS.REQ.QUESTION.DOMAIN</td>
<td>Return the domain name (the value of the QNAME field) in the question section of the DNS query. The domain name is returned as a text string, which can be passed to EQ(), NE(), and any other functions that work with text.</td>
</tr>
<tr>
<td>DNS.REQ.QUESTION.TYPE</td>
<td>Return the query type (the value of the QTYPE field) in the DNS query. The field indicates the type of resource record (for example, A, NS, or CNAME) for which the name server is being queried. The returned value can be compared to one of the following values by using the EQ() and NE() functions: A, AAAA, NS, SRV, PTR, CNAME, SOA, MX, and ANY. Note: You can use only the EQ() and NE() functions with the TYPE function. Example: DNS.REQ.QUESTION.TYPE.EQ(MX)</td>
</tr>
</tbody>
</table>

The following functions return the contents of a DNS response.
## Function Description

### DNS.RES.HEADER.RCODE
Return the response code (the value of the RCODE field) in the header section of the DNS response. You can use only the EQ() and NE() functions with the RCODE function. Following are the possible values: NOERROR, FORMERR, SERVFAIL, NXDOMAIN, NOTIMP, and REFUSED.

### DNS.RES.QUESTION.DOMAIN
Return the domain name (the value of the QNAME field) in the question section of the DNS response. The domain name is returned as a text string, which can be passed to EQ(), NE(), and any other functions that work with text.

### DNS.RES.QUESTION.TYPE
Return the query type (the value of the QTYPE field) in the question section of the DNS response. The field indicates the type of resource record (for example, A, NS, or CNAME) that is contained in the response. The returned value can be compared to one of the following values by using the EQ() and NE() functions: A, AAAA, NS, SRV, PTR, CNAME, SOA, MX, and ANY. You can use only the EQ() and NE() functions with the TYPE function. Example: DNS.RES.QUESTION.TYPE.EQ(SOA)

The following functions return the transport layer protocol name.

### DNS.REQ.TRANSPORT
Return the name of the transport layer protocol that was used to send the DNS query. Possible values returned are TCP and UDP. You can use only the EQ() and NE() functions with the TRANSPORT function. Example: DNS.REQ.TRANSPORT.EQ(TCP)
Function Description

DNS.RES.TRANSPORT Return the name of the transport layer protocol that was used for the DNS response. Possible values returned are TCP and UDP. You can use only the EQ() and NE() functions with the TRANSPORT function. Example: DNS.RES.TRANSPORT.EQ(TCP)

**XPath and HTML, XML, or JSON expressions**

September 24, 2018

The Advanced policy infrastructure supports expressions for evaluating and retrieving data from HTML, XML, and JavaScript Object Notation (JSON) files. This enables you to find specific nodes in an HTML, XML, or JSON document, determine if a node exists in the file, locate nodes in XML contexts (for example, nodes that have specific parents or a specific attribute with a given value), and return the contents of such nodes. Additionally, you can use XPath expressions in rewrite expressions.

The Advanced policy expression implementation for XPath comprises an Advanced policy expression prefix (such as “HTTP.REQ.BODY”) that designates HTML or XML text, and the XPATH operator that takes the XPath expression as its argument.

HTML files are a largely free-form collection of tags and text elements. You can use the XPATH_HTML operator, which takes an XPath expression as its argument, to process HTML files. JSON files are either a collection of name/value pairs or an ordered list of values. You can use the XPATH_JSON operator, which takes an XPath expression as its argument, to process JSON files.

- `<text>.XPATH(xpathex)`: Operate on an XML file and return a Boolean value.
  
  For example, the following expression returns a Boolean TRUE if a node called “creator” exists under the node “Book” within the first 1000 bytes of the XML file.

  ```
  HTTP.REQ.BODY(1000).XPATH(xpathex).boolean(//'Book/creator')%
  ```

  Parameters:
  - xpathex - XPath Boolean expression

- `<text>.XPATH(xpathex)`: Operate on an XML file and return a value of data type “double.”
  
  For example, the following expression converts the string “36” (a price value) to a value of data type “double” if the string is in the first 1000 bytes of the XML file:
HTTP.REQ.BODY(1000).XPATH(xp%number(/Book/price))

Parameters:

xpathex - XPath numeric expression

• `<text>` .XPATH(xpathex):

  Operate on an XML file and return a node-set or a string. Node-sets are converted to corresponding strings by using the standard XPath string conversion routine.

  For example, the following expression selects all the nodes that are enclosed by “/Book/creator” (a node-set) in the first 1000 bytes of the body:

  HTTP.REQ.BODY(1000).XPATH(xp%/Book/creator)

Parameters:

xpathex - XPath expression

• `<text>` .XPATH_HTML(xpathex)

  Operate on an HTML file and return a text value.

  For example, the following expression operates on an HTML file and returns the text enclosed in `<title></title>` tags if the title HTML element is found in the first 1000 bytes:

  HTTP.REQ.BODY(1000).XPATH_HTML(xp%/html/head/title)

Parameters:

xpathex - XPath text expression

• `<text>` .XPATH_HTML_WITH_MARKUP(xpathex)

  Operate on an HTML file and return a string that contains the entire selected portion of the document, including markup such as including the enclosing element tags.

  The following expression operates on the HTML file and selects all content within the `<title>` tag, including markup.

  HTTP.REQ.BODY(1000).XPATH_HTML_WITH_MARKUP(xp%/html/head/title)

The portion of the HTML body that is selected by the expression is marked for further processing.

Parameters:

xpathex - XPath expression

• `<text>` .XPATH_JSON(xpathex)

  Operate on a JSON file and return a Boolean value.

  For example, consider the following JSON file:

  ```json
  { "Book": { "creator": { "person": { "name": '<name>' }, "title": '<title>' } }, "title": '<title>' }
  ```

© 1999-2018 Citrix Systems, Inc. All rights reserved.
The following expression operates on the JSON file and returns a Boolean TRUE if the JSON file contains a node named “creator,” whose parent node is “Book,” in the first 1000 bytes:

```plaintext
HTTP.REQ.BODY(1000).XPATH_JSON(xp%boolean(/Book/creator%))
```

Parameters:

- xpathex - XPath Boolean expression

- `<text>` .XPATH_JSON(xpathex)
  Operate on a JSON file and return a value of data type “double.”

  For example, consider the following JSON file:

  ```json
  { "Book":{ "creator":{ "person":{ "name":'<name>' } }, "title":'<title>' , "price":"36" } }
  ```

  The following expression operates on the JSON file and converts the string “36” to a value of data type “double” if the string is present in the first 1000 bytes of the JSON file.

  ```plaintext
  HTTP.REQ.BODY(1000).XPATH_JSON(xp%number(/Book/price%))
  ```

  Parameters:

  - xpathex - XPath numeric expression

- `<text>` .XPATH_JSON_WITH_MARKUP(xpathex)
  Operate on an XML file and return a string that contains the entire portion of the document for the result node, including markup such as including the enclosing element tags.

  For example, consider the following JSON file:

  ```json
  { "Book":{ "creator":{ "person":{ "name":'<name>' } }, "title":'<title>' } }
  ```

  The following expression operates on the JSON file and selects all the nodes that are enclosed by “/Book/creator” in the first 1000 bytes of the body, which is “creator:{ person:{ name:'<name>' } }.”
HTTP.REQ.BODY(1000).XPATH_JSON_WITH_MARKUP(xp%//Book/creator%)

The portion of the JSON body that is selected by the expression is marked for further processing.

Parameters:

xpathex - XPath expression

• <text>XPATH_WITH_MARKUP(xpathex):

Operate on an XML file and return a string that contains the entire portion of the document for the result node, including markup such as including the enclosing element tags.

For example, the following expression operates on an XML file and selects all the nodes enclosed by “/Book/creator” in the first 1000 bytes of the body.

HTTP.REQ.BODY(1000).XPATH_WITH_MARKUP(xp%//Book/creator%)

The portion of the JSON body that is selected by the expression is marked for further processing.

Parameters:

xpathex - XPath expression

Encrypt and decrypt XML payloads

September 24, 2018

You can use the XML.ENCRYPT() and XML.DECRYPT() functions in Advanced policy expressions to encrypt and decrypt, respectively, XML data. These functions conform to the W3C XML Encryption standard defined at “http://www.w3.org/TR/2001/PR-xmldsig-core-20010820/.” XML.ENCRYPT() and XML.DECRYPT() support a subset of the XML Encryption specification. In the subset, data encryption uses a bulk cipher method (RC4, DES3, AES128, AES192, or AES256), and an RSA public key is used to encrypt the bulk cipher key.

Note: If you want to encrypt and decrypt text in a payload, you must use the ENCRYPT and DECRYPT functions. For more information about these functions, see Encrypt and decrypt text.

The XML.ENCRYPT() and XML.DECRYPT() functions are not dependent on the encryption/decryption service that is used by the ENCRYPT and DECRYPT commands for text. The cipher method is specified explicitly as an argument to the XML.ENCRYPT() function. The XML.DECRYPT() function obtains the information about the specified cipher method from the
<xenc:EncryptedData> element. Following are synopses of the XML encryption and decryption functions:

- **XML_ENCRYPT(certKeyName, method [, flags])**: Returns an <xenc:EncryptedData> element that contains the encrypted input text and the encryption key, which is itself encrypted by using RSA.

- **XML_DECRYPT(certKeyName)**: Returns the decrypted text from the input <xenc:EncryptedData> element, which includes the cipher method and the RSA-encrypted key.

**Note**: The <xenc:EncryptedData> element is defined in the W3C XML Encryption specification.

Following are descriptions of the arguments:

- **certKeyName**: Selects an X.509 certificate with an RSA public key for XML_ENCRYPT() or an RSA private key for XML_DECRYPT(). The certificate key must have been previously created by an add_ssl_certKey command.

- **method**: Specifies which cipher method to use for encrypting the XML data. Possible values: RC4, DES3, AES128, AES192, AES256.

- **flags**: A bitmask specifying the following optional key information ( <ds:KeyInfo> ) to be included in the <xenc:EncryptedData> element that is generated by XML_ENCRYPT():
  -  1 - Include a KeyName element with the certKeyName. The element is <ds:KeyName>.
  -  2 - Include a KeyValue element with the RSA public key from the certificate. The element is <ds:KeyValue>.
  -  4 - Include an X509IssuerSerial element with the certificate serial number and issuer DN. The element is <ds:X509IssuerSerial>.
  -  8 - Include an X509SubjectName element with the certificate subject DN. The element is <ds:X509SubjectName>.
  - 16 - Include an X509Certificate element with the entire certificate. The element is <ds:X509Certificate>.

**Use the XML_ENCRYPT() and XML_DECRYPT() functions in expressions**

The XML encryption feature uses SSL certificate-key pairs to provide X.509 certificates (with RSA public keys) for key encryption and RSA private keys for key decryption. Therefore, before you use the XML_ENCRYPT() function in an expression, you must create an SSL certificate-key pair. The following command creates an SSL certificate-key pair, my-certkey, with the X.509 certificate, my-cert.pem, and the private key file, my-key.pem.
The following CLI commands create rewrite actions and policies for encrypting and decrypting XML content.

```
add ssl certKey my-certkey -cert my-cert.pem -key my-key.pem -passcrypt
kxPeMRYnitY=
```

In the above example, the rewrite action my-xml-encrypt-action encrypts the entire XML document (XPATH_WITH_MARKUP(xp%/%)) in the request by using the AES-256 bulk encryption method and the RSA public key from my-certkey to encrypt the bulk encryption key. The action replaces the document with an <xenc:EncryptedData> element containing the encrypted data and an encrypted key. The flags represented by 31 include all of the optional <ds:KeyInfo> elements.

The action my-xml-decrypt-action decrypts the first <xenc:EncryptedData> element in the response (XPATH_WITH_MARKUP(xp%/xenc:EncryptedData%)). This requires the prior addition of the xenc XML namespace by use of the following CLI command:

```
add ns xmlnamespace xenc http://www.w3.org/2001/04/xmlenc#
```

The my-xml-decrypt-action action uses the RSA private key in my-certkey to decrypt the encrypted key and then uses the bulk encryption method specified in the element to decrypt the encrypted contents. Finally, the action replaces the encrypted data element with the decrypted content.

The rewrite policy my-xml-encrypt-policy applies my-xml-encrypt-action to requests for URLs containing xml-encrypt. The action encrypts the entire response from a service configured on the NetScaler appliance.

The rewrite policy my-xml-decrypt-policy applies my-xml-decrypt-action to requests that contain an
<xenc:EncryptedData> element (XPath(xp://xenc:EncryptedData%) returns a non-empty string). The action decrypts the encrypted data in requests that are bound for a service configured on the NetScaler appliance.

Advanced policy expressions: parsing SSL

November 5, 2018

There are advanced policy expressions to parse SSL certificates and SSL client hello messages.

Parse SSL certificates

You can use advanced policy expressions to evaluate X.509 Secure Sockets Layer (SSL) client certificates. A client certificate is an electronic document that can be used to authenticate a user's identity. A client certificate contains (at a minimum) version information, a serial number, a signature algorithm ID, an issuer name, a validity period, a subject (user) name, a public key, and signatures.

You can examine both SSL connections and data in client certificates. For example, you may want to send SSL requests that use low-strength ciphers to a particular load balancing virtual server farm. The following command is an example of a Content Switching policy that parses the cipher strength in a request and matches cipher strengths that are less than or equal to 40:

```
1 add cs policy p1 -rule "client.ssl.cipher\_bits.le(40)"
```

As another example, you can configure a policy that determines whether a request contains a client certificate:

```
1 add cs policy p2 -rule "client.ssl.client\_cert EXISTS"
```

Or, you might want to configure a policy that examines particular information in a client certificate. For example, the following policy verifies that the certificate has one or more days before expiration:

```
1 add cs policy p2 -rule "client.ssl.client\_cert exists &amp; client.ssl.client\_cert.days\_to\_expire.ge(1)"
```

Note

For information on parsing dates and times in a certificate, see Format of Dates and Times in an Expression and Expressions for SSL Certificate Dates.
Prefixes for text-based SSL and certificate data

The following table describes expression prefixes that identify text-based items in SSL transactions and client certificates.

Table 1. Prefixes That Return Text or Boolean Values for SSL and Client Certificate Data

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLIENT.SSL.CLIENT_CERT</td>
<td>Returns the SSL client certificate in the current SSL transaction.</td>
</tr>
<tr>
<td>CLIENT.SSL.CLIENT_CERT.TO_PEM</td>
<td>Returns the SSL client certificate in binary format.</td>
</tr>
<tr>
<td>CLIENT.SSL.CIPHER_EXPORTABLE</td>
<td>Returns a Boolean TRUE if the SSL cryptographic SSL cryptographic cipher is exportable.</td>
</tr>
<tr>
<td>CLIENT.SSL.CIPHER_NAME</td>
<td>Returns the name of the SSL Cipher if invoked from an SSL connection, and a NULL string if invoked from a non-SSL connection.</td>
</tr>
<tr>
<td>CLIENT.SSL.IS_SSL</td>
<td>Returns a Boolean TRUE if the current connection is SSL-based.</td>
</tr>
</tbody>
</table>

Prefixes for numeric data in SSL certificates

The following table describes prefixes that evaluate numeric data other than dates in SSL certificates. These prefixes can be used with the operations that are described in Basic Operations on Expression Prefixes and Compound Operations for Numbers.

Table 2. Prefixes That Evaluate Numeric Data Other Than Dates in SSL Certificates

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLIENT.SSL.CLIENT_CERT.DAYS_TO_EXPIRE</td>
<td>Returns the number of days that the certificate is valid, or returns -1 for expired certificates.</td>
</tr>
<tr>
<td>CLIENT.SSLCLIENT_CERT.PK_SIZE</td>
<td>Returns the size of the public key used in the certificate.</td>
</tr>
<tr>
<td>CLIENT.SSL.CLIENT_CERT.VERSION</td>
<td>Returns the version number of the certificate. If the connection is not SSL-based, returns zero (0).</td>
</tr>
</tbody>
</table>
Prefix Description

CLIENT.SSL.CIPHER_BITS Returns the number of bits in the cryptographic key. Returns 0 if the connection is not SSL-based.

CLIENT.SSL.VERSION Returns a number that represents the SSL protocol version, as follows: 0. The transaction is not SSL-based.; 0x002. The transaction is SSLv2.; 0x300. The transaction is SSLv3.; 0x301. The transaction is TLSv1.; 0x302. The transaction is TLSv1.1.; 0x303. The transaction is TLSv1.2.

Note

For expressions related to expiration dates in a certificate, see Expressions for SSL Certificate Dates.

Expressions for SSL certificates

You can parse SSL certificates by configuring expressions that use the following prefix:

CLIENT.SSL.CLIENT_CERT

This section discusses the expressions that you can configure for certificates, with the exception of expressions that examine certificate expiration. Time-based operations are described in Advanced Policy Expressions: Working with Dates, Times, and Numbers.

The following table describes operations that you can specify for the CLIENT.SSL.CLIENT_CERT prefix.

Table 3. Operations That Can Be Specified with the CLIENT.SSL.CLIENT_CERT Prefix

<table>
<thead>
<tr>
<th>SSL Certificate Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;certificate&gt;.EXISTS</td>
<td>Returns a Boolean TRUE if the client has an SSL certificate.</td>
</tr>
</tbody>
</table>
### SSL Certificate Operation

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;certificate&gt;.ISSUER</code></td>
<td>Returns the Distinguished Name (DN) of the Issuer in the certificate as a name-value list. An equals sign (&quot;=&quot;) is the delimiter for the name and the value, and the slash (&quot;/&quot;) is the delimiter that separates the name-value pairs. Following is an example of the returned DN: <code>/C=US/O=myCompany/OU=www.mycompany.com/CN=www.mycompany.com/emailAddress=myuserid@mycompany.com</code></td>
</tr>
<tr>
<td><code>&lt;certificate&gt;.ISSUER.IGNORE_EMPTY_ELEMENTS</code></td>
<td>Returns the Issuer and ignores the empty elements in a name-value list. For example, consider the following: Cert-Issuer: <code>/c=in/st=kar/l=bangelore/o=mycompany/ou=sales/emailAddress=myuserid@mycompany.com</code>. The following Rewrite action returns a count of 6 based on the preceding Issuer definition: <code>sh rewrite action insert_ssl_header Name: insert_sslOperation insert_http_header Target:Cert-Issuer Value:CLIENT.SSL.CLIENT_CERT.ISSUER .COUNT</code>. However, if you change the value to the following, the returned count is 9: <code>CLIENT.SSL.CLIENT_CERT.ISSUER.IGNORE_EMPTY_ELEMENTS.COUNT</code></td>
</tr>
</tbody>
</table>

---

**Advanced policy expressions: IP and MAC addresses, throughput, VLAN IDs**

November 5, 2018

You can use Advanced policy expression prefixes that return IPv4 and IPv6 addresses, MAC addresses, IP subnets, useful client and server data such as the throughput rates at the interface ports (Rx, Tx, and RxTx), and the IDs of the VLANs through which packets are received. You can then use various operators to evaluate the data that is returned by these expression prefixes.
Expressions for IP Addresses and IP Subnets

You can use Advanced policy expressions to evaluate addresses and subnets that are in Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6) format. Expression prefixes for IPv6 addresses and subnets include IPv6 in the prefix. Expression prefixes for IPv4 addresses and subnets include IP in the prefix. Following is an example of an expression that identifies whether a request has originated from a particular IPv4 subnet.

```
1 client.ip.src.in_subnet(147.1.0.0/16)
```

Following are two examples of Rewrite policies that examine the subnet from which the packet is received and perform a rewrite action on the Host header. With these two policies configured, the rewrite action that is performed depends on the subnet in the request. These two policies evaluate IP addresses that are in the IPv4 address format.

```
1 - add rewrite action URL1-rewrite-action replace "http.req.header("Host")" "www.mycompany1.com"
2 - add rewrite policy URL1-rewrite-policy "http.req.header("Host").contains("www.test1.com") && client.ip.src.in_subnet(147.1.0.0/16)" URL1-rewrite-action
3 - add rewrite action URL2-rewrite-action replace "http.req.header("Host")" "www.mycompany2.com"
4 - add rewrite policy URL2-rewrite-policy "http.req.header("Host").contains("www.test2.com") && client.ip.src.in_subnet(10.202.0.0/16)" URL2-rewrite-action
```

Note

The preceding examples are commands that you type at the NetScaler command-line interface (CLI) and, therefore, each quotation mark must be preceded by a backslash (\). For more information, see Configuring advanced policy expressions in a policy.

Prefixes for IPv4 Addresses and IP Subnets

The following table describes prefixes that return IPv4 addresses and subnets, and segments of IPv4 addresses. You can use numeric operators and operators that are specific to IPv4 addresses with these prefixes. For more information about numeric operations, see Basic Operations on Expression Prefixes and Compound Operations for Numbers.

Table 1. Prefixes That Evaluate IP and MAC Addresses

© 1999-2018 Citrix Systems, Inc. All rights reserved. 1244
### Prefixes and Their Descriptions

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLIENT.IP.SRC</td>
<td>Returns the source IP of the current packet as an IP address or as a number.</td>
</tr>
<tr>
<td>CLIENT.IP.DST</td>
<td>Returns the destination IP of the current packet as an IP address or as a number.</td>
</tr>
<tr>
<td>SERVER.IP.SRC</td>
<td>Returns the source IP of the current packet as an IP address or as a number.</td>
</tr>
<tr>
<td>SERVER.IP.DST</td>
<td>Returns the destination IP of the current packet as an IP address or as a number.</td>
</tr>
</tbody>
</table>

### Operations for IPv4 Addresses

The following table describes the operators that can be used with prefixes that return an IPv4 address.

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;ip address&gt;.EQ(&lt;address&gt;)</code></td>
<td>Returns a Boolean TRUE if the IP address value is same as the <code>&lt;address&gt;</code> argument. The following example checks whether the client’s destination IP address is equal to 10.100.10.100: <code>client.ip.dst.eq(10.100.10.100)</code></td>
</tr>
<tr>
<td><code>&lt;ip address&gt;.GET1 . . GET4</code></td>
<td>Returns a portion of an IP address as a numeric value. For example, if the IP address value is 10.100.200.1, the following is returned: <code>client.ip.src.get1 Returns 10; client.ip.src.get2 returns 100; client.ip.src.get3 returns 200</code></td>
</tr>
<tr>
<td><code>&lt;ip address&gt;.IN_SUBNET(&lt;subnet&gt;)</code></td>
<td>Returns a Boolean TRUE if the <code>&lt;subnet&gt;</code> argument matches the subnet of the IP address value. For example, the following determines whether the client’s destination IP address subnet is 10.100.100/18: <code>client.ip.dst.eq(10.100.10.100/18)</code></td>
</tr>
</tbody>
</table>
### Prefix Description

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;ip address&gt;.SUBNET(&lt;n&gt;)</code></td>
<td>Returns the IP address after applying the subnet mask specified as the argument. The subnet mask can take values between 0 and 32. For example: <code>CLIENT.IP.SRC.SUBNET (24)</code> returns <code>192.168.1.0</code> if the IP address represented by the prefix is <code>192.168.1.[0-255]</code>.</td>
</tr>
<tr>
<td><code>&lt;ip address&gt;.IS_IPV6</code></td>
<td>Returns a Boolean TRUE if this is an Internet Protocol version 6 (IPv6) host for the client or server. Following is an example: <code>client.ip.src.is_ipv6</code></td>
</tr>
<tr>
<td><code>&lt;ip address&gt;.MATCHES(&lt;hostname&gt;)</code></td>
<td>Returns a Boolean TRUE if the IP address for the host specified in <code>&lt;hostname&gt;</code> matches the current IP address. The <code>&lt;hostname&gt;</code> cannot exceed 255 characters.</td>
</tr>
<tr>
<td><code>&lt;ip address&gt;.MATCHES_LOCATION(&lt;location&gt;)</code></td>
<td>Returns a Boolean TRUE if the location of the IP address matches the <code>&lt;location&gt;</code> argument. The Location string can take the following form: <code>qual1.qual2.qual3.qual4.qual5.qual6</code>, for example: <code>NorthAmerica.CA.*</code> Following is an example: <code>client.ip.src.matches_location &quot;Europe.GB.17.London.*.*\&quot;</code></td>
</tr>
</tbody>
</table>

### About IPv6 expressions

The IPv6 address format allows more flexibility than the older IPv4 format. IPv6 addresses are in the hexadecimal format (RFC 2373). In the following examples, Example 1 is an IPv6 address, Example 2 is a URL that includes the IPv6 address, and Example 3 includes the IPv6 address and a port number.

#### Example 1:

```
  1 9901:0ab1:22a2:88a3:3333:4a4b:5555:6666
```

#### Example 2:

```
  1 http://[9901:0ab1:22a2:88a3:3333:4a4b:5555:6666]/
```
Example 3:

```
https://[9901:0ab1:22a2:88a3:3333:4a4b:5555:6666]:8080/
```

In Example 3, the brackets separate the IP address from the port number (8080).

Note that you can only use the ‘+’ operator to combine IPv6 expressions with other expressions. The output is a concatenation of the string values that are returned from the individual expressions. You cannot use any other arithmetic operator with an IPv6 expression. The following syntax is an example:

```
client.ipv6.src + server.ip.dst
```

For example, if the client source IPv6 address is ABCD:1234::ABCD, and the server destination IPv4 address is 10.100.10.100, the preceding expression returns “ABCD:1234::ABCD10.100.10.100”.

Note that when the NetScaler appliance receives an IPv6 packet, it assigns a temporary IPv4 address from an unused IPv4 address range and changes the source address of the packet to this temporary address. At response time, the outgoing packet’s source address is replaced with the original IPv6 address.

Note

You can combine an IPv6 expression with any other expression except an expression that produces a Boolean result.

Expression prefixes for IPv6 addresses

The IPv6 addresses that are returned by the expression prefixes in the following table can be treated as text data. For example, the prefix client.ipv6.dst returns the destination IPv6 address as a string that can be evaluated as text.

The following table describes expression prefixes that return an IPv6 address.

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLIENT.IPV6</td>
<td>Operates on the IPv6 address in with the current packet.</td>
</tr>
<tr>
<td>CLIENT.IPV6.DST</td>
<td>Returns the IPv6 address in the destination field of the IP header.</td>
</tr>
</tbody>
</table>
Prefix Description
---
SERVER.IPV6 Operates on the IPv6 address in with the current packet.
SERVER.IPV6.DST Returns the IPv6 address in the destination field of the IP header.
SERVER.IPV6.SRC Returns the IPv6 address in the source field of the IP header. Following are examples: server.ipv6.src.in_subnet(2007::2008/64) server.ipv6.src.get1.le(2008)

**Operations for IPv6 prefixes**

The following table describes the operators that can be used with prefixes that return an IPv6 address:

**Table 4. Operations That Evaluate IPv6 Addresses**

<table>
<thead>
<tr>
<th>IPv6 Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;ipv6&gt;.EQ(&lt;IPv6_address&gt;</code></td>
<td>Returns a Boolean TRUE if the IP address value is same as the argument. Following is an example: ‘client.ipv6.dst.eq(ABCD:1234::ABCD)’</td>
</tr>
<tr>
<td><code>&lt;ipv6&gt;.GET1. . .GET8  </code></td>
<td>Returns a segment of an IPv6 address as a number. The following example expressions retrieve segments from the ipv6 address 1000:1001:CD10:0000:0000:89AB:4567:CDEF: client.ipv6.dst.get5 extracts 0000, which is the fifth set of bits in the address. client.ipv6.dst.get6 extracts 89AB. client.ipv6.dst.get7 extracts 4567. You can perform numeric operations on these segments. Note that you cannot perform numeric operations when you retrieve an entire IPv6 address. This is because expressions that return an entire IPv6 address, such as CLIENT.IPV6.SRC, return the address in text format.</td>
</tr>
</tbody>
</table>
IPv6 Operation | Description
--- | ---
<ipv6>.IN_SUBNET(<subnet>) | Returns a Boolean TRUE if the IPv6 address value is in the subnet specified by the <subnet> argument. Following is an example: client.ipv6.dst.eq(1000:1001:CD10:0000:0000:89AB:4567:CDEF/60)
<ipv6>.IS_IPV4 | Returns a Boolean TRUE if this is an IPv4 client, and returns a Boolean FALSE if it is not.
<ipv6>.SUBNET(<n>) | Returns the IPv6 address after applying the subnet mask specified as the argument. The subnet mask can take values between 0 and 128. For example: CLIENT.IPV6.SRC.SUBNET(24)

Expressions for MAC addresses

A MAC address consists of colon-delimited hexadecimal values in the format ###:###:###:###:###:###, where each “#” represents either a number from 0 through 9 or a letter from A through F. Default syntax expression prefixes and operators are available for evaluating source and destination MAC addresses.

Prefixes for MAC addresses

The following table describes prefixes that return MAC addresses.

Table 5. Prefixes That Evaluate MAC Addresses

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>client.ether.dstmac</td>
<td>Returns the MAC address in the destination field of the Ethernet header.</td>
</tr>
<tr>
<td>client.ether.srcmac</td>
<td>Returns the MAC address in the source field of the Ethernet header.</td>
</tr>
</tbody>
</table>

Operations for MAC addresses

The following table describes the operators that can be used with prefixes that return a MAC address.

Table 6. Operations on MAC Addresses
Expressions for Numeric Client and Server Data

The following table describes prefixes for working with numeric client and server data, including throughput, port numbers, and VLAN IDs.

Table 7. Prefixes That Evaluate Numeric Client and Server Data

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>client.interface.rxthroughput</td>
<td>Returns an integer representing the raw received traffic throughput in kilobytes per second (KBps) for the previous seven seconds.</td>
</tr>
<tr>
<td>client.interface.txthroughput</td>
<td>Returns an integer representing the raw transmitted traffic throughput in KBps for the previous seven seconds.</td>
</tr>
<tr>
<td>client.interface.rxtxthroughput</td>
<td>Returns an integer representing the raw received and transmitted traffic throughput in KBps for the previous seven seconds.</td>
</tr>
<tr>
<td>server.interface.rxthroughput</td>
<td>Returns an integer representing the raw received traffic throughput in KBps for the previous seven seconds.</td>
</tr>
<tr>
<td>server.interface.txthroughput</td>
<td>Returns an integer representing the raw transmitted traffic throughput in KBps for the previous seven seconds.</td>
</tr>
<tr>
<td>server.interface.rxtxthroughput</td>
<td>Returns an integer representing the raw received and transmitted traffic throughput in KBps for the previous seven seconds.</td>

Advanced policy expressions: stream analytics functions

September 24, 2018

Stream Analytics expressions begin with the ANALYTICS.STREAM(<identifier_name>) prefix. The following list describes the functions that can be used with this prefix.

- **COLLECT_STATS**
  
  Collect statistical data from the requests that are evaluated against the policy and create a record for each request.

- **REQUESTS**
  
  Return the number of requests that exist for the specified record grouping. The value returned is of type unsigned long.

- **BANDWIDTH**
  
  Return the bandwidth statistic for the specified record grouping. The value returned is of type unsigned long.

- **RESPTIME**
  
  Return the response time statistic for the specified record grouping. The value returned is of type unsigned long.

- **CONNECTIONS**
  
  Return the number of concurrent connections that exist for the specified record grouping. The value returned is of type unsigned long.

- **IS_TOP(n)**
  
  Return a Boolean TRUE if the statistical value for the specified record grouping is one among the top n groups. Otherwise, return a Boolean FALSE.
• **CHECK_LIMIT**
  
  Return a Boolean TRUE if the statistic for the specified record grouping has hit the preconfigured limit. Otherwise, return a Boolean FALSE.

---

### Advanced policy expressions: DataStream

September 24, 2018

The policy infrastructure on the NetScaler appliance includes expressions that you can use to evaluate and process database server traffic when the appliance is deployed between a farm of application servers and their associated database servers.

This topic includes the following sections:

- Expressions for the MySQL Protocol
- Expressions for Evaluating Microsoft SQL Server Connections

### Expressions for the MySQL protocol

The following expressions evaluate traffic associated with MySQL database servers. You can use the request-based expressions (expressions that begin with MYSQL.CLIENT and MYSQL.REQ) in policies to make request switching decisions at the content switching virtual server bind point and the response-based expressions (expressions that begin with MYSQL.RES) to evaluate server responses to user-configured health monitors.

- **MYSQL.CLIENT.** Operates on the client properties of a MySQL connection.

- **MYSQL.CLIENT.CAPABILITIES.** Returns the set of flags that the client has set in the capabilities field of the handshake initialization packet during authentication. Examples of the flags that are set are CLIENT_FOUND_ROWS, CLIENT_COMPRESS, and CLIENT_SSL.

- **MYSQL.CLIENT.CHAR_SET.** Returns the enumeration constant assigned to the character set that the client uses. The EQ(<m>) and NE(<m>) operators, which return Boolean values to indicate the result of a comparison, are used with this prefix. Following are the character set enumeration constants:
  - LATIN2_CZECH_CS
  - DEC8_SWEDISH_CI
  - CP850_GENERAL_CI
  - GREEK General_CI
  - LATIN1_GERMAN1_CI
- HP8_ENGLISH_CI
- KO18R_GENERAL_CI
- LATIN1_SWEDISH_CI
- LATIN2_GENERAL_CI
- SWE7_SWEDISH_CI
- ASCII_GENERAL_CI
- CP1251_BULGARIAN_CI
- LATIN1_DANISH_CI
- HEBREW_GENERAL_CI
- LATIN7_ESTONIAN_CS
- LATIN2_HUNGARIAN_CI
- KO18U_GENERAL_CI
- CP1251_UKRAINIAN_CI
- CP1250_GENERAL_CI
- LATIN2_CROATIAN_CI
- CP1257_LITHUANIAN_CI
- LATIN5_TURKISH_CI
- LATIN1_GERMAN2_CI
- ARMSCII8_GENERAL_CI
- UTF8_GENERAL_CI
- CP1250_CZECH_CS
- CP866_GENERAL_CI
- KEYBCS2_GENERAL_CI
- MACCE_GENERAL_CI
- MACROMAN_GENERAL_CI
- CP852_GENERAL_CI
- LATIN7_GENERAL_CI
- LATIN7_GENERAL_CS
- MACCE_BIN
- CP1250_CROATIAN_CI
- LATIN1_BIN
- LATIN1_GENERAL_CI
- LATIN1_GENERAL_CS
- CP1251_BIN
- CP1251_GENERAL_CI
- CP1251_GENERAL_CS
- MACROMAN_BIN
- CP1256_GENERAL_CI
- CP1257_BIN
- CP1257_GENERAL_CI
- ARMSCII8_BIN
- ASCII_BIN
- CP1250_BIN
- CP1256_BIN
- CP866_BIN
- DEC8_BIN
- GREEK_BIN
- HEBREW_BIN
- HP8_BIN
- KEYBCS2_BIN
- KOI8R_BIN
- KOI8U_BIN
- LATIN2_BIN
- LATIN5_BIN
- LATIN7_BIN
- CP850_BIN
- CP852_BIN
- SWE7_BIN
- UTF8_BIN
- GEOSTD8_GENERAL_CI
- GEOSTD8_BIN
- LATIN1_SPANISH_CI
- UTF8_UNICODE_CI
- UTF8_ICELANDIC_CI
- UTF8_LATVIAN_CI
- UTF8_ROMANIAN_CI
- UTF8_SLOVENIAN_CI
- UTF8_POLISH_CI
- UTF8_ESTONIAN_CI
- UTF8_SPANISH_CI
- UTF8_SWEDISH_CI
- UTF8_TURKISH_CI
- UTF8_CZECH_CI
- UTF8_DANISH_CI
- UTF8_LITHUANIAN_CI
- UTF8_SLOVAK_CI
- UTF8_SPANISH2_CI
- UTF8_ROMAN_CI
- UTF8_PERSIAN_CI
- UTF8_ESPERANTO_CI
- UTF8_HUNGARIAN_CI
- INVAL_CHARSET

- **MYSQL.CLIENT.DATABASE.** Returns the name of the database specified in the authentication packet that the client sends to the database server. This is the databasename attribute.

- MYSQL.CLIENT.USER. Returns the user name (in the authentication packet) with which the client is attempting to connect to the database. This is the user attribute.

- **MYSQL.REQ.** Operates on a MySQL request.

- **MYSQL.REQ.COMMAND.** Identifies the enumeration constant assigned to the type of command in the request. The EQ(<m>) and NE(<m>) operators, which return Boolean values to indicate the result of a comparison, are used with this prefix. Following are the enumeration constant values:
  - SLEEP
  - QUIT
  - INIT_DB
  - QUERY
  - FIELD_LIST
  - CREATE_DB
  - DROP_DB
  - REFRESH
  - SHUTDOWN
  - STATISTICS
  - PROCESS_INFO
  - CONNECT
  - PROCESS_KILL
  - DEBUG
  - PING
  - TIME
  - DELAYED_INSERT
  - CHANGE_USER
  - BINLOG_DUMP
  - TABLE_DUMP
  - CONNECT_OUT
  - REGISTER_SLAVE
  - STMT_PREPARE
  - STMT_EXECUTE
  - STMT_SEND_LONG_DATA
- STMT_CLOSE
- STMT_RESET
- SET_OPTION
- STMT_FETCH

- **MYSQL.REQ.QUERY.** Identifies the query in the MySQL request.

- **MYSQL.REQ.QUERY.COMMAND.** Returns the first keyword in the MySQL query.

- **MYSQL.REQ.QUERY.SIZE.** Returns the size of the request query in integer format. The SIZE method is similar to the CONTENT_LENGTH method that returns the length of an HTTP request or response.

- **MYSQL.REQ.QUERY.TEXT.** Returns a string covering the entire query.

- **MYSQL.REQ.QUERY.TEXT(<n>).** Returns the first n bytes of the MySQL query as a string. This is similar to HTTP.BODY(<n>).

  **Parameters:**
  
  n - Number of bytes to be returned

- **MYSQL.RES.** Operates on a MySQL response.

- **MYSQL.RES.ATLEAST_ROWS_COUNT(<i>).** Checks whether the response has at least i number of rows and returns a Boolean TRUE or FALSE to indicate the result.

  **Parameters:**
  
  i - Number of rows

- **MYSQL.RES.ERROR.** Identifies the MySQL error object. The error object includes the error number and the error message.

- **MYSQL.RES.ERROR.MESSAGE.** Returns the error message that is retrieved from the server's error response.

- **MYSQL.RES.ERROR.NUM.** Returns the error number that is retrieved from the server's error response.

- **MYSQL.RES.ERROR.SQLSTATE.** Returns the value of the SQLSTATE field in the server's error response. The MySQL server translates error number values to SQLSTATE values.

- **MYSQL.RES.FIELD(<i>).** Identifies the packet that corresponds to the i<sup>th</sup> individual field in the server's response. Each field packet describes the properties of the associated column. The packet count (i) begins at 0.

  **Parameters:**
  
  i - Packet number

- **MYSQL.RES.FIELD(<i>).CATALOG.** Returns the catalog property of the field packet.
• **MYSQL.RES.FIELD(<i>).CHAR_SET.** Returns the character set of the column. The EQ(<m>) and NE(<m>) operators, which return Boolean values to indicate the result of a comparison, are used with this prefix.

• **MYSQL.RES.FIELD(<i>).DATATYPE.** Returns an enumeration constant that represents the data type of the column. This is the type (also called enum_field_type) attribute of the column. The EQ(<m>) and NE(<m>) operators, which return Boolean values to indicate the result of a comparison, are used with this prefix. The possible values for the various data types are:
  - DECIMAL
  - TINY
  - SHORT
  - LONG
  - FLOAT
  - DOUBLE
  - NULL
  - TIMESTAMP
  - LONGLONG
  - INT24
  - DATE
  - TIME
  - DATETIME
  - YEAR
  - NEWDATE
  - VARCHAR (new in MySQL 5.0)
  - BIT (new in MySQL 5.0)
  - NEWDECIMAL (new in MySQL 5.0)
  - ENUM
  - SET
  - TINY_BLOB
  - MEDIUM_BLOB
  - LONG_BLOB
  - BLOB
  - VAR_STRING
  - STRING
  - GEOMETRY

• **MYSQL.RES.FIELD(<i>).DB.** Returns the database identifier (db) attribute of the field packet.

• **MYSQL.RES.FIELD(<i>).DECIMALS.** Returns the number of positions after the decimal point if the type is DECIMAL or NUMERIC. This is the decimals attribute of the field packet.

• **MYSQL.RES.FIELD(<i>).FLAGS.** Returns the flags property of the field packet. Following are
the possible hexadecimal flag values:

- 0001: NOT_NULL_FLAG
- 0002: PRI_KEY_FLAG
- 0004: UNIQUE_KEY_FLAG
- 0008: MULTIPLE_KEY_FLAG
- 0010: BLOB_FLAG
- 0020: UNSIGNED_FLAG
- 0040: ZEROFILL_FLAG
- 0080: BINARY_FLAG
- 0100: ENUM_FLAG
- 0200: AUTO_INCREMENT_FLAG
- 0400: TIMESTAMP_FLAG
- 0800: SET_FLAG

- **MYSQL.RES.FIELD(<i>).LENGTH.** Returns the length of the column. This is the value of the length attribute of the field packet. The value that is returned might be larger than the actual value. For example, an instance of a VARCHAR(2) column might return a value of 2 even when it contains only one character.

- **MYSQL.RES.FIELD(<i>).NAME.** Returns the column identifier (the name after the AS clause, if any). This is the name attribute of the field packet.

- **MYSQL.RES.FIELD(<i>).ORIGINAL_NAME.** Returns the original column identifier (before the AS clause, if any). This is the org_name attribute of the field packet.

- **MYSQL.RES.FIELD(<i>).ORIGINAL_TABLE.** Returns the original table identifier of the column (before the AS clause, if any). This is the org_table attribute of the field packet.

- **MYSQL.RES.FIELD(<i>).TABLE.** Returns the table identifier of the column (after the AS clause, if any). This is the table attribute of the field packet.

- **MYSQL.RES.FIELDS_COUNT.** Returns the number of field packets in the response (the field_count attribute of the OK packet).

- **MYSQL.RES.OK.** Identifies the OK packet sent by the database server.

- **MYSQL.RES.OK.AFFECTED_ROWS.** Returns the number of rows affected by an INSERT, UPDATE, or DELETE query. This is the value of the affected_rows attribute of the OK packet.

- **MYSQL.RES.OK.INSERT_ID.** Identifies the unique_id attribute of the OK packet. If an auto-increment identity is not generated by the current MySQL statement or query, the value of unique_id, and hence the value returned by the expression, is 0.

- **MYSQL.RES.OK.MESSAGE.** Returns the message property of the OK packet.

- **MYSQL.RES.OK.STATUS.** Identifies the bit string in the server_status attribute of the OK packet. Clients can use the server status to check whether the current command is a part of a running
transaction. The bits in the server_status bit string correspond to the following fields (in the
given order):

- IN TRANSACTION
- AUTO_COMMIT
- MORE RESULTS
- MULTI QUERY
- BAD INDEX USED
- NO INDEX USED
- CURSOR EXISTS
- LAST ROW SEEN
- DATABASE DROPPED
- NO BACKSLASH ESCAPES

- **MYSQL.RES.OK.WARNING_COUNT.** Returns the warning_count attribute of the OK packet.

- **MYSQL.RES.ROW(<i>)**. Identifies the packet that corresponds to the $i^{th}$ individual row in the database server’s response.

  **Parameters:**
  
i - Row number

- **MYSQL.RES.ROW(<i>).DOUBLE_ELEM(<j>).** Checks whether the $j^{th}$ column of the $i^{th}$ row of the table is NULL. Following C conventions, both indexes $i$ and $j$ start from 0. Therefore, row $i$ and column $j$ are actually the $(i+1)^{th}$ row and the $(j+1)^{th}$ column, respectively.

  **Parameters:**
  
i - Row number
  
j - Column number

- **MYSQL.RES.ROW(<i>).IS_NULL_ELEM(j).** Checks whether the $j^{th}$ column of the $i^{th}$ row of the table is NULL. Following C conventions, both indexes $i$ and $j$ start from 0. Therefore, row $i$ and column $j$ are actually the $(i+1)^{th}$ row and the $(j+1)^{th}$ column, respectively.

  **Parameters:**
  
i - Row number
  
j - Column number

- **MYSQL.RES.ROW(<i>).NUM_ELEM(<j>).** Returns an integer value from the $j^{th}$ column of the $i^{th}$ row of the table. Following C conventions, both indexes $i$ and $j$ start from 0. Therefore, row $i$ and column $j$ are actually the $(i+1)^{th}$ row and the $(j+1)^{th}$ column, respectively.
Parameters:
i - Row number
j - Column number

- **MYSQL.RES.ROW(\(<i>\)).TEXT_ELEM(\(j\)).** Returns a string from the \(j^{th}\) column of the \(i^{th}\) row of the table. Following C conventions, both indexes \(i\) and \(j\) start from 0. Therefore, row \(i\) and column \(j\) are actually the \((i+1)^{th}\) row and the \((j+1)^{th}\) column, respectively.

Parameters:
i - Row number
j - Column number

- **MYSQL.RES.TYPE.** Returns an enumeration constant for the response type. Its values can be ERROR, OK, and RESULT_SET. The EQ(\(<m>\)) and NE(\(<m>\)) operators, which return Boolean values to indicate the result of a comparison, are used with this prefix.

Expressions for evaluating Microsoft SQL server connections

The following expressions evaluate traffic associated with Microsoft SQL Server database servers. You can use the request-based expressions (expressions that begin with MSSQL.CLIENT and MSSQL.REQ) in policies to make request switching decisions at the content switching virtual server bind point and the response-based expressions (expressions that begin with MSSQL.RES) to evaluate server responses to user-configured health monitors.

<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSSQL.CLIENT.CAPABILITIES</td>
<td>Returns the OptionFlags1, OptionFlags2, OptionFlags3, and TypeFlags fields of the LOGIN7 authentication packet, in that order, as a 4-byte integer. Each field is 1 byte long and specifies a set of client capabilities.</td>
</tr>
<tr>
<td>MSSQL.CLIENT.DATABASE</td>
<td>Returns the name of the client database. The value returned is of type text.</td>
</tr>
<tr>
<td>MSSQL.CLIENT.USER</td>
<td>Returns the user name with which the client authenticated. The value returned is of type text.</td>
</tr>
</tbody>
</table>
### Expression Description

<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSSQL.REQ.COMMAND</td>
<td>Returns an enumeration constant that identifies the type of command in the request sent to a Microsoft SQL Server database server. The value returned is of type text. Examples of the values of the enumeration constant are QUERY, RESPONSE, RPC, and ATTENTION. The EQ(&lt;m&gt;) and NE(&lt;m&gt;) operators, which return Boolean values to indicate the result of a comparison, are used with this expression.</td>
</tr>
<tr>
<td>MSSQL.REQ.QUERY.COMMAND</td>
<td>Returns the first keyword in the SQL query. The value returned is of type text.</td>
</tr>
<tr>
<td>MSSQL.REQ.QUERY.SIZE</td>
<td>Returns the size of the SQL query in the request. The value returned is a number.</td>
</tr>
<tr>
<td>MSSQL.REQ.QUERY.TEXT</td>
<td>Returns the entire SQL query as a string. The value returned is of type text.</td>
</tr>
<tr>
<td>MSSQL.REQ.QUERY.TEXT(&lt;n&gt;)</td>
<td>Returns the first n bytes of the SQL query. The value returned is of type text. Parameters: n - Number of bytes</td>
</tr>
<tr>
<td>MSSQL.REQ.RPC.NAME</td>
<td>Returns the name of the procedure that is being called in a remote procedure call (RPC) request. The name is returned as a string.</td>
</tr>
<tr>
<td>MSSQL.REQ.RPC.IS_PROCID</td>
<td>Returns a Boolean value that indicates whether the remote procedure call (RPC) request contains a procedure ID or an RPC name. A return value of TRUE indicates that the request contains a procedure ID and a return value of FALSE indicates that the request contains an RPC name.</td>
</tr>
<tr>
<td>MSSQL.REQ.RPC.PROCID</td>
<td>Returns the procedure ID of the remote procedure call (RPC) request as an integer.</td>
</tr>
<tr>
<td>MSSQL.REQ.RPC.BODY</td>
<td>Returns the body of the SQL request as a string in the form of parameters represented as “a=b” clauses separated by commas, where “a” is the RPC parameter name and “b” is its value.</td>
</tr>
<tr>
<td>Expression</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-------------</td>
</tr>
<tr>
<td>MSSQL.REQ.RPC.BODY(n)</td>
<td>Returns part of the body of the SQL request as a string in the form of parameters represented as “a=b” clauses separated by commas, where “a” is the RPC parameter name and “b” is its value. Parameters are returned from only the first “n” bytes of the request, skipping the SQL header. Only complete name-value pairs are returned.</td>
</tr>
<tr>
<td>MSSQL.RES.ATLEAST_ROWS_COUNT(i)</td>
<td>Checks whether the response has at least i number of rows. The value returned is a Boolean TRUE or FALSE value. Parameters: i - Number of rows</td>
</tr>
<tr>
<td>MSSQL.RES.DONE.ROWCOUNT</td>
<td>Returns a count of the number of rows affected by an INSERT, UPDATE, or DELETE query. The value returned is of type unsigned long.</td>
</tr>
<tr>
<td>MSSQL.RES.DONE.STATUS</td>
<td>Returns the status field from the DONE token sent by a Microsoft SQL Server database server. The value returned is a number.</td>
</tr>
<tr>
<td>MSSQL.RES.ERROR.MESSAGE</td>
<td>Returns the error message from the ERROR token sent by a Microsoft SQL Server database server. This is the value of the MsgText field in the ERROR token. The value returned is of type text.</td>
</tr>
<tr>
<td>MSSQL.RES.ERROR.NUM</td>
<td>Returns the error number from the ERROR token sent by a Microsoft SQL Server database server. This is the value of the Number field in the ERROR token. The value returned is a number.</td>
</tr>
<tr>
<td>MSSQL.RES.ERROR.STATE</td>
<td>Returns the error state from the ERROR token sent by a Microsoft SQL Server database server. This is the value of the State field in the ERROR token. The value returned is a number.</td>
</tr>
<tr>
<td>Expression</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>MSSQL.RES.FIELD(&lt;i&gt;).DATATYPE</td>
<td>Returns the data type of the ith field in the server response. The EQ(&lt;m&gt;) and NE(&lt;m&gt;) functions, which return Boolean values to indicate the result of a comparison, are used with this prefix. For example, the following expression returns a Boolean TRUE if the DATATYPE function returns a value of datetime for the third field in the response: MSSQL.RES.FIELD(&lt;2&gt;).DATATYPE.EQ(datetime) Parameters: i - Row number</td>
</tr>
<tr>
<td>MSSQL.RES.FIELD(&lt;i&gt;).LENGTH</td>
<td>Returns the maximum possible length of the ith field in the server response. The value returned is a number. Parameters: i - Row number</td>
</tr>
<tr>
<td>MSSQL.RES.FIELD(&lt;i&gt;).NAME</td>
<td>Returns the name of the ith field in the server response. The value returned is of type text. Parameters: i - Row number</td>
</tr>
<tr>
<td>MSSQL.RES.ROW(&lt;i&gt;).DOUBLE_ELEM(&lt;j&gt;)</td>
<td>Returns a value of type double from the jth column of the ith row of the table. If the value is not a double value, an UNDEF condition is raised. Following C conventions, both indexes i and j start from 0 (zero). Therefore, row i and column j are actually the (i + 1)th row and the (j + 1)th column, respectively. Parameters: i - Row number j - Column number</td>
</tr>
<tr>
<td>MSSQL.RES.ROW(&lt;i&gt;).NUM_ELEM(j)</td>
<td>Returns an integer value from the jth column of ith row of the table. If the value is not an integer value, an UNDEF condition is raised. Following C conventions, both indexes i and j start from 0 (zero). Therefore, row i and column j are actually the (i + 1)th row and the (j + 1)th column, respectively. Parameters: i - Row number j - Column number</td>
</tr>
</tbody>
</table>
### Expression Description

<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSSQL.RES.ROW(&lt;i&gt;).IS_NULL_ELEM(j)</td>
<td>Checks whether the jth column of the ith row of the table is NULL and returns a Boolean TRUE or FALSE to indicate the result. Following C conventions, both indexes i and j start from 0 (zero). Therefore, row i and column j are actually the (i + 1)th row and the (j + 1)th column, respectively. Parameters: i - Row number j - Column number</td>
</tr>
<tr>
<td>MSSQL.RES.ROW(&lt;i&gt;).TEXT_ELEM(j)</td>
<td>Returns a text string from the jth column of ith row of the table. Following C conventions, both indexes i and j start from 0 (zero). Therefore, row i and column j are actually the (i + 1)th row and the (j + 1)th column, respectively. Parameters: i - Row number j - Column number</td>
</tr>
<tr>
<td>MSSQL.RES.TYPE</td>
<td>Returns an enumeration constant that identifies the response type. Following are the possible return values: ERROR, OK, and RESULT_SET. The EQ(&lt;m&gt;) and NE(&lt;m&gt;) operators, which return Boolean values to indicate the result of a comparison, are used with this expression.</td>
</tr>
</tbody>
</table>

### Typecasting data

**January 6, 2019**

You can extract data of one type (for example, text or an integer) from requests and responses and transform it to data of another type. For example, you can extract a string and transform the string to time format. You can also extract a string from an HTTP request body and treat it like an HTTP header or extract a value from one type of request header and insert it in a response header of a different type.

After typecasting the data, you can apply any operation that is appropriate for the new data type. For example, if you typecast text to an HTTP header, you can apply any operation that is applicable to HTTP headers to the returned value.

For more information about typecasting data, see the [Typecasting Operations pdf](#).
Regular Expressions

September 24, 2018

When you want to perform string matching operations that are more complex than the operations that you perform with the CONTAINS(“<string>”) or EQ(“<string>”) operators, you use regular expressions. The policy infrastructure on the Citrix® NetScaler® appliance includes operators to which you can pass regular expressions as arguments for text matching. The names of the operators that work with regular expressions include the string REGEX. The regular expressions that you pass as arguments must conform to the regular expression syntax that is described in “http://www.pcre.org/pcre.txt.” You can learn more about regular expressions at “http://www.regular-expressions.info/quickstart.html” and at “http://www.silverstones.com/thebat/Regex.html.”

The target text for an operator that works with regular expressions can be either text or the value of an HTTP header. Following is the format of a default syntax expression that uses a regular expression operator to operate on text:

```
<text>.<regex_operator>(re<delimiter><regex_pattern><delimiter>)
```

The string <text> represents the default syntax expression prefix that identifies a text string in a packet (for example, HTTP.REQ.URL). The string <regex_operator> represents the regular expression operator. The regular expression always begins with the string re. A pair of matching delimiters, represented by <delimiter>, enclose the string <regex_pattern>, which represents the regular expression.

The following example expression checks whether the URL in an HTTP packet contains the string *.jpeg (where * is a wildcard) and returns a Boolean TRUE or FALSE to indicate the result. The regular expression is enclosed within a pair of slash marks (/), which act as delimiters.

```
http.req.url.regex_match(re/*.*jpeg/)  
```

Regular expression operators can be combined to define or refine the scope of a search. For example, `<text>.AFTER_REGEX(re/regex_pattern1/).BEFORE_REGEX(re/regex_pattern2/)` specifies that the target for string matching is the text between the patterns regex_pattern1 and regex_pattern2. You can use a text operator on the scope that is defined by the regular expression operators. For example, you can use the CONTAINS(“<strings>”) operator to check whether the defined scope contains the string abc:

```
<text>.AFTER_REGEX(re/regex_pattern1/).BEFORE_REGEX(re/regex_pattern2/).CONTAINS("abc")
```

Note

The process of evaluating a regular expression inherently takes more time than that for an operator such as CONTAINS(“<string>”) or EQ(“<string>”), which work with simple string arguments. You should use regular expressions only if your requirement is beyond the scope of other operators.
Basic characteristics of regular expressions

September 24, 2018

Following are notable characteristics of regular expressions as defined on the NetScaler appliance:

- A regular expression always begins with the string “re” followed by a pair of delimiting characters (called delimiters) that enclose the regular expression that you want to use.

  For example, re#<regex_pattern># uses the number sign (#) as a delimiter.

- A regular expression cannot exceed 1499 characters.

- Digit matching can be done by using the string \\d (a backslash followed by d).

- White space can be represented by using \s (a backslash followed by s).

- A regular expression can contain white spaces.

Following are the differences between the NetScaler syntax and the PCRE syntax:

- The NetScaler does not allow back references in regular expressions.
- You should not use recursive regular expressions.
- The dot meta-character also matches the newline character.
- Unicode is not supported.
- The operation SET_TEXT_MODE(IGNORECASE) overrides the (?i) internal option in the regular expression.

Operations for regular expressions

September 24, 2018

The following table describes the operators that work with regular expressions. The operation performed by a regular expression operator in a given default syntax expression depends on whether the expression prefix identifies text or HTTP headers. Operations that evaluate headers override any text-based operations for all instances of the specified header type. When you use an operator, replace <text> with the default syntax expression prefix that you want to configure for identifying text.
<table>
<thead>
<tr>
<th>Regular Expression Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;text&gt;.BEFORE_REGEX(&lt;regular expression&gt;)</code></td>
<td>Selects the text that precedes the string that matches the <code>&lt;regular expression&gt;</code> argument. If the regular expression does not match any data in the target, the expression returns a text object of length 0. The following expression selects the string “text” from “text/plain”. http.res.header(“content-type”).before_regex(re#/#)</td>
</tr>
<tr>
<td><code>&lt;text&gt;.AFTER_REGEX(&lt;regular expression&gt;)</code></td>
<td>Selects the text that follows the string that matches the <code>&lt;regular expression&gt;</code> argument. If the regular expression does not match any text in the target, the expression returns a text object of length 0. The following expression extracts “Example” from “myExample”: http.req.header(“etag”).after_regex(re/my/)</td>
</tr>
<tr>
<td><code>&lt;text&gt;.REGEX_SELECT(&lt;regular expression&gt;)</code></td>
<td>Selects a string that matches the <code>&lt;regular expression&gt;</code> argument. If the regular expression does not match the target, a text object of length 0 is returned. The following example extracts the string “NS-CACHE-9.0: 90” from a Via header: http.req.header(“via”).regex_select(reNS-CACHE-\d+?\d+\s*\d{1,3}!)</td>
</tr>
</tbody>
</table>
Regular Expression Operation | Description
--- | ---
`<text>.REGEX_MATCH(<regular expression>)` | Returns TRUE if the target matches a `<regular expression>` argument of up to 1499 characters. The regular expression must be of the following format: `re<delimiter>regular expression< delimiter>` Both delimiters must be the same. Additionally, the regular expression must conform to the Perl-compatible (PCRE) regular expression library syntax. For more information, go to http://www.pcre.org/pcre.txt. In particular, see the pcrepattern man page. However, note the following: Back-references are not allowed. Recursive regular expressions are not recommended. The dot metacharacter also matches the newline character. The Unicode character set is not supported. SET_TEXT_MODE(IGNORECASE) overrides the (?i) internal option specified in the regular expression. The following are examples:
http.req.hostname.regex_match(re/[:alpha:]+(abc){2,3}/) and
http.req.url.set_text_mode(urlencoded).regex_match(re#ab+c#)
The following example matches ab and aB: http.req.url.regex_match(re/a(?i)b/) The following example matches ab, aB, Ab and AB: http.req.url.set_text_mode(ignorecase).regex_match(re/ab/) The following example performs a case-insensitive, multiline match in which the dot meta-character also matches a newline character: http.req.body.regex_match(re/(?ixm)\s+ab\n\s+) cd$/)

---

Configuring classic policies and expressions

January 6, 2019

Some NetScaler features use classic policies and classic expressions. As with default syntax policies,
NetScaler 12.0

classic policies can be either global or specific to a virtual server. However, to a certain extent, the configuration method and bind points for classic policies are different from those of default syntax policies. As with default syntax expressions, you can configure named expressions and use a named expression in multiple classic policies.

The following table summarizes NetScaler features that can be configured by using classic policies. Click here to view the table.

**Configure a classic policy**

September 24, 2018

You can configure classic policies and classic expressions by using either the GUI or the command-line interface. A policy rule cannot exceed 1,499 characters. When configuring the policy rule, you can use named classic expressions. For more information about named expressions, see Create named classic expressions. After configuring the policy, you bind it either globally or to a virtual server.

Note that there are small variations in the policy configuration methods for various NetScaler features.

Note: You can embed a classic expression in a default syntax expression by using the syntax SYS.EVAL_CLASSIC_EXPR(classic_expression), specifying the classic_expression as the argument.

**Create a classic policy by using the CLI**

At the command prompt, type the following commands to set the parameters and verify the configuration:

1. `add cmp policy <name> -rule <expression> -action <action>`
2. `show cmp policy [policyName]`

**Example**

The following commands first create a compression action and then create a compression policy that applies the action:

```plaintext
1 > add cmp action cmp-act-compress compress
Done
3 > show cmp action cmp-act-compress
4 1) Name: cmp-act-compress Compression Type: compress
5 Done
```
Create a policy with classic expressions by using the GUI

1. In the navigation pane, expand the feature for which you want to configure a policy and, depending on the feature, do the following:
   - For Content Switching, Cache Redirection, and the application firewall, click Policies.
   - For SSL, click Policies, and then in the details pane, click the Policies tab.
   - For System Authentication, click Authentication, and then in the details pane, click the Policies tab.
   - For Filter, SureConnect, and Priority Queuing, expand Protection Features, select the desired function, and then in the details pane, click the Policies tab.
   - For the NetScaler Gateway, expand NetScaler Gateway, expand Policies, select the desired function, and then in the details pane, click the Policies tab.

2. For most features, click the Add button.

3. In the Create <feature name> Policy dialog box, in the Name* text box, enter a name for the policy.
   
   **Note:** You must begin a policy name with a letter or underscore. A policy name can consist of 1 to 31 characters, including letters, numbers, hyphen (-), period (.), pound sign (#), space ( ), and underscore (_).

4. For most features, you associate an action or a profile. For example, you may be required to select an action, or, in the case of a NetScaler Gateway or application firewall policy, you select a profile to associate with the policy. A profile is a set of configuration options that operate as a set of actions that are applied when the data being analyzed matches the policy rule.

5. Create an expression that describes the type of data that you want this policy to match.
   
   Depending on the type of policy you want to create, you can choose a predefined expression, or you can create a new expression.

   Named expressions are predefined expressions that you can reference by name in a policy rule.

6. Click Create to create your new policy.
7. Click Close to return to the Policies screen for the type of policy you were creating.

**Configure a classic expression**

September 24, 2018

Classic expressions consist of the following expression elements, listed in hierarchical order:

- **Flow Type.** Specifies whether the connection is incoming or outgoing. The flow type is REQ for incoming connections and RES for outgoing connections.
- **Protocol.** Specifies the protocol, the choices for which are HTTP, SSL, TCP, and IP.
- **Qualifier.** The protocol attribute, which depends on the selected protocol.
- **Operator.** The type of test you want to perform on the connection data. Your choice of operator depends upon the connection information you are testing. If the connection information you are testing is text, you use text operators. If it is a number, you use standard numeric operators.
- **Value.** The string or number against which the connection data element—defined by the flow type, protocol, and qualifier—is tested. The value can be either a literal or an expression. The literal or expression must match the data type of the connection data element.

In a policy, classic expressions can be combined to create more complex expressions using Boolean and comparative operators.

Expression elements are parsed from left to right. The leftmost element is either REQ or RES and designates a request or a response, respectively. Successive terms define a specific connection type and a specific attribute for that connection type. Each term is separated from any preceding or following term by a period. Arguments appear in parentheses and follow the expression element to which they are passed.

The following classic expression fragment returns the client source IP for an incoming connection.

```
REQ.IP.SOURCEIP
```

The example identifies an IP address in a request. The expression element SOURCEIP designates the source IP address. This expression fragment may not be useful by itself. You can use an additional expression element, an operator, to determine whether the returned value meets specific criteria. The following expression tests whether the client IP is in the subnet 200.0.0.0/8 and returns a Boolean TRUE or FALSE:

```
REQ.IP.SOURCEIP == 200.0.0.0 -netmask 255.0.0.0
```

**Create a classic policy expression by using the CLI**

At the command prompt, type the following commands to set the parameters and verify the configuration:
Example

```
1 > set appfw policy GenericApplicationSSL_ 'HTTP.REQ.METHOD.EQ("get")' APPFW_DROP
2   Done
3 > show appfw policy GenericApplicationSSL_
4   Name: GenericApplicationSSL_   Rule: HTTP.REQ.METHOD.EQ("get")
5   Profile: APPFW_DROP   Hits: 0
6   Undef Hits: 0
7   Policy is bound to following entities
8     1) REQ VSERVER app_u_GenericApplicationSSLPortalPages
       PRIORITY : 100
9   Done
```

Add an expression for a classic policy by using the GUI

This procedure documents the Add Expression dialog box. Depending on the feature for which you are configuring a policy, the route by which you arrive at this dialog box may be different.

1. Perform steps 1-4 in “To create a policy with classic expressions by using the GUI.”

2. In the Add Expression dialog box, in Expression Type, click the type of expression you want to create.

3. Under Flow Type, click the down arrow and choose a flow type.

   The flow type is typically REQ or RES. The REQ option specifies that the policy applies to all incoming connections or requests. The RES option applies the policy to all outgoing connections or responses.

   For Application Firewall policies, you should leave the expression type set to General Expression, and the flow type set to REQ. The Application Firewall treats each request and response as a single paired entity, so all Application Firewall policies begin with REQ.

4. Under Protocol, click the down arrow and choose the protocol you want for your policy expression. Your choices are:

   - HTTP. Evaluates HTTP requests that are sent to a Web server. For classic expressions, HTTP includes HTTPS requests.
NetScaler 12.0

- SSL. Evaluates SSL data associated with the current connection.
- TCP. Evaluates the TCP data associated with the current connection.
- IP. Evaluates the IP addresses associated with the current connection.

5. Under Qualifier, click the down arrow and choose a qualifier for your policy.

The qualifier defines the type of data to be evaluated. The list of qualifiers that appears depends on which protocol you selected in step 4.

The following choices appear for the HTTP protocol:

- METHOD. Filters HTTP requests that use a particular HTTP method.
- URL. Filters HTTP requests for a specific Web page.
- URLQUERY. Filters HTTP requests that contain a particular query string.
- VERSION. Filters HTTP requests on the basis of the specified HTTP protocol version.
- HEADER. Filters on the basis of a particular HTTP header.
- URLLEN. Filters on the basis of the length of the URL.
- URLQUERY. Filters on the basis of the query portion of the URL.
- URLQUERYLEN. Filters on the basis of the length of the query portion of the URL only.

6. Under Operator, click the down arrow and choose the operator for your policy expression. Some common operators are:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>==</td>
<td>Matches the specified value exactly or is exactly equal to the specified value.</td>
</tr>
<tr>
<td>!=</td>
<td>Does not match the specified value.</td>
</tr>
<tr>
<td>&gt;</td>
<td>Is greater than the specified value.</td>
</tr>
<tr>
<td>&lt;</td>
<td>Is less than the specified value.</td>
</tr>
<tr>
<td>&gt;=</td>
<td>Is greater than or equal to the specified value.</td>
</tr>
<tr>
<td>&lt;=</td>
<td>Is less than or equal to the specified value.</td>
</tr>
<tr>
<td>CONTAINS</td>
<td>Contains the specified value.</td>
</tr>
<tr>
<td>CONTENTS</td>
<td>Returns the contents of the designated header, URL, or URL query.</td>
</tr>
<tr>
<td>EXISTS</td>
<td>The specified header or query exists.</td>
</tr>
<tr>
<td>NOTCONTAINS</td>
<td>Does not contain the specified value.</td>
</tr>
<tr>
<td>NOTEXISTS</td>
<td>The specified header or query does not exist.</td>
</tr>
</tbody>
</table>

7. If a Value text box appears, type a string or numeric value, as appropriate. For example, chose
REQ as the Flow Type, HTTP as the Protocol, and HEADER as the qualifier, and then type the value of the header string in the Value field and the header type for which you want to match the string in the Header Name text box.

8. Click OK.

9. To create a compound expression, click Add. Note that the type of compounding that is done depends on the following choices in the Create Policy dialog box:

   - **Match Any Expression.** The expressions are in a logical OR relationship.
   - **Match All Expressions.** The expressions are in a logical AND relationship.
   - **Tabular Expressions.** Click the AND, OR, and parentheses buttons to control evaluation.
   - **Advanced Free-Form.** Enter the expressions components directly into the Expression field, and click the AND, OR, and parentheses buttons to control evaluation.

### Bind a classic policy

September 24, 2018

Depending on the policy type, you can bind a classic policy either globally or to a virtual server. Policy bind points are described in the table, “Policy Type and Bind Points for Policies in Features That Use Classic Policies.”

**Note:** You can bind a classic policy to multiple bind points.

### Bind a classic policy globally by using the CLI

At the command prompt, type the following commands to set the parameters and verify the configuration:

```
1 - bind cmp global <policyName> [-priority <positive_integer>]
2
3 - show cmp global
```

**Example**

```
1 > bind cmp global cmp-pol-compress -priority 2
2   Done
3 > show cmp global
4  1) Policy Name: cmp-pol-compress       Priority: 2
5  2) Policy Name: ns_nocmp_xml_ie       Priority: 8700
6  3) Policy Name: ns_nocmp_mozilla_47   Priority: 8800
```
Bind a classic policy to a virtual server by using the CLI

At the command prompt, type the following commands to set the parameters and verify the configuration:

```
1  bind lb vserver <name> [<targetVserver>] [-policyName <string> [-priority <positive_integer>]]
2  show lb vserver <name>
```

Example

```
1  > bind lb vserver lbtemp -policyName cmp-pol-compress -priority 1
2  Done
3  > show lb vserver lbtemp
4  lbtemp (10.102.29.101:80) - HTTP  Type: ADDRESS
5  State: UP
6  Last state change was at Tue Oct 27 06:40:38 2009 (+557 ms)
7  Time since last state change: 0 days, 02:00:40.330
8  Effective State: UP
9  Client Idle Timeout: 180 sec
10  Down state flush: ENABLED
11  Disable Primary Vserver On Down : DISABLED
12  Port Rewrite : DISABLED
13  No. of Bound Services : 1 (Total) 1 (Active)
14  Configured Method: LEASTCONNECTION
15  Current Method: Round Robin, Reason: Bound service's state changed to UP
16  Group: vserver-grp
17  Mode: IP
18  Persistence: COOKIEINSERT (version 0) Persistence Backup: SOURCEIP Persistence Mask: 255.255.255.255
19  Persistence Timeout: 2 min Backup Persistence Timeout: 2 min
20  Vserver IP and Port insertion: OFF
21  Push: DISABLED Push VServer:
```
Bind a classic policy globally by using the GUI

Note: This procedure documents the Global Bindings dialog box. Depending on the feature for which you want to globally bind a policy, the route by which you arrive at this dialog box may be different.

1. In the navigation pane, expand the feature for which you want to globally bind a classic policy, and then locate the policy that you want to bind globally.
   
   Note: You cannot globally bind policies for Content Switching, Cache Redirection, SureConnect, Priority Queuing, or NetScaler Gateway Authorization.

2. In the details pane, click Global Bindings.

3. In the Bind/Unbind <feature name> Policy(s) to Global dialog box, click Insert Policy.

4. In the Policy Name column, click the name of an existing policy that you want to globally bind, or click New Policy to open the Create <feature name> Policy dialog box.

5. After you have selected the policy or created a new policy, in the Priority column, type the priority value.

   The lower the number, the sooner this policy is applied relative to other policies. For example, a policy assigned a priority of 10 is applied before a policy with a priority of 100. You can use the same priority for different policies. All features that use classic policies implement only the first policy that a connection matches, so policy priority is important for getting the results you intend.

   As a best practice, leave room to add policies by setting priorities with intervals of 50 (or 100) between each policy.

6. Click OK.

Bind a classic policy to a virtual server by using the GUI

1. In the navigation pane, expand the feature that contains the virtual server to which you want to bind a classic policy (for example, if you want to bind a classic policy to a content switching
virtual server, expand Traffic Management > Content Switching), and then click Virtual Servers.

2. In the details pane, select the virtual server, and then click Open.

3. In the Configure <Feature> Virtual Server dialog box, on the Policies tab, click the feature icon for the type policy that you want, and then click Insert Policy.

4. In the Policy Name column, click the name of an existing policy that you want to bind to a virtual server, or click A to open the Create <feature name> Policy dialog box.

5. After you have selected the policy or created a new policy, in the Priority column, set the priority. If you are binding a policy to a content switching virtual server, in the Target column, select a load balancing virtual server to which traffic that matches the policy should be sent.

6. Click OK.

View classic policies

September 24, 2018

You can view classic policies by using either the GUI or the command line. You can view details such as the policy's name, expression, and bindings.

View a classic policy and its binding information by using the CLI

At the command prompt, type the following commands to view a classic policy and its binding information:

```
show <featureName> policy [policyName]
```

Example

```
  1 > show appfw policy GenericApplicationSSL_
  2     Name: GenericApplicationSSL_    Rule: ns_only_get_adv
  3     Profile: GenericApplicationSSL_Prof1    Hits: 0
  4     Undef Hits: 0
  5     Policy is bound to following entities
  6     1)  REQ VSERVER app_u_GenericApplicationSSLPortalPages
              PRIORITY : 100
  7     Done
```

Note: If you omit the policy name, all policies are listed without the binding details.

© 1999-2018 Citrix Systems, Inc. All rights reserved.
**View classic policies and policy bindings by using the GUI**

1. In the navigation pane, expand the feature whose policies you want to view, (for example, if you want to view application firewall policies, expand Application Firewall), and then click Policies.
2. In the details pane, do one or more of the following:
   - To view details for a specific policy, click the policy. Details appear in the Details area of the configuration pane.
   - To view bindings for a specific policy, click the policy, and then click Show Bindings.
   - To view global bindings, click the policy, and then click Global Bindings. Note that you cannot bind a Content Switching, Cache Redirection, SureConnect, Priority Queuing, or NetScaler Gateway Authorization policy globally.

**Create named classic expressions**

September 24, 2018

A named classic expression is a classic expression that can be referenced through an assigned name. Often, you need to configure classic expressions that are large or complex and form a part of a larger compound expression. You might also configure classic expressions that you need to use frequently and in multiple compound expressions or classic policies. In these scenarios, you can create the classic expression you want, save it with a name of your choice, and then reference the expression from compound expressions or policies through its name. This saves configuration time and improves the readability of complex compound expressions. Additionally, any modifications to a named classic expression need to be made only once.

Some named expressions are built-in, and a subset of these are read-only. Built-in named expressions are divided into four categories: General, Anti-Virus, Personal Firewall, and Internet Security. General named expressions have a wide variety of uses. For example, from the General category, you can use the expressions ns_true and ns_false to specify a value of TRUE or FALSE, respectively, to be returned for all traffic. You can also identify data of a particular type (for example, HTM, DOC, or GIF files), determine whether caching headers are present, or determine whether the round trip time for packets between a client and the NetScaler is high (over 80 milliseconds).

Anti-Virus, Personal Firewall, and Internet Security named expressions test clients for the presence of a particular program and version and are used primarily in NetScaler Gateway policies.

**Note:** You cannot modify or delete built-in named expressions.

**Create a named classic expression by using the CLI**

At the command prompt, type the following commands to set the parameters and verify the configuration:
Example

1 > add expression classic_ne "REQ.HTTP.URL CONTAINS www.example1.com" -
   comment "Checking the URL for www.example1.com"
2   Done
3 > show expression classic_ne
4 1)   Name: classic_ne   Expr: REQ.HTTP.URL CONTAINS www.example1.com
      Hits: 0   Type : CLASSIC
      Comment: "Checking the URL for www.example1.com"
6   Done
7 >

Create a named classic expression by using the GUI

1. In the navigation pane, expand AppExpert, expand Expressions, and then click Classic Expressions.

2. In the details pane, click Add.

   Note: Some of the built-in expressions in the Expressions list are read-only.

3. In the Create Policy Expression dialog box, specify values for the following parameters:
   • Expression Name*—name
   • Client Security Message—clientSecurityMessage
   • Comments—comment

   *A required parameter

4. To create the expression, do one of the following:
   • You can choose inputs to this expression from the Named Expressions drop-down list.
   • You can create a new expression, as described in Add an expression for a classic policy by
     using the GUI.

5. When you are done, click Close. Verify that your new expression was created by scrolling to the
   bottom of the Classic Expressions list to view it.
Expressions reference-advanced policy expressions

January 6, 2019

Warning
Q and S prefixes are deprecated from NetScaler 12.0 build 56.20 onwards and are no longer supported in Advanced policy expressions.

The following table is a listing of default syntax expression prefixes, with cross-references to descriptions of these prefixes and the operators that you can specify for them. Note that some prefixes can work with multiple types of operators. For example, a cookie can be parsed by using operators for text or operators for HTTP headers.

You can use any element in the following tables as a complete expression on its own, or you can use various operators to combine these expression elements with others to form more complex expressions.

Note: The Description column in the following table contains cross-references to additional information about prefix usage and applicable operators for the prefix.

Click here to view the table.

Expressions reference-classic expressions

January 6, 2019

Warning
Classic policy expressions are no longer supported from NetScaler 12.0 build 56.20 onwards and as an alternative, Citrix recommends you to use Advanced policies. For more information, see Advanced Policies

The subtopics listed in the table of contents on the left side of your screen contain tables listing the NetScaler classic expressions.

In the table of operators, the result type of each operator is shown at the beginning of the description. In the other tables, the level of each expression is shown at the beginning of the description. For named expressions, each expression is shown as a whole.

Operators
<table>
<thead>
<tr>
<th>Expression Element</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>==</td>
<td>Boolean. Returns TRUE if the current expression equals the argument. For text operations, the items being compared must exactly match one another. For numeric operations, the items must evaluate to the same number.</td>
</tr>
<tr>
<td>!=</td>
<td>Boolean. Returns TRUE if the current expression does not equal the argument. For text operations, the items being compared must not exactly match one another. For numeric operations, the items must not evaluate to the same number.</td>
</tr>
<tr>
<td>CONTAINS</td>
<td>Boolean. Returns TRUE if the current expression contains the string that is designated in the argument.</td>
</tr>
<tr>
<td>NOTCONTAINS</td>
<td>Boolean. Returns TRUE if the current expression does not contain the string that is designated in the argument.</td>
</tr>
<tr>
<td>CONTENTS</td>
<td>Text. Returns the contents of the current expression.</td>
</tr>
<tr>
<td>EXISTS</td>
<td>Boolean. Returns TRUE if the item designated by the current expression exists.</td>
</tr>
<tr>
<td>NOTEXISTS</td>
<td>Boolean. Returns TRUE if the item designated by the current expression does not exist.</td>
</tr>
<tr>
<td>&gt;</td>
<td>Boolean. Returns TRUE if the current expression evaluates to a number that is greater than the argument.</td>
</tr>
<tr>
<td>&lt;</td>
<td>Boolean. Returns TRUE if the current expression evaluates to a number that is less than the argument.</td>
</tr>
<tr>
<td>&gt;=</td>
<td>Boolean. Returns TRUE if the current expression evaluates to a number that is greater than or equal to the argument.</td>
</tr>
</tbody>
</table>
## Expression Element Definition

<td>REQ.SSL.CLIENT.CERT.VERSION</td>
<td>Qualifier. Designates the client certificate version.</td>
</tr>
<tr>
<td>Expression Element</td>
<td>Definition</td>
</tr>
<tr>
<td>--------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>REQ.SSL.CLIENT.CERT.VALIDFROM</td>
<td>Qualifier. Designates the date before which the client certificate is not valid.</td>
</tr>
<tr>
<td>REQ.SSL.CLIENT.CERT.VALIDTO</td>
<td>Qualifier. Designates the date after which the client certificate is not valid.</td>
</tr>
<tr>
<td>REQ.SSL.CLIENT.CERT_SERIALNUMBER</td>
<td>Qualifier. Designates the serial number of the client certificate.</td>
</tr>
<tr>
<td>REQ.SSL.CLIENT.CIPHER.TYPE</td>
<td>Qualifier. Designates the encryption protocol used by the client.</td>
</tr>
<tr>
<td>REQ.SSL.CLIENT.CIPHER_BITS</td>
<td>Qualifier. Designates the number of bits used by the client’s SSL key.</td>
</tr>
<tr>
<td>REQ.SSL.CLIENT.SSL.VERSION</td>
<td>Qualifier. Designates the SSL version that the client is using.</td>
</tr>
<tr>
<td>REQ.TCP</td>
<td>Protocol. Operates on incoming TCP packets.</td>
</tr>
<tr>
<td>REQ.TCP.SOURCEPORT</td>
<td>Qualifier. Designates the source port of the incoming packet.</td>
</tr>
<tr>
<td>REQ.TCP.DESTPORT</td>
<td>Qualifier. Designates the destination port of the incoming packet.</td>
</tr>
<tr>
<td>REQ.IP</td>
<td>Protocol. Operates on incoming IP packets.</td>
</tr>
<tr>
<td>REQ.IP.SOURCEIP</td>
<td>Qualifier. Designates the source IP of the incoming packet.</td>
</tr>
<tr>
<td>REQ.IP.DESTIP</td>
<td>Qualifier. Designates the destination IP of the incoming packet.</td>
</tr>
<tr>
<td>RES</td>
<td>Flow Type. Operates on outgoing (or response) packets.</td>
</tr>
<tr>
<td>RES.HTTP</td>
<td>Protocol. Operates on HTTP responses.</td>
</tr>
<tr>
<td>RES.HTTP.VERSION</td>
<td>Qualifier. Designates the HTTP version.</td>
</tr>
<tr>
<td>RES.HTTP.HEADER</td>
<td>Qualifier. Designates the HTTP header.</td>
</tr>
<tr>
<td>RES.HTTP.STATUSCODE</td>
<td>Qualifier. Designates the status code of the HTTP response.</td>
</tr>
<tr>
<td>RES.TCP</td>
<td>Protocol. Operates on incoming TCP packets.</td>
</tr>
<tr>
<td>RES.TCP.SOURCEPORT</td>
<td>Qualifier. Designates the source port of the outgoing packet.</td>
</tr>
</tbody>
</table>
Expression Element | Definition
--- | ---
RES.TCP.DESTPORT | Qualifier. Designates the destination port of the outgoing packet.
RES.IP | Protocol. Operates on outgoing IP packets.
RES.IP.SOURCEIP | Qualifier. Designates the source IP of the outgoing packet. This can be in IPv4 or IPv6 format. For example: add expr exp3 “sourceip == 10.102.32.123 –netmask 255.255.255.0 && destip == 2001::23/120”.
RES.IP.DESTIP | Qualifier. Designates the destination IP of the outgoing packet.

Client security expressions

The expressions to configure client settings on the Access Gateway with the following software:

- Antivirus
- Personal firewall
- Antispam
- Internet Security

For example usage, see [http://support.citrix.com/article/CTX112599](http://support.citrix.com/article/CTX112599).

<table>
<thead>
<tr>
<th>Actual Expression</th>

</thead>
<tbody>
<tr>
<td>TIME</td>
<td>Qualifier. Operates on the date and time of day, GMT.</td>
</tr>
<tr>
<td>DATE</td>
<td>Qualifier. Operates on the date, GMT.</td>
</tr>
<tr>
<td>DAYOFWEEK</td>
<td>Operates on the specified day in the week, GMT.</td>
</tr>
</tbody>
</table>

#### File system expressions

You can specify file system expressions in authorization policies for users and groups who access file sharing through the NetScaler Gateway file transfer utility (the VPN portal). These expressions work with the NetScaler Gateway file transfer authorization feature to control user access to file servers, folders, and files. For example, you can use these expressions in authorization policies to control access based on file type and size.

For more information, refer to the File Name Expression pdf.

**Note:** File system expressions do not support regular expressions.
### Built-in named expressions (General)

<table>
<thead>
<tr>
<th>Expression</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>ns_all_apps_ncomp</td>
<td>Tests for connections with destination ports between 0 and 65535. In other words, tests for all applications.</td>
</tr>
<tr>
<td>ns_cachecontrol_nocache</td>
<td>Tests for connections with an HTTP Cache-Control header that contains the value “no-cache”.</td>
</tr>
<tr>
<td>ns_cachecontrol_nostore</td>
<td>Tests for connections with an HTTP Cache-Control header that contains the value “no-store”.</td>
</tr>
<tr>
<td>ns_cmpclient</td>
<td>Tests the client to determine if it accepts compressed content.</td>
</tr>
<tr>
<td>ns_content_type</td>
<td>Tests for connections with an HTTP Content-Type header that contains “text”.</td>
</tr>
<tr>
<td>ns_css</td>
<td>Tests for connections with an HTTP Content-Type header that contains “text/css”.</td>
</tr>
<tr>
<td>ns_ext_asp</td>
<td>Tests for HTTP connections to any URL that contains the string .asp—in other words, any connection to an active server page (ASP).</td>
</tr>
<tr>
<td>ns_ext_cfm</td>
<td>Tests for HTTP connections to any URL that contains the string .cfm</td>
</tr>
<tr>
<td>ns_ext_cgi</td>
<td>Tests for HTTP connections to any URL that contains the string .cgi—in other words, any connection to a common gateway interface (CGI) script.</td>
</tr>
<tr>
<td>ns_ext_ex</td>
<td>Tests for HTTP connections to any URL that contains the string .ex</td>
</tr>
<tr>
<td>ns_ext_exe</td>
<td>Tests for HTTP connections to any URL that contains the string .exe—in other words, any connection to an executable file.</td>

<tr>
<td>Check for the presence of a header in a request (req) or response (res).</td>
<td>http.req.header(&quot;myHeader&quot;).exists</td>
</tr>
<tr>
<td></td>
<td>http.res.header(&quot;myHeader&quot;).exists</td>
</tr>
<tr>
<td>extension.</td>
<td></td>
</tr>
<tr>
<td>Look for anything that is other than a particular file type in an HTTP</td>
<td>http.req.url.contains(&quot;.gif&quot;).not;</td>
</tr>
<tr>
<td>request.</td>
<td>http.req.url.contains(&quot;.jpeg&quot;).not</td>
</tr>
</tbody>
</table>
Check the type of file that is being sent in an HTTP response based on the Content-Type header.

```
http.res.header("Content-Type").contains("text")
http.res.header("Content-Type").contains("application/msword")
http.res.header("Content-Type").contains("vnd.ms-excel")
http.res.header("Content-Type").contains("application/vnd.ms-powerpoint")
http.res.header("Content-Type").contains("text/css")
http.res.header("Content-Type").contains("text/xml")
http.res.header("Content-Type").contains("image/")
```

Check whether this response contains an expiration header.

```
'http.res.header("Expires").exists
```

Check for a Set-Cookie header in a response.

```
http.res.header("Set-Cookie").exists
```

Check the agent that sent the response.

```
http.res.header("User-Agent").contains("Mozilla/4.7")
http.res.header("User-Agent").contains("MSIE")
```

Check if the first 1024 bytes of the body of a request starts with the string "some text".

```
http.req.body(1024).contains("some text")
```

The following table shows examples of policy configurations and bindings for commonly used functions.

Tutorial examples of default syntax policies for rewrite

September 24, 2018

With the rewrite feature, you can modify any part of an HTTP header, and, for responses, you can modify the HTTP body. You can use this feature to accomplish a number of useful tasks, such as removing unnecessary HTTP headers, masking internal URLs, redirecting Web pages, and redirecting queries or keywords.

In the following examples, you first create a rewrite action and a rewrite policy. Then you bind the policy globally.

This document includes the following details:

- Redirecting an External URL to an Internal URL
- Redirecting a Query
- Rewriting HTTP to HTTPS
- Removing Unwanted Headers
- Reducing Web Server Redirects
- Masking the Server Header

For more information about the commands and syntax descriptions, see Rewrite Command Reference page.

Redirecting an external URL to an internal URL

Updated: 2013-10-29

This example describes how to create a rewrite action and rewrite policy that redirects an external URL to an internal URL. You create an action, called act_external_to_internal, that performs the rewrite. Then you create a policy called pol_external_to_internal.

To redirect an external URL to an internal URL by using the command line interface

- To create the rewrite action, at the command prompt, type:
  ```
  add rewrite action act_external_to_internal REPLACE 'http.req.hostname.server' "'host_name_of_internal_Web_server"
  ```
- To create the rewrite policy, at the NetScaler command prompt, type:
  ```
  add rewrite policy pol_external_to_internal 'http.req.hostname.server.eq("host_name_of_external_Web_server")' act_external_to_internal
  ```
- Bind the policy globally.
To redirect an external URL to an internal URL by using the GUI

1. Navigate to AppExpert > Rewrite > Actions.
2. In the details pane, click Add.
3. In the Create Rewrite Action dialog box, enter the name act_external_to_internal.
4. To replace the HTTP server host name with the internal server name, choose Replace from the Type list box.
5. In the Header Name field, type Host.
6. In the String expression for replacement text field, type the internal host name of your Web server.
7. Click Create and then click Close.
8. In the navigation pane, click Policies.
9. In the details pane, click Add.
10. In the Name field, type pol_external_to_internal. This policy will detect connections to the Web server.
11. In the Action drop-down menu, choose the action act_external_to_internal.
12. In the Expression editor, construct the following expression:

   ```plaintext
   HTTP.REQ.HOSTNAME.SERVER.EQ("www.example.com")
   ```

13. Bind your new policy globally.

Redirecting a query

This example describes how to create a rewrite action and rewrite policy that redirects a query to the proper URL. The example assumes that the request contains a Host header set to `www.example.com` and a GET method with the `string/query.cgi?server=5`. The redirect extracts the domain name from the host header and the number from the query string, and redirects the user’s query to the server `Web5.example.com`, where the rest of the user’s query is processed.

Note: Although the following commands appears on multiple lines, you should enter them on a single line without line breaks.

To redirect a query to the appropriate URL using the command line

- To create a rewrite action named act_redirect_query that replaces the HTTP server host name with the internal server name, type:
add rewrite action act_redirect_query REPLACE q#http.req.header(“Host”).before_str(“.example.com”)’ “Web” + http.req.url.query.value(“server”)#

• To create a rewrite policy named pol_redirect_query, type the following commands at the NetScaler command prompt. This policy detects connections to the Web server, that contain a query string. Do not apply this policy to connections that do not contain a query string:

add rewrite policy pol_redirect_query q#http.req.header(“Host”).eq(“www.example.com”) && http.req.url.contains(“?”)’ act_redirect_query#

• Bind your new policy globally.

Because this rewrite policy is highly specific and should be run before any other rewrite policies, it is advisable to assign it a high priority. If you assign it a priority of 1, it will be evaluated first.

**Rewriting HTTP to HTTPS**

Updated: 2014-09-17

This example describes how to rewrite Web server responses to find all URLs that begin with the string “http” and replace that string with “https.” You can use this to avoid having to update Web pages after moving a server from HTTP to HTTPS.

**To redirect HTTP URLs to HTTPS by using the command line interface**

• To create a rewrite action named act_replace_http_with_https that replaces all instances of the string “http” with the string “https,” enter the following command:

```bash
add rewrite action act_replace_http_with_https replace_all ‘http.res.body(100)’ “https” -pattern http
```

• To create a rewrite policy named pol_replace_http_with_https that detects connections to the Web server, enter the following command:

```bash
add rewrite policy pol_replace_http_with_https TRUE act_replace_http_with_https NOREWRITE
```

• Bind your new policy globally.

To troubleshoot this rewrite operation, see “Case Study: Rewrite Policy for Converting HTTP Links to HTTPS not Working.”

**Removing Unwanted Headers**

Updated: 2013-09-02
This example explains how to use a Rewrite policy to remove unwanted headers. Specifically, the example shows how to remove the following headers:

- **Accept Encoding header.** Removing the Accept Encoding header from HTTP responses prevents compression of the response.
- **Content Location header.** Removing the Content Location header from HTTP responses prevents your server from providing a hacker with information that might allow a security breach.

To delete headers from HTTP responses, you create a rewrite action and a rewrite policy, and you bind the policy globally.

**To create the appropriate Rewrite action by using the command line interface**

At the command prompt, type one of the following commands to either remove the Accept Encoding header and prevent response compression or remove the Content Location header:

- add rewrite action “act_remove-ae” delete_http_header “Accept-Encoding”
- add rewrite action “act_remove-cl” delete_http_header “Content-Location”

**To create the appropriate Rewrite policy by using the command line interface**

At the command prompt, type one of the following commands to remove either the Accept Encoding header or the Content Location header:

- add rewrite policy “pol_remove-ae” true “act_remove-ae”
- add rewrite policy “pol_remove-cl” true “act_remove-cl”

**To bind the policy globally by using the command line interface**

At the command prompt, type one of the following commands, as appropriate, to globally bind the policy that you have created:

- bind rewrite global pol_remove_ae 100
- bind rewrite global pol_remove_cl 200

**Reducing Web Server Redirects**

This example explains how to use a Rewrite policy to modify connections to your home page and other URLs that end with a forward slash (/) to the default index page for your server, preventing redirects and reducing load on your server.
To modify directory-level HTTP requests to include the default home page by using the command line

- To create a Rewrite action named action-default-homepage that modifies URLs that end in a forward slash to include the default home page index.html, type:
  
  add rewrite action “action-default-homepage” replace q#http.req.url.path “/” “/index.html”#

- To create a Rewrite policy named policy-default-homepage that detects connections to your home page and applies your new action, type:
  
  add rewrite policy “policy-default-homepage” q#http.req.url.path.EQ(“/”) “action-default-homepage”#

- Globally bind your new policy to put it into effect.

Masking the Server Header

This example explains how to use a Rewrite policy to mask the information in the Server header in HTTP responses from your Web server. That header contains information that hackers can use to compromise your Web site. While masking the header will not prevent a skilled hacker from finding out information about your server, it will make hacking your Web server more difficult and encourage hackers to choose less well protected targets.

To mask the Server header in responses from the command line

1. To create a Rewrite action named act_mask-server that replaces the contents of the Server header with an uninformative string, type:

   add rewrite action “act_mask-server” replace “http.RES.HEADER\("Server\)" ""Web Server 1.0\""

2. To create a Rewrite policy named pol_mask-server that detects all connections, type:

   add rewrite policy “pol_mask-server” true “act_mask-server”

3. Globally bind your new policy to put it into effect.

Tutorial Examples of Classic Policies

September 24, 2018

The following examples describe useful examples of classic policy configuration for certain NetScaler features, such as NetScaler Gateway, application firewall, and SSL.
This document includes the following details:

- NetScaler Gateway Policy to Check for a Valid Client Certificate
- Application Firewall Policy to Protect a Shopping Cart Application
- Application Firewall Policy to Protect Scripted Web Pages
- DNS Policy to Drop Packets from Specific IPs
- SSL Policy to Require Valid Client Certificates

**NetScaler Gateway Policy to Check for a Valid Client Certificate**

Updated: 2014-09-25

The following policies enable the NetScaler to ensure that a client presents a valid certificate before establishing a connection to a company’s SSL VPN.

**To check for a valid client certificate by using the command line interface**

- Add an action to perform client certificate authentication.
  
  `add ssl action act1 -clientAuth DOCLIENTAUTH`

- Create an SSL policy to evaluate the client requests.
  
  `add ssl policy pol1 -rule "REQ.HTTP.METHOD == GET"-action act1`

- Add a rewrite action to insert the certificate issuer details into the HTTP header of the requests being sent to web server.
  
  `add rewrite action act2 insert\_http\_header "CertDN"CLIENT.SSL.CLIENT\_CERT.SUBJECT`

- Create a rewrite policy to insert the certificate issuer details, if the client certificate exists.
  
  `add rewrite policy pol2 "CLIENT.SSL.CLIENT\_CERT EXISTS"act2`

Bind these new policies to the NetScaler VIP to put them into effect.

**Application firewall policy to protect a shopping cart application**

Shopping cart applications handle sensitive customer information, for example, credit card numbers and expiration dates, and they access back-end database servers. Many shopping cart applications also use legacy CGI scripts, which can contain security flaws that were unknown at the time they were written, but are now known to hackers and identity thieves.

A shopping cart application is particularly vulnerable to the following attacks:
• **Cookie tampering.** If a shopping cart application uses cookies, and does not perform the appropriate checks on the cookies that users return to the application, an attacker could modify a cookie and gain access to the shopping cart application under another user’s credentials. Once logged on as that user, the attacker could obtain sensitive private information about the legitimate user or place orders using the legitimate user’s account.

• **SQL injection.** A shopping cart application normally accesses a back-end database server. Unless the application performs the appropriate safety checks on the data users return in the form fields of its Web forms before it passes that information on to the SQL database, an attacker can use a Web form to inject unauthorized SQL commands into the database server. Attackers normally use this type of attack to obtain sensitive private information from the database or modify information in the database.

The following configuration will protect a shopping cart application against these and other attacks.

**To protect a shopping cart application by using the GUI**

1. Navigate to **Security > Application Firewall > Profiles**, and then click **Add**.

2. In the **Create Application Firewall Profile** dialog box, in the Profile Name field, enter **shopping_cart**.

3. In the Profile Type drop-down list, select Web Application.

4. In the **Configure Select Advanced defaults**.

5. Click **Create** and then click **Close**.

6. In the details view, double-click the new profile.

7. In the **Configure Web Application Profile** dialog box, configure your new profile as described below:

   - Click the Checks tab, double-click the Start URL check, and in the Modify Start URL Check dialog box, click the General tab and disable blocking, and enable learning, logging, statistics, and URL closure. Click OK and then click Close.

   Note that if you are using the command line, you configure these settings by typing the following at the prompt, and pressing ENTER:

   ```
   set appfw profile shopping\_cart -startURLAction LEARN LOG STATS -startURLClosure ON
   ```

   - For the Cookie Consistency check and Form Field Consistency checks, disable blocking, and enable learning, logging, statistics, using a similar method to the Modify Start URL Check configuration.
If you are using the command line, you configure these settings by typing the following commands:

```bash
set appfw profile shopping\_cart -cookieConsistencyAction LEARN LOG STATS
set appfw profile shopping\_cart -fieldConsistencyAction LEARN LOG STATS
```

- For the SQL Injection check, disable blocking, and enable learning, logging, statistics, and transformation of special characters in the Modify SQL Injection Check dialog box, General tab, Check Actions section.

If you are using the command line, you configure these settings by typing the following at the prompt, and pressing ENTER:

```bash
set appfw profile shopping\_cart -SQLInjectionAction LEARN LOG STATS -SQLInjectionTransformSpecialChars ON
```

- For the Credit Card check, disable blocking; enable logging, statistics, and masking of credit card numbers; and enable protection for those credit cards you accept as forms of payment.
  - If you are using the GUI, you configure blocking, logging, statistics, and masking (or x-out) in the Modify Credit Card Check dialog box, General tab, Check Actions section.
    You configure protection for specific credit cards in the Settings tab of the same dialog box.
  - If you are using the command line, you configure these settings by typing the following at the prompt, and pressing ENTER:

    ```bash
    set appfw profile shopping\_cart -creditCardAction LOG STATS -creditCardXOut ON -creditCard <name> [<name>...]
    ```

    For `<name>` you substitute the name of the credit card you want to protect. For Visa, you substitute VISA. For Master Card, you substitute MasterCard. For American Express, you substitute Amex. For Discover, you substitute Discover. For Diners Club, you substitute DinersClub. For JCB, you substitute JCB.

8. Create a policy named shopping\_cart that detects connections to your shopping cart application and applies the shopping\_cart profile to those connections.

   To detect connections to the shopping cart, you examine the URL of incoming connections. If you host your shopping cart application on a separate host (a wise measure for security and other reasons), you can simply look for the presence of that host in the URL. If you host your shopping cart in a directory on a host that handles other traffic, as well, you must determine that the connection is going to the appropriate directory and/or HTML page.
The process for detecting either of these is the same; you create a policy based on the following expression, and substitute the proper host or URL for .

```plaintext
1  REQ.HTTP.HEADER URL CONTAINS <string>
```

- If you are using the GUI, you navigate to the application firewall Policies page, click the Add... button to add a new policy, and follow the policy creation process described in “To create a policy with classic expressions using the GUI” beginning on page 201 and following.
- If you are using the command line, you type the following command at the prompt and press Enter:
  ```plaintext
  add appfw policy shopping_cart "REQ.HTTP.HEADER URL CONTAINS <string>"shopping_cart
  ```

2. Globally bind your new policy to put it into effect.

Because you want to ensure that this policy will match all connections to the shopping cart, and not be preempted by another more general policy, you should assign a high priority to it. If you assign one (1) as the priority, no other policy can preempt this one.

**Application firewall policy to protect scripted web pages**

Web pages with embedded scripts, especially legacy JavaScripts, often violate the “same origin rule,” which does not allow scripts to access or modify content on any server but the server where they are located. This security vulnerability is called cross-site scripting. The application firewall Cross-Site Scripting rule normally filters out requests that contain cross-site scripting.

Unfortunately, this can cause Web pages with older JavaScripts to stop functioning, even when your system administrator has checked those scripts and knows that they are safe. The example below explains how to configure the application firewall to allow cross-site scripting in Web pages from trusted sources without disabling this important filter for the rest of your Web sites.

**To protect Web pages with cross-site scripting by using the command line interface**

- At the command line, to create an advanced profile, type:
  ```plaintext
  add appfw profile pr_xssokay -defaults advanced
  ```
- To configure the profile, type:
  ```plaintext
  set appfw profile pr_xssokay -startURLAction NONE -startURLClosure OFF -cookieConsistencyAction LEARN LOG STATS -fieldConsistencyAction LEARN LOG STATS -crossSiteScriptingAction LEARN LOG STATS$
  ```
- Create a policy that detects connections to your scripted Web pages and applies the pr_xssokay profile, type:

```
add appfw policy pol_xssokay "REQ.HTTP.HEADER URL CONTAINS ^\\.pl\?\$ || REQ.HTTP.HEADER URL CONTAINS ^\\.js$" pr\_xssokay
```

- Globally bind the policy.

**To protect Web pages with cross-site scripting by using the GUI**

1. Navigate to Security > Application Firewall > Profiles.

2. In the details view, click **Add**.

3. In the Create Application Firewall Profile dialog box, create a Web Application profile with advanced defaults and name it pr_xssokay. Click **Create** and then click **Close**.

4. In the details view, click the profile, click Open, and in the Configure Web Application Profile dialog box, configure the pr_xssokay profile as shown below.

   - Start URL Check: Clear all actions.
   - Cookie Consistency Check: Disable blocking.
   - Form Field Consistency Check: Disable blocking.
   - Cross-Site Scripting Check: Disable blocking.

   This should prevent blocking of legitimate requests involving Web pages with cross-site scripting that you know are nonetheless safe.

5. Click **Policies**, and then click **Add**.

6. In the Create Application Firewall Policy dialog box, create a policy that detects connections to your scripted Web pages and applies the pr_xssokay profile:

   - Policy name: pol_xssokay
   - Associated profile: pr_xssokay

```
Policy expression:
“REQ.HTTP.HEADER URL CONTAINS ^\\.pl\?$
```

```
REQ.HTTP.HEADER URL CONTAINS ^\\.js$"
```

7. Globally bind your new policy to put it into effect.
**DNS Policy to drop packets from specific IPs**

The following example describes how to create a DNS action and DNS policy that detects connections from unwanted IPs or networks, such as those used in a DDoS attack, and drops all packets from those locations. The example shows networks within the IANA reserved IP block 192.168.0.0/16. A hostile network will normally be on publicly routable IPs.

**To drop packets from specific IPs by using the command line interface**

- To create a DNS policy named pol_ddos_drop that detects connections from hostile networks and drops those packets, type:

  ```bash
  ```

  For the example networks in the 192.168.0.0/16 range, you substitute the IP and netmask in `#####.#####.#####/##` format of each network you want to block. You can include as many networks as you want, separating each `CLIENT.IP.SRC.IN_SUBNET(###.###.###.###/##)` command with the OR operator.

- Globally bind your new policy to put it into effect.

**SSL policy to require valid client certificates**

The following example shows an SSL policy that checks the user's client certificate validity before initiating an SSL connection with a client.

**To block connections from users with expired client certificates**

- Log on to the command line interface.
  
  If you are using the GUI, navigate to the SSL Policies page, then in the Data area, click the Actions tab.

- Create an SSL action named act_current_client_cert that requires that users have a current client certificate to establish an SSL connection with the NetScaler.

  ```bash
  add ssl action act_current_client_cert -clientAuth DOCLIENTAUTH -clientCert ENABLED -certHeader "clientCertificateHeader"-clientCertNotBefore ENABLED -certNotBeforeHeader "Mon, 01 Jan 2007 00:00:00 GMT"
  ```

- Create an SSL policy named pol_current_client_cert that detects connections to the Web server that contain a query string.
add ssl policy pol_current_client_cert 'REQ.SSL.CLIENT.CERT.VALIDFROM >= "Mon, 01 Jan 2007 00:00:00 GMT"' act_block_ssl

- Bind your new policy globally.

Because this SSL policy should apply to any user's SSL connection unless a more specific SSL policy applies, you may want to assign it a low priority. If you assign it a priority of one thousand (1000), that should ensure that other SSL policies are evaluated first, meaning that this policy will apply only to connections that do not match more specific policy criteria.

Migration of Apache mod_rewrite rules to the default syntax

November 5, 2018

The Apache HTTP Server provides an engine known as mod_rewrite for rewriting HTTP request URLs. If you migrate the mod_rewrite rules from Apache to the NetScaler, you boost back-end server performance. In addition, because the NetScaler typically load balances multiple (sometimes thousands of) Web servers, after migrating the rules to the NetScaler you will have a single point of control for these rules.

Following are examples of mod_rewrite functions, and translations of these functions into Rewrite and Responder policies on the NetScaler.

Converting URL variations into canonical URLs

On some Web servers you can have multiple URLs for a resource. Although the canonical URLs should be used and distributed, other URLs can exist as shortcuts or internal URLs. You can make sure that users see the canonical URL regardless of the URL used to make an initial request.

In the following examples, the URL /~user is converted to /u/user.

Apache mod_rewrite solution for converting a URL

1  RewriteRule ^/~([^/]+)\?\.(.*) /u/$1/$2\[R

NetScaler solution for converting a URL

1  add responder action act1 redirect '/u/"+HTTP.REQ.URL.AFTER_STR("/-")' -bypassSafetyCheck yes
2  add responder policy pol1 'HTTP.REQ.URL.STARTSWITH("/~") && HTTP.REQ.URL.LENGTH.GT(2)' act1
Converting host name variations to canonical host names

You can enforce the use of a particular host name for reaching a site. For example, you can enforce the use of www.example.com instead of example.com.

Apache mod_rewrite solution for enforcing a particular host name for sites running on a port other than 80

```
1 RewriteCond %{HTTP_HOST} !^www.example.com
2 RewriteCond %{HTTP_HOST} !^$
3 RewriteCond %{SERVER_PORT} !^80$
4 RewriteRule ^/(.*) http://www.example.com:%{SERVER_PORT} /$1 [L,R]
```

Apache mod_rewrite solution for enforcing a particular host name for sites running on port 80

```
1 RewriteCond %{HTTP_HOST} !^www.example.com
2 RewriteCond %{HTTP_HOST} !^$
3 RewriteRule ^/(.*) http://www.example.com/$1 [L,R]
```

NetScaler solution for enforcing a particular host name for sites running on a port other than 80

```
3 bind responder global poll 100
```
NetScaler solution for enforcing a particular host name for sites running on port 80

```
1 add responder action act1 redirect '/"http://www.example.com:"+CLIENT.TCP.DSTPORT+HTTP.REQ.URL' -bypassSafetyCheck yes
2 add responder policy poll '!'HTTP.REQ.HOSTNAME.CONTAINS("www.example.com")&&!HTTP.REQ.HOSTNAME.EQ("")&&!HTTP.REQ.HOSTNAME.PORT.EQ(80) &&HTTP.REQ.HOSTNAME.CONTAINS("example.com")' act1
3 bind responder global poll 100 END
```

Moving a document root

Usually the document root of a Web server is based on the URL “/”. However, the document root can be any directory. You can redirect traffic to the document root if it changes from the top-level “/” directory to another directory.

In the following examples, you change the document root from / to /e/www. The first two examples simply replace one string with another. The third example is more universal because, along with replacing the root directory, it preserves the rest of the URL (the path and query string), for example, redirecting /example/file.html to /e/www/example/file.html.

Apache mod_rewrite solution for moving the document root

```
1 RewriteEngine on
2 RewriteRule ^/$ /e/www/ [R]
```

NetScaler solution for moving the document root

```
1 add responder action act1 redirect '/"e/www/"' -bypassSafetyCheck yes
2 add responder policy poll 'HTTP.REQ.URL.EQ("/")' act1
3 bind responder global poll 100
```
NetScaler solution for moving the document root and appending path information to the request

```plaintext
1 add responder action act1 redirect "/e/www"+HTTP.REQ.URL' -
   bypassSafetyCheck yes
2 add responder policy poll '!HTTP.REQ.URL.STARTSWITH("/e/www")' act1
3 bind responder global poll 100 END
```

Moving home directories to a new web server

You may want to redirect requests that are sent to home directories on a Web server to a different Web server. For example, if a new Web server is replacing an old one over time, as you migrate home directories to the new location you need to redirect requests for the migrated home directories to the new Web server.

In the following examples, the host name for the new Web server is newserver.

Apache mod_rewrite solution for redirecting to another Web server

```plaintext
1 RewriteRule ^/(.+)$ http://newserver/$1 [R,L]
```

NetScaler solution for redirecting to another Web server (method 1)

```plaintext
1 add responder action act1 redirect "http://newserver"+HTTP.REQ.URL' -
   bypassSafetyCheck yes
2 add responder policy poll 'HTTP.REQ.URL.REGEX_MATCH(re^/(.+)#)' act1
3 bind responder global poll 100 END
```

NetScaler solution for redirecting to another Web server (method 2)

```plaintext
1 add responder action act1 redirect "http://newserver"+HTTP.REQ.URL' -
   bypassSafetyCheck yes
2 add responder policy poll 'HTTP.REQ.URL.LENGTH.GT(1)' act1
3 bind responder global poll 100 END
```
Working with structured home directories

Typically, a site with thousands of users has a structured home directory layout. For example, each home directory may reside under a subdirectory that is named using the first character of the user name. For example, the home directory for jsmith (/~jsmith/anypath) might be /home/j/jsmith/.www/anypath, and the home directory for rvalveti (/~rvalveti/anypath) might be /home/r/rvalveti/.www/anypath.

The following examples redirect requests to the home directory.

Apache mod_rewritesolution for structured home directories

```bash
RewriteRule ^/~((\[a-z]\[a-z0-9]+)(.*) /home/$2/$1/.www$3
```

NetScaler solution for structured home directories

```bash
1 NetScaler solution for structured home directories
2 add rewrite action act1 replace 'HTTP.REQ.URL' '/home/' HTTP.REQ.URL
3 .AFTER_STR("~") .PREFIX(1)+"/" HTTP.REQ.URL .AFTER_STR("~")
4 BEFORE_STR("~")+/" www"+HTTP.REQ.URL .SKIP(\'/\',1)
5 bypassSafetyCheck yes
6 add rewrite policy pol1 'HTTP.REQ.URL .PATH .STARTSWITH("/~")' act1
7 bind rewrite global pol1 100
```

Redirecting invalid URLs to other web servers

If a URL is not valid, it should be redirected to another Web server. For example, you should redirect to another Web server if a file that is named in a URL does not exist on the server that is named in the URL.

On Apache, you can perform this check using mod_rewrite. On the NetScaler, an HTTP callout can check for a file on a server by running a script on the server. In the following NetScaler examples, a script named file_check.cgi processes the URL and uses this information to check for the presence of the target file on the server. The script returns TRUE or FALSE, and the NetScaler uses the value that the script returns to validate the policy.

In addition to performing the redirection, the NetScaler can add custom headers or, as in the second NetScaler example, it can add text in the response body.
Apache mod_rewritem solution for redirection if a URL is wrong

1 RewriteCond /your/docroot/%{REQUEST_FILENAME} !-f
2 RewriteRule ^(.+) http://webserverB.com/$1 [R]

NetScaler solution for redirection if a URL is wrong (method 1)

1 add HTTPCallout Call
2 set policy httpCallout Call -IPAddress 10.102.59.101 -port 80 -hostExpr "10.102.59.101" -returnType BOOL -ResultExpr 'HTTP.RES.BODY(100).CONTAINS("True")' -urlStemExpr '/cgi-bin/file_check.cgi' -parameters query=http.req.url.path -headers Name("ddd")
3 add responder action act1 redirect "http://webserverB.com"+HTTP.REQ.URL -bypassSafetyCheck yes
4 add responder policy pol1 !HTTP.REQ.HEADER("Name").EXISTS && !SYS.HTTP_CALLOUT(call) act1
5 bind responder global pol1 100

NetScaler solution for redirection if a URL is wrong (method 2)

1 add HTTPCallout Call
2 set policy httpCallout Call -IPAddress 10.102.59.101 -port 80 -hostExpr "10.102.59.101" -returnType BOOL -ResultExpr 'HTTP.RES.BODY(100).CONTAINS("True")' -urlStemExpr '/cgi-bin/file_check.cgi' -parameters query=http.req.url.path -headers Name("ddd")
3 add responder action act1 respondwith "HTTP/1.1 302 Moved Temporarily\r\n\nLocation: http://webserverB.com"+HTTP.REQ.URL+"\r\n\nHTTPCallout Used" -bypassSafetyCheck yes
4 add responder policy pol1 !HTTP.REQ.HEADER("Name").EXISTS && !SYS.HTTP_CALLOUT(call) act1
5 bind responder global pol1 100

Rewriting a URL based on time

You can rewrite a URL based on the time. The following examples change a request for example.html to example.day.html or example.night.html, depending on the time of day.
Apache mod_rewrite solution for rewriting a URL based on the time

```bash
1  RewriteCond %{TIME_HOUR} %{TIME_MIN} >0700
2  RewriteRule ^example\.html$ example.day.html [L]
3  RewriteCond %{TIME_HOUR} %{TIME_MIN} <1900
4  RewriteRule ^example\.html$ example.night.html
```

NetScaler solution for rewriting a URL based on the time

```bash
1  add rewrite action act1 insert_before 'HTTP.REQ.URL.PATH.SUFFIX (\'.\',0) ' "day."'
2  add rewrite action act2 insert_before 'HTTP.REQ.URL.PATH.SUFFIX (\'.\',0) ' "night."'
3  add rewrite policy pol1 'SYS.TIME.WITHIN(LOCAL 07h 00m,LOCAL 18h 59m)' act1
4  add rewrite policy pol2 'true' act2
5  bind rewrite global pol1 101
6  bind rewrite global pol2 102
```

Redirecting to a new file name (Invisible to the User)

If you rename a Web page, you can continue to support the old URL for backward compatibility while preventing users from recognizing that the page was renamed.

In the first two of the following examples, the base directory is /~quux/. The third example accommodates any base directory and the presence of query strings in the URL.

Apache mod_rewrite solution for managing a file name change in a fixed location

```bash
1  RewriteEngine on
2  RewriteBase /~quux/
3  RewriteRule ^foo\.html$ bar.html
```
NetScaler solution for managing a file name change in a fixed location

```
1 add rewrite action act1 replace 'HTTP.REQ.URL.AFTER_STR("/~quux").SUBSTR("foo.html")' '"bar.html"
2 add rewrite policy pol1 'HTTP.REQ.URL.ENDSWITH("/~quux/foo.html")' act1
3 bind rewrite global pol1 100
```

NetScaler solution for managing a file name change regardless of the base directory or query strings in the URL

```
1 add rewrite action act1 replace 'HTTP.REQ.URL.PATH.SUFFIX("\'/\',0) '"bar.html"
2 Add rewrite policy pol1 'HTTP.REQ.URL.PATH.CONTAINS("foo.html")' act1
3 Bind rewrite global pol1 100
```

Redirecting to new file name (user-visible URL)

If you rename a Web page, you may want to continue to support the old URL for backward compatibility and allow users to see that the page was renamed by changing the URL that is displayed in the browser.

In the first two of the following examples, redirection occurs when the base directory is /~quux/. The third example accommodates any base directory and the presence of query strings in the URL.

Apache mod_rewrite solution for changing the file name and the URL displayed in the browser

```
1 RewriteEngine on
2 RewriteBase /~quux/
3 RewriteRule ^old\./html$ new.html [R]
```

NetScaler solution for changing the file name and the URL displayed in the browser

```
1 add responder action act1 redirect 'HTTP.REQ.URL.BEFORE_STR("foo.html") +"new.html"' -bypassSafetyCheck yes
2 add responder policy pol1 'HTTP.REQ.URL.ENDSWITH("/~quux/old.html")' act1
3 bind responder global pol1 100
```
NetScaler solution for changing the file name and the URL displayed in the browser regardless of the base directory or query strings in the URL

```
1  add responder action act1 redirect 'HTTP.REQ.URL.PATH.BEFORE_STR("old.html")+"new.html"+HTTP.REQ.URL.AFTER_STR("old.html")' -
   bypassSafetyCheck yes
2  add responder policy poll 'HTTP.REQ.URL.PATH.CONTAINS("old.html")' act1
3  bind responder global poll 100
```

Accommodating browser dependent content

To accommodate browser-specific limitations—at least for important top-level pages—it is sometimes necessary to set restrictions on the browser type and version. For example, you might want to set a maximum version for the latest Netscape variants, a minimum version for Lynx browsers, and an average feature version for all others.

The following examples act on the HTTP header “User-Agent”, such that if this header begins with “Mozilla/3”, the page MyPage.html is rewritten to MyPage.NS.html. If the browser is “Lynx” or “Mozilla” version 1 or 2, the URL becomes MyPage.20.html. All other browsers receive page MyPage.32.html.

Apache mod_rewrite solution for browser-specific settings

```
1  RewriteCond %{HTTP_USER_AGENT} ^Mozilla/3.*
2  RewriteRule ^MyPage\.html$ MyPage.NS.html [L]
3  RewriteCond %{HTTP_USER_AGENT} ^Lynx/.* [OR]
4  RewriteCond %{HTTP_USER_AGENT} ^Mozilla/[12].*
5  RewriteRule ^MyPage\.html$ MyPage.20.html [L]
6  RewriteRule ^fMyPage\.html$ MyPage.32.html [L]
7  NetScaler solution for browser-specific settings
8  add patset pat1
9  bind patset pat1 Mozilla/1
10  bind Patset pat1 Mozilla/2
11  bind patset pat1 Lynx
12  bind Patset pat1 Mozilla/3
13  add rewrite action act1 insert_before 'HTTP.REQ.URL.SUFFIX' '"NS."'
14  add rewrite action act2 insert_before 'HTTP.REQ.URL.SUFFIX' '"20."'
```
Blocking access by robots

You can block a robot from retrieving pages from a specific directory or a set of directories to ease up the traffic to and from these directories. You can restrict access based on the specific location or you can block requests based on information in User-Agent HTTP headers.

In the following examples, the Web location to be blocked is /~quux/foo/arc/, the IP addresses to be blocked are 123.45.67.8 and 123.45.67.9, and the robot’s name is NameOfBadRobot.

Apache mod_rewrite solution for blocking a path and a User-Agent header

```
1  RewriteCond %{HTTP_USER_AGENT} ^NameOfBadRobot.*
2  RewriteCond %{REMOTE_ADDR} ^123\.[45]\.67\.[8-9]$
3  RewriteRule ^/~quux/foo/arc/.* - [F]
```

NetScaler solution for blocking a path and a User-Agent header

```
1  add responder action act1 respondwith ’HTTP/1.1 403 Forbidden\r\n\n’
2  add responder policy pol1 'HTTP.REQ.HEADER("User-Agent").STARTSWITH("NameOfBadRobot")&CLIENT.IP.SRC.EQ(123.45.67.8)&CLIENT.IP.SRC.EQ(123.45.67.9) & HTTP.REQ.URL.STARTSWITH("/~quux/foo/arc")' act1
3  bind responder global pol1 100
```
**Blocking access to inline images**

If you find people frequently going to your server to copy inline graphics for their own use (and generating unnecessary traffic), you may want to restrict the browser’s ability to send an HTTP Referer header.

In the following example, the graphics are located in Example.

**Apache mod_rewrite solution for blocking access to an inline image**

```plaintext
1 RewriteCond %{HTTP_REFERER} !^$
2 RewriteCond %{HTTP_REFERER} !^http://www.quux-corp.de/~quux/.*$
3 RewriteRule .*\.gif$ - [F]
```

**NetScaler solution for blocking access to an inline image**

```plaintext
1 add patset pat1
2 bind patset pat1 .gif
3 bind patset pat1 .jpeg
4 add responder action act1 respondwith 'HTTP/1.1 403 Forbidden\r\n\r\n',
5 add responder policy poll '!HTTP.REQ.HEADER("Referer").EQ("") & & !HTTP.REQ.HEADER("Referer").STARTSWITH("http://www.quux-corp.de/~quux/")& & HTTP.REQ.URL.ENDSWITH_ANY("pat1")' act1
6 bind responder global pol1 100
```

**Creating extensionless links**

To prevent users from knowing application or script details on the server side, you can hide file extensions from users. To do this, you may want to support extensionless links. You can achieve this behavior by using rewrite rules to add an extension to all requests, or to selectively add extensions to requests.

The first two of the following examples show adding an extension to all request URLs. In the last example, one of two file extensions is added. Note that in the last example, the mod_rewrite module can easily find the file extension because this module resides on the Web server. In contrast, the NetScaler
NetScaler 12.0

must invoke an HTTP callout to check the extension of the requested file on the Web server. Based on
the callout response, the NetScaler adds the .html or .php extension to the request URL.

Note
In the second NetScaler example, an HTTP callout is used to query a script named
file_check.cgi hosted on the server. This script checks whether the argument that is provided in
the callout is a valid file name.

Apache mod_rewrite solution for adding a .php extension to all requests

```bash
1 RewriteRule ^/?([a-z]+)$ $1.php [L]
```

NetScaler policy for adding a .php extension to all requests

```bash
1 add rewrite action act1 insert_after 'HTTP.REQ.URL' ":"'.php"
2 add rewrite policy poll1 'HTTP.REQ.URL ПаTH.REGEX_MATCH(re^*)(([a-z]+)$)#' 
   act1
3 bind rewrite global poll1 100
```

Apache mod_rewrite solution for adding either .html or .php extensions to requests

```bash
1 RewriteCond %{REQUEST_FILENAME} .php -f
2 RewriteRule ^/?([a-zA-Z0-9]+)$ $1.php [L]
3 RewriteCond %{REQUEST_FILENAME} .html -f
4 RewriteRule ^/?([a-zA-Z0-9]+)$ $1.html [L]
```

NetScaler policy for adding either .html or .php extensions to requests

```bash
1 add HTTPCallout Call_html
2 add HTTPCallout Call_php
3 set policy httpCallout Call_html -IPAddress 10.102.59.101 -port 80 -
   hostExpr "10.102.59.101" -returnType 80L -ResultExpr 'HTTP.RES.
   BODY(100).CONTAINS("True")' -urlStemExpr "/cgi-bin/file_check.cgi"
   -parameters query=http.req.url+".html"
```
Redirecting a Working URI to a New Format

Suppose that you have a set of working URLs that resemble the following:

```php
/index.php?id=nnnn
```

To change these URLs to /nnnn and make sure that search engines update their indexes to the new URI format, you need to do the following:

- Redirect the old URIs to the new ones so that search engines update their indexes.
- Rewrite the new URI back to the old one so that the index.php script runs correctly.

To accomplish this, you can insert marker code into the query string (making sure that the marker code is not seen by visitors), and then removing the marker code for the index.php script.

The following examples redirect from an old link to a new format only if a marker is not present in the query string. The link that uses the new format is re-written back to the old format, and a marker is added to the query string.

**Apache mod_rewrite solution**

```python
RewriteCond %{QUERY_STRING} !marker
RewriteRule ^index.php?id=nnnn$ /nnnn [R=301]
```

```python
RewriteCond %{QUERY_STRING} !marker
RewriteRule ^nnnn$ /index.php?id=nnnn [L,R=301]
```
Ensuring That a Secure Server Is Used for Selected Pages

To make sure that only secure servers are used for selected Web pages, you can use the following Apache mod_rewrite code or NetScaler Responder policies.

**Apache mod_rewrite solution**

```apache
1 RewriteCond %{SERVER_PORT} !^443$
2 RewriteRule ^?(page1|page2|page3|page4|page5)$ https://www.example.com/%1 [R,L]
```

**NetScaler solution using regular expressions**

```net-scaler
1 add responder action res_redirect redirect "https://www.example.com" HTTP.REQ.URL -bypassSafetyCheck yes
2 add responder policy pol_redirect '!CLIENT.TCP DSTPORT.EQ(443) & HTTP.REQ.URL REGEX_MATCH(re/page\[1-5]/)" res_redirect
3 bind responder global pol_redirect 100 END
```
NetScaler solution using pattern sets

```
1 add patset pat1
2 bind patset pat1 page1
3 bind patset pat1 page2
4 bind patset pat1 page3
5 bind patset pat1 page4
6 bind patset pat1 page5
7 add responder action res_redirect redirect '"https://www.example.com"'+HTTP.REQ.URL' -bypassSafetyCheck yes
8 add responder policy pol_redirect '||CLIENT.TCP.DSTPORT.EQ(443)&&HTTP.REQ.URL.CONTAINS_ANY("pat1")' res_redirect
9 bind responder global pol_redirect 100 END
```

Rate limiting

September 24, 2018

The rate limiting feature enables you to define the maximum load for a given network entity or virtual entity on the NetScaler appliance. The feature enables you to configure the appliance to monitor the rate of traffic associated with the entity and take preventive action, in real time, based on the traffic rate. This feature is particularly useful when the network is under attack from a hostile client that is sending the appliance a flood of requests. You can mitigate the risks that affect the availability of resources to clients, and you can improve the reliability of the network and the resources that the appliance manages.

You can monitor and control the rate of traffic that is associated with virtual and user-defined entities, including virtual servers, URLs, domains, and combinations of URLs and domains. You can throttle the rate of traffic if it is too high, base information caching on the traffic rate, and redirect traffic to a given load balancing virtual server if the traffic rate exceeds a predefined limit. You can apply rate-based monitoring to HTTP, TCP, and DNS requests.

To monitor the rate of traffic for a given scenario, you configure a rate limit identifier. A rate limit identifier specifies numeric thresholds such as the maximum number of requests or connections (of a particular type) that are permitted in a specified time period called a time slice.

Optionally, you can configure filters, known as stream selectors, and associate them with rate limit identifiers when you configure the identifiers. After you configure the optional stream selector and the limit identifier, you must invoke the limit identifier from a default syntax policy. You can invoke identifiers from any feature in which the identifier may be useful, including rewrite, responder, DNS, and integrated caching.
You can globally enable and disable SNMP traps for rate limit identifiers. Each trap contains cumulative data for the rate limit identifier’s configured data collection interval (time slice), unless you specified multiple traps to be generated per time slice. For more information about configuring SNMP traps and managers, see “SNMP.”

Configuring a Stream Selector

September 24, 2018

A traffic stream selector is an optional filter for identifying an entity for which you want to throttle access. The selector is applied to a request or a response and selects data points (keys) that can be analyzed by a rate stream identifier. These data points can be based on almost any characteristic of the traffic, including IP addresses, subnets, domain names, TCP or UDP identifiers, and particular strings or extensions in URLs.

A stream selector consists of individual default syntax expressions called selectlets. Each selectlet is a non-compound default syntax expression. A traffic stream selector can contain up to five non-compound expressions called selectlets. Each selectlet is considered to be in an AND relationship with the other expressions. Following are some examples of selectlets:

```
1 http.req.url
2 http.res.body(1000>after_str("car_model").before_str("made_in"))
3 "client.ip.src.subnet(24)"
```

The order in which you specify parameters is significant. For example, if you configure an IP address and a domain (in that order) in one selector, and then specify the domain and the IP address (in the reverse order) in another selector, the NetScaler considers these values to be unique. This can lead to the same transaction being counted twice. Also, if multiple policies invoke the same selector, the NetScaler, again, can count the same transaction more than once.

Note: If you modify an expression in a stream selector, you may get an error if any policy that invokes it is bound to a new policy label or bind point. For example, suppose that you create a stream selector named myStreamSelector1, invoke it from myLimitID1, and invoke the identifier from a DNS policy named dnsRateLimit1. If you change the expression in myStreamSelector1, you might receive an error when binding dnsRateLimit1 to a new bind point. The workaround is to modify these expressions before creating the policies that invoke them.

To configure a traffic stream selector by using the command line interface

At the command prompt, type:
add stream selector <name> <rule> ...

Example:

add stream selector myStreamSel HTTP.REQ.URL CLIENT.IP.SRC

To configure a stream selector by using the GUI

Navigate to AppExpert > Rate Limiting > Selectors, click Add and specify the relevant details.

Viewing the Traffic Rate

September 24, 2018

If traffic through one or more virtual servers matches a rate-based policy, you can view the rate of this traffic. The rate statistics are maintained in the limit identifier that you named in the rule for the rate-based policy. If more than one policy uses the same limit identifier, you can view the traffic rate as defined by hits to all of the policies that use the particular limit identifier.

To view the traffic rate by using the command line interface

At the command prompt, type the following command to view the traffic rate:

show ns limitSessions <limitIdentifier>

Example:

sh limitsession myLimitSession

To view the traffic rate by using the GUI

1. Navigate to AppExpert > Rate Limiting > Limit Identifiers.
2. Select a limit identifier whose traffic rate you want to view.
3. Click the Show Sessions button. If traffic through one or more virtual servers has matched a rate limiting policy that uses this limit identifier (and the hits are within the configured time slice for this identifier), the Session Details dialog box appears. Otherwise, you receive a “No session exists” message.
Testing a Rate-Based Policy

September 24, 2018

To test a rate-based policy, you can send traffic to any virtual server to which a rate-based policy is bound.

**Task overview: Testing a rate-based policy**

1. Configure a stream selector (optional) and a rate limit identifier (required). For example:

   ```
   1 add stream selector sel_subnet Q.URL "CLIENT.IP.SRC.SUBNET(24)"
   2 add ns limitIdentifier k_subnet -Threshold 4 -timeSlice 3600 -mode REQUEST_RATE -limittype smooth -selectorName sel_subnet -trapsInTimeSlice 8
   ```

2. Configure the action that you want to associate with the policy that uses the rate limit identifier. For example:

   ```
   1 add responder action resp_redirect redirect "http://response_site.com/"
   ```

3. Configure a policy that uses the sys.check_limit expression prefix to call the rate limit identifier. For example, the policy can apply a rate limit identifier to all requests arriving from a particular subnet, as follows:

   ```
   1 add responder policy resp_subnet "SYS.CHECK_LIMIT("k_subnet")" resp_redirect
   ```

4. Bind the policy globally or to a virtual server. For example:

   ```
   1 bind responder global resp_subnet 6 END -type DEFAULT
   ```

5. In a browser address bar, send a test HTTP query to a virtual server. For example:

   ```
   1 http://<IP of a vserver>/testsitesteast.txt
   ```

6. At the NetScaler command prompt, type:

   ```
   1 show ns limitSessions \<limitIdentifier\>
   ```

**Example**
7. Repeat the query and check the limit identifier statistics again to verify that the statistics are being updated correctly.

**Viewing the Traffic Rate**

September 24, 2018

If traffic through one or more virtual servers matches a rate-based policy, you can view the rate of this traffic. The rate statistics are maintained in the limit identifier that you named in the rule for the rate-based policy. If more than one policy uses the same limit identifier, you can view the traffic rate as defined by hits to all of the policies that use the particular limit identifier.

**To view the traffic rate by using the command line interface**

At the command prompt, type the following command to view the traffic rate:

```bash
> sh limitsession k_subnet
1) Time Remaining: 98 secs Hits: 2
   Action Taken: 0
2) Total Hash: 1718618 Hash String: /test.txt
3) IPs gathered:
   1) 10.217.253.0
4) Active Transactions: 0
7) Done
> 
```

**Example:**

```bash
sh limitsession myLimitSession
```

**To view the traffic rate by using the GUI**

1. Navigate to AppExpert > Rate Limiting > Limit Identifiers.
2. Select a limit identifier whose traffic rate you want to view.
3. Click the Show Sessions button. If traffic through one or more virtual servers has matched a rate limiting policy that uses this limit identifier (and the hits are within the configured time slice for this identifier), the Session Details dialog box appears. Otherwise, you receive a “No session exists” message.
Testing a Rate-Based Policy

September 24, 2018

To test a rate-based policy, you can send traffic to any virtual server to which a rate-based policy is bound.

Task overview: Testing a rate-based policy

1. Configure a stream selector (optional) and a rate limit identifier (required). For example:

```
1 add stream selector sel_subnet Q.URL "CLIENT.IP.SRC.SUBNET(24)"
2 add ns limitIdentifier k_subnet -Threshold 4 -timeSlice 3600 -mode REQUEST_RATE -limittype smooth -selectorName sel_subnet -trapsInTimeSlice 8
```

2. Configure the action that you want to associate with the policy that uses the rate limit identifier. For example:

```
1 add responder action resp_redirect redirect "\"http://response_site.com/\"
```

3. Configure a policy that uses the sys.check_limit expression prefix to call the rate limit identifier. For example, the policy can apply a rate limit identifier to all requests arriving from a particular subnet, as follows:

```
1 add responder policy resp_subnet "SYS.CHECK_LIMIT("k_subnet")"
   resp_redirect
```

4. Bind the policy globally or to a virtual server. For example:

```
1 bind responder global resp_subnet 6 END -type DEFAULT
```

5. In a browser address bar, send a test HTTP query to a virtual server. For example:

```
1 http://<IP of a vserver>/testsite/test.txt
```

6. At the NetScaler command prompt, type:

```
1 show ns limitSessions \<limitIdentifier\>
```

Example
### Examples of Rate-Based Policies

January 6, 2019

The following table shows examples of rate-based policies.

<table>
<thead>
<tr>
<th>#</th>
<th>Time Remaining</th>
<th>Hits</th>
<th>Action Taken</th>
<th>Total Hash</th>
<th>Hash String</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>98 secs</td>
<td>2</td>
<td>0</td>
<td>1718618</td>
<td>/test.txt</td>
</tr>
</tbody>
</table>

### Sample Use Cases for Rate-Based Policies

September 24, 2018

The following scenarios describe two uses of rate-based policies in global server load balancing (GSLB):

- The first scenario describes the use of a rate-based policy that sends traffic to a new data center if the rate of DNS requests exceed 1000 per second.
- In the second scenario, if more than five DNS requests arrive for a local DNS (LDNS) client within a particular period, the additional requests are dropped.

### Redirecting Traffic on the Basis of Traffic Rate

In this scenario, you configure a proximity-based load balancing method, and a rate-limiting policy that identifies DNS requests for a particular region. In the rate-limiting policy, you specify a threshold of 1000 DNS requests per second. A DNS policy applies the rate limiting policy to DNS requests for the region “Europe.GB.17.London.UK-East.ISP-UK.” In the DNS policy, DNS requests that exceed the rate limiting threshold, starting with request 1001 and continuing to the end of the one-second interval, are to be forwarded to the IP addresses that are associated with the region “North America.US.TX.Dallas.US-East.ISP-US.”
The following configuration demonstrates this scenario:

```
add stream selector DNSSelector1 client.udp.dns.domain
add ns limitIdentifier DNSLimitIdentifier1 -threshold 5 -timeSlice 1000 -selectorName DNSSelector1
add dns policy DNSLimitPolicy1 "client.ip.src.matches_location("Europe .GB.17.London.*.*") && sys.check_limit("DNSLimitIdentifier1")" -preferredLocation "North America.US.TX.Dallas.*.*"
bind dns global DNSLimitPolicy1 5
```

**Dropping DNS Requests on the Basis of Traffic Rate**

In the following example of global server load balancing, you configure a rate limiting policy that permits a maximum of five DNS requests in a particular interval, per domain, to be directed to an LDNS client for resolution. Any requests that exceed this rate are dropped. This type of policy can help protect the NetScaler from resource exploitation. For example, in this scenario, if the time to live (TTL) for a connection is five seconds, this policy prevents the LDNS from requerying a domain. Instead, it uses data that is cached on the NetScaler.

```
add stream selector LDNSSelector1 client.udp.dns.domain client.ip.src 1000
add ns limitIdentifier LDNSLimitIdentifier1 -threshold 5 -timeSlice selectorName LDNSSelector1
add dns policy LDNSPolicy1 "client.udp.dns.domain.contains(".") && sys.check_limit("LDNSLimitIdentifier1")" -drop YES
bind dns global LDNSPolicy1 6
show gslb vserver gvip
gvip - HTTP State: UP

---

**Rate Limiting for Traffic Domains**

September 24, 2018

You can configure rate limiting for traffic domains. The following expression in the NetScaler expressions language for identifies traffic associated with traffic domains.

- `client.traffic_domain.id`

You can configure rate limiting for traffic associated with a particular traffic domain, a set of traffic domains, or all traffic domains.

For configuring rate limiting for traffic domains, you perform the following steps on a NetScaler appliance by using the GUI or the NetScaler command line:

1. Configure a stream selector that uses the `client.traffic_domain.id` expression for identifying the traffic, associated with traffic domains, to be rate limited.
2. Configure a rate limit identifier that specifies parameters such as maximum threshold for traffic to be rate limited. You also associate a stream selector to the rate limiter in this step.
3. Configure an action that you want to associate with the policy that uses the rate limit identifier.
4. Configure a policy that uses the `sys.check_limit` expression prefix to call the rate limit identifier, and associate the action with this policy.

5. Bind the policy globally.

Consider an example in which two traffic domains, with IDs 10 and 20, are configured on NetScaler NS1. On traffic domain 10, LB1-TD-1 is configured to load balance servers S1 and S2; LB2-TD1 is configured to load balance servers S3 and S4.

On traffic domain 20, LB1-TD-2 is configured to load balance servers S5 and S6; LB2-TD2 is configured to load balance servers S7 and S8.

The following table lists some examples of rate limiting policies for traffic domains in the example setup.

<table>
<thead>
<tr>
<th>Purpose</th>
<th>CLI commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limit the number of requests to 10 per second for each of the traffic domains.</td>
<td>add stream selector tdratelimit-1 CLIENT.TRAFFIC_DOMAIN.ID add ns limitIdentifier limitidf-1 -threshold 10 -selectorName tdratelimit-1 -trapsInTimeSlice 0 add responder policy ratelimit-pol “sys.check_limit(&quot;limitidf-1&quot;)” DROP bind responder global ratelimit-pol 1</td>
</tr>
<tr>
<td>Limit the number of requests to 5 per client per second for each of the traffic domains.</td>
<td>add stream selector tdandclientip CLIENT.IP.SRC,CLIENT.TRAFFIC_DOMAIN.ID add ns limitIdentifier td_limitidf -threshold 5 -selectorName tdandclientip -trapsInTimeSlice 5 add responder policy tdratelimit-pol “sys.check_limit(&quot;td_limitidf&quot;)” DROP bind responder global tdratelimit-pol 2</td>
</tr>
<tr>
<td>Limit the number of requests sent for a particular traffic domain (for example traffic domain 10) to 30 requests every 3 seconds.</td>
<td>add stream selector tdratelimit CLIENT.TRAFFIC_DOMAIN.ID add ns limitIdentifier td10_limitidf -threshold 30 -timeSlice 3000 -selectorName tdratelimit -trapsInTimeSlice 5 add responder policy td10ratelimit “client.traffic_domain.id==10 &amp;&amp; sys.check_limit(&quot;td10_limitidf&quot;)” DROP bind responder global td10ratelimit 3</td>
</tr>
</tbody>
</table>
NetScaler 12.0

<table>
<thead>
<tr>
<th>Purpose</th>
<th>CLI commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limit the number of connections to 5 per client per second for a particular traffic domain (for example traffic domain 20).</td>
<td>add stream selector tdandclientip CLIENT.IP.SRC CLIENT.TRAFFIC_DOMAIN.ID add ns limitIdentifier td20_limitidf -threshold 5 -mode CONNECTION -selectorName tdandclientip -trapsInTimeSlice 5 add responder policy td20_ratelimit “client.traffic_domain.id==20 &amp;&amp; sys.check_limit(&quot;td20_limitidf&quot;)” DROP bind responder global td20_ratelimit 4</td>
</tr>
</tbody>
</table>

**Configure rate limit at packet level**

September 24, 2018

**Note:** This feature was introduced in NetScaler release 11.1 build 51.21.

You can collect statistics at the packet level to determine bad/attack prone packets flowing through all the connections identified by the selector. At any point, if the percentage of bad or attack-prone packets exceed the configured threshold, a corrective action (RESET or DROP) is triggered as per the configuration. This functionality can be used to address DDoS attacks involving small TCP packets in which PUSH flag is enabled.

The following configuration demonstrates this functionality. This configuration tracks packet credits for all the TCP connections flowing through the system. This creates a session and associates on pcb/natpcb and the performs the per packet check.

**Example:**

1. add stream selector packetcreditrateselector client.ip.src client.tcp.srcport client.ip.dst client.tcp.dstport
2. add stream identifier packetcreditrateselector interval 1
3. add responder policy packetcreditratesessionpolicy "ANALYTICS.STREAM(" packetcreditrateselector ").COLLECT_STATS("PACKET_CREDITS", < max_threshold_percentage>, ACTION)" NOOP
4. <max_threshold_percentage> is any value between 0-100.
ACTION can be either DROP/RESET

After the configuration is complete, we must bind this responder policy globally.

**Example:**

```
1 bind responder global packetcreditratesessionpolicy 101 END -type
   REQ_DEFAULT
2
3 bind responder global packetcreditratesessionpolicy 102 END -type
   NAT_REQ_DEFAULT
```

---

**Responder**

September 24, 2018

**Warning**

Responder and Rewrite filters are deprecated and as an alternative, Citrix recommends you to use filters using advanced policy infrastructure.

Today’s complex Web configurations often require different responses to HTTP requests that appear, on the surface, to be similar. When users request a Web site’s home page, you may want to provide a different home page depending on where each user is located, which browser the user is using, or which language(s) the browser accepts and the order of preference. You might want to break the connection immediately if the request is coming from an IP range that has been generating DDoS attacks or initiating hacking attempts.

With the Responder feature, responses can be based on who sends the request, where it is sent from, and other criteria with security and system management implications. The feature is simple and quick to use. By avoiding the invocation of more complex features, it reduces CPU cycles and time spent in handling requests that do not require complex processing.

For handling sensitive data such as financial information, if you want to ensure that the client uses a secure connection to browse a site, you can redirect the request to secure connection by using https:// instead of http://.

To use the Responder feature, do the following:

- Enable the Responder feature on the NetScaler.
- Configure responder actions. The action can be to generate a custom response, redirect a request to a different Web page, or reset a connection.
- Configure responder policies. The policy determines the requests (traffic) on which an action has to be taken.
• Bind each policy to a bind point put it into effect. A bind point refers to an entity at which NetScaler examines the traffic to see if it matches a policy. For example, a bind point can be a load balancing virtual server.

You can specify a default action for requests that do not match any policy, and you can bypass the safety check for actions that would otherwise generate error messages.

The Rewrite feature of NetScaler helps in rewriting some information in the requests or responses handled by NetScaler. The following section shows some differences between the two features.

**Comparison between Rewrite and Responder options**

The main difference between the rewrite feature and the responder feature is as follows:

Responder cannot be used for response or server-based expressions. Responder can be used only for the following scenarios depending on client parameters:

- Redirecting a http request to new Web sites or Web pages
- Responding with some custom response
- Dropping or resetting a connection at request level

In case of a responder policy, the NetScaler examines the request from the client, takes action according to the applicable policies, sends the response to the client, and closes the connection with the client.

In case of a rewrite policy, the NetScaler examines the request from the client or response from the server, takes action according to the applicable policies, and forwards the traffic to the client or the server.

In general, it is recommended to use responder if you want the NetScaler to reset or drop a connection based on a client or request-based parameter. Use responder to redirect traffic, or respond with custom messages. Use rewrite for manipulating data on HTTP requests and responses.

**Enabling the Responder Feature**

September 24, 2018

To use the Responder feature, you must first enable it.

To enable the responder feature by using the NetScaler command line:

At the command prompt, type the following commands to enable the responder feature and verify the configuration:

- enable ns feature <feature>
• show ns feature

Example:

```plaintext
1 enable ns feature Responder
2   Done
3   > show ns feature
4
5               Feature          Acronym      Status
6               -------          ------      -------
7   1)      Web Logging      WL          ON
8   2)      Surge Protection SP          ON
9
10
11
12   1)      Responder      RESPONDER ON
13   2)      HTML Injection  HTMLInjection ON
14   3)      NetScaler Push  push        OFF
15   Done
16   >
```

To enable the responder feature by using the GUI:

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Change advanced features.
3. In the Configure Advanced Features dialog box, select the Responder check box, and then click OK.
4. In the Enable/Disable Feature(s)? dialog box, click YES. A message appears in the status bar, stating that the feature has been enabled.

### Configuring a Responder Action

September 24, 2018

After enabling the responder feature, you must configure one or more actions for handling requests. The responder supports the following types of actions:

- **Respond with.** Sends the response defined by the Target expression without forwarding the request to a web server. (The NetScaler appliance substitutes for and acts as a web server.) Use this type of action to manually define a simple HTML-based response. Normally the text for a Respond with action consists of a web server error code and brief HTML page.

- **Respond with SQL OK.** Sends the designated SQL OK response defined by the Target expression. Use this type of action to send an SQL OK response to an SQL query.
- **Respond with SQL Error.** Sends the designated SQL Error response defined by the Target expression. Use this type of action to send an SQL Error response to an SQL query.

- **Respond with HTML page.** Sends the designated HTML page as the response. You can choose from a drop-down list of HTML pages that were previously uploaded, or upload a new HTML page. Use this type of action to send an imported HTML page as the response.

- **Redirect.** Redirects the request to a different web page or web server. A Redirect action can redirect requests originally sent to a “dummy” web site that exists in DNS, but for which there is no actual web server, to an actual web site. It can also redirect search requests to an appropriate URL. Normally, the redirection target for a Redirect action consists of a complete URL.

To configure a responder action by using the NetScaler command line:

Displays the current settings for the specified responder action. If no action name is provided, displays a list of all responder actions currently configured on the NetScaler appliance, with abbreviated settings.

At the command prompt, type the following commands to configure a responder action and verify the configuration:

- add responder action <name> <type> <target> [-bypassSafetyCheck (YES | NO) ]
- show responder action

**Parameters:**

- **Name.** Name of the responder action. Maximum Length: 127
- **type.** Type of responder action. It can be: (respondwith).
- **target.** An expression specifying what to respond with
- **htmlpage.** Option specifying to respondwith htmlpage
- **bypassSafetyCheck.** The safety check to allow unsafe expressions. **Note:** This attribute is deprecated.
- **hits.** The number of times the action has been taken.
- **referenceCount.** The number of references to the action.
- **undefHits.** The number of times the action resulted in UNDEF.
- **comment.** Any type of information about this responder action.
- **builtin.** Flag to determine whether responder action is built-in or not

**Example:**

```bash
To create a responder action that displays a “Not Found” error page for URLs that do not exist:
```
To create a responder action that displays a “Not Found” error page for URLs that do not exist:

```bash
> add responder action act404Error respondWith "'"HTTP/1.1 404 Not Found
\r\n\r\n" HTTP.REQ.URL.HTTP_URL_SAFE" + "does not exist on the web server."
```

Done

To modify an existing responder action by using the NetScaler command line:

At the command prompt, type the following command to modify an existing responder action and verify the configuration:

- `set responder action -target [-bypassSafetyCheck \YES | \NO ]` 
- `show responder action`
Example:

```
1 set responder action act404Error -target "HTTP/1.1 404 Not Found\n\n+ "HTTP.REQ.URL.HTTP_URL_SAFE" + "does not exist on the web server."
2 Done
3 > show responder action
4
5 1) Name: act404Error
6       Operation: respondwith
7       Target: "HTTP/1.1 404 Not Found
8    + "HTTP.REQ.URL.HTTP_URL_SAFE" + "does not exist on the web server."
9       BypassSafetyCheck : NO
10      Hits: 0
11      Undef Hits: 0
12      Action Reference Count: 0
13 Done
```

To remove a responder action by using the NetScaler command line:

At the command prompt, type the following command to remove a responder action and verify the configuration:

- `rm responder action`
- `show responder action`

Example:

```
1 rm responder action act404Error
2 Done
3
4 > show responder action
5 Done
```

To configure a responder action by using the GUI:

2. In the details pane, do one of the following:
   - To create a new action, click Add.
   - To modify an existing action, select the action, and then click Open.
3. Click Create or OK, depending on whether you are creating a new action or modifying an existing action.
4. Click Close. A message appears in the status bar, stating that the feature has been enabled.
5. To delete a responder action, select the action, and then click Remove. A message appears in the status bar, stating that the feature has been disabled.
To add an expression by using the Add Expression dialog box

1. In the Create Responder Action or Configure Responder Action dialog box, click Add.

2. In the Add Expression dialog box, in the first list box choose the first term for your expression.
   - HTTP. The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol.
   - SYS. The protected web site(s). Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.
   - CLIENT. The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.
   - ANALYTICS. The analytics data associated with the request. Choose this if you want to examine request metadata.
   - SIP. A SIP request. Choose this if you want to examine some aspect of a SIP request.

   When you make your choice, the rightmost list box lists appropriate terms for the next part of your expression.

3. In the second list box, choose the second term for your expression. The choices depend upon which choice you made in the previous step, and are appropriate to the context. After you make your second choice, the Help window below the Construct Expression window (which was blank) displays help describing the purpose and use of the term you just chose.

4. Continue choosing terms from the list boxes that appear to the right of the previous list box, or typing strings or numbers in the text boxes that appear to prompt you to enter a value, until your expression is finished.

**Configuring the Global HTTP Action**

You can configure the global HTTP action to invoke a responder action when an HTTP request times out. To configure this feature, you must first create the responder action that you want to invoke. Then, you configure the global HTTP timeout action to respond to a timeout with that responder action.

To configure the global HTTP action by using the NetScaler command line:

At the command prompt, type the following command:

- set ns httpProfile -reqTimeoutAction <responder action name>
- save ns config

For <responder action name>, substitute the name of the responder action.
Configuring a Responder Policy

September 24, 2018

After you configure a responder action, you must next configure a responder policy to select the requests to which the NetScaler appliance should respond. A responder policy is based on a rule, which consists of one or more expressions. The rule is associated with an action, which is performed if a request matches the rule.

**Note:** For creating and managing responder policies, the GUI provides assistance that is not available at the NetScaler command prompt.

To configure a responder policy by using the NetScaler command line:

At the command prompt, type:

- add responder policy
- show responder policy

**Example:**

```
1 > add responder policy policyThree "CLIENT.IP.SRC.IN_SUBNET (222.222.0.0/16)" RESET
2 Done
3 > show responder policy policyThree
4
5 Name: policyThree
6 Rule: CLIENT.IP.SRC.IN_SUBNET(222.222.0.0/16)
7 Responder Action: RESET
8 UndefAction: Use Global
9 Hits: 0
10 Undef Hits: 0
11 Done
```

To modify an existing responder policy by using the NetScaler command line:

At the command prompt, type:

- set responder policy [-rule ] [-action ] [-undefAction ]
- show responder policy

To remove a responder policy by using the NetScaler command line:

At the command prompt, type:

- rm responder policy
- show responder policy
Example:

```
1  >rm responder policy pol404Error
2   Done
3
4  > show responder policy
5   Done
```

To configure a responder policy by using the GUI:

2. In the details pane, do one of the following:
   - To create a new policy, click Add.
   - To modify an existing policy, select the policy, and then click Open.
3. Click Create or OK, depending on whether you are creating a new policy or modifying an existing policy.
4. Click Close. A message appears in the status bar, stating that the feature has been configured.

## Binding a Responder Policy

September 26, 2018

To put a policy into effect, you must bind it either globally, so that it applies to all traffic that flows through the NetScaler, or to a specific virtual server, so that the policy applies only to requests whose destination IP address is the VIP of that virtual server.

When you bind a policy, you assign a priority to it. The priority determines the order in which the policies you define are evaluated. You can set the priority to any positive integer.

In the NetScaler operating system, policy priorities work in reverse order—the higher the number, the lower the priority. For example, if you have three policies with priorities of 10, 100, and 1000, the policy assigned a priority of 10 is performed first, then the policy assigned a priority of 100, and finally the policy assigned an order of 1000. The responder feature implements only the first policy that a request matches, not any additional policies that it might also match, so policy priority is important for getting the results you intend.

You can leave yourself plenty of room to add other policies in any order, and still set them to evaluate in the order you want, by setting priorities with intervals of 50 or 100 between each policy when you globally bind it. You can then add additional policies at any time without having to reassign the priority of an existing policy.

For additional information about binding policies on the NetScaler, see Policies and Expressions.

**Note:** Responder policies cannot be bound to TCP-based virtual servers.
To globally bind a responder policy by using the NetScaler command line:

At the command prompt, type the following command to globally bind a responder policy and verify the configuration:

- bind responder global <policyName> <priority> [<-gotoPriorityExpression] [-type <type>] [-invoke (<labelType> <labelName>)]
- show responder global

Example:

```
1 > bind responder global poliError 100
2 Done
3 > show responder global
4 1) Global bindpoint: REQ_DEFAULT
5    Number of bound policies: 1
6
7 Done
```

To bind responder policy to a specific virtual server by using the NetScaler command line:

At the command prompt, type:

- bind lb vserver <name> -policyname <policy_name> -priority <priority>
- sh lb vserver <name>

Example:

```
1 > bind lb vserver vs-loadbal -policyName policyTwo -priority 100
2 Done
3 > show lb vserver
4 1) vs-loadbal (10.102.29.20:80) - HTTP    Type: ADDRESS
5    State: OUT OF SERVICE
6    Last state change was at Wed Aug 19 09:05:47 2009 (+211 ms)
7    Time since last state change: 2 days, 00:58:03.260
8    Effective State: DOWN
9    Client Idle Timeout: 180 sec
10   Down state flush: ENABLED
11   Disable Primary Vserver On Down : DISABLED
12   Port Rewrite : DISABLED
13   No. of Bound Services : 0 (Total) 0 (Active)
14   Configured Method: LEASTCONNECTION
15   Mode: IP
16   Persistence: NONE
17   Vserver IP and Port insertion: OFF
18   Push: DISABLED    Push VServer:
19   Push Multi Clients: NO
20   Push Label Rule: none
```
### NetScaler 12.0

| 21 | vs-cont-sw (0.0.0.0:0) - TCP | Type: ADDRESS |
| 22 | State: DOWN |
| 23 | Last state change was at Wed Aug 19 10:03:46 2009 (+213 ms) |
| 24 | Time since last state change: 2 days, 00:00:04.260 |
| 25 | Effective State: DOWN |
| 26 | Client Idle Timeout: 9000 sec |
| 27 | Down state flush: ENABLED |
| 28 | Disable Primary Vserver On Down : DISABLED |
| 29 | No. of Bound Services : 0 (Total) 0 (Active) |
| 30 | Configured Method: LEASTCONNECTION |
| 31 | Mode: IP |
| 32 | Persistence: NONE |
| 33 | Connection Failover: DISABLED |
| 34 | Done |

### To globally bind a responder policy by using the GUI:

1. Navigate to **AppExpert > Responder > Policies.**
2. On the **Responder Policies** page, select a responder policy, and then click **Policy Manager.**
3. In the **Responder Policy Manager** dialog box **Bind Points** menu, select Default Global.
4. Click **Insert Policy** to insert a new row and display a drop-down list of all unbound responder policies.
5. Click one of the policies on the list. That policy is inserted into the list of globally bound responder policies.
6. Click **Apply Changes.**
7. Click **Close.** A message appears in the status bar, stating that the configuration has been successfully completed.

### To bind a responder policy to a specific virtual server by using the GUI:

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers.**
2. On the **Load Balancing Virtual Servers** page, select the virtual server to which you want to bind the responder policy, and then click **Open.**
3. In the **Configure Virtual Server** (Load Balancing) dialog box, select the **Policies** tab, which displays a list of all policies configured on your NetScaler appliance.
4. Select the check box next to the name of the policy you want to bind to this virtual server.
5. Click **OK.** A message appears in the status bar, stating that the configuration has been successfully completed.

### Setting the default action for a responder policy

September 24, 2018
The NetScaler appliance generates an undefined event (UNDEF event) when a request does not match a responder policy, and then carries out the default action assigned to undefined events. By default, that action is to forward the request to the next feature without changing it. This default behavior is normally what you want; it ensures that requests that do not require special handling by a specific responder action are sent to your Web servers and clients receive access to the content that they requested.

If the Web site(s) your NetScaler appliance protects receive a significant number of invalid or malicious requests, however, you may want to change the default action to either reset the client connection or drop the request. In this type of configuration, you would write one or more responder policies that would match any legitimate requests, and simply redirect those requests to their original destinations. Your NetScaler appliance would then block any other requests as specified by the default action you configured.

You can assign any one of the following actions to an undefined event:

- **NOOP**
  
  The NOOP action aborts responder processing but does not alter the packet flow. This means that the appliance continues to process requests that do not match any responder policy, and eventually forwards them to the requested URL unless another feature intervenes and blocks or redirects the request. This action is appropriate for normal requests to your Web servers and is the default setting.

- **RESET**
  
  If the undefined action is set to RESET, the appliance resets the client connection, informing the client that it must re-establish its session with the Web server. This action is appropriate for repeat requests for Web pages that do not exist, or for connections that might be attempts to hack or probe your protected Web site(s).

- **DROP**
  
  If the undefined action is set to DROP, the appliance silently drops the request without responding to the client in any way. This action is appropriate for requests that appear to be part of a DDoS attack or other sustained attack on your servers.

**Note:** UNDEF events are triggered only for client requests. No UNDEF events are triggered for responses.

To set the undefined action by using the NetScaler command line:

At the command prompt, type the following command to set the undefined action and verify the configuration:
NetScaler 12.0

<table>
<thead>
<tr>
<th>set responder param</th>
<th>DROP</th>
<th>NOOP</th>
</tr>
</thead>
<tbody>
<tr>
<td>-undefAction (RESET</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- show responder param

**Example:**

```bash
1 > set responder param -undefAction RESET
2   Done
3 > show responder param
4   Action Name: RESET
5   Done
6 >
```

To set the undefined action by using the GUI:

1. Navigate to **AppExpert > Responder**, and then under **Settings**, click the **Change Responder Settings** link.
2. In the **Set Responder Params** dialog box, under **Global Undefined-Result Action**, select **NOOP**, **RESET**, or **DROP**.
3. Click **OK**. A message appears in the status bar, stating that the Responder Parameters have been configured.

**Responder action and policy examples**

November 13, 2018

Responder actions and policies are powerful and complex, but you can get started with relatively simple applications.

**Example: Blocking access from specified IP addresses**

The following procedures block access to your protected Web site(s) by clients originating from the CIDR 222.222.0.0/16. The responder sends an error message stating that the client is not authorized to access the URL requested.

To block access by using the NetScaler command line:

At the command prompt, type the following commands to block access:
add responder action act_unauthorized respond with “HTTP/1.1 403 Forbidden\r\n\r
Client: “ + CLIENT.IP.SRC + “ is not authorized to access URL:" + HTTP.REQ.URL.HTTP_URL_SAFE’
add responder policy pol_un “CLIENT.IP.SRC.IN_SUBNET (222.222.0.0/16)” act_unauthorized
bind responder global pol_un 10

To block access by using the GUI:

1. In the navigation pane, expand Responder, and then click Actions.
2. In the details pane, click Add.
3. In the Create Responder Action dialog box, do the following:
   a) In the Name text box, type act_unauthorized.
   b) Under Type, select Respond with.
   c) In the Target text area, type the following string: “HTTP/1.1 200 OK\r\n\r
Client: “ + CLIENT.IP.SRC + “ is not authorized to access URL:" + HTTP.REQ.URL.HTTP_URL_SAFE
   d) Click Create, and then click Close.
   The responder action you configured, named act_unauthorized, now appears in the Responder Actions page.
4. In the navigation pane, click Policies.
5. In the details pane, click Add.
6. In the Create Responder Policy dialog box, do the following:
   a) In the Name text box, type pol_unauthorized.
   b) Under Action, select act_unauthorized.
   c) In the Expression window, type the following rule: CLIENT.IP.SRC.IN_SUBNET(222.222.0.0/16)
   d) Click Create, then click Close.
   The responder policy you configured, named pol_unauthorized, now appears in the Responder Policies page.
7. Globally bind your new policy, pol_unauthorized, as described in Binding a Responder Policy.

Example: Redirecting a client to a new URL

The following procedures redirect clients who access your protected Web site(s) from within the CIDR 222.222.0.0/16 to a specified URL.

To redirect clients by using the NetScaler command line:

At the command prompt, type the following commands to redirect clients and verify the configuration:

```
• add responder action act_redirect redirect ”<http://www.example.com /404.html>”
• show responder action act_redirect
• add responder policy pol_redirect ”CLIENT.IP.SRC.IN_SUBNET(222.222.0.0/16) ”act_redirect
• show responder policy pol_redirect
```
NetScaler 12.0

- **bind responder global pol_redirect 10**

**Example:**

```
> add responder action act_redirect redirect "http://www.example.com/404.html"
Done

> add responder policy pol_redirect "CLIENT.IP.SRC.IN_SUBNET(222.222.0.0/16)" act_redirect
Done
```

To redirect clients by using the GUI:

1. Navigate to **AppExpert > Responder > Actions**.
2. In the details pane, click **Add**.
3. In the **Create Responder Action** dialog box, do the following:
   a) In the Name text box, type act_redirect.
   b) Under Type, select **Redirect**.
   c) In the Target text area, type the following string: "<http://www.example.com/404.html>"
   d) Click **Create**, then **Close**.
      The responder action you configured, named act_redirect, now appears in the Responder Actions page.
4. In the navigation pane, click **Policies**.
5. In the details pane, click **Add**.
6. In the Create Responder Policy dialog box, do the following:
   a) In the **Name** text box, type pol_redirect.
   c) In the Expression window, type the following rule: CLIENT.IP.SRC.IN_SUBNET(222.222.0.0/16)
   d) Click **Create**, then click **Close**.
      The responder policy you configured, named pol_redirect, now appears in the **Responder Policies** page.
7. Globally bind your new policy, pol_redirect, as described in **Binding a Responder Policy**.

**Diameter Support for Responder**

September 24, 2018

The Responder feature now supports the Diameter protocol. You can configure Responder to respond to Diameter requests as it does HTTP and TCP requests. For example, you could configure Responder to respond to requests from a specific Diameter origin with a redirect to a web page enhanced for
NetScaler 12.0

mobile devices. A number of NetScaler expressions have been added that support examination of the Diameter header and the attribute-value pairs (AVPs). These expressions support lookup of specific AVPs by index, ID or name, examine the information in each AVP, and send an appropriate response.

To configure Responder to respond to a Diameter request:

At the command prompt, type the following commands:

- add responder action <actname> RESPONDWITH “DIAMETER.NEW_REDIRECT("aaa://host.example.com")”

  For <actname>, substitute a name for your new action. The name can consist of from one to 127 characters in length, and can contain letters, numbers, and the hyphen (-) and underscore (_) symbols. For aaa://host.example.com, substitute the URL of the diameter host to which you want to redirect connections.

- add responder policy <polname> “diameter.req.avp(264).value.eq("host1.example.net")”

  For <polname>, substitute a name for your new policy. As with <actname>, the name can consist of from one to 127 characters in length, and can contain letters, numbers, and the hyphen (-) and underscore (_) symbols. For host1.example.net, substitute the name of the originating host of the requests that you want to redirect. For <actname>, substitute the name of the action that you just created.

- bind lb vserver <vservername> -policyName <polname> -priority <priority> -type REQUEST

  For <vservername>, substitute the name of the load balancing virtual server to which you want to bind the policy. For <polname>, substitute the name of the policy you just created. For <priority>, substitute a priority for the policy.

Example:

To create a Responder action and policy to respond to Diameter requests that originate from “host1.example.net” with a redirect to “host.example.com”, you could add the following action and policy, and bind the policy as shown.

1  > add responder action act_resp-dm-redirect RESPONDWITH "DIAMETER.NEW_REDIRECT("aaa://host.example.com")"
2  Done
3 4  > add responder pol_resp-dm-redirect "diameter.req.avp(264).value.eq("host1.example.net")” act_resp-dm-redirect
5  Done
6 7  > bind lb vserver vs1 -policyName pol_resp-dm-redirect -priority 10 -type REQUEST
8  Done
RADIUS Support for Responder

September 24, 2018

The NetScaler expressions language contains expressions that can extract information from and manipulate RADIUS requests. These expressions enable you to use the Responder feature to respond to RADIUS requests. Your responder policies and actions can use any expression that is appropriate or relevant to a RADIUS request. The available expressions enable you to identify the RADIUS message type, extract any attribute-value pair (AVP) from the connection, and send different responses on the basis of that information. You can also create policy labels that invoke all responder policies for RADIUS connections.

You can use RADIUS expressions to construct simple responses that do not require communication with the RADIUS server to which the request was sent. When a responder policy matches a connection, the NetScaler constructs and sends the appropriate RADIUS response without contacting the RADIUS authentication server. For example, if the source IP address of a RADIUS request is from a subnet that is specified in the responder policy, the NetScaler can reply to that request with an access-reject message, or can simply drop the request.

You can also create policy labels to route specific types of RADIUS requests through a series of policies that are appropriate to those requests.

**Note:** The current RADIUS expressions do not work with RADIUS IPv6 attributes.

The NetScaler documentation for expressions that support RADIUS assumes familiarity with the basic structure and purpose of RADIUS communications. If you need more information about RADIUS, see your RADIUS server documentation or search online for an introduction to the RADIUS protocol.

Configuring Responder Policies for RADIUS

The following procedure uses the NetScaler command line to configure a responder action and policy, and bind the policy to a RADIUS-specific global bind point.

To configure a Responder action and policy, and bind the policy:

At the command prompt, type the following commands:

- add responder action <actName> <actType>
- add responder policy <polName> <rule> <actName>
- bind responder policy <polName> <priority> <nextExpr> -type <bindPoint> where <bindPoint> represents one of the RADIUS-specific global bind points.
RADIUS Expressions for Responder

In a responder configuration, you can use the following NetScaler expressions to refer to various portions of a RADIUS request.

Identifying the Type of Connection:

- **RADIUS.IS_CLIENT**
  
  Returns TRUE if the connection is a RADIUS client (request) message.

- **RADIUS.IS_SERVER**
  
  Returns TRUE if the connection is a RADIUS server (response) message.

Request Expressions:

- **RADIUS.REQ.CODE**

  Returns the number that corresponds to the RADIUS request type. A derivative of the num_at class. For example, a RADIUS access request would return 1 (one). A RADIUS accounting request would return 4.

- **RADIUS.REQ.LENGTH**

  Returns the length of the RADIUS request, including the header. A derivative of the num_at class.

- **RADIUS.REQ.IDENTIFIER**

  Returns the RADIUS request identifier, a number assigned to each request that allows the request to be matched to the corresponding response. A derivative of the num_at class.

- **RADIUS.REQ.AVP(<AVP Code No>).VALUE**

  Returns the value of first occurrence of this AVP as a string of type text_t.

- **RADIUS.REQ.AVP(<AVP code no>).INSTANCE(instance number)**

  Returns the specified instance of the AVP as a string of type RAVP_t. A specific RADIUS AVP can occur multiple times in a RADIUS message. INSTANCE (0) returns the first instance, INSTANCE (1) returns second instance, and so on, up to sixteen instances.

- **RADIUS.REQ.AVP(<AVP code no>).VALUE(instance number)**

  Returns the value of specified instance of the AVP as a string of type text_t.

- **RADIUS.REQ.AVP(<AVP code no>).COUNT**

  Returns the number of instances of a specific AVP in a RADIUS connection, as an integer.
• RADIUS.REQ.AVP(<AVP code no>).EXISTS

Returns TRUE if the specified type of AVP exists in the message, or FALSE if it does not.

Response Expressions:

RADIUS response expressions are identical to RADIUS request expressions, except that RES replaces REQ.

Typecasts of AVP Values:

The ADC supports expressions to typecast RADIUS AVP values to the text, integer, unsigned integer, long, unsigned long, ipv4 address, ipv6 address, ipv6 prefix and time data types. The syntax is the same as for other NetScaler typecast expressions.

Example:

The ADC supports expressions to typecast RADIUS AVP values to the text, integer, unsigned integer, long, unsigned long, ipv4 address, ipv6 address, ipv6 prefix and time data types. The syntax is the same as for other NetScaler typecast expressions.

1 RADIUS.REQ.AVP(8).VALUE(0).typecast_ip_address_at

AVP Type Expressions:

The NetScaler supports expressions to extract RADIUS AVP values by using the assigned integer codes described in RFC2865 and RFC2866. You can also use text aliases to accomplish the same task. Some examples follow.

• RADIUS.REQ.AVP (1).VALUE or RADIUS.REQ.USERNAME.value
  Extracts the RADIUS user-name value.

• RADIUS.REQ.AVP (4). VALUE or RADIUS.REQ. ACCT_SESSION_ID.value
  Extracts the Acct-Session-ID AVP (code 44) from the message.

• RADIUS.REQ.AVP (26). VALUE or RADIUS.REQ.VENDOR_SPECIFIC.VALUE
  Extracts the vendor-specific value.

The values of most commonly-used RADIUS AVPs can be extracted in the same manner.

RADIUS Bind Points:

Four global bind points are available for policies that contain RADIUS expressions.

• RADIUS_REQ_OVERRIDE
  Priority/override request policy queue.

• RADIUS_REQ_DEFAULT
  Standard request policy queue.
- **RADIUS_RES_OVERRIDE**
  Priority/override response policy queue.

- **RADIUS_RES_DEFAULT**
  Standard response policy queue.

**RADIUS Responder-Specific Expressions:**

- **RADIUS_RESPONDWITH**
  Respond with the specified RADIUS response. The response is created with NetScaler expressions, both RADIUS expressions and any others that are applicable.

- **RADIUS.NEW_ANSWER**
  Sends a new RADIUS answer to the user.

- **RADIUS.NEW_ACCESSREJECT**
  Rejects the RADIUS request.

- **RADIUS.NEW_AVP**
  Adds the specified new AVP to the response.

**Use Cases**

Following are use cases for RADIUS with responder.

**Blocking RADIUS Requests from a Specific Network**

To configure the responder feature to block authentication requests from a specific network, begin by creating a responder action that rejects requests. Use the action in a policy that selects requests from the networks that you want to block. Bind the responder policy to a RADIUS-specific global bind point, specifying:

- The priority
- END as the nextExpr value, to ensure that policy evaluation stops when this policy is matched
- RADIUS_REQ_OVERRIDE as the queue to which you assign the policy, so that it is evaluated before policies assigned to the default queue

To configure Responder to block logons from a specific network**

- add responder action <actName> <actType>
- add responder policy <polName> <rule> <actName>
- bind responder global <polName> <priority> <nextExpr> -type <bindPoint>
**Example:**

1. `> add responder action rspActRadiusReject respondwith radius.
   new_accessreject
   Done
2. `> add responder policy rspPolRadiusReject client.ip.src.in_subnet
   (10.224.85.0/24) rspActRadiusReject
   Done
3. `> bind responder global rspPolRadiusReject 1 END -type
   RADIUS_REQ_OVERRIDE

**DNS Support for the Responder Feature**

September 24, 2018

You can configure the responder feature to respond to DNS requests as it does to HTTP and TCP requests. For example, you could configure it to send DNS responses over UDP and ensure that the DNS requests from the client are sent over TCP. A number of NetScaler expressions support examination of the DNS header in the request. These expressions examine specific header fields and send an appropriate response.

- **DNS Expressions.** In a responder configuration, you can use the following NetScaler expressions to refer to various portions of a DNS request:

<table>
<thead>
<tr>
<th>Expressions</th>
<th>Descriptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>DNS.NEW_RESPONSE</td>
<td>Creates a new empty DNS response based on the request.</td>
</tr>
<tr>
<td>DNS.NEW_RESPONSE &lt;AA, TC, rcode&gt;</td>
<td>Creates a new DNS response based on the specified parameters.</td>
</tr>
</tbody>
</table>

- **DNS Bind Points.** The following global bind points are available for policies that contain DNS expressions:

<table>
<thead>
<tr>
<th>Bind Points</th>
<th>Descriptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>DNS_REQ_OVERRIDE</td>
<td>Priority/override request policy queue.</td>
</tr>
<tr>
<td>DNS_REQ_DEFAULT</td>
<td>Standard request policy queue.</td>
</tr>
</tbody>
</table>
In addition to the default bind points, you can create policy labels of type DNS and bind DNS policies to them.

**Configuring Responder Policies for DNS**

The following procedure uses the NetScaler command line to configure a responder action and policy and bind the policy to a responder-specific global bind point.

To configure Responder to respond to a DNS request:

At the command prompt, type the following commands:

1. `add responder action <actName> <actType>`
   
   For `<actName>`, substitute a name for your new action. The name can be 1 to 127 characters in length, and can contain letters, numbers, hyphen (-), and underscore (_) symbols. For `<actType>`, substitute a responder action type, `respondWith`.

2. `add responder policy <polName> <rule> <actName>`
   
   For `<polName>`, substitute a name for your new policy. For `<actName>`, the name can be 1 to 127 characters in length, and can contain letters, numbers, hyphen (-), and underscore (_) symbols. For `<actName>`, substitute the name of the action that you just created.

3. `bind responder policy <polName> <priority> <nextExpr> -type <bindPoint>`
   
   For `<bindPoint>`, specify one of the responder-specific global bind points. For `<polName>`, substitute the name of the policy that you just created. For `<priority>`, specify the priority of the policy.

**Sample configuration - Enforce all DNS request over TCP:**

To enforce all the DNS requests over TCP, create a responder action that will set the TC bit and rcode as NOERROR.

```
> add responder action resp_act_set_tc_bit respondwith DNS.NEW_RESPONSE (true, true, NOERROR)
Done
```

```
> add responder policy enforce_tcp dns.REQ.TRANSPORT.EQ(udp)
  resp_act_set_tc_bit
Done
```

```
>bind lb vserver dns_udp -policyName enforce_tcp -type request -priority 100
Done
```
Troubleshooting

September 24, 2018

If the responder feature does not work as expected after you have configured it, you can use some common tools to access NetScaler resources and diagnose the problem.

Resources for Troubleshooting

For best results, use the following resources to troubleshoot an integrated cache issue on a NetScaler appliance:

- The ns.conf file
- The relevant trace files from the client and the NetScaler appliance

In addition to the above resources, the following tools expedite troubleshooting:

- The iehttpheaders or a similar utility
- The Wireshark application customized for the NetScaler trace files

Troubleshooting Responder Issues

- **Issue**

  The Responder feature is configured, but the responder action is not working.

  **Resolution**

  - Verify that the feature is enabled.
  - Check the hit counters of any of the policies to see if the counters are getting incremented.
  - Verify that the policies and actions are configured correctly.
  - Verify that the actions and policies are bound appropriately.
  - Record the packet traces on the client and the NetScaler appliance, and analyze them to get some pointer to the issue.
  - Record the iehttpHeaters packet traces on the client and verify the HTTP requests and responses to get some pointer to the issue.

- **Issue**

  You need to create a maintenance page.

  **Resolution**

  1. Configure the services and virtual Server.
  2. Configure a backup virtual server with a service bound to it. This ensures that the status of the Web site is always displayed as UP.
3. Configure the primary virtual server to use the backup virtual server as a backup.

4. Create a responder action with an appropriate target. Following is an example for your reference:

   ```
   add responder action sorry_page respondwith q("HTTP/1.0 200 OK" +"\r\n\r\n" +
   "<html><body>Sorry, this page is not available</body></html>" + "\r\n")
   ```

5. Create a responder policy and bind the action to it.

6. Bind the responder policy to the backup virtual Server.

---

**Rewrite**

September 24, 2018

May 24, 2018

**Warning**

Responder and Rewrite filters are deprecated and as an alternative, Citrix recommends you to use filters using Advanced policy infrastructure.

Rewrite refers to the rewriting of some information in the requests or responses handled by the NetScaler appliance. Rewriting can help in providing access to the requested content without exposing unnecessary details about the Web site’s actual configuration. A few situations in which the rewrite feature is useful are described below:

- To improve security, the NetScaler can rewrite all the `http://` links to `https://` in the response body.
- In the SSL offload deployment, the insecure links in the response have to be converted into secure links. Using the rewrite option, you can rewrite all the `http://` links to `https://` for making sure that the outgoing responses from NetScaler to the client have the secured links.
- If a Web site has to show an error page, you can show a custom error page instead of the default `404 Error page`. For example, if you show the home page or site map of the Web site instead of an error page, the visitor remains on the site instead of moving away from the Web site.
- If you want to launch a new Web site, but use the old URL, you can use the Rewrite option.
- When a topic in a site has a complicated URL, you can rewrite it with a simple, easy-to-remember URL (also referred to as ‘cool URL’).
- You can append the default page name to the URL of a Web site. For example, if the default page of a company’s Web site is `http://www.abc.com/index.php`, when the user types ‘abc.com’ in the address bar of the browser, you can rewrite the URL to ‘abc.com/index.php’.

When you enable the rewrite feature, NetScaler can modify the headers and body of HTTP requests and responses.
To rewrite HTTP requests and responses, you can use protocol-aware NetScaler policy expressions in the rewrite policies you configure. The virtual servers that manage the HTTP requests and responses must be of type HTTP or SSL. In HTTP traffic, you can take the following actions:

- Modify the URL of a request
- Add, modify or delete headers
- Add, replace, or delete any specific string within the body or headers.

To rewrite TCP payloads, consider the payload as a raw stream of bytes. Each of the virtual servers that managing the TCP connections must be of type TCP or SSL_TCP. The term TCP rewrite is used to refer to the rewrite of TCP payloads that are not HTTP data. In TCP traffic, you can add, modify, or delete any part of the TCP payload.

For examples to use the rewrite feature, see Rewrite Action and Policy Examples.

Comparison between Rewrite and Responder options

The main difference between the rewrite feature and the responder feature is as follows:

Responder cannot be used for response or server-based expressions. Responder can be used only for the following scenarios depending on client parameters:

- Redirecting a http request to new Web sites or Web pages
- Responding with some custom response
- Dropping or resetting a connection at request level

In case of a responder policy, the NetScaler examines the request from the client, takes action according to the applicable policies, sends the response to the client, and closes the connection with the client.

In case of a rewrite policy, the NetScaler examines the request from the client or response from the server, takes action according to the applicable policies, and forwards the traffic to the client or the server.

In general, it is recommended to use responder if you want the NetScaler to reset or drop a connection based on a client or request-based parameter. Use responder to redirect traffic, or respond with custom messages. Use rewrite for manipulating data on HTTP requests and responses.

How rewrite works

January 6, 2019
A rewrite policy consists of a rule and action. The rule determines the traffic on which rewrite is applied and the action determines the action to be taken by the NetScaler. You can define multiple rewrite policies. For each policy, specify the bind point and priority.

A bind point refers to a point in the traffic flow at which the NetScaler examines the traffic to verify whether any rewrite policy can be applied to it. You can bind a policy to a specific load balancing or content switching virtual server, or make the policy global if you want the policy to be applied to the entire traffic handled by the NetScaler. These policies are referred to as global policies.

In addition to the user-defined policies, the NetScaler has some default policies. You cannot modify or delete a default policy.

For evaluating the policies, NetScaler follows the order mentioned below:

- Global policies
- Policies bound to specific virtual servers
- Default policies

Note: NetScaler can apply a rewrite policy only when it is bound to a point.

NetScaler implements the rewrite feature in the following steps:

- The NetScaler appliance checks for global policies and then checks for policies at individual bind points.

- If multiple policies are bound to a bind point, the NetScaler evaluates the policies in the order of their priority. The policy with the highest priority is evaluated first. After evaluating each policy, if the policy is evaluated to TRUE (the traffic matches the rule), it adds the action associated with the policy to a list of actions to be performed. A match occurs when the characteristics specified in the policy rule match the characteristics of the request or response being evaluated.

- For any policy, in addition to the action, you can specify the policy that should be evaluated after the current policy is evaluated. This policy is referred to as the ‘Go to Expression’. For any policy, if a Go to Expression (gotoPriorityExpr) is specified, the NetScaler evaluates the Go to Expression policy; it ignores policy with the next highest priority.

  You can specify the priority of the policy to indicate the Go to Expression policy; you cannot use the name of the policy. If you want the NetScaler to stop evaluating other policies after evaluating a particular policy, you can set the Go to Expression to ‘END’.

- After all the policies are evaluated or when a policy has the Go to Expression set as END, the NetScaler starts performing the actions according to the list of actions.

For more information about configuring rewrite policies, see “Configuring a Rewrite Policy” and about binding rewrite policies, see “Binding a Rewrite Policy.”

The following figure illustrates how NetScaler processes a request or response when the rewrite feature is used.
Figure 1. The Rewrite Process

Policy Evaluation

The policy with the highest priority is evaluated first. NetScaler does not stop the evaluation of rewrite policies when it finds a match; it evaluates all the rewrite policies configured on the NetScaler.

- If a policy evaluates to TRUE, the NetScaler follows the procedure below:
  - If the policy has the Go to Expression set to END, the NetScaler stops evaluating all the other policies and starts performing the rewrite.
  - The gotoPriorityExpression can be set to ‘NEXT’, ‘END’, some integer or ‘INVOCATION_LIST’. The value determines the policy with the next priority. The following table shows the action taken by NetScaler for each value of the expression.

| | |
| ———————————– | ———————————————————————– |
| Value of the expression | Action |
| NEXT | Policy with the next priority gets evaluated. |
| END | Evaluation of policies stops. |
| <an integer> | Policy with specified priority gets evaluated. |
| INVOCATION_LIST | Goto NEXT or END is applied based on the result of the invocation list. |

- If a policy evaluates to FALSE, the NetScaler continues the evaluation in the order of priority.
- If a policy evaluates to UNDEFINED (cannot be evaluated on the received traffic due to an error), the NetScaler performs the action assigned to the UNDEFINED condition (referred to as undefinedAction) and stops further evaluation of polices.

The NetScaler starts the actual rewriting only after the evaluation is complete. It refers to the list of actions identified by policies that are evaluated to TRUE, and starts the rewriting. After implementing all the actions in the list, the NetScaler forwards the traffic as required.

Note: Ensure that the policies do not specify conflicting or overlapping actions on the same part of the HTTP header or body, or TCP payload. When such a conflict occurs, the NetScaler encounters an undefined situation and aborts the rewrite.

Rewrite Actions

On the NetScaler appliance, specify the actions to be taken such as adding, replacing, or deleting text within the body, or adding, modifying or deleting headers, or any changes in the TCP payload as rewrite actions. For more information about rewrite actions, see Configuring a Rewrite Action.

The following table describes the steps the NetScaler can take when a policy evaluates to TRUE.
<table>
<thead>
<tr>
<th>Action</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Insert</td>
<td>The rewrite action specified for the policy is carried out.</td>
</tr>
<tr>
<td>NOREWRITE</td>
<td>The request or response is not rewritten. NetScaler forwards the traffic without rewriting any part of the message.</td>
</tr>
<tr>
<td>RESET</td>
<td>The connection is aborted at the TCP level.</td>
</tr>
<tr>
<td>DROP</td>
<td>The message is dropped.</td>
</tr>
</tbody>
</table>

Note: For any policy, you can configure the undefaction (action to be taken when the policy evaluates to UNDEFINED) as NOREWRITE, RESET, or DROP.

To use the Rewrite feature, take the following steps:

- Enable the feature on the NetScaler.
- Define rewrite actions.
- Define rewrite policies.
- Bind the policies to a bind point to bring a policy into effect.

**Enabling the rewrite feature**

September 24, 2018

Enable the rewrite feature on the NetScaler appliance if you want to rewrite the HTTP or TCP requests or responses. If the feature is enabled, NetScaler takes rewrite action according to the specified policies. For more information, see How rewrite works.

**To enable the rewrite feature by using the command line interface**

At the command prompt, type the following commands to enable the rewrite feature and verify the configuration:

- `enable ns feature REWRITE`
- `show ns feature`

**Example:**
To enable the rewrite feature by using the GUI

1. <In the navigation pane, click System, and then click Settings.
2. <In the details pane, under Modes and Features, click Configure basic features.
3. <In the Configure Basic Features dialog box, select the Rewrite check box, and then click OK.
4. <In the Enable/Disable Feature(s) dialog box, click Yes. A message appears in the status bar, stating that the selected feature was enabled.

Configuring a Rewrite Action

January 6, 2019

Warning

The Pattern function in a rewrite action is deprecated from NetScaler 12.0 build 56.20 onwards and as an alternative, Citrix recommends you to use the Search rewrite action parameter.

After enabling the rewrite feature, you need to configure one or more actions unless a built-in rewrite action is sufficient. All of the built-in actions have names beginning with the string ns_cvpn, followed by a string of letters and underscore characters. Built-in actions perform useful and complex tasks such as decoding parts of a clientless VPN request or response or modifying JavaScript or XML data. The built-in actions can be viewed, enabled, and disabled, but cannot be modified or deleted.

Target expressions in actions for TCP rewrite must begin with one of the following expression prefixes:
• `<CLIENT.TCP.PAYLOAD>`. For rewriting TCP payloads in client requests. For example, `CLIENT.TCP.PAYLOAD(10000).AFTER_STR("string1")`.

• `<SERVER.TCP.PAYLOAD>`. For rewriting TCP payloads in server responses. For example, `SERVER.TCP.PAYLOAD(1000).B64DECODE.BETWEEN("string1","string2")`.

You can use all types of existing string manipulation functions with these prefixes to identify the strings that you want to rewrite. To configure a rewrite action, you assign it a name, specify an action type, and add one or more arguments specifying additional data. The following table describes the action types and the arguments you use with them.

Note: Action types that can be used only for HTTP rewrite are identified in the **Rewrite Action Type** column.

See the **Rewrite Action Types and their Arguments** table.

---

**To create a new rewrite action by using the command line interface**

At the command prompt, type the following commands to create a new rewrite action and verify the configuration:

- add rewrite action <name> <type> <target> ["stringBuilderExpr"] [([- pattern <expression> | -patset <string>]) [-bypassSafetyCheck (YES|NO)]]
- show rewrite action <name>

**Example 1. Inserting an HTTP Header With the Client IP:**

```
> add rewrite action insertact INSERT_HTTP_HEADER "client-IP" CLIENT.IP .SRC
Done

> show rewrite action insertact

Name: insertact
Operation: insert_http_header Target: Client-IP
Value: CLIENT.IP .SRC
BypassSafetyCheck: NO
Hits: 0
Undef Hits: 0
Action Reference Count: 0
Done
```

**Example 2. Replacing Strings in a TCP Payload (TCP Rewrite):**

```
> add rewrite action client_tcp_payload_replace_all REPLACE_ALL
'client.tcp.payload(1000) "new-string"' -search text("old-string")
```
To modify an existing rewrite action by using the command line interface

At the command prompt, type the following commands to modify an existing rewrite action and verify the configuration:

```
<set rewrite action <name> [-target <string>] [-stringBuilderExpr <string>] [-pattern <expression>] [-patset <string>] [-bypassSafetyCheck (YES NO)]
```

```
•
• <show rewrite action <name>
```

**Example:**

```
> set rewrite action insertact -target ”Client-IP”
Done
> show rewrite action insertact
Done
```

```
Name: insertact
Operation: insert_http_header Target:Client-IP
Value:CLIENT.IP.SRC
BypassSafetyCheck : NO
Hits: 0
Undef Hits: 0
Action Reference Count: 0
```
To remove a rewrite action by using the command line interface

At the command prompt, type the following commands to remove a rewrite action:
rm rewrite action <name>

Example:

```
1 > rm rewrite action insertact
2 Done
```

To configure a rewrite action by using the GUI

1. Navigate to AppExpert > Rewrite > Actions.
2. In the details pane, do one of the following:
   - To create a new action, click Add.
   - To modify an existing action, select the action, and then click Open.
3. Click Create or OK. A message appears in the status bar, stating that the Action has been configured successfully.
4. Repeat steps 2 through 4 to create or modify as many rewrite actions as you wish.
5. Click Close.

To add an expression by using the Add Expression dialog box

1. In the Create Rewrite Action or Configure Rewrite Action dialog box, under the text area for the type argument you want to enter, click Add.
2. In the Add Expression dialog box, in the first list box choose the first term for your expression.
   - HTTP
     The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol.
   - SYS
     The protected Web site(s). Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.
   - CLIENT
     The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.
When you make your choice, the rightmost list box lists appropriate terms for the next part of your expression.

3. In the second list box, choose the second term for your expression. The choices depend upon which choice you made in the previous step, and are appropriate to the context. After you make your second choice, the Help window below the Construct Expression window (which was blank) displays help describing the purpose and use of the term you just chose.

4. Continue choosing terms from the list boxes that appear to the right of the previous list box, or typing strings or numbers in the text boxes that appear to prompt you to enter a value, until your expression is finished.

For more information about the PI expressions language and creating expressions for responder policies, see “Policies and Expressions.”

If you want to test the effect of a rewrite action when used on sample HTTP data, you can use the Rewrite Expression Evaluator.

Note: The Rewrite Expression Evaluator is only available in the GUI. There is no NetScaler command line version.

To evaluate a rewrite action by using the Rewrite Action Evaluator dialog box

1. In the Rewrite Actions details pane, select the rewrite action that you want to evaluate, and then click Evaluate.

2. In the Rewrite Expression Evaluator dialog box, specify values for the following parameters. (An asterisk indicates a required parameter.)
   - Rewrite Action*—If the rewrite action you want to evaluate is not already selected, select it from the drop-down list. After you select a Rewrite action, the Details section displays the details of the selected Rewrite action.
   - New*—Select New to open the Create Rewrite Action dialog box and create a new rewrite action.
   - Modify*—Select Modify to open the Configure Rewrite Action dialog box and modify the selected rewrite action.
   - Flow Type*—Specifies whether to test the selected rewrite action with HTTP Request data or HTTP Response data. The default is Request. If you want to test with Response data, select Response.
   - HTTP Request/Response Data*—Provides a space for you to provide the HTTP data that the Rewrite Action Evaluator will use for testing. You can paste the data directly into the window, or click Sample to insert some sample HTTP headers.
   - Show end-of-line—Specifies whether to show UNIX-style end-of-line characters (\n) at the end of each line of sample HTTP data.
• Sample—Inserts sample HTTP data into the HTTP Request/Response Data window. You can choose either GET or POST data.
• Browse—Opens a local browse window so that you can choose a file containing sample HTTP data from a local or network location.
• Clear—Clears the current sample HTTP data from the HTTP Request/Response Data window.

3. Click Evaluate. The Rewrite Action Evaluator evaluates the effect of the Rewrite action on the sample data that you chose, and displays the results as modified by the selected Rewrite action in the Results window. Additions and deletions are highlighted as indicated in the legend in the lower left-hand corner of the dialog box.

4. Continue evaluating Rewrite actions until you have determined that all of your actions have the effect that you wanted.
   • You can modify the selected rewrite action and test the modified version by clicking Modify to open the Configure Rewrite Action dialog box, making and saving your changes, and then clicking Evaluate again.
   • You can evaluate a different rewrite action using the same request or response data by selecting it from the Rewrite Action drop-down list, and then clicking Evaluate again.

5. Click Close to close the Rewrite Expression Evaluator and return to the Rewrite Actions pane.

   To delete a rewrite action, select the rewrite action you want to delete, then click Remove and, when prompted, confirm your choice by clicking OK.

**Configuring a Rewrite Policy**

September 24, 2018

After you create any needed rewrite action(s), you must create at least one rewrite policy to select the requests that you want the NetScaler appliance to rewrite.

A rewrite policy consists of a rule, which itself consists of one or more expressions, and an associated action that is performed if a request or response matches the rule. Policy rules for evaluating HTTP requests and responses can be based on almost any part of a request or response.

Even though you cannot use TCP rewrite actions to rewrite data other than the TCP payload, you can base the policy rules for TCP rewrite policies on the information in the transport layer and the layers below the transport layer.

If a configured rule matches a request or response, the corresponding policy is triggered and the action associated with it is carried out.
Note: You can use either the command line interface or the GUI to create and configure rewrite policies. Users who are not thoroughly familiar with the command line interface and the NetScaler Policy expression language will usually find using the GUI much easier.

To add a new rewrite policy by using the command line interface

At the command prompt, type the following commands to add a new rewrite policy and verify the configuration:

- `<add rewrite policy <name> <expression> <action> [<undefaction>]>
- `<show rewrite policy <name>

Example 1. Rewriting HTTP Content:

```
> add rewrite policy policyNew "HTTP.RES.IS_VALID" insertact NOREWRITE
Done
> show rewrite policy policyNew
  Name: policyNew
  Rule: HTTP.RES.IS_VALID
  RewriteAction: insertact
  UndefAction: NOREWRITE
  Hits: 0
  Undef Hits: 0
Done
```

Example 2. Rewriting a TCP Payload (TCP Rewrite):

```
> add rewrite policy client_tcp_payload_policy CLIENT.IP.SRC.EQ (172.168.12.232) client_tcp_payload_replace_all
Done
> show rewrite policy client_tcp_payload_policy
  Name: client_tcp_payload_policy
  Rule: CLIENT.IP.SRC.EQ(172.168.12.232)
  RewriteAction: client_tcp_payload_replace_all
  UndefAction: Use Global
  LogAction: Use Global
  Hits: 0
  Undef Hits: 0
Done
```
**To modify an existing rewrite policy by using the command line interface**

At the command prompt, type the following commands to modify an existing rewrite policy and verify the configuration:

- `<set rewrite policy <name> -rule <expression> -action <action> [undefaction]>`
- `<show rewrite policy <name>`

**Example:**

```
1 > set rewrite policy policyNew -rule "HTTP.RES.IS_VALID" -action insertaction
2   Done
3
4 > show rewrite policy policyNew
5   Name: policyNew
6   Rule: HTTP.RES.IS_VALID
7   RewriteAction: insertaction
8   UndefAction: NOREWRITE
9   Hits: 0
10  Undef Hits: 0
11
12 Done
```

**To remove a rewrite policy by using the command line interface**

At the command prompt, type the following command to remove a rewrite policy:

`rm rewrite policy <name>`

**Example:**

```
1 > rm rewrite policy policyNew
2   Done
```

**To configure a rewrite policy by using the GUI**

2. In the details pane, do one of the following:
   - To create a new policy, click Add.
   - To modify an existing policy, select the policy, and then click Open.
3. Click Create or OK. A message appears in the status bar, stating that the Policy has been configured successfully.
4. Repeat steps 2 through 4 to create or modify as many rewrite actions as you wish.

5. Click Close. To delete a rewrite policy, select the rewrite policy you want to delete, then click Remove and, when prompted, confirm your choice by clicking OK.

**Binding a Rewrite Policy**

September 24, 2018

After creating a rewrite policy, you must bind it to put it into effect. You can bind your policy to Global if you want to apply it to all traffic that passes through your NetScaler, or you can bind your policy to a specific virtual server or bind point to direct only that virtual server or bind point’s incoming traffic to that policy. If an incoming request matches a rewrite policy, the action associated with that policy is carried out.

Rewrite policies for evaluating HTTP requests and responses can be bound to virtual servers of type HTTP or SSL, or they can be bound to the
REQ_OVERRIDE,
REQ_DEFAULT,
RES_OVERRIDE, and
RES_DEFAULT bind points. Rewrite policies for TCP rewrite can be bound only to virtual servers of type
TCP or
SSL_TCP, or to the
OTHERTCP_REQ_OVERRIDE,
OTHERTCP_REQ_DEFAULT,
OTHERTCP_RES_OVERRIDE, and
OTHERTCP_RES_DEFAULT bind points.

Note: The term
OTHERTCP is used in the context of the NetScaler appliance to refer to all TCP or
SSL_TCP requests and responses that you want to treat as a raw stream of bytes regardless of the protocols that the TCP packets encapsulate.

When you bind a policy, you assign it a priority. The priority determines the order in which the policies you define are evaluated. You can set the priority to any positive integer.

In the NetScaler operating system, policy priorities work in reverse order - the higher the number, the lower the priority. For example, if you have three policies with priorities of 10, 100, and 1000, the policy assigned a priority of 10 is applied first, then the policy assigned a priority of 100, and finally the policy assigned an order of 1000.
Unlike most other features in the NetScaler operating system, the rewrite feature continues to evaluate and implement policies after a request matches a policy. However, the effect of a particular action policy on a request or response will often be different depending on whether it is performed before or after another action. Priority is important to get the results you intended.

You can leave yourself plenty of room to add other policies in any order, and still set them to evaluate in the order you want, by setting priorities with intervals of 50 or 100 between each policy when you bind it. If you do this, you can add additional policies at any time without having to reassign the priority of an existing policy.

When binding a rewrite policy, you also have the option of assigning a goto expression (gotoPriorityExpression) to the policy. A goto expression can be any positive integer that matches the priority assigned to a different policy that has a higher priority than the policy that contains the goto expression. If you assign a goto expression to a policy, and a request or response matches the policy, the NetScaler will immediately go to the policy whose priority matches the goto expression. It will skip over any policies with priority numbers that are lower than that of the current policy, but higher than the priority number of the goto expression, and not evaluate those policies.

**To globally bind a rewrite policy by using the command line interface**

At the command prompt, type the following commands to globally bind a rewrite policy and verify the configuration:

- bind rewrite global <policyName> <priority> [gotoPriorityExpression] [-type <type>] [-invoke (labelType <labelName>)]
- show rewrite global

**Example:**

```
> bind rewrite global policyNew 10
Done

> show rewrite global
1) Global bindpoint: RES_DEFAULT
   Number of bound policies: 1

2) Global bindpoint: REQ_OVERRIDE
   Number of bound policies: 1

Done
```
To bind rewrite policy to a specific virtual server by using the command line interface

At the command prompt, type the following commands to bind rewrite policy to a specific virtual server and verify the configuration:

```
bind lb vserver <name>@ (<serviceName>@ [-weight <positive_integer>])
[policyName <string>@ [-priority <positive_integer>] [-gotoPriorityExpression <expression>] [-type (REQUEST | RESPONSE)] [-invoke (<labelType> <labelName>))]...

•
• show lb vserver <name>
```

**Example:**

```
1> bind lb vserver lbvip -policyName ns_cmp_msapp -priority 50
Done
2>
3> show lb vserver lbvip
4  lbvip (8.7.6.6:80) - HTTP        Type: ADDRESS
5    State: DOWN
6    Last state change was at Wed Jul 15 05:54:24 2009 (+226 ms)

```
To bind a rewrite policy to a bind point by using the GUI

2. In the details pane, select the rewrite policy you want to globally bind, and then click Policy Manager.
3. In the Rewrite Policy Manager dialog box, in the Bind Points menu, do one of the following:
   a) If you want to configure bindings for HTTP rewrite policies, click HTTP, and then click either Request or Response, depending on whether you want to configure request-based rewrite policies or response-based rewrite policies.
   b) If you want to configure bindings for TCP rewrite policies, click TCP, and then click either Client or Server, depending on whether you want to configure client-side TCP rewrite policies or server-side TCP rewrite policies.
4. Click the bind point to which you want to bind the rewrite policy. The Rewrite Policy Manager dialog box displays all the rewrite policies that are bound to the selected bind point.
5. Click Insert Policy to insert a new row and display a drop-down list with all available, unbound rewrite policies.
6. Click the policy you want to bind to the bind point. The policy is inserted into the list of rewrite policies bound to the bind point.
7. In the Priority column, you can change the priority to any positive integer. For more information about this parameter, see priority in “Parameters for binding a rewrite policy.”
8. If you want to skip over policies and go directly to a specific policy in the event that the current policy is matched, change the value in the Goto Expression column to equal the priority of the next policy to be applied. For more information about this parameter, see gotoPriorityExpression in “Parameters for binding a rewrite policy.”
9. To modify a policy, click the policy, and then click Modify Policy.
10. To unbind a policy, click the policy, and then click Unbind Policy.
11. To modify an action, in the Action column, click the action you want to modify, and then click Modify Action.
12. To modify an invoke label, in the Invoke column, click the invoke label you want to modify, and then click Modify Invoke Label.
13. To regenerate the priorities of all the policies that are bound to the bind point you are currently configuring, click Regenerate Priorities. The policies retain their existing priorities relative to the other policies, but the priorities are renumbered in multiples of ten.
14. Click Apply Changes.
15. Click Close. A message appears in the status bar, stating that the Policy has been configured successfully.

To bind a rewrite policy to a specific virtual server by using the GUI

2. In the details pane list of virtual servers, select the virtual server to which you want to bind the rewrite policy, and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, select the Policies tab. All policies configured on your NetScaler appear on the list.
4. Select the check box next to the name of the policy you want to bind to this virtual server.
5. Click OK. A message appears in the status bar, stating that the Policy has been configured successfully.

Configuring Rewrite Policy Labels

September 24, 2018

If you want to build a more complex policy structure than is supported by single policies, you can create policy labels and then bind them as you would policies. A policy label is a user-defined point to which policies are bound. When a policy label is invoked, all the policies bound to it are evaluated in the order of the priority you configured. A policy label can include one or multiple policies, each of which can be assigned its own result. A match on one policy in the policy label can result in proceeding to the next policy, invoking a different policy label or appropriate resource, or an immediate end to policy evaluation and the return of control to the policy that invoked the policy label.

A rewrite policy label consists of a name, a transform name that describes the type of policy included in the policy label, and a list of policies bound to the policy label. Each policy that is bound to the policy label contains all of the elements described in Configuring a Rewrite Policy.

Note: You can use either the command line interface or the GUI to create and configure rewrite policy labels. Users who are not thoroughly familiar with the command line interface and the NetScaler Policy Infrastructure (PI) language will usually find using the GUI much easier.

To configure a rewrite policy label by using the command line interface

To add a new rewrite policy label, at the command prompt, type the following command:

```
add rewrite policylabel <labelName> <transform>
```

For example, to add a rewrite policy label named polLabelHTTPResponses to group all policies that work on HTTP responses, you would type the following:

```
add rewrite policylabel polLabelHTTPResponses http_res
```

To modify an existing rewrite policy label, at the NetScaler command prompt, type the following command:

```
set rewrite policy <name> <transform>
```
Note: The set rewrite policy command takes the same options as the add rewrite policy command.

To remove a rewrite policy label, at the NetScaler command prompt, type the following command:

```
rm rewrite policy<name>
```

For example, to remove a rewrite policy label named polLabelHTTPResponses, you would type the following:

```
rm rewrite policy polLabelHTTPResponses
```

**To configure a rewrite policy label by using the GUI**

2. In the details pane, do one of the following:
   - To create a new policy label, click Add.
   - To modify an existing policy label, select the policy, and then click Open.
3. Add or remove policies from the list that is bound to the policy label.
   - To add a policy to the list, click Insert Policy, and choose a policy from the drop-down list. You can create a new policy and add it to the list by choosing New Policy in the list, and following the instructions in “Configuring a Rewrite Policy.”
   - To remove a policy from the list, select that policy, and then click Unbind Policy.
4. Modify the priority of each policy by editing the number in the Priority column.
   You can also automatically renumber policies by clicking Regenerate Priorities.
5. Click Create or OK, and then click Close.

To remove a policy label, select it, and then click Remove. To rename a policy label, select it and then click Rename. Edit the name of the policy, and then click OK to save your changes.

**Configuring the Default Rewrite Action**

September 24, 2018

An undefined event is triggered when the NetScaler cannot evaluate a policy, usually because it detects a logical or other error in the policy or an error condition on the NetScaler. When the rewrite policy evaluation results in an error, the specified undefined action is carried out. Undefined actions configured at the rewrite policy level are carried out before a globally configured undefined action.

The NetScaler supports following three types of undefined actions:
• undefAction NOREWRITE

Aborts rewrite processing, but does not alter the packet flow. This means that the NetScaler continues to process requests and responses that do not match any rewrite policy, and eventually forwards them to the requested URL unless another feature intervenes and blocks or redirects the request. This action is appropriate for normal requests to your Web servers, and is the default setting.

• undefAction RESET

Resets the client connection. This means that the NetScaler tells the client that it must re-establish its session with the Web server. This action is appropriate for repeat requests for Web pages that do not exist, or for connections that might be attempts to hack or probe your protected Web site(s).

• undefAction DROP

Silently drops the request without responding to the client in any way. This means that the NetScaler simply discards the connection without responding to the client. This action is appropriate for requests that appear to be part of a DDoS attack or another sustained attack on your servers.

Note: Undefined events can be triggered for both request and response flow specific policies.

To configure the default action by using the command line interface

At the command prompt, type the following commands to configure the default action and verify the configuration:

```
<set rewrite param
-undefAction ( NOREWRITE
RESET
DROP )
```

```
Example:

1  > set rewrite param -undefAction NOREWRITE
2    Done
3  > show rewrite param
4      Action Name: NOREWRITE
5    Done
```
To configure the default action by using the GUI

1. Navigate to AppExpert > Rewrite.
2. In the details pane, under Rewrite Overview, click the Change Rewrite Settings link. The Set Rewrite Params dialog box appears.
3. Under Global Undefined-Result Action, select an option as follows:
   - NoRewrite—NOREWRITE
   - Reset—RESET
   - Drop—DROP
4. Click OK. The global undefined action is set to the value you chose.

Bypassing the Safety Check

September 24, 2018

When you create a rewrite action, the NetScaler verifies that the expression you used to create the action is safe. Expressions created by the NetScaler from run-time data, such as URLs contained in HTTP requests, can cause unexpected errors. The NetScaler reports expressions that cause such errors as unsafe expressions.

In some cases, the expressions may be safe. For example, the NetScaler cannot validate an expression that contains a URL that does not resolve, even if the URL does not resolve because the Web server is temporarily unavailable. You can manually bypass the Safety Check to allow these expressions.

To bypass the safety check by using the command line interface

At the command prompt, type the following commands to bypass the safety check and verify the configuration:

- `<set rewrite action <name> -bypassSafetyCheck YES`
- `<show rewrite action <name>`

Example:

```
1 > set rewrite action insertact -bypassSafetyCheck YES
2 Done
3 > show rewrite action insertact
4
5     Name: insertact
6     Operation: insert_http_header   Target:Client-IP
7     Value:CLIENT.IP.SRC
8     BypassSafetyCheck : YES
9     Hits: 0
```
To bypass safety check by using the GUI

1. Navigate to AppExpert > Rewrite > Actions.
2. In the details pane, select the rewrite action to be exempted from the safety check, and then click Open.
3. In the Configure Rewrite Action dialog box, select the Bypass Safety Check check box.
4. Click OK.

Rewrite Action and Policy Examples

September 24, 2018

The examples in this section demonstrate how to configure rewrite to perform various useful tasks. The examples occur in the server room of Example Manufacturing Inc., a mid-sized manufacturing company that uses its Web site to manage a considerable portion of its sales, deliveries, and customer support.

Example Manufacturing has two domains: example.com for its Web site and email to customers, and example.net for its intranet. Customers use the Example Web site to place orders, request quotes, research products, and contact customer service and technical support.

As an important part of Example's revenue stream, the Web site must respond quickly and keep customer data confidential. Example therefore has several Web servers and uses NetScaler appliances to balance the Web site load and manage traffic to and from its Web servers.

The Example system administrators use the rewrite features to perform the following tasks:

**Example 1: Delete old X-Forwarded-For and Client-IP Headers**

Example Inc. removes old X-Forwarded-For and Client-IP HTTP headers from incoming requests.

**Example 2: Adding a Local Client-IP Header**

Example Inc. adds a new, local Client-IP header to incoming requests.

**Example 3: Tagging Secure and Insecure Connections**

Example Inc. tags incoming requests with a header that indicates whether the connection is a secure connection.

**Example 4: Mask the HTTP Server Type**
Example Inc. modifies the HTTP Server: header so that unauthorized users and malicious code cannot use that header to determine the HTTP server software it uses.

**Example 5: Redirect an External URL to an Internal URL**

Example Inc. hides information about the actual names of its Web servers and the configuration of its server room from users, to make URLs on its Web site shorter and easier to remember and to improve security on its site.

**Example 6: Migrating Apache Rewrite Module Rules**

Example Inc. moved its Apache rewrite rules to a NetScaler appliance, translating the Apache PERL-based script syntax to the NetScaler rewrite rule syntax.

**Example 7: Marketing Keyword Redirection**

The marketing department at Example Inc. sets up simplified URLs for certain predefined keyword searches on the company's Web site.

**Example 8: Redirect Queries to the Queried Server.**

Example Inc. redirects certain query requests to the appropriate server.

**Example 9: Home Page Redirection**

Example Inc. recently acquired a smaller competitor, and it now redirects requests to the acquired company's home page to a page on its own Web site.

**Example 10: Policy-based RSA Encryption**

Example Inc. encrypt HTTP predefined and user-defined header or body content by using PEM RSA public key.

Each of these tasks requires that the system administrators create rewrite actions and policies and bind them to a valid bind point on the NetScaler.

---

**Example 1: Delete Old X-Forwarded-For and Client-IP Headers**

September 24, 2018

Example Inc. wants to remove old X-Forwarded-For and Client-IP HTTP headers from incoming requests, so that the only X-Forwarded-For headers that appear are the ones added by the local server. This configuration can be done through the NetScaler command line or the GUI. The Example Inc. system administrator is an old-school networking engineer and prefers to use a CLI where possible, but wants to be sure he understands the GUI interface so that he can show new system administrators on the team how to use it.
The examples below demonstrate how to perform each configuration with both the CLI and the GUI. The procedures are abbreviated on the assumption that users will already know the basics of creating rewrite actions, creating rewrite policies, and binding policies.

- For more detailed information about creating rewrite actions, see Configuring a Rewrite Action.
- For more detailed information about creating rewrite policies, see Configuring a Rewrite Policy.
- For more detailed information about binding rewrite policies, see Binding a Rewrite Policy.

**To delete old X-Forwarded and Client-IP headers from a request by using the command line interface**

At the command prompt, type the following commands in the order shown:

```plaintext
1  add rewrite action act_del_xfor delete_http_header x-forwarded-for
2  add rewrite action act_del_cip delete_http_header client-ip
3  add rewrite policy pol_check_xfor 'HTTP.REQ.HEADER("x-forwarded-for").EXISTS' act_del_xfor
4  add rewrite policy pol_check_cip 'HTTP.REQ.HEADER("client-ip").EXISTS' act_del_cip
5  bind rewrite global pol_check_xfor 100 200
6  bind rewrite global pol_check_cip 200 300
```

**To delete old X-Forwarded and Client-IP headers from a request by using the GUI**

In the Create Rewrite Action dialog box, create two rewrite actions with the following descriptions.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Argument(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>act_del_xfor</td>
<td>delete_http_header</td>
<td>x-forwarded-for</td>
</tr>
<tr>
<td>act_del_cip</td>
<td>delete_http_header</td>
<td>client-ip</td>
</tr>
</tbody>
</table>

In the Create Rewrite Policy dialog box, create two rewrite policies with the following descriptions.

<table>
<thead>
<tr>
<th>Name</th>
<th>Expression</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>pol_check_xfor</td>
<td>‘HTTP.REQ.HEADER(&quot;x-forwarded-for&quot;).EXISTS’</td>
<td>act_del_xfor</td>
</tr>
<tr>
<td>pol_check_cip</td>
<td>‘HTTP.REQ.HEADER(&quot;client-ip&quot;).EXISTS’</td>
<td>act_del_cip</td>
</tr>
</tbody>
</table>
Bind both policies to global, assigning the priorities and goto expression values shown below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Priority</th>
<th>Goto Expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>pol_check_xfor</td>
<td>100</td>
<td>200</td>
</tr>
<tr>
<td>pol_check_cip</td>
<td>200</td>
<td>300</td>
</tr>
</tbody>
</table>

All old X-Forwarded-For and Client-IP HTTP headers are now deleted from incoming requests.

**Example 2: Adding a Local Client-IP Header**

September 24, 2018

Example Inc. wants to add a local Client-IP HTTP header to incoming requests. This example contains two slightly different versions of the same basic task.

**To add a local Client-IP header by using the command line interface**

At the command prompt, type the following commands in the order shown:

1. `add rewrite action act_ins_client insert_http_header NS-Client 'CLIENT.IP.SRC'
2. `add rewrite policy pol_ins_client 'HTTP.REQ.HEADER("x-forwarded-for").EXISTS || HTTP.REQ.HEADER("client-ip").EXISTS' act_ins_client`  
3. `bind rewrite global pol_ins_client 300 END`

**To add a local Client-IP header by using the GUI**

In the Create Rewrite Action dialog box, create a rewrite action with the following description.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Argument(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>act_ins_client</td>
<td>insert_http_header</td>
<td>NS-Client ‘CLIENT.IP.SRC’</td>
</tr>
</tbody>
</table>

In the Create Rewrite Policy dialog box, create a rewrite policy with the following description.
NetScaler 12.0

<table>
<thead>
<tr>
<th>Name</th>
<th>Expression</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>pol_ins_client</td>
<td>‘HTTP.REQ.HEADER(&quot;x-forwarded-for&quot;).EXISTS</td>
<td>HTTP.REQ.HEADER act_ins_client ip”).EXISTS’</td>
</tr>
</tbody>
</table>

Bind policy to global, assigning the priorities and goto expression values shown below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Priority</th>
<th>Goto Expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>pol_ins_client</td>
<td>100</td>
<td>Next</td>
</tr>
</tbody>
</table>

A local Client-IP HTTP header is now added to incoming requests. You can also modify the configuration above to append all IPs from X-Forwarded-For headers to the new Client-IP header, as shown below.

Example 3: Tagging Secure and Insecure Connections

September 24, 2018

Example Inc. wants to tag incoming requests with a header that indicates whether or not the connection is a secure connection. This helps the server keep track of secure connections after the NetScaler has decrypted the connections.

To implement this configuration, you would begin by creating rewrite actions with the values shown in the following tables. These actions label connections to port 80 as insecure connections, and connections to port 443 as secure connections.

<table>
<thead>
<tr>
<th>Action Name</th>
<th>Type of Rewrite Action</th>
<th>Header Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Action-Rewrite-SSL_YES</td>
<td>INSERT_HTTP_HEADER</td>
<td>SSL</td>
<td>YES</td>
</tr>
<tr>
<td>Action-Rewrite-SSL_NO</td>
<td>INSERT_HTTP_HEADER</td>
<td>SSL</td>
<td>NO</td>
</tr>
</tbody>
</table>

You would then create a rewrite policy with the values shown in the following tables. These policies
check incoming requests to determine which requests are directed to port 80 and which are directed to port 443. The policies then add the correct SSL header.

<table>
<thead>
<tr>
<th>Policy Name</th>
<th>Action Name</th>
<th>Undefined Action</th>
<th>Expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>Policy-Rewrite-SSL_YES</td>
<td>Action-Rewrite-SSL_YES</td>
<td>NOREWRITE</td>
<td>CLIENT.TCP.DSTPORT.EQ(443)</td>
</tr>
<tr>
<td>Policy-Rewrite-SSL_NO</td>
<td>Action-Rewrite-SSL_NO</td>
<td>NOREWRITE</td>
<td>CLIENT.TCP.DSTPORT.EQ(80)</td>
</tr>
</tbody>
</table>

Finally, you would bind the rewrite policies to NetScaler, assigning the first policy a priority of 200, and the second a priority of 300, and setting the goto expression of both policies to END.

Each incoming connection to port 80 now has an SSL:NO HTTP header added to it and each incoming connection to port 443 has an SSL:YES HTTP header added to it.

Example 4: Mask the HTTP Server Type

December 14, 2018

Example Inc. wants to modify the HTTP Server: header so that unauthorized users and malicious code cannot use the header to identify the software that the HTTP server uses.

To modify the HTTP Server: header, you would create a rewrite action and a rewrite policy with the values in the following tables.

<table>
<thead>
<tr>
<th>Action Name</th>
<th>Type of Rewrite Action</th>
<th>Expression to choose target reference</th>
<th>String expression for replacement text</th>
</tr>
</thead>
<tbody>
<tr>
<td>Action-Rewrite-Server_Mask</td>
<td>REPLACE</td>
<td>HTTP.RES_HEADER(“Server”)</td>
<td>“Web Server 1.0”</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Policy Name</th>
<th>Action Name</th>
<th>Undefined Action</th>
<th>Expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>Policy-Rewrite-Server_Mask</td>
<td>Action-Rewrite-Server_Mask</td>
<td>NOREWRITE</td>
<td>HTTP.RES.IS_VALID</td>
</tr>
</tbody>
</table>

Example commands:

> add rewrite action Action-Rewrite-Server_Mask REPLACE HTTP.RES.HEADER(“Web Server 1.0”)
Example 5: Redirect an external URL to an internal URL

December 12, 2018

Example Inc. wants to hide its actual server room configuration from users to improve security on its Web servers.

To do this, you would create a rewrite action with the values as shown in the following tables. For request headers, the action in the table modifies www.example.com to web.hq.example.net. For response headers, the action does the opposite, translating web.hq.example.net to www.example.com.

<table>
<thead>
<tr>
<th>Action Name</th>
<th>Type of Rewrite Action</th>
<th>Expression to choose target reference</th>
<th>String expression for replacement text</th>
</tr>
</thead>
<tbody>
<tr>
<td>Action-Rewrite-Request_Server_Repl</td>
<td>REPLACE</td>
<td>HTTP.REQ.HOSTNAME.: “Web.hq.example.net”</td>
<td></td>
</tr>
<tr>
<td>Action-Rewrite-Response_Server_Repl</td>
<td>REPLACE</td>
<td>HTTP.RES.HEADER(“Server”)’”www.example.com”</td>
<td></td>
</tr>
</tbody>
</table>

Next, you would create rewrite policies using the values shown in the following tables. The first policy checks incoming requests to see if they are valid, and if they are, it performs the Action-Rewrite-Request_Server_Repl action. The second policy checks responses to see if they originate at the server web.hq.example.net. If they do, it performs the Action-Rewrite-Response_Server_Repl action.

Examples of rewrite action and policy for redirect

```
add rewrite action Action-Rewrite-Request_Server_Repl REPLACE HTTP.REQ.HOSTNAME.SERVER ’”Web.hq.example.net”
add rewrite action Action-Rewrite-Response_Server_Repl REPLACE HTTP.RES.HEADER(“Server”)’”www.example.com"
```
add rewrite policy Policy-Rewrite-Request_Server_Replacement HTTP.REQ.HEADER SERVER.EQ("www.example.com") Action-Rewrite-Request_Server_Replacement NOREWRITE
add rewrite policy Policy-Rewrite-Response_Server_Replacement HTTP.RESP.HEADER ("Server").EQ("web.hq.example.net") Action-Rewrite-Response_Server_Replacement NOREWRITE

Finally, you would bind the rewrite policies, assigning each a priority of 500 because they are in different policy banks and therefore will not conflict. You should set the goto expression to NEXT for both bindings.

All instances of www.example.com in the request headers are now changed to web.hq.example.net, and all instances of web.hq.example.net in response headers are now changed to www.example.com.

**Example 6: Migrating Apache Rewrite Module Rules**

September 24, 2018

Example Inc., is currently using the Apache rewrite module to process search requests sent to its Web servers and redirect those requests to the appropriate server on the basis of information in the request URL. Example Inc. wants to simplify its setup by migrating these rules onto the NetScaler platform.

Several Apache rewrite rules that Example currently uses are shown below. These rules redirect search requests to a special results page if they do not have a SiteID string or if they have a SiteID string equal to zero (0), or to the standard results page if these conditions do not apply.

The following are the current Apache rewrite rules:

- RewriteCond %{REQUEST_FILENAME} ˆ/search$ [NC]
- RewriteCond %{QUERY_STRING} !SiteId= [OR]
- RewriteCond %{QUERY_STRING} SiteId=0
- RewriteCond %{QUERY_STRING} CallName=DisplayResults [NC]
- RewriteRule ˆ. *$ /results2.html [P,L]
- RewriteRule ˆ. *$ /results.html [P,L]

To implement these Apache rewrite rules on the NetScaler, you would create rewrite actions with the values in the following tables.

<table>
<thead>
<tr>
<th>Action Name</th>
<th>Type of Rewrite</th>
<th>Expression to choose target reference</th>
<th>String expression for replacement text</th>
</tr>
</thead>
<tbody>
<tr>
<td>Action-Rewrite-Display_Results_NulSiteID</td>
<td>REPLACE</td>
<td>HTTP.REQ.URL</td>
<td>“/results2.html”</td>
</tr>
</tbody>
</table>
You would then create rewrite policies with the values as shown in the tables below.

<table>
<thead>
<tr>
<th>Policy Name</th>
<th>Action Name</th>
<th>Action Expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>Policy-Rewrite-Display_Results</td>
<td>Action-Rewrite-Display_Results</td>
<td>HTTP.REQ.URL.PATH.SET_TEXT_MODE(IGNORECASE).EQ(&quot;/search&quot;) &amp;&amp; !HTTP.REQ.URL.QUERY.CONTAINS(&quot;SiteId=&quot;) !HTTP.REQ.URL.QUERY.CONTAINS(&quot;SiteId=0&quot;) HTTP.REQ.URL.QUERY.SET_TEXT_MODE(IGNORECASE).CONTAINS(&quot;CallName=DisplayResults&quot;)</td>
</tr>
</tbody>
</table>

Finally, you would bind the rewrite policies, assigning the first a priority of 600 and the second a priority of 700, and then set the goto expression to NEXT for both bindings.

The NetScaler now handles these search requests exactly as the Web server did before the Apache rewrite module rules were migrated.

**Example 7: Marketing Keyword Redirection**

September 24, 2018

The marketing department at Example Inc. wants to set up simplified URLs for certain predefined keyword searches on the company's Web site. For these keywords, it wants to redefine the URL as shown below.

- **External URL:**
  
  http://www.example.com/\<marketingkeyword\>

- **Internal URL:**
  
  http://www.example.com/go/kwsearch.asp?keyword=\<marketingkeyword\>

To set up redirection for marketing keywords, you would create a rewrite action with the values in the following table.
You would then create a rewrite policy with the values in the following table.

<table>
<thead>
<tr>
<th>Policy Name</th>
<th>Action Name</th>
<th>Undefined Action</th>
<th>Expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>Policy-Rewrite-Modify_URL</td>
<td>Action-Rewrite-Modify_URL</td>
<td>NOREWRITE</td>
<td>HTTP.REQ.HOSTNAME.SERVER.EQ(&quot;www.example.com&quot;)</td>
</tr>
</tbody>
</table>

Finally, you would bind the rewrite policy, assigning it a priority of 800. Unlike the previous rewrite policies, this policy should be the last to be applied to a request that matches its criteria. For this reason, NetScaler administrator sets its Goto Priority Expression to END.

Any request using a marketing keyword is redirected to the keyword search CGI page, whereupon a search is performed and all remaining policies are skipped.

**Example 8: Redirect Queries to the Queried Server**

December 13, 2018

Example Inc. wants to redirect query requests to the appropriate server, as shown here.

- **Request**: GET /query.cgi?server=5
- **Redirect URL**: <http://web-5.example.com/>

To implement this redirection, you would first create a rewrite action with the values in the following table.

<table>
<thead>
<tr>
<th>Action Name</th>
<th>Type of Rewrite Action</th>
<th>Expression to choose target reference</th>
<th>String expression for replacement text</th>
</tr>
</thead>
<tbody>
<tr>
<td>Action-Rewrite-Replace_Hostheader</td>
<td>REPLACE</td>
<td>HTTP.REQ.HEADER(&quot;Host&quot;).BEFORE\_STR(&quot;.example.com&quot;)</td>
<td>“server.&quot; + HTTP.REQ.URL.QUERY.VALUE(&quot;web&quot;)</td>
</tr>
</tbody>
</table>

You would then create a rewrite policy with the values in the following table.
**Example CLI commands:**

```bash
> add rewrite action Action-Rewrite-Server_Mask REPLACE HTTP.RES.HEADER("Server")"\"Web Server 1.0\""
Done
> add rewrite policy Policy-Rewrite-Server_Mask HTTP.RES.IS_VALID Action-Rewrite-Server_Mask NOREWRITE
Done
```

Finally, you would bind the rewrite policy, assigning it a priority of 900. Because this policy should be the last policy applied to a request that matches its criteria, you set the goto expression to END.

Incoming requests to any URL that begins with \<http://www.example.com/query.cgi?server \= are redirected to the server number in the query.

**Example 9: Home Page Redirection**

September 24, 2018

New Company, Inc. recently acquired a smaller competitor, Purchased Company, and wants to redirect the home page for Purchased Company to a new page on its own Web site, as shown here.

- **Old URL:** http://www.purchasedcompany.com/\*
- **New URL:** http://www.newcompany.com/products/page.htm

To redirect requests to the Purchased Company home page, you would create rewrite actions with the values in the following table.

<table>
<thead>
<tr>
<th>Action Name</th>
<th>Type of Rewrite Action</th>
<th>Expression to choose target reference</th>
<th>String expression for replacement text</th>
</tr>
</thead>
<tbody>
<tr>
<td>Action-Rewrite-Replace_URL</td>
<td>REPLACE</td>
<td>HTTP.REQ.URL.PATH_A</td>
<td>&quot;/products/page.htm&quot;</td>
</tr>
<tr>
<td>Action-Rewrite-Replace_Host</td>
<td>REPLACE</td>
<td>HTTP.REQ.HOSTNAME</td>
<td>&quot;www.newcompany.com&quot;</td>
</tr>
</tbody>
</table>
You would then create rewrite policies with the values in the following table.

<table>
<thead>
<tr>
<th>Policy Name</th>
<th>Action Name</th>
<th>Undefined Action</th>
<th>Expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>Policy-Rewrite-Replace-None</td>
<td>Action-Rewrite-Replace-None</td>
<td>NOREWRITE</td>
<td>!HTTP.REQ.HOSTNAME.SERVER.EQ(&quot;www.purchasedcompany.com&quot;)</td>
</tr>
<tr>
<td>Policy-Rewrite-Replace-Host</td>
<td>Action-Rewrite-Replace_Host</td>
<td>NOREWRITE</td>
<td>HTTP.REQ.HOSTNAME.SERVER.EQ(&quot;www.purchasedcompany.com&quot;)</td>
</tr>
<tr>
<td>Policy-Rewrite-Replace-URL</td>
<td>Action-Rewrite-Replace_URL</td>
<td>NOREWRITE</td>
<td>HTTP.REQ.IS_VALID</td>
</tr>
</tbody>
</table>

Finally, you would bind the rewrite policies globally, assigning the first a priority of 100, the second a priority of 200, and the third a priority of 300. These policies should be the last policies applied to a request that matches the criteria. For this reason, set the goto expression to END for the first and third policies, and to 300 for the second policy. This ensures that all remaining requests are processed correctly.

Requests to the acquired company’s old Web site are now redirected to the correct page on the New Company home page.

**Example 10: Policy-based RSA Encryption**

September 24, 2018

The RSA algorithm uses the PKEY_ENCRYPT_PEM() function to encrypt HTTP predefined and user-defined header or body content. The function accepts only RSA public keys (not private keys) and the encrypted data cannot be longer than the length of the public key. When the data being encrypted is shorter than the key length, the algorithm uses RSA_PKCS1 padding method.

In a sample scenario, the function can be used with B64ENCODE() function in a rewrite action to replace an HTTP header value with a value encrypted by an RSA public key. The data being encrypted is then decrypted by the recipient using the RSA private key.

You can implement the feature by using a rewrite policy. To do this, you must complete the following tasks:

1. Add RSA public key as a policy expression.
2. Create rewrite action.
3. Create rewrite policy.
4. Bind rewrite policy as global.
5. Verify RSA encryption
Policy-based RSA encryption by using NetScaler command interface

Complete the following tasks to configure policy-based RSA encryption by using the NetScaler command interface.

To add RSA public key as a policy expression by using the NetScaler command interface:

```bash
add policy expression pubkey "-----BEGIN RSA PUBLIC KEY-----
MIGJAoGBAKl5vQEj73Kxp+9
yn1v5gPR1pnc4oLM2a0kaWwBOsB6rzCIy6zmwnvwCY1xRvQhRlJSAy3b0L7wZFIJ2FOR8Cz
+8ZQWXU2syG+udi4EnWqLfYowF9zK+o79az597eNPAjsHZ/C2oL/+6qV5a/
 f1z8bQPrHC4GpFfAEJhh/+NnAgMBAAE======END RSA PUBLIC KEY-----"
```

To add rewrite an action to encrypt an HTTP header request by using the NetScaler command interface:

```bash
add rewrite action encrypt_act insert_http_header encrypted_data
'HTTP.REQ.HEADER("data_to_encrypt").PKEY_ENCRYPT_PEM(pubkey).B64ENCODE'
```

To add rewrite policy by using the NetScaler command interface:

```bash
add rewrite policy encrypt_pol 'HTTP.REQ.HEADER("data_to_encrypt").EXISTS' encrypt_act
```

To bind rewrite policy global by using the NetScaler command interface:

```bash
bind rewrite global encrypt_pol 10 -type RES_DEFAULT
```

To verify RSA encryption by using the NetScaler command interface:

```bash
> curl -v -H "data_to_encrypt: Now is the time that tries men's souls"
   http://10.217.24.7/

* About to connect() to 10.217.24.7 port 80 (#0)
* Trying 10.217.24.7...
* connected
* Connected to 10.217.24.7 (10.217.24.7) port 80 (#0)
> GET / HTTP/1.1
> User-Agent: curl/7.24.0 (amd64-portbld-freebsd8.4) libcurl/7.24.0 OpenSSL/0.9.8y zlib/1.2.3
```
Subsequent execution of this curl command with the same data to encrypt shows that the encrypted data is different each execution. This is because the padding inserts random bytes at the beginning of the data to encrypt, causing the encrypted data to be different each time.

```bash
> curl -v -H "data_to_encrypt: Now is the time that tries men's souls" http://10.217.24.7/
...
Policy-based RSA encryption by using the GUI

The GUI enables you to complete the following tasks:

To add RSA public key as a policy expression by using the GUI:

1. Sign into the NetScaler appliance and navigate to Configurations > AppExpert > Advanced Expressions.
2. In the details pane, click Add to define an RSA public key as an advanced policy expression.
3. In Create Expression page, set the following parameters:
   a) Expression name. Name of the advanced expression.
   b) Expression. Define RSA public key as an advanced expression using the Expression Editor.
   c) Comments. A brief description of the expression.
4. Click Create.

To add rewrite an action to encrypt an HTTP header request by using the GUI:

1. Sign into the NetScaler appliance and navigate to Configurations > AppExpert > Rewrite > Actions.
2. In the details pane, click Add to add a rewrite action.
3. In the Create Rewrite Action screen, set the following parameters:
   a) Name. Name of the rewrite action.
   b) Type. Select action type as INSERT_HTTP_HEADER.
   c) Use the action type to insert a header. Enter the name of the HTTP header that needs to be rewritten.
   d) Expression. Name of the advanced policy expression associated to the action.
   e) Comments. A brief description of the rewrite action.
4. Click **Create**.

**To add rewrite advanced policy by using the GUI:**

1. Sign into the NetScaler appliance and navigate to **Configurations > AppExpert > Rewrite > Policies**.
2. In the **Rewrite Policies** page, click **Add** to add a rewrite policy.
3. In the **Create Rewrite Policy** page, set the following parameters:
   a) **Name**. Name of the rewrite policy.
   b) **Action**. Name of the rewrite action to perform if the request or response matches this rewrite policy.
   c) **Log Action**. Name of message log action to use when a request matches this policy.
   d) **Undefined-Result Action**. Action to perform if the result of policy evaluation is undefined.
   e) **Expression**. Name of the advanced policy expression that triggers the action.
   f) **Comments**. A brief description of the rewrite action.
4. Click **Create**.

**To bind rewrite policy global by using the GUI:**

1. Sign into the NetScaler appliance and navigate to **Configurations > AppExpert > Rewrite > Policies**.
2. In the **Rewrite Policies** screen, select a rewrite policy that you want to bind and click **Policy Manager**.
3. In the Rewrite Policy Manager page, in the Bind Points section, set the following parameters:
   a) **Bind Point**. Select the binding point as Default Global.
   b) **Protocol**. Select the protocol type as HTTP.
   c) **Connection Type**. Select the connection type as Request.
   d) Click **Continue** to view the **Policy Binding** section.
   e) In the **Policy Binding** section, select the rewrite policy and set the bind parameters.
4. Click **Bind**.

**URL Transformation**

September 24, 2018

The URL transformation feature provides a method for modifying all URLs in designated requests from an external version seen by outside users to an internal URL seen only by your Web servers and IT staff. You can redirect user requests seamlessly, without exposing your network structure to users. You can also modify complex internal URLs that users may find difficult to remember into simpler, more easily remembered external URLs.
Before you can use the URL transformation feature, you must enable the Rewrite feature. To enable the Rewrite feature, see Enabling the Rewrite Feature.

URL transform feature rewrites URLs in HTML response body and is not applied to JavaScript and other variables.

To begin configuring URL transformation, you create profiles, each describing a specific transformation. Within each profile, you create one or more actions that describe the transformation in detail. Next, you create policies, each of which identifies a type of HTTP request to transform, and you associate each policy with an appropriate profile. Finally, you globally bind each policy to put it into effect.

Configuring URL Transformation Profiles

September 24, 2018

A profile describes a specific URL transformation as a series of actions. The profile functions primarily as a container for the actions, determining the order in which the actions are performed. Most transformations transform an external hostname and optional path into a different, internal hostname and path. Most useful transformations are simple and require only a single action, but you can use multiple actions to perform complex transformations.

You cannot create actions and then add them to a profile. You must create the profile first, and then add actions to it. In the CLI, creating an action and configuring the action are separate steps. Creating a profile and configuring the profile are separate steps in both the CLI and the GUI.

To create a URL transformation profile by using the NetScaler command line

At the NetScaler command prompt, type the following commands, in the order shown, to create a URL transformation profile and verify the configuration. You can then repeat the second and third commands to configure additional actions:

```
add transform profile <profileName> -type URL [-onlyTransformAbsURLinBody (ON OFF)] [-comment <comment>]
add transform action <name> <profileName> <priority>
```
To modify an existing URL transformation profile or action by using the NetScaler command line

At the NetScaler command prompt, type the following commands to modify an existing URL transformation profile or action and verify the configuration:

Note: Use a set transform profile or set transform action command, respectively. The set transform profile command takes the same arguments as does the add transform profile command, and set transform action is the same command that was used for initial configuration.

- show transform profile <name>

Example:

```
1 > set transform action actshopping -priority 1000 -reqUrlFrom 'searching.example.net' -reqUrlInto 'www.example.net/searching' -resUrlFrom 'www.example.net/searching' -resUrlInto 'searching.example.com' -cookieDomainInto 'example.net' -state ENABLED -comment 'URL transformation for searching cart.'
2 Done
3 > show transform profile shoppingcart
4 Name: shoppingcart
5 Type: URL onlyTransformAbsURLinBody: OFF
6 Comment:
7 Actions:
8
9 1) Priority 1000 Name: actshopping ENABLED
10 Done
```

To remove a URL transformation profile and actions by using the NetScaler command line

First remove all actions associated with that profile by typing the following command once for each action:

- rm transform action <name> After you have removed all actions associated with a profile, remove the profile as shown below.
- rm transform profile <name>

To create a URL transformation profile by using the GUI

1. In the navigation pane, expand Rewrite, expand URL Transformation, and then click Profiles.
2. In the details pane, click Add.
3. In the Create URL Transformation Profile dialog box, type or select values for the parameters. The contents of the dialog box correspond to the parameters described in “Parameters for configuring URL transformation profiles” as follows (asterisk indicates a required parameter):
   - Name*—name
   - Comment—comment
   - Only transform absolute URLs in response body—onlyTransformAbsURLinBody
4. Click Create, and then click Close. A message appears in the status bar, stating that the Profile has been configured successfully.

To configure a URL transformation profile and actions by using the GUI

1. In the navigation pane, expand Rewrite, expand URL Transformation, and then click Profiles.
2. In the details pane, select the profile you want to configure, and then click Open.
3. In the Configure URL Transformation Profile dialog box, do one of the following.
   - To create a new action, click Add.
   - To modify an existing action, select the action, and then click Open.
4. Fill in the Create URL Transformation Action or Modify URL Transformation Action dialog box by typing or selecting values for the parameters. The contents of the dialog box correspond to the parameters described in “Parameters for configuring URL transformation profiles” as follows (asterisk indicates a required parameter):
   - Action Name*—name
   - Comments—comment
   - Priority*—priority
   - Request URL from—reqUrlFrom
   - Request URL into—reqUrlInto
   - Response URL from—resUrlFrom
   - Response URL into—resUrlInto
   - Cookie Domain from—cookieDomainFrom
   - Cookie Domain into—cookieDomainInto
   - Enabled—state
5. Save your changes.
   - If you are creating a new action, click Create, and then Close.
   - If you are modifying an existing action, click OK.
     A message appears in the status bar, stating that the Profile has been configured successfully.
6. Repeat step 3 through step 5 to create or modify any additional actions.
7. To delete an action, select the action, and then click Remove. When prompted, click OK to confirm the deletion.
8. Click OK to save your changes and close the Modify URL Transformation Profile dialog box.
9. To delete a profile, in the details pane select the profile, and then click Remove. When prompted, click OK to confirm the deletion.

Configuring URL Transformation Policies

September 24, 2018

After you create a URL transformation profile, you next create a URL transformation policy to select the requests and responses that the NetScaler should transform by using the profile. URL transformation considers each request and the response to it as a single unit, so URL transformation policies are evaluated only when a request is received. If a policy matches, the NetScaler transforms both the request and the response.

Note: The URL transformation and rewrite features cannot both operate on the same HTTP header during request processing. Because of this, if you want to apply a URL transformation to a request, you must make sure that none of the HTTP headers it will modify are manipulated by any rewrite action.

To configure a URL transformation policy by using the NetScaler command line

You must create a new policy. On the command line, an existing policy can only be removed. At the NetScaler command prompt, type the following commands to configure a URL transformation policy and verify the configuration:

• `<add transform policy <name> <rule> <profileName>`
• `<show transform policy <name>`

Example:

```
1 > add transform policy polsearch HTTP.REQ.URL.SUFFIX.EQ("Searching")
   prosearching
2 Done
3 > show transform policy polsearch
4 1) Name: polsearch
5        Rule: HTTP.REQ.URL.SUFFIX.EQ("Searching")
6        Profile: prosearching
7        Priority: 0
8        Hits: 0
9 Done
```
**To remove a URL transformation policy by using the NetScaler command line**

At the NetScaler command prompt, type the following command to remove a URL transformation policy:

`rm transform policy <name>`

**Example:**

```
1 > rm transform policy polsearch
2 Done
```

**To configure a URL transformation policy by using the GUI**

1. In the navigation pane, expand Rewrite, expand URL Transformation, and then click Policies.

2. In the details pane, do one of the following:
   
   - To create a new policy, click Add.
   - To modify an existing policy, select the policy, and then click Open.

3. In the Create URL Transformation Policy or Configure URL Transformation Policy dialog box, type or select values for the parameters. The contents of the dialog box correspond to the parameters described in “Parameters for configuring URL transformation policies” as follows (asterisk indicates a required parameter):
   
   - **Name***—name (Cannot be changed for a previously configured policy.)
   - **Profile***—profileName
   - **Expression**—rule

If you want help with creating an expression for a new policy, you can either hold down the Control key and press the space bar while your cursor is in the Expression text box. To create the expression, you can type it directly as described below, or you can use the Add Expression dialog box.

   a) Click Prefix, and choose the prefix for your expression.

   Your choices are:
   
   - **HTTP**—The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol.
   - **SYS**—The protected Web site(s). Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.
   - **CLIENT**—The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.
• SERVER—The computer to which the request was sent. Choose this if you want to examine some aspect of the recipient of the request.

• URL—The URL of the request. Choose this if you want to examine some aspect of the URL to which the request was sent.

• TEXT—Any text string in the request. Choose this if you want to examine a text string in the request.

• TARGET—The target of the request. Choose this if you want to examine some aspect of the request target.

After you choose a prefix, the NetScaler displays a two-part prompt window that displays the possible next choices at the top, and a brief explanation of what the selected choice means at the bottom. The choices depend on which prefix you chose.

b) Select your next term.

If you chose HTTP as your prefix, your choices are REQ, which specifies HTTP requests, and RES, which specifies HTTP responses. If you chose another prefix, your choices are more varied. For help on a specific choice, click that choice once to display information about it in the lower prompt window.

When you are certain which choice you want, double-click it to insert it into the Expression window.

c) Type a period, and then continue selecting terms from the list boxes that appear to the right of the previous list box. You type the appropriate text strings or numbers in the text boxes that appear to prompt you to enter a value, until your expression is finished.

4. Click Create or OK, depending on whether you are creating a new policy or modifying an existing policy.

5. Click Close. A message appears in the status bar, stating that the Policy has been configured successfully.

To add an expression by using the Add Expression dialog box

1. In the Create Responder Action or Configure Responder Action dialog box, click Add.

2. In the Add Expression dialog box, in the first list box choose the first term for your expression.

   • HTTP

   The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol.

   • SYS
The protected Web site(s). Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.

- **CLIENT**
  The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.

- **SERVER**
  The computer to which the request was sent. Choose this if you want to examine some aspect of the recipient of the request.

- **URL**
  The URL of the request. Choose this if you want to examine some aspect of the URL to which the request was sent.

- **TEXT**
  Any text string in the request. Choose this if you want to examine a text string in the request.

- **TARGET**
  The target of the request. Choose this if you want to examine some aspect of the request target.
  When you make your choice, the rightmost list box lists appropriate terms for the next part of your expression.

3. In the second list box, choose the second term for your expression. The choices depend upon which choice you made in the previous step, and are appropriate to the context. After you make your second choice, the Help window below the Construct Expression window (which was blank) displays help describing the purpose and use of the term you just chose.

4. Continue choosing terms from the list boxes that appear to the right of the previous list box, or typing strings or numbers in the text boxes that appear to prompt you to enter a value, until your expression is finished.

---

**Globally Binding URL Transformation Policies**

September 24, 2018

After you have configured your URL transformation policies, you bind them to Global or a bind point to put them into effect. After binding, any a request or response that matches a URL transformation policy is transformed by the profile associated with that policy.
When you bind a policy, you assign a priority to it. The priority determines the order in which the policies you define are evaluated. You can set the priority to any positive integer. In the NetScaler OS, policy priorities work in reverse order - the higher the number, the lower the priority.

Because the URL transformation feature implements only the first policy that a request matches, not any additional policies that it might also match, policy priority is important for achieving the results that you intend. If you give your first policy a low priority (such as 1000), you tell the NetScaler to perform it only if other policies with a higher priority do not match a request. If you give your first policy a high priority (such as 1), you tell the NetScaler to perform it first, and skip any other policies that might also match. You can leave yourself plenty of room to add other policies in any order, without having to reassign priorities, by setting priorities with intervals of 50 or 100 between each policy when you globally bind your policies.

Note: URL transformation policies cannot be bound to TCP-based virtual servers.

**To bind a URL transformation policy by using the NetScaler command line**

At the NetScaler command prompt, type the following commands to globally bind a URL transformation policy and verify the configuration:

- `bind transform global `<policyName>` `<priority`
- `show transform global`

**Example:**

```
1 > bind transform global polisearching 100
2  Done
3 > show transform global
4 1) Policy Name: polisearching
5    Priority: 100
6
7  Done
```

**To bind a URL transformation policy by using the GUI**

1. In the navigation pane, expand Rewrite, then expand URL Transformation, and then click Policies.
2. In the details pane, click Policy Manager.
3. In the Transform Policy Manager dialog box, choose the bind point to which you want to bind the policy. The choices are:
   - **Override Global.** Policies that are bound to this bind point process all traffic from all interfaces on the NetScaler appliance, and are applied before any other policies.
Global Binding URL Transformation Policies

September 24, 2018

After you have configured your URL transformation policies, you bind them to Global or a bind point to put them into effect. After binding, any a request or response that matches a URL transformation policy is transformed by the profile associated with that policy.

When you bind a policy, you assign a priority to it. The priority determines the order in which the
policies you define are evaluated. You can set the priority to any positive integer. In the NetScaler OS, policy priorities work in reverse order - the higher the number, the lower the priority.

Because the URL transformation feature implements only the first policy that a request matches, not any additional policies that it might also match, policy priority is important for achieving the results that you intend. If you give your first policy a low priority (such as 1000), you tell the NetScaler to perform it only if other policies with a higher priority do not match a request. If you give your first policy a high priority (such as 1), you tell the NetScaler to perform it first, and skip any other policies that might also match. You can leave yourself plenty of room to add other policies in any order, without having to reassign priorities, by setting priorities with intervals of 50 or 100 between each policy when you globally bind your policies.

Note: URL transformation policies cannot be bound to TCP-based virtual servers.

To bind a URL transformation policy by using the NetScaler command line

At the NetScaler command prompt, type the following commands to globally bind a URL transformation policy and verify the configuration:

- bind transform global \<policyName\> \<priority\>
- show transform global

Example:

```
1 > bind transform global polisearching 100
2   Done
3 > show transform global
4 1) Policy Name: polisearching
5     Priority: 100
6
7 Done
```

To bind a URL transformation policy by using the GUI

1. In the navigation pane, expand Rewrite, then expand URL Transformation, and then click Policies.
2. In the details pane, click Policy Manager.
3. In the Transform Policy Manager dialog box, choose the bind point to which you want to bind the policy. The choices are:
   - **Override Global.** Policies that are bound to this bind point process all traffic from all interfaces on the NetScaler appliance, and are applied before any other policies.
• **LB Virtual Server.** Policies that are bound to a load balancing virtual server are applied only to traffic that is processed by that load balancing virtual server, and are applied before any Default Global policies. After selecting LB Virtual Server, you must also select the specific load balancing virtual server to which you want to bind this policy.

• **CS Virtual Server.** Policies that are bound to a content switching virtual server are applied only to traffic that is processed by that content switching virtual server, and are applied before any Default Global policies. After selecting CS Virtual Server, you must also select the specific content switching virtual server to which you want to bind this policy.

• **Default Global.** Policies that are bound to this bind point process all traffic from all interfaces on the NetScaler appliance.

• **Policy Label.** Policies that are bound to a policy label process traffic that the policy label routes to them. The policy label controls the order in which policies are applied to this traffic.

4. Select Insert Policy to insert a new row and display a drop-down list with all available, unbound URL transformation policies.

5. Select the policy you want to bind, or select New Policy to create a new policy. The policy that you selected or created is inserted into the list of globally bound URL transformation policies.

6. Make any additional adjustments to the binding.
   • <To modify the policy priority, click the field to enable it, and then type a new priority. You can also select Regenerate Priorities to renumber the priorities evenly.
   • To modify the policy expression, double click that field to open the Configure Transform Policy dialog box, where you can edit the policy expression.
   • To set the Goto Expression, double click field in the Goto Expression column heading to display the drop-down list, where you can choose an expression.
   • To set the Invoke option, double click field in the Invoke column heading to display the drop-down list, where you can choose an expression.

7. Repeat steps 3 through 6 to add any additional URL transformation policies you want to globally bind.

8. Click OK to save your changes. A message appears in the status bar, stating that the Policy has been configured successfully.

**Diameter Support for Rewrite**

September 24, 2018

The Rewrite feature now supports the Diameter protocol. You can configure Rewrite to modify Diameter requests and response as you would HTTP or TCP requests and responses, allowing you to use Rewrite to manage the flow of Diameter requests and make necessary modifications. For example, if the “Origin-Host” value in a Diameter request is inappropriate, you can use Rewrite to replace it with
a value that is acceptable to the Diameter server.

**To configure Rewrite to modify a Diameter request**

To configure the Rewrite feature to replace the Origin-Host in a Diameter request with a different value, at the command prompt, type the following commands:

- `add rewrite action <actname> replace "DIAMETER.REQ.AVP(264,"netscaler.example.net")"`
  For `<actname>`, substitute a name for your new action. The name can consist of from one to 127 characters in length, and can contain letters, numbers, and the hyphen (-) and underscore (_) symbols. For NetScaler.example.net, substitute the Host-Origin that you want to use instead of the original Host-Name.

- `add rewrite policy <polname> "diameter.req.avp(264).value.eq("host.example.com")"`
  For `<polname>`, substitute a name for your new policy. As with `<actname>`, the name can consist of from one to 127 characters in length, and can contain letters, numbers, and the hyphen (-) and underscore (_) symbols. For host.example.com, substitute the name of the Host-Origin that you want to change. For `<actname>`, substitute the name of the action that you just created.

- `bind lb vserver <vservername> -policyName <polname> -priority <priority> -type REQUEST`
  For `<vservername>`, substitute the name of the load balancing virtual server to which you want to bind the policy. For `<polname>`, substitute the name of the policy you just created. For `<priority>`, substitute a priority for the policy.

**Example:**

To create a Rewrite action and policy to modify all Diameter Host-Origins of “host.example.com” to “NetScaler.example.net”, you could add the following action and policy, and bind the policy as shown.

```
1 > add rewrite action rw_act_replace_avp replace "diameter.req.avp(264)"
   "diameter.new.avp(264,"netscaler.example.net")"
2 > add rewrite policy rw_diam_pol "diameter.req.avp(264).value.eq("client.realm2.net")" rw_act_replace_avp
3 > bind lb vserver vs1 -policyName rw_diam_pol -priority 10 -type REQUEST
4
5 Done
```

**DNS Support for the Rewrite Feature**

January 6, 2019
You can configure the rewrite feature to modify DNS requests and responses, as you would for HTTP or TCP requests and responses. You can use rewrite to manage the flow of DNS requests, and make necessary modifications in the header, or in the answer section. For example, if the DNS response does not have the AA bit set in the header flag, you can use rewrite to set the AA bit in the DNS response and send it to the client.

**DNS Expressions**

In a rewrite configuration, you can use the following NetScaler expressions to refer to various portions of a DNS request or response:

See [Expressions and Descriptions](#).

**DNS Bind Points**

The following global bind points are available for policies that contain DNS expressions.

<table>
<thead>
<tr>
<th>Bind Points</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DNS_REQ_OVERRIDE</td>
<td>Override request policy queue.</td>
</tr>
<tr>
<td>DNS_REQ_DEFAULT</td>
<td>Standard request policy queue.</td>
</tr>
<tr>
<td>DNS_RES_OVERRIDE</td>
<td>Override response policy queue.</td>
</tr>
<tr>
<td>DNS_RES_DEFAULT</td>
<td>Standard response policy queue.</td>
</tr>
</tbody>
</table>

In addition to the default bind points, you can create policy labels of type DNS_REQ or DNS_RES and bind DNS policies to them.

**Rewrite Action Types for DNS**

- **replace_dns_answer_section**—This action replaces the DNS answers section with the defined expression in the DNS policy.
- **replace_dns_header_field**—Checks the opcode type in the DNS request. Returns True or False, indicating whether the opcode type in the DNS request matches the specified opcode type. This action replaces the DNS header section with the defined expression in the DNS policy.
Configuring Rewrite Policies for DNS

The following procedure uses the NetScaler command line to configure a rewrite action and policy and bind the policy to a rewrite-specific global bind point.

Configure Rewrite action and policy, and bind the policy for DNS

At the command prompt, type the following commands:

1. add rewrite action <actName> <actType>
   
   For <actName>, substitute a name for your new action. The name can be 1 to 127 characters in length, and can contain letters, numbers, hyphen (-), and underscore (_) symbols. For <actType>, specify the rewrite action types provided for DNS expressions.

2. add rewrite policy <polName> <rule> <actName>
   
   For <polName>, substitute a name for your new policy. For <actName>, the name can be 1 to 127 characters in length, and can contain letters, numbers, hyphen (-), and underscore (_) symbols. For <actName>, substitute the name of the action that you just created.

3. bind rewrite global <polName> <priority> <gotoPriorityExpression> -type <bindPoint>
   
   For <polName>, substitute the name of the policy that you just created. For <priority>, specify the priority of the policy. For <bindPoint>, substitute one of the rewrite -specific global bind points.

Example:

Set the AA bit of DNS request to load balance virtual server.

The following commands configure the NetScaler appliance to act as an authoritative DNS server for all the queries that it serves.

```
1 add rewrite action set_aa replace_dns_header_field dns.req.header.flags.set(aa)
2 add rewrite policy pol !dns.req.header.flags.is_set(aa) set_aa
3 bind rewrite global pol 100 -type dns_res_override
```

Modify the response answer and header section.

If the server responds with an NX domain, you can set the rewrite action to replace the response with specified IP address. A NOPOLICY-REWRITE enables you to invoke an external bank without processing an expression (a rule). This entry is a dummy policy that does not contain a rule but directs the entry to a policy label or virtual server specific policy banks.

```
1 add rewrite action set_aa_res replace_dns_header_field "dns.res.header.flags.set(aa)"
```
Limitations:

- Rewrite policies are evaluated only if the NetScaler appliance is configured as a DNS proxy server and there is a cache miss.
- If the Recursion Available (RA) flag in the header is set to YES, the RA flag will not be modified in the rewrites.
- If the RA flag in the header is set to YES, the CD flag in the header is modified regardless of any rewrite action.

String maps

January 6, 2019

You can use string maps to perform pattern matching in all NetScaler features that use the default policy syntax. A string map is a NetScaler entity that consists of key-value pairs. The keys and values are strings in either ASCII or UTF-8 format. String comparison uses two new functions, MAP_STRING() and IS_STRINGMAP_KEY().

A policy configuration that uses string maps performs better than one that does string matching through policy expressions, and you need fewer policies to perform string matching with a large number of key-value pairs. String maps are also intuitive, simple to configure, and result in a smaller configuration.

How String Maps Work

String maps are similar in structure to pattern sets (a pattern set defines a mapping of index values to strings; a string map defines a mapping of strings to strings) and the configuration commands for string maps (commands such as add, bind, unbind, remove, and show) are syntactically similar to configuration commands for pattern sets. Also, as with index values in a pattern set, each key
in a string map must be unique across the map. The following table illustrates a string map called
url_string_map, which contains URLs as keys and values.

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>/url_1.html</td>
<td>http://www.redirect_url_1.com/url_1.html</td>
</tr>
<tr>
<td>/url_2.html</td>
<td>http://www.redirect_url_2.com/url_2.html</td>
</tr>
</tbody>
</table>

Table 1. String Map “url_string_map”

The following table describes the two functions that have been introduced to enable string matching
with keys in a string map. String matching is always performed with the keys. Additionally, the follow-
ing functions perform a comparison between the keys in the string map and the complete string that
is returned by the expression prefix. The examples in the descriptions refer to the preceding example.

For completed information about the two functions introduced for enabling string matching with keys
in a string map, see String Map Function table pdf.

**Configuring a String Map**

You first create a string map and then bind key-value pairs to it. You can create a string map from the
command line interface (CLI) or the GUI.

To configure a string map by using the command line interface

At the command prompt, do the following:

1. Create a string map.

   ```
   add policy stringmap <name> -comment <string>
   ```

2. Bind a key-value pair to the string map.

   ```
   bind policy stringmap <name> <key> <value>
   ```

   Example:

   ```
   ! > bind policy stringmap url_string_map1 ”/url_1.html” ”http://www.
   redirect_url_1.com/url_1.html”
   ```

   To configure a string map by using the GUI
Create a string map and bind the key-value pair to the created entity.

Navigate to **AppExpert > String Maps**, click **Add** and specify the relevant details.

**Example: responder policy with a redirect action**

The following use case involves a responder policy with a redirect action. In the example below, the first four commands create the string map `url_string_map` and bind the three key-value pairs used in the earlier example. After creating the map and binding the key-value pairs, you create a responder action (act_url_redirects) that redirects the client to the corresponding URL in the string map or to www.default.com. You also configure a responder policy (pol_url_redirects) that checks whether requested URLs match any of the keys in `url_string_map` and then performs the configured action. Finally, you bind the responder policy to the content switching virtual server that receives the client requests that are to be evaluated.

```
add stringmap url_string_map
bind stringmap url_string_map /url_1.html http://www.redirect_url_1.com/url_1.html
bind stringmap url_string_map /url_2.html http://www.redirect_url_2.com/url_2.html
bind stringmap url_string_map /url_3.html http://www.redirect_url_1.com/url_1.html
add responder action act_url_redirects redirect 'HTTP.REQ.URL.MAP_STRING("url_string_map")ALT "www.default.com"'-bypassSafetyCheck yes
add responder policy pol_url_redirects TRUE act_url_redirects
bind cs vserver csw_redirect -policyname pol_url_redirects -priority 1 -type request
```

**URL Sets**

September 24, 2018

This feature enables you to blacklist one million URLs. The section includes the following topics:

- Getting Started
- Using Advanced Policy Expressions for URL Evaluation
- Configuring a URL Set
- URL Pattern Semantics
- Blacklisted URL Categories
To prevent access to restricted websites, a NetScaler appliance uses a specialized URL matching algorithm. The algorithm uses a URL set that can contain a list of URLs up to one million (1,000,000) blacklisted entries. Each entry can include metadata that defines URL categories and category groups as indexed patterns. The appliance can also periodically download URLs of highly sensitive URL sets managed by internet enforcement agencies (with government websites) or independent internet organizations such as the Internet Watch Foundation (IWF). Once the URL set is downloaded from a website and imported into the appliance, the appliance encrypts the URL sets in the appliance (as required by these agencies) and kept confidential so that the entries are not tampered.

The NetScaler appliance uses advanced policies to determine whether an incoming URL should be blocked, allowed, or redirected. These policies use advanced expressions to evaluate incoming URLs against blacklisted entries. An entry can include metadata. For entries that have no metadata, you might want to use an expression that evaluates the URL on the basis of an exact string match. For other URLs, you might want to use an expression that evaluates the URL's metadata, in addition to an expression that checks for an exact string match.

**Use Case for Safe Internet Access Policies for ISPs/Telcos**

A URL set enables an Internet Service Provider (ISP) or a Telco customer to enforce government mandated safe internet access policies such as:

1. Block access to illegal internet sites (child abuse, drugs, and so on)
2. Safe browsing for children

A NetScaler appliance enables you to periodically download URL sets managed by internet enforcement agencies or independent internet organizations such as IWF (Internet Watch Foundation). The appliance periodically downloads the list and updates it securely. The list is stored as confidential URL sets so that it is not tampered or human readable. The periodically downloaded URL set functions as a blacklisted set for URL evaluation purposes.

If you have a private URL set and the contents of the list are kept confidential and the network administrator does not know about the blacklisted URLs present in the list. To make sure if the policy is configured correctly and the correct list is referenced to evaluate an incoming URL, you configure an internal URL called Canary URL and add it to the URL set. Using the Canary URL, the administrator can request through the appliance use the private URL set to ensure it is looked up for every URL request.
Advanced Policy Expressions for URL Evaluation

September 24, 2018

The following table describes the expressions you can use to evaluate incoming URLs with entries in an URL set.

**Note:** HTTP.REQ.URL is generalized to be used as `<URL expression>`

<table>
<thead>
<tr>
<th>Expression</th>
<th>Operation</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;URL expression&gt;.URLSET_MATCHES_ANY</code></td>
<td>Evaluates to TRUE if the URL exactly matches any entry in the URL set.</td>
</tr>
<tr>
<td><code>&lt;URL expression&gt;</code> .GET_URLSET_METADATA(&lt;URLSET&gt;)</td>
<td>The GET_URLSET_METADATA() expression returns the associated metadata if the URL exactly matches any pattern within the URL set. An empty string is returned if there was no match.</td>
</tr>
<tr>
<td><code>&lt;URL expression&gt;</code> .GET_URLSET_METADATA(&lt;URLSET&gt;).EQ(&lt;METADATA&gt;)</td>
<td>Evaluates to TRUE if the matched metadata is equal to <code>&lt;METADATA&gt;</code>.</td>
</tr>
<tr>
<td><code>&lt;URL expression&gt;</code> .GET_URLSET_METADATA(&lt;URLSET&gt;). TYPECAST_LIST_T(',').GET(0).EQ(&lt;CATEGORY&gt;)</td>
<td>Evaluates to TRUE if the matched metadata is at the beginning of the category. This pattern can be used to encode separate fields within metadata, but match only the 1st field.</td>
</tr>
<tr>
<td>HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ.URL)</td>
<td>Joins the host and URL parameters, which can then be used as a <code>&lt;URL expression&gt;</code> for matching.</td>
</tr>
</tbody>
</table>

Configuring URL Set

September 24, 2018

You can perform the following tasks to configure a URL set and restrict URLs on a NetScaler platform:

1. Import a URL set (download and encrypt it). Importing a URL set in a NetScaler appliance allows you to download the URL file, adding the file to the appliance, and then encrypting the file. Until you add the URL set to the system, it will not be visible to the user.
You can download a set in the following ways:

- Download a URL set once from a specific URL using HTTP and HTTPS supported for the file download.
- Download a URL set using FTP.
- Downloading a URL set periodically, using a scheduler that periodically downloads or imports URL sets for example, IWF URL set. The time interval is set in seconds for example, 

Sample URL Set without a meta data

`http://10.102.145.135/top10k`

Sample URL Set with a meta data

`http://10.102.145.135/blacklists/audio-video/categorized_av`

The imported URL set is further categorized into different categories and category groups in the database. This is valid only if categories exist in the metadata of the URL set file.

**Note:** There can be a chance that you might have URL patterns without metadata.

Once you have downloaded the file, it is pushed into the appliance and at this point of interval, you can update, delete or display file properties. After the file is pushed into the appliance, you can modify the entries by adding further rows as it remains static.

The imported set is then stored in an encrypted file format on the NetScaler directory. The imported list contains millions of URL entries. Otherwise, the appliance returns an error message saying that the value exceeds the limit. If the imported URL set has blacklisted entries with metadata, the metadata it is detected by the appliance when it is imported.

Once you import a URL set and add it into the appliance, the URL set is available for advanced policies to identify the correct URL set during incoming URL evaluation. `HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ.URL).URLSET_MATCHES_ANY(<URL set name>)`

2. Updating a URL set on the NetScaler appliance. Once you have pushed the file into the appliance, at this interval you can manually update a URL file by using command line interface.

3. Exporting a URL set. If you prefer a backup of the URL set, you can export the list of URL patterns and save a copy of it to a destination URL. Before you export, check whether the URL set is marked as private. If is marked private, the URL set cannot be exported.

4. Removing a URL set. If you want to delete a URL set of blacklisted entries, you can use the remove command to delete the URL set from the NetScaler appliance.

5. Displaying a URL set. You can display the properties of a URL set by using the show command.

**Example:**
To import a URL set with meta by using the command line interface

At command prompt, type:

```
```

Where,
- delimiter is a CSV file record with default value set as 44.
- rowSeparator is a CSV file row separator with default value set as 10.
- Interval is the time interval in secs, rounded to the nearest 15 minutes at which the update of urlset occurs.
- CanaryURL is a URL used for testing when contents of the urlset is kept confidential.

To show URL set by using the command line interface

At the command prompt, type:

```
show urlset <name>
```

To export an URL set by using the command line interface

At the command prompt, type:

```
export urlset <name> <url>
```
**To add an URL set by using the command line interface**

At the command prompt, type:

```
add urlset <urlset_name>
```

**To update an URL set by using the command line interface**

At the command prompt, type:

```
update urlset <name>
```

**To remove a URL set command by using the command line interface**

At the command prompt, type:

```
remove urlset <name>
```

**Example**

```
import policy urlset top1k -url http://10.78.79.80/alytra/top1k.csv -delimiter "," -rowSeparator "$" -interval 10 -privateSet -overwrite -canaryUrl http://www.in.gr
add policy urlset top1k
update policy urlset top1k
sh policy urlset
ish policy urlset top1k
export policy urlset urlset1 -url http://www.example.com/PUT_file_1
import policy urlset top10k -url http://10.102.145.135/top10k -private
add policy urlset top10k
update policy urlset top10k
show policy urlset top10k
```
To import a URL set by using the GUI

Navigate to AppExpert > URL Sets, click Import to download the URL set.

To add a URL set by using the GUI

Navigate to AppExpert > URL Sets, click Add to create a URL set file for the downloaded URL set.

To edit a URL set by using the GUI

Navigate to AppExpert > URL Sets, select a URL set and click Edit to modify.

To Update a URL set by using the GUI

Navigate to AppExpert > URL Sets, select a URL set and click Update URL Set to update URL set with the latest modifications made to the file.

To Export a URL set by using the GUI

Navigate to AppExpert > URL Sets, select a URL set and click Export URL Set to export the URL patterns in a set to a destination URL and save it in that location.

URL Pattern Semantics

January 6, 2019

The following table shows the URL patterns used for specifying the list of pages you want to filter. For example, the pattern, www.example.com/bar will only match the single page www.example.com/bar. To cover all the pages where the URL starts with www.example.com/bar, you must explicitly add a ‘*’ at the end.

For more information, see Following is the semantics for a URL pattern to match the metadata mapping

URL Categories

September 24, 2018

Following is a list of blacklisted categories.
<table>
<thead>
<tr>
<th>S.no</th>
<th>Blacklisted Categories</th>
</tr>

**AppFlow**

January 6, 2019

The NetScaler appliance is a central point of control for all application traffic in the data center. It collects flow and user-session level information valuable for application performance monitoring, analytics, and business intelligence applications. It also collects web page performance data and database information. AppFlow transmits the information by using the Internet Protocol Flow Information export (IPFIX) format, which is an open Internet Engineering Task Force (IETF) standard defined in RFC 5101. IPFIX (the standardized version of Cisco’s NetFlow) is widely used to monitor network flow information. AppFlow defines new Information Elements to represent application-level information, web page performance data, and database information.

Using UDP as the transport protocol, AppFlow transmits the collected data, called flow records, to one or more IPv4 collectors. The collectors aggregate the flow records and generate real-time or historical reports.

AppFlow provides visibility at the transaction level for HTTP, SSL, TCP, and SSL_TCP flows. You can sample and filter the flow types that you want to monitor.

AppFlow use actions and policies to send records for a selected flow to specific set of collectors.
AppFlow action specifies which set of collectors will receive the AppFlow records. Policies, which are based on Advanced expressions can be configured to select flows for which flow records will be sent to the collectors specified by the associated AppFlow action.

To limit the types of flows, you can enable AppFlow for a virtual server. AppFlow can also provide statistics for the virtual server.

You can also enable AppFlow for a specific service, representing an application server, and monitor the traffic to that application server.

Note: This feature is supported only on NetScaler nCore builds.

How AppFlow Works

In the most common deployment scenario, inbound traffic flows to a Virtual IP address (VIP) on the NetScaler appliance and is load balanced to a server. Outbound traffic flows from the server to a mapped or subnet IP address on the NetScaler and from the VIP to the client. A flow is a unidirectional collection of IP packets identified by the following five tuples: sourceIP, sourcePort, destIP, destPort, and protocol.

The following figure describes how the AppFlow feature works.

Figure 1. NetScaler Flow Sequence

As shown in the figure, the network flow identifiers for each leg of a transaction depend on the direction of the traffic.

The different flows that form a flow record are:

Flow1: <Client-IP, Client-Port, VIP-IP, VIP-port, Protocol>
Flow2: <NS-MIP/SNIP, NS-port, Server-IP, Server-Port, Protocol>
Flow3: <Server-IP, Server-Port, NS-MIP/SNIP, NS-Port, Protocol>
Flow4: <VIP-IP, VIP-port, Client-IP, Client-Port, Protocol>

To help the collector link all four flows in a transaction, AppFlow adds a custom transactionID element to each flow. For application-level content switching, such as HTTP, it is possible for a single client TCP connection to be load balanced to different backend TCP connections for each request. AppFlow provides a set of records for each transaction.

This topic includes the following details:

- Flow Records
- Templates
Flow Records

AppFlow records contain standard NetFlow or IPFIX information, such as time stamps for the beginning and end of a flow, packet count, and byte count. AppFlow records also contain application-level information (such as HTTP URLs, HTTP request methods and response status codes, server response time, and latency), web page performance data (such as page load time, page render time, and time spent on the page), and database information (such as database protocol, database response status and database response size). IPFIX flow records are based on templates that need to be sent before sending flow records.

Templates

AppFlow defines a set of templates, one for each type of flow. Each template contains a set of standard Information Elements (IEs) and Enterprise-specific Information Elements (EIEs). IPFIX templates define the order and sizes of the Information Elements (IE) in the flow record. The templates are sent to the collectors at regular intervals, as described in RFC 5101.

A template can include the following EIEs:

- transactionID
  
  An unsigned 32-bit number identifying an application-level transaction. For HTTP, this corresponds to a request and response pair. All flow records that correspond to this request and response pair have the same transaction ID. In the most common case, there are four uniflow records that correspond to this transaction. If the NetScaler generates the response by itself (served from the integrated cache or by a security policy), there may be only two flow records for this transaction.

- connectionID
  
  An unsigned 32-bit number identifying a layer-4 connection (TCP or UDP). The NetScaler flows are usually bidirectional, with two separate flow records for each direction of the flow. This information element can be used to link the two flows.

  For the NetScaler, connectionID is an identifier for the connection data structure to track the progress of a connection. In an HTTP transaction, for instance, a given connectionID may have multiple transactionID elements corresponding to multiple requests that were made on that connection.

- tcpRTT
  
  The round trip time, in milliseconds, as measured on the TCP connection. This can be used as a metric to determine the client or server latency on the network.

- httpRequestMethod
An 8-bit number indicating the HTTP method used in the transaction. An options template with the number-to-method mapping is sent along with the template.

- **httpRequestSize**
  An unsigned 32-bit number indicating the request payload size.

- **httpRequestURL**
  The HTTP URL requested by the client.

- **httpUserAgent**
  The source of incoming requests to the Web server.

- **httpResponseStatus**
  An unsigned 32-bit number indicating the response status code.

- **httpResponseSize**
  An unsigned 32-bit number indicating the response size.

- **httpResponseTimeToFirstByte**
  An unsigned 32-bit number indicating the time taken to receive the first byte of the response.

- **httpResponseTimeToLastByte**
  An unsigned 32-bit number indicating the time taken to receive the last byte of the response.

- **flowFlags**
  An unsigned 64-bit flag used to indicate different flow conditions.

**EIEs for web page performance data**

- **clientInteractionStartTime**
  Time at which the browser receives the first byte of the response to load any objects of the page such as images, scripts, and stylesheets.

- **clientInteractionEndTime**
  Time at which the browser received the last byte of response to load all the objects of the page such as images, scripts, and stylesheets.

- **clientRenderStart-time**
  Time at which the browser starts to render the page.

- **clientRenderEndTime**
  Time at which browser finished rendering the entire page, including the embedded objects.
EIEs for database information

- **dbProtocolName**
  An unsigned 8-bit number indicating the database protocol. Valid values are 1 for MS SQL and 2 for MySQL.

- **dbReqType**
  An unsigned 8-bit number indicating the database request method used in the transaction. For MS SQL, valid values are 1 for QUERY, 2 is for TRANSACTION, and 3 is for RPC. For valid values for MySQL, see the MySQL documentation.

- **dbReqString**
  Indicates the database request string without the header.

- **dbRespStatus**
  An unsigned 64-bit number indicating the status of the database response received from the web server.

- **dbRespLength**
  An unsigned 64-bit number indicating the response size.

- **dbRespStatString**
  The response status string received from the web server.

Configuring the AppFlow Feature

January 10, 2019

You configure AppFlow in the same manner as most other policy-based features. First, you enable the AppFlow feature. Then you specify the collectors to which the flow records are sent. After that, you define actions, which are sets of configured collectors. Then you configure one or more policies and associate an action to each policy. The policy tells the Citrix ADC appliance to select requests the flow records of which are sent to the associated action. Finally, you bind each policy either globally or to specific vservers to put it into effect.

You can further set AppFlow parameters to specify the template refresh interval and to enable the exporting of httpURL, httpCookie, and httpReferer information. On each collector, you must specify the Citrix ADC IP address as the address of the exporter.

**Note:** For information about configuring the Citrix ADC as an exporter on the collector, see the documentation for the specific collector.
The configuration utility provides tools that help users define the policies and actions that determine exactly how the Citrix ADC appliance export records for a particular flow to a set of collectors. The command line interface provides a corresponding set of CLI-based commands for experienced users who prefer a command line.

**Enabling AppFlow**

To be able to use the AppFlow feature, you must first enable it.

*Note:* AppFlow can be enabled only on nCore Citrix ADC appliances.

**To enable the AppFlow feature by using the command line interface**

At the command prompt, type one of the following commands:

```
1 enable ns feature AppFlow
```

**To enable the AppFlow feature by using the configuration utility**

Navigate to System > Settings, click Configure Advanced Features and select the AppFlow option.

**Specifying a Collector**

A collector receives AppFlow records generated by the Citrix ADC appliance. To send the AppFlow records, you must specify at least one collector. By default, the collector listens to IPFIX messages on UDP port 4739. You can change the default port, when configuring the collector. Similarly, by default, NSIP is used as the source IP for appflow traffic. You can change this default source IP to a SNIP or MIP address when configuring a collector. You can also remove unused collectors.

**To specify a collector by using the command line interface**

At the command prompt, type the following commands to add a collector and verify the configuration:

```
1 add appflow collector <name> -IPAddress <ipaddress> -port <port_number> -netprofile <netprofile_name>
2 show appflow collector <name>
```
Example

```
add appflow collector col1 -IPaddress 10.102.29.251 -port 8000 -netprofile n2
```

To specify multiple collectors by using the command line interface

At the command prompt, type the following commands to add multiple collectors:

```
1 add appflow collector <collector1> -IPAddress <IP>
2 add appflow collector <collector2> -IPAddress <IP>
3 add appflow action <action> -collectors <collector1> <collector2>
4 add appflow policy <policy> true <action>
5 bind lbvserver <lbvserver> -policy <policy> -priority <priority>
```

To specify one or more collectors by using the configuration utility

Navigate to System > AppFlow > Collectors, and create the AppFlow collector.

Configuring an AppFlow Action

An AppFlow action is a set collectors, to which the flow records are sent if the associated AppFlow policy matches.

To configure an AppFlow action by using the command line interface

At the command prompt, type the following commands to configure an Appflow action and verify the configuration:

```
1 add appflow action <name> --collectors <string> ... [-clientSideMeasurements (Enabled|Disabled)] [-comment <string>]
2 show appflow action
```
Example

```
1 add appflow action apfl-act-collector=1-and-3 -collectors collector=1 collector=3
```

To configure an AppFlow action by using the configuration utility

Navigate to System > AppFlow > Actions, and create the AppFlow action.

Configuring an AppFlow Policy

After you configure an AppFlow action, you must next configure an AppFlow policy. An AppFlow policy is based on a rule, which consists of one or more expressions.

**Note:** For creating and managing AppFlow policies, the configuration utility provides assistance that is not available at the command line interface.

To configure an AppFlow policy by using the command line interface

At the command prompt, type the following command to add an AppFlow policy and verify the configuration:

```
1 add appflow policy <name> <rule> <action>
2
3 show appflow policy <name>
```

Example

```
1 add appflow policy apfl-pol-tcp-dsprt client.TCP.DSTPORT.EQ(22) apfl-act-collector=1-and-3
```

To configure an AppFlow policy by using the configuration utility

Navigate to System > AppFlow > Policies, and create the AppFlow policy.

To add an expression by using the Add Expression dialog box

1. In the Add Expression dialog box, in the first list box choose the first term for your expression.
• HTTP
  The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol.

• SSL
  The protected Web site(s). Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.

• CLIENT
  The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.
  When you make your choice, the rightmost list box lists appropriate terms for the next part of your expression.

2. In the second list box, choose the second term for your expression. The choices depend upon which choice you made in the previous step, and are appropriate to the context. After you make your second choice, the Help window below the Construct Expression window (which was blank) displays help describing the purpose and use of the term you just chose.

3. Continue choosing terms from the list boxes that appear to the right of the previous list box, or typing strings or numbers in the text boxes that appear to prompt you to enter a value, until your expression is finished.

**Binding an AppFlow Policy**

To put a policy into effect, you must bind it either globally, so that it applies to all traffic that flows through the Citrix ADC, or to a specific virtual server, so that the policy applies only to the traffic related to that virtual server.

When you bind a policy, you assign it a priority. The priority determines the order in which the policies you define are evaluated. You can set the priority to any positive integer.

In the Citrix ADC operating system, policy priorities work in reverse order—the higher the number, the lower the priority. For example, if you have three policies with priorities of 10, 100, and 1000, the policy assigned a priority of 10 is performed first, then the policy assigned a priority of 100, and finally the policy assigned an order of 1000.

You can leave yourself plenty of room to add other policies in any order, and still set them to evaluate in the order you want, by setting priorities with intervals of 50 or 100 between each policy when you globally bind it. You can then add additional policies at any time without having to change the priority of an existing policy.
To globally bind an AppFlow policy by using the command line interface

At the command prompt, type the following command to globally bind an AppFlow policy and verify the configuration:

```
1 bind appflow global <policyName> <priority> [<gotoPriorityExpression [-type <type>]] [-invoke (<labelType> <labelName>)]]
2
3 show appflow global
```

Example

```
1 bind appflow global af_policy_lb1_10.102.71.190 1 NEXT -type REQ_OVERRIDE -invoke vserver google
```

To bind an AppFlow policy to a specific virtual server by using the command line interface

At the command prompt, type the following command to bind an appflow policy to a specific virtual server and verify the configuration:

```
1 bind lb vserver <name> -policyname <policy_name> -priority <priority>
```

Example

```
1 bind lb vserver google -policyname af_policy_google_10.102.19.179 -priority 251
```

To globally bind an AppFlow policy by using the configuration utility

Navigate to System > AppFlow, click AppFlow policy Manager and select the relevant Bind Point (Default Global) and Connection Type, and then bind the AppFlow policy.

To bind an AppFlow policy to a specific virtual server by using the configuration utility

Navigate to Traffic Management > Load Balancing > Virtual Servers, select the virtual server, and click Policies, and bind the AppFlow policy.
Enabling AppFlow for Virtual Servers

If you want to monitor only the traffic through certain virtual servers, enable AppFlow specifically for those virtual servers. You can enable AppFlow for load balancing, content switching, cache redirection, SSL VPN, GSLB, and authentication virtual servers.

To enable AppFlow for a virtual server by using the command line interface

At the command prompt, type:

```
set cs vserver <name> <protocol> <IPAddress> <port> -appflowLog ENABLED
```

Example

```
set cs vserver Vserver-CS-1 HTTP 10.102.29.161 80 -appflowLog ENABLED
```

To enable AppFlow for a virtual server by using the configuration utility

Navigate to Traffic Management > Content Switching > Virtual Servers, select the virtual server, and enable AppFlow Logging option.

Enabling AppFlow for a Service

You can enable AppFlow for services that are to be bound to the load balancing virtual servers.

To enable AppFlow for a service by using the command line interface

At the command prompt, type:

```
set service <name> -appflowLog ENABLED
```

Example

```
set service ser -appflowLog ENABLED
```
To enable AppFlow for a service by using the configuration utility

Navigate to Traffic Management > Load Balancing > Services, select the service, and enable AppFlow Logging option.

Setting the AppFlow Parameters

You can set AppFlow parameters to customize the exporting of data to the collectors.

To set the AppFlow Parameters by using the command line interface

At the command prompt, type the following commands to set the AppFlow parameters and verify the settings:

```
1  set appflow param [-templateRefresh <secs>] [-appnameRefresh <secs>] [-flowRecordInterval <secs>] [-udpPmtu <positive_integer>] [-httpUrl ( **ENABLED** | **DISABLED** )] [-httpCookie ( **ENABLED** | **DISABLED** )] [-httpReferer ( **ENABLED** | **DISABLED** )] [-httpMethod ( **ENABLED** | **DISABLED** )] [-httpHost ( **ENABLED** | **DISABLED** )] [-httpUserAgent ( **ENABLED** | **DISABLED** )] [-httpXForwardedFor ( **ENABLED** | **DISABLED** )][-clientTrafficOnly ( **YES** | **NO** )]
2
3  show appflow Param
```

Example

```
1  set appflow Param -templateRefresh 240 -udpPmtu 128 -httpUrl enabled
```

To set the AppFlow parameters by using the configuration utility

Example: Configuring AppFlow for DataStream

The following example illustrates the procedure for configuring AppFlow for DataStream using the command line interface.
When the Citrix ADC appliance receives a database request, the appliance evaluates the request against a configured policy. If a match is found, the details are sent to the AppFlow collector configured in the policy.

Exporting performance data of web pages to AppFlow collector

January 10, 2019

The EdgeSight Monitoring application provides web page monitoring data with which you can monitor the performance of various Web applications served in a Citrix ADC environment. You can now export this data to AppFlow collectors to get an in-depth analysis of the web page applications. AppFlow, which is based on IPFIX standard, provides more specific information about web application performance than does EdgeSight monitoring alone.

You can configure both load balancing and content switching virtual servers to export EdgeSight Monitoring data to AppFlow collectors. Before configuring a virtual server for AppFlow export, associate an Appflow action with the EdgeSight Monitoring responder policy.

The following web page performance data is exported to AppFlow:

- **Page Load Time.** Elapsed time, in milliseconds, from when the browser starts to receive the first byte of a response until the user starts to interact with the page. At this stage, all the page content might not be loaded.
- **Page Render Time.** Elapsed time, in milliseconds, from when the browser receives the first byte of response until either all page content has been rendered or the page load action has timed
• **Time Spent on the Page.** Time spent by users on a page. Represents the period of time from one page request to the next one.

AppFlow transmits the performance data by using the Internet Protocol Flow Information eXport (IP-FIX) format, which is an open Internet Engineering Task Force (IETF) standard defined in RFC 5101. The AppFlow templates use the following enterprise-specific Information Elements (EIEs) to export the information:

- **Client Load End Time.** Time at which the browser received the last byte of a response to load all the objects of the page such as images, scripts, and stylesheets.
- **Client Load Start Time.** Time at which the browser receives the first byte of the response to load any objects of the page such as images, scripts, and stylesheets.
- **Client Render End Time.** Time at which browser finished rendering the entire page, including the embedded objects.
- **Client Render Start Time.** Time at which the browser started rendering the page.

### Prerequisites for Exporting Performance Data of Web Pages to AppFlow Collectors

Before associating the AppFlow action with the AppFlow policy, verify that the following prerequisites have been met:

- The AppFlow feature has been enabled and configured.
- The Responder feature has been enabled.
- The EdgeSight Monitoring feature has been enabled.
- EdgeSight Monitoring has been enabled on the load balancing or content switching virtual servers bound to the services of applications for which you want to collect the performance data.

### Associating an AppFlow Action with the EdgeSight Monitoring Responder Policy

To export the web page performance data to the AppFlow collector, you must associate an AppFlow action with the EdgeSight Monitoring responder policy. An AppFlow action specifies which set of collectors receive the traffic.

**To associate an AppFlow action with the EdgeSight Monitoring Responder policy by using the command line interface**

At the command prompt, type:

```
set responder policy <name> -appflowAction <action_Name>
```
Example

```bash
set responder policy pol -appflowAction actn
```

To associate an AppFlow action with the EdgeSight Monitoring Responder policy by using the configuration utility

2. In the details pane, select an EdgeSight Monitoring responder policy, and then click Open.
3. In the Configure Responder Policy dialog box, in the AppFlow Action drop-down list, select the AppFlow action associated with the collectors to which you want to send the web-page performance data.
4. Click OK.

Configuring a Virtual Server to Export EdgeSight Statistics to Appflow Collectors

To export EdgeSight statistics information from a virtual server to the AppFlow collector, you must associate an AppFlow action with the virtual server.

To associate an AppFlow action with a Load Balancing or Content Switching virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers. You can also navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, select a virtual server, or multiple virtual servers, and then click Enable EdgeSight Monitoring.
3. In the Enable EdgeSight Monitoring dialog box, select the Export EdgeSight statistics to Appflow check box.
4. From the Appflow Action drop-down list, select the AppFlow action. The AppFlow action defines the list of AppFlow collectors to which it exports EdgeSight Monitoring statistics. If you have selected multiple load balancing virtual servers, the same AppFlow Action will be associated with the responder policies bound to them. You can later change the AppFlow Action configured for each of the selected Load Balancing virtual server individually, if required.
5. Click OK.

Session reliability on NetScaler high availability pair

January 10, 2019
When a network disruption or a device failover occurs during an ICA session, session reconnection can use one of two mechanisms: Session Reliability or Auto Client Reconnect.

**Session Reliability**, the preferred mode, is a seamless experience for the user. The disruption is barely noticeable for brief network interruptions.

**Auto Client Reconnect**, the fallback option, involves restarting the client. This mechanism is disruptive for the user and is not always supported.

Receivers can now reconnect their ICA sessions seamlessly using the ICA Session Reliability feature, when HDX Insight is enabled.

This feature works both in standalone and in a NetScaler HA pair configuration and even when a NetScaler failover happens.

**Note**

- NetScaler appliances should be running on software version 11.1 build 49.16 or later.
- You should not Enable or disable Session Reliability mode when the NetScaler appliances have active connections.
- Enabling or Disabling the feature when connections are still active causes HDX Insight to stop parsing those sessions after a failover occurs and result in loss of information about the sessions.
- Session Reliability on a high availability setup is enabled by default for NetScaler software version 11.1 49.16 or later. Session reliability is supported on a high availability setup only if both the nodes of the setup run the same build (for example, release 11.1 build 53). In other words, session reliability is not supported on a high availability setup if both the nodes run different builds (for example, one node has release 11.1 build 53 whereas the other has release 11.1 build 56).

**To configure Session reliability from NetScaler CLI:**

1. At the command line, use the default system administrator credentials to log on to the system.
2. To enable Session Reliability on HA failover, at the prompt, type: `set ica parameter EnableSRon-HAFailover YES`
3. To disable Session Reliability on HA failover, at the prompt, type: `set ica parameter EnableSRon-HAFailover NO`

**To Enable Session reliability on HA failover from NetScaler GUI:**

1. In a web browser, type the IP address of the primary NetScaler instance in the HA pair (for example, `http://192.168.100.1`).
2. In **User Name** and **Password**, enter the administrator credentials.
3. On the **Configuration** tab, navigate to **System > Settings**, and click **Change ICA Parameters**.
4. In in the Change ICA parameters section, select **Session Reliability on HA Failover**.
5. Click **OK**.
Limitations

- Enabling this feature will result in increased bandwidth consumption which is due to ICA compression being turned off by the feature, and the extra traffic between the primary and secondary nodes to keep them in sync.
- This feature is supported in Active-Passive mode only. Active-Active mode is not currently supported.
- When HDX Insight is enabled, and Session Reliability on HA knob is set to NO, only ACR reconnect mode is supported in NetScaler high availability failover scenario. The HA knob does not disable Session Reliability if HDX Insight is disabled.

The **Session Reconnect Semantics** table is as follows:

<table>
<thead>
<tr>
<th>Status</th>
<th>EnableSRonHAFailover Yes (Default)</th>
<th>EnableSRonHAFailover No</th>
</tr>
</thead>
<tbody>
<tr>
<td>HDX Insight Enabled</td>
<td>Session reconnect for ICA</td>
<td>Session reconnect for ICA Sessions works</td>
</tr>
<tr>
<td>HDX Insight disabled</td>
<td>Session reconnect for ICA</td>
<td>Session reconnect for ICA Sessions works</td>
</tr>
</tbody>
</table>

**Points to note**

- Session Reliability for ICA sessions works out of the box with Gateway.
- Session Reliability for ICA sessions does not work ONLY when both the following conditions are met:
  - HDX Insight is enabled
  - EnableSRonHAFailover is set to NO.
- Setting EnableSRonHAFailover knob to either YES or NO does not make any difference, when HDX Insight is disabled.

Application Firewall

September 20, 2018

The following topics cover installation and configuration of the Citrix Application Firewall feature.
The Citrix Application Firewall offers easy to configure options to meet a wide range of application security requirements. Web App Firewall profiles, which consist of sets of security checks, can be used to protect both the requests and the responses by providing deep packet-level inspections. Each pro-

© 1999-2018 Citrix Systems, Inc. All rights reserved.
file includes an option to select basic protections or advanced protections. Some protections might require use of other files. For example, xml validation checks might require WSDL or schema files. The profiles can also use other files, such as signatures or error objects. These files can be added locally, or they can be imported ahead of time and saved on the appliance for future use. They can be shared by multiple profiles.

Profiles work in conjunction with the Web App Firewall policies. Each policy identifies a type of traffic, and that traffic is inspected for the security check violations specified in the profile that is associated with the policy. The policies can have different bind points, which determine the scope of the policy. For example, a policy that is bound to a specific virtual server is invoked and evaluated for only the traffic flowing through that virtual server. The policies are evaluated in the order of their designated priorities, and the first one that matches the request or response is applied.

- Quick Deployment of Web App Firewall Protection

You can use the following procedure for quick deployment of Web App Firewall security:

1. Add an appfw profile and select the appropriate type (html, xml, web2.0) for the security requirements of the application.
2. Select the required level of security (basic or advanced).
3. Add or import the required files, such as signatures or WSDL.
4. Configure the profile to use the files, and make any other necessary changes to the default settings.
5. Add an appfw policy for this profile.
6. Bind the policy to the target bind point and specify the priority.

- Web App Firewall entities

Following are brief overviews of the Web App Firewall entities. For details, see the Web App Firewall Guide.

Profile—An Web App Firewall profile specifies what to look for and what to do. It inspects both the request and the response to determine which potential security violations should be checked and what actions should be taken when processing a transaction. A profile can protect an HTML, XML or HTML and XML payload. Depending on the security requirements of the application, you can create either a basic or an advanced profile. A basic profile can protect against known attacks. If higher security is required, you can deploy an advanced profile to allow controlled access to the application resources, blocking zero day attacks. However, a basic profile can be modified to offer advanced protections, and vice versa. Multiple action choices (for example, block, log, learn, and transform) are available. Advanced security checks might use session cookies and hidden form tags for controlling and monitoring the client connections. Web App Firewall profiles can learn the triggered violations and suggest the relaxation rules.

Basic Protections—A basic profile includes a preconfigured set of Start URL and Deny URL relaxation rules. These relaxation rules determine which requests should be allowed and which
should be denied. Incoming requests are matched against these lists and the configured actions are applied. This allows the user to be able to secure applications with minimal configuration for relaxation rules. The Start URL rules protect against forceful browsing. Known web server vulnerabilities that are exploited by hackers can be detected and blocked by enabling a set of default Deny URL rules. Commonly launched attacks, such as Buffer Overflow, SQL, or Cross-site scripting can also be easily detected.

**Advanced Protections**—As the name indicates, advanced protections are used for applications that have higher security requirements. Relaxation rules are configured to allow access to only specific data and block the rest. This positive security model mitigates unknown attacks, which might not be detected by basic security checks. In addition to all the basic protections, an advanced profile keeps track of a user session by controlling the browsing, checking for cookies, specifying input requirements for various form fields, and protecting against tampering of forms or cross-site request forgery attacks. Learning, which observes the traffic and deploys the appropriate relaxations, is enabled by default for many security checks. Although easy to use, advanced protections require due consideration, because they offer tighter security but also require more processing and do not allow use of caching, which can affect performance.

**Import**—Import functionality is useful when Web App Firewall profiles need to use external files, that is, files hosted on an external or internal web server, or that have to be copied from a local machine. Importing a file and storing it on the appliance is very useful, especially in situations where you have to control access to external websites, or where compilation takes a long time, large files have to be synced across HA deployments, or you can reuse a file by copying it across multiple devices. For example:

- WSDLs hosted on external web servers can be imported locally before blocking access to external websites.
- Large signature files generated by an external scan tool such as Cenzic can be imported and precompiled, using schema on the Citrix appliance.
- A customized HTML or XML error page can be imported from an external web server or copied from a local file.

**Signatures**—Signatures are very powerful, because they use pattern matching to detect malicious attacks and can be configured to check both the request and the response of a transaction. They are a preferred option when a customizable security solution is needed. Multiple choices (for example, block, log, learn, and transform) are available for the action to take when a signature match is detected. The Web App Firewall has a built-in default signature object consisting of more than 1,300 signature rules, with an option to get the latest rules by using the auto-update feature. Rules created by other scan tools can also be imported. The signature object can be customized by adding new rules, which can work in conjunction with the other security checks specified in the Web App Firewall profile. A signature rule can have multiple patterns and can flag a violation only when all the patterns are matched, thereby avoiding false positives. Careful
selection of a literal fastmatch pattern for a rule can significantly optimize processing time.

**Policies**—Web App Firewall Policies are used to filter and separate the traffic into different types. This provides the flexibility to implement different levels of security protections for the application data. Access to highly sensitive data can be directed to advanced security-check inspections, while less sensitive data is protected by basic-level security inspections. Policies can also be configured to bypass security-check inspection for harmless traffic. Higher security requires more processing, so careful design of the policies can provide desired security along with optimized performance. The priority of the policy determines the order in which it is evaluated, and its bind point determines the scope of its application.

**Highlights**

1. Ability to secure a wide range of applications by protecting different types of data, implementing the right level of security for different resources, and still getting maximum performance.
2. Flexibility to add or modify a security configuration. You can tighten or relax security checks by enabling or disabling basic and advanced protections.
3. Option to convert an HTML profile to an XML or Web2.0 (HTML+XML) profile and vice-versa, providing the flexibility to add security for different types of payload.
4. Easily deployed actions to block attacks, monitor them in logs, collect statistics, or even transform some attack strings to render them harmless.
5. Ability to detect attacks by inspecting incoming requests, and to prevent leakage of sensitive data by inspecting the responses sent by the servers.
6. Capability to learn from the traffic pattern to get recommendations for easily editable relaxation rules that can be deployed to allow exceptions.
7. Hybrid security model that applies the power of customizable signatures to block attacks that match specified patterns, and provides the flexibility to use the positive-security-model checks for basic or advanced security protections.
8. Availability of comprehensive configuration reports, including information about PCI-DSS compliance.

**FAQs and Deployment Guide**

September 18, 2018

**Q: Why is NetScaler App Firewall the preferred choice for securing applications?**

**With the following features, the NetScaler App App Firewall offers a comprehensive security solution:**
• **Hybrid security model**: NetScaler hybrid security model allows you to take advantage of both a positive security model and a negative security model to come up with a configuration ideally suited for your applications.

  - **Positive security model** protects against Buffer Overflow, CGI-BIN Parameter Manipulation, Form/Hidden Field Manipulation, Forceful Browsing, Cookie or Session Poisoning, Broken ACLs, Cross-Site Scripting (XSS), Command Injection, SQL Injection, Error Triggering Sensitive Information Leak, Insecure Use of Cryptography, Server Misconfiguration, Back Doors and Debug Options, Rate-Based Policy Enforcement, Well Known Platform Vulnerabilities, Zero-Day Exploits, Cross Site Request Forgery (CSRF), and leakage of Credit Card and other sensitive data.

  - **Negative security model** uses a rich set signatures to protect against L7 and HTTP application vulnerabilities. The App Firewall is integrated with several third party scanning tools, such as those offered by Cenzic, Qualys, Whitehat, and IBM. The built-in XSLT files allow easy importation of rules, which can be used in conjunction with the native-format Snort based rules. An auto-update feature gets the latest updates for new vulnerabilities.

The positive security model might be the preferred choice for protecting applications that have a high need for security, because it gives you the option to fully control who can access what data. You allow only what you want and block the rest. This model includes a built-in security check configuration, which is deployable with few clicks. However, keep in mind that the tighter the security, the greater the processing overhead.

The negative security model might be preferable for customized applications. The signatures allow you to combine multiple conditions, and a match and the specified action are triggered only when all the conditions are satisfied. You block only what you don’t want and allow the rest. A specific fast-match pattern in a specified location can significantly reduce processing overhead to optimize performance. The option to add your own signature rules, based on the specific security needs of your applications, gives you the flexibility to design your own customized security solutions.

• **Request as well as response side detection and protection**: You can inspect the incoming requests to detect any suspicious behavior and take appropriate actions, and you can check the responses to detect and protect against leakage of sensitive data.

• **Rich set of built-in protections for HTML, XML and JSON payloads**: The App Firewall offers 19 different security checks. Six of them (such as Start URL and Deny URL) apply to both HTML and XML data. Five checks (such as Field Consistency and Field Format) are specific to HTML, and eight (such as XML Format and Web Service Interoperability) are specific to XML payloads. This feature includes a rich set of actions and options. For example, URL Closure enables you to control and optimize the navigation through your website, to safeguard against forceful browsing without having to configure relaxation rules to allow each and every legitimate URL. You have the option to remove or x-out the sensitive data, such as credit-card numbers, in the response. Be it SOAP Array attack protection, XML denial of Service (XDoS), WSDL scan prevention, Attach-
ment check, or any number of other XML attacks, you have the comfort of knowing that you have an ironclad shield protecting your data when your applications are protected by the App Firewall. The signatures allow you to configure rules using XPATH-Expressions to detect violations in the body as well as the header of a JSON payload.

- **GWT:** Support for protecting Google Web Toolkit applications to safeguard against SQL, XSS and Form Field Consistency check violations.

- **Java-free, user friendly graphical user interface (GUI):** An intuitive GUI and preconfigured security checks make it easy to deploy security by clicking a few buttons. A wizard prompts and guides you to create the required elements, such as profiles, policies, signatures, and bindings. The HTML5 based GUI is free of any Java dependency. It’s performance is significantly better than that of the older, Java based versions.

- **Easy to Use and automatable CLI:** Most of the configuration options that are available in GUI are also available in the command line interface (CLI). The CLI commands can be executed by a batch file and are easy to automate.

- **Support for REST API:** The NetScaler NITRO protocol supports a rich set of REST API’s to automate App Firewall configuration and collect pertinent statistics for ongoing monitoring of security violations.

- **Learning:** The App Firewall’s ability to learn by monitoring traffic to fine tune security is very user friendly. The learning engine recommends rules, which makes it easy to deploy relaxations without proficiency in regular expressions.

- **RegEx editor support:** Regular expression offer an elegant solution to the dilemma of wanting to consolidate rules and yet optimize search. You can capitalize on the power of regular expressions to configure URLs, field names, signature patterns, and so on. The rich built-in GUI RegEx editor offers you a quick reference for the expressions and provides a convenient way to validate and test your RegEx for accuracy.

- **Customized error page:** Blocked requests can be redirected to an error URL. You also have the option to display a customized error object that uses supported variables and Citrix default syntax (advanced PI expressions) to embed troubleshooting information for the client.

- **PCI-DSS, stats, and other violation reports:** The rich set of reports makes it easy to meet the PCI-DSS compliance requirement, gather stats about traffic counters, and view violation reports for all profiles or just one profile.

- **Logging and click-to-rule from log:** Detailed logging is supported for native as well as CEF format. The App Firewall offers you the ability to filter targeted log messages in the syslog viewer. You can select a log message and deploy a corresponding relaxation rule by a simple click of a button. You have the flexibility to customize log messages and also have support for generating web logs. For additional details, see [App Firewall Log topic](#).
• **Include violation logs in trace records:** The ability to include log messages in the trace records makes it very easy to debug unexpected behavior such as reset and block.

• **Cloning:** The useful Import/Export profile option allows you to clone the security configuration from one NetScaler appliance to others. Export learned data options make it easy to export the learned rules to an Excel file. You can then get them reviewed and approved by application owner before applying them.

• **An AppExpert template** (a set of configuration settings) can be designed to provide appropriate protection for your websites. You can simplify and expedite the process of deploying similar protection on other appliances by exporting these cookie-cutter templates to a template. For additional details, see [AppExpert Template](#).

• **Sessionless security checks:** Deploying sessionless security checks can help you reduce the memory footprint and expedite the processing.

• **Interoperability with other NetScaler features:** The App Firewall works seamlessly with other NetScaler features, such as rewrite, URL transformation, integrated caching, CVPN, and rate limiting.

• **Support of PI expressions in policies:** You can leverage the power of advanced PI expressions to design policies to implement different levels of security for different parts of your application.

• **Support for IPv6:** The App Firewall supports both IPv4 and IPv6 protocols.

• **Geolocation based security protection:** You have the flexibility of using Citrix default syntax (PI Expressions) for configuring location based policies, which can be used in conjunction with a built-in location database to customize firewall protection. You can identify the locations from which malicious requests originate, and enforce the desired level of security-check inspections for requests that originate from a specific geographical location.

• **Performance:** Request-side streaming significantly improves performance. As soon as a field is processed, the resulting data is forwarded to the back end while evaluation continues for the remaining fields. The improvement in processing time is especially significant when handling large posts.

• **Other security features:** The App Firewall has several other security knobs that can help ensure the security of your data. For example, the **Confidential Field** lets you block leakage of sensitive information in the log messages, and **Strip HTML Comment** allows you to remove the HTML comments from the response before forwarding it to the client. **Field Types** can be used to specify what inputs are allowed in the forms submitted to your application.

### Q: What do I need to do to configure App Firewall?

Do the following:
• Add an App Firewall profile and select the appropriate type (html, xml, web2.0) for the security requirements of the application.
• Select the required level of security (basic or advanced).
• Add or import the required files, such as signatures or WSDL.
• Configure the profile to use the files, and make any other necessary changes to the default settings.
• Add an App Firewall policy for this profile.
• Bind the policy to the target bind point and specify the priority.

Q: How do I know what profile type to choose?

The App Firewall profile offers protection for both HTML and XML payloads. Depending on the need of your application, you can choose either a HTML profile or XML profile. If your application supports both HTML and XML data, you can choose a Web2.0 profile.

Q: What is the difference between basic and advanced profiles? How do I decide which one I need?

The decision to use a basic or an advance profile depends on the security need of your application. A basic profile includes a preconfigured set of Start URL and Deny URL relaxation rules. These relaxation rules determine which requests are allowed and which are denied. Incoming requests are matched with the preconfigured rules, and the configured actions are applied. The user can secure applications with minimal configuration of relaxation rules. The Start URL rules protect against forceful browsing. Known web server vulnerabilities that are exploited by hackers can be detected and blocked by enabling a set of default Deny URL rules. Commonly launched attacks, such as Buffer Overflow, SQL, or Cross-Site Scripting can also be easily detected.

As the name indicates, advanced protections are for applications that have higher security requirements. Relaxation rules are configured to allow access to only specific data and block the rest. This positive security model mitigates unknown attacks, which might not be detected by basic security checks. In addition to all the basic protections, an advanced profile keeps track of a user session by controlling the browsing, checking for cookies, specifying input requirements for various form fields, and protecting against tampering of forms or Cross-Site Request Forgery attacks. Learning, which observes the traffic and recommends the appropriate relaxations, is enabled by default for many security checks. Although easy to use, advanced protections require due consideration, because they offer tighter security but also require more processing. Some advance security checks do not allow use of caching, which can affect performance.

Keep the following points in mind when deciding whether to use basic or advanced profiles:
• Basic and advanced profiles are just starting templates. You can always modify the basic profile to deploy advanced security features, and vice versa.
• Advanced security checks require more processing and can affect performance. Unless your application needs advanced security, you might want to start with a basic profile and tighten the security as required for your application.
• You do not want to enable all security checks unless your application needs it.

Q: What is a policy? How do I select the bind point and set the priority?

App Firewall policies can help you sort your traffic into logical groups for configuring different levels of security implementation. Carefully select the bind points for the policies to determine which traffic is matched against which policy. For example, if you want every incoming request to be checked for SQL/XSS attacks, you can create a generic policy and bind it globally. Or, if you want to apply more stringent security checks to the traffic of a virtual server hosting applications that contain sensitive data, you can bind a policy to that virtual server.

Careful assignment of priorities can enhance the traffic processing. You want to assign higher priorities to more specific policies and lower priorities to generic policies. Note that the higher the number, the lower the priority. A policy with a priority of 10 is evaluated before a policy that has a priority of 15.

You can apply different levels of security for different kinds of contents, e.g. requests for static objects like images and text can be by-passed by using one policy and requests for other sensitive contents can be subjected to a much stringent check by using a second policy.

Q: How do I go about configuring the rules to secure my application?

The App Firewall makes it very easy to design the right level of security for your web-site. You can have multiple App Firewall policies, bound to different App Firewall profiles, to implement different levels of security-check inspections for your applications. You can initially monitor the logs to observe what security threats are being detected and which violations are being triggered. You can either manually add the relaxation rules or take advantage of the App Firewall’s recommended learned rules to deploy the required relaxations to avoid false positives.

The NetScaler App Firewall offers **visualizer** support in GUI, which makes rule management very easy. You can easily view all the data on one screen, and take action on several rules with one click. The biggest advantage of the visualizer is that it recommends regular expressions to consolidate several rules. You can select a subset of the rules, basing your selection on the delimiter and Action URL. Visualizer support is available for viewing 1) learned rules and 2) relaxation rules.

1) The visualizer for learned rules offers the option to edit the rules and deploy them as relaxations. You can also skip (ignore) rules.
2) The visualizer for deployed relaxations offers you the option to add a new rule or edit an existing one. You can also enable or disable a group of rules by selecting a node and clicking the Enable or Disable button in the relaxation visualizer.

**Q: What are signatures? How do I know which signatures to use?**

A signature is an object that can have multiple rules. Each rule consists of one or more patterns that can be associated with a specified set of actions. The App Firewall has a built-in default signature object consisting of more than 1,300 signature rules, with an option to get the latest rules by using the auto-update feature to get protection against new vulnerabilities. Rules created by other scan tools can also be imported.

Signatures are very powerful because they use pattern matching to detect malicious attacks and can be configured to check both the request and the response of a transaction. They are a preferred option when a customizable security solution is needed. Multiple action choices (for example, block, log, learn, and transform) are available for when a signature match is detected. The default signatures cover rules to protect different types of applications, such as web-cgi, web-coldfusion, web-frontpage, web-iis, web-php, web-client, web-activex, web-shell-shock, and web-struts. To match the needs of your application, you can select and deploy the rules belonging to a specific category.

Signature-usage tips:

- You can just make a copy of the default signature object and modify it to enable the rules you need and configure the actions you want.
- The signature object can be customized by adding new rules, which can work in conjunction with other signature rules.
- The signature rules can also be configured to work in conjunction with the security checks specified in the App Firewall profile. If a match indicating a violation is detected by a signature as well as a security check, the more restrictive action is the one that gets enforced.
- A signature rule can have multiple patterns and be configured to flag a violation only when all the patterns are matched, thereby avoiding false positives.
- Careful selection of a literal fast-match pattern for a rule can significantly optimize processing time.

**Q: Does the App Firewall work with other NetScaler features?**

The App Firewall is fully integrated into the NetScaler appliance and works seamlessly with other features. You can configure maximum security for your application by using other NetScaler security features in conjunction with the App Firewall. For example, AAA-TM can be used to authenticate the user, check the user’s authorization to access the content, and log the accesses, including invalid login
attempts. **Rewrite** can be used to modify the URL or to add, modify or delete headers, and **Responder** can be used to deliver customized content to different users. You can define the maximum load for your website by using **Rate Limiting** to monitor the traffic and throttle the rate if it is too high. **HTTP Denial-of-Service (DoS)** protection can help distinguish between real HTTP clients and malicious DoS clients. You can narrow the scope of security-check inspection by binding the App Firewall policies to virtual servers, while still optimizing the user experience by using the **Load Balancing** feature to manage heavily used applications. Requests for static objects such as images or text can bypass security check inspection, taking advantage of **integrated caching** or **compression** to optimize the bandwidth usage for such content.

**Q: How is the payload processed by the App Firewall and the other NetScaler features?**

A diagram showing details of the L7 packet flow in a NetScaler appliance is available in the Processing Order of Features section at **Getting Started** topic.

**Q: What is the recommended workflow for App Firewall deployment?**

Now that you know the advantages of using the state-of-the-art security protections of the NetScaler App Firewall, you might want to collect additional information that can help you design the optimal solution for your security needs. Citrix recommends that you do the following:

- **Know your environment:** Knowing your environment will help you to identify the best security protection solution (signatures, security checks, or both) for your needs. Before you begin configuration, you should gather the following information.
  - **OS:** What kind of OS (MS Windows, Linux, BSD, Unix, others) do you have?
  - **Web Sever:** What web server (IIS, Apache or NetScaler Enterprise Server) are you running?
  - **Application:** What type of applications are running on your application server (for example, ASP.NET, PHP, Cold Fusion, ActiveX, FrontPage, Struts, CGI, Apache Tomcat, Domino, and WebLogic)?
  - Do you have customized applications or off-the-shelf (for example, Oracle, SAP) applications? What version you are using?
  - **SSL:** Do you require SSL? If so, what key size (512, 1024, 2048, 4096) is used for signing certificates?
  - **Traffic Volume:** What is the average traffic rate through your applications? Do you have seasonal or time-specific spikes in the traffic?
  - **Server Farm:** How many servers do you have? Do you need to use load balancing?
  - **Database:** What type of database (MS-SQL, MySQL, Oracle, Postgres, SQLite, nosql, Sybase, Informix etc.) do you use?
  - **DB Connectivity:** What kind of database connectivity do you have (DSN, per-file connection string, single file connection string) and what drivers are used?
• **Identify your security needs**: You might want to evaluate which applications or specific data need maximum security protection, which ones are less vulnerable, and the ones for which security inspection can safely be bypassed. This will help you in coming up with an optimal configuration, and in designing appropriate policies and bind points to segregate the traffic. For example, you might want to configure a policy to bypass security inspection of requests for static web content, such as images, MP3 files, and movies, and configure another policy to apply advanced security checks to requests for dynamic content. You can use multiple policies and profiles to protect different contents of the same application.

• **License requirement**: Citrix offers a unified solution to optimize the performance of your application by taking advantage of a rich set of features such as load balancing, content switching, caching, compression, responder, rewrite, and content filtering, to name a few. Identifying the features that you want can help you decide which license you need.

• **Install and baseline a NetScaler appliance**: Create a virtual server and run test traffic through it to get an idea of the rate and amount of traffic flowing through your system. This information will help you to identify your capacity requirement and select the right appliance (VPX, MPX, or SDX).

• **Deploy the App Firewall**: Use the App Firewall wizard to proceed with a simple security configuration. The wizard walks you through several screens and prompts you to add a profile, policy, signature, and security checks.
  - **Profile**: Select a meaningful name and the appropriate type (HTML, XML or WEB 2.0) for your profile. The policy and signatures will be auto-generated using the same name.
  - **Policy**: The auto-generated policy has the default Expression (true), which selects all traffic and is bound globally. This is a good starting point unless you have in mind a specific policy that you want to use.
  - **Protections**: The wizard helps you take advantage of the hybrid security model, in which you can use the default signatures offering a rich set of rules to protect different types of applications. **Simple edit mode** allows you to view the various categories (CGI, Cold Fusion, PHP, etc.). You can select one or more categories to identify a specific set of rules applicable to your application. Use the **Action** option to enable all the signature rules in the selected categories. Make sure that blocking is disabled, so that you can monitor the traffic before tightening the security. Click **Continue**. In the **Specify Deep protections** pane, you can make changes as needed to deploy the security check protections. In most cases, basic protections are sufficient for initial security configuration. Run the traffic for a while to collect a representative sample of the security-inspection data.
  - **Tightening the security**: After deploying App Firewall and observing the traffic for a while, you can start tightening the security of your applications by deploying relaxations and then enabling blocking. **Learning, Visualizer**, and **Click to deploy rules** are useful features that make it very easy to tweak your configuration to come up with just the right level of relaxation. At this point, you can also change the policy expression and/or configure
additional policies and profiles to implement desired levels of security for different types of content.

- **Debugging:** If you see unexpected behavior of your application, the App Firewall offers various options for easy debugging:
  * **Log.** If legitimate requests are getting blocked, your first step is to check the ns.log file to see if any unexpected security-check violation is being triggered.
  * **Disable feature.** If you do not see any violations but are still seeing unexpected behavior, such as an application resetting or sending partial responses, you can disable the App Firewall feature for debugging. If the issue persists, it rules out the App Firewall as a suspect.
  * **Trace records with log messages.** If the issue appears to be App Firewall related and needs closer inspection, you have the option to include security violation messages in an nstrace. You can use “Follow TCP stream” in the trace to view the details of the individual transaction, including headers, payload, and the corresponding log message, together on the same screen. Details of how to use this functionality are available at Appendixes.

**Introduction**

September 18, 2018

The NetScaler App App Firewall prevents security breaches, data loss, and possible unauthorized modifications to web sites that access sensitive business or customer information. It does so by filtering both requests and responses, examining them for evidence of malicious activity, and blocking those that exhibit such activity. Your site is protected not only from common types of attacks, but also from new, as yet unknown attacks. In addition to protecting web servers and web sites from unauthorized access and misuse by hackers and malicious programs, the App Firewall provides protection against security vulnerabilities in legacy CGI code or scripts, other web frameworks, web server software, and the underlying operating systems.

The NetScaler App Firewall is available as a stand-alone appliance, or as a feature on a NetScaler virtual appliance (VPX). In the App Firewall documentation, the term NetScaler refers to the platform on which the App Firewall is running, regardless of whether that platform is a dedicated firewall appliance, a NetScaler on which other features have also been configured, or a NetScaler VPX.

To use the App Firewall, you must create at least one security configuration to block connections that violate the rules that you set for your protected web sites. The number of security configurations that you might want to create depends on the complexity of your web site. In some cases, a single configuration is sufficient. In other cases, particularly those that include interactive web sites, web sites that access database servers, online stores with shopping carts, you might need several different configurations to best protect sensitive data without wasting significant effort on content that is not
vulnerable to certain types of attacks. You can often leave the defaults for the global settings, which affect all security configurations, unchanged. However, you can change the global settings if they conflict with other parts of your configuration or you prefer to customize them.

**Web application security**

September 18, 2018

Web application security is network security for computers and programs that communicate by using the HTTP and HTTPS protocols. This is an extremely broad area in which security flaws and weaknesses abound. Operating systems on both servers and clients have security issues and are vulnerable to attack. Web server software and web site enabling technologies such as CGI, Java, JavaScript, PERL and PHP have underlying vulnerabilities. Browsers and other client applications that communicate with web-enabled applications also have vulnerabilities. Web sites that use any technology but the simplest of HTML, including any site that allows interaction with visitors, often have vulnerabilities of their own.

In the past, a breach in security was often just an annoyance, but today that is seldom the case. For example, attacks in which a hacker gained access to a web server and made unauthorized modifications to (defaced) a web site used to be common. They were usually launched by hackers who had no motivation beyond demonstrating their skills to fellow hackers or embarrassing the targeted person or company. Most current security breaches, however, are motivated by a desire for money. The majority attempt to accomplish one or both of the following goals: to obtain sensitive and potentially valuable private information, or to obtain unauthorized access to and control of a web site or web server.

Certain forms of web attacks focus on obtaining private information. These attacks are often possible even against web sites that are secure enough to prevent an attacker from taking full control. The information that an attacker can obtain from a web site can include customer names, addresses, phone numbers, social security numbers, credit card numbers, medical records, and other private information. The attacker can then use this information or sell it to others. Much of the information obtained by such attacks is protected by law, and all of it by custom and expectation. A breach of this type can have extremely serious consequences for customers whose private information is compromised. At best, these customers will have to exercise vigilance to prevent others from abusing their credit cards, opening unauthorized credit accounts in their name, or appropriating their identities outright (identity theft). At worst, the customers may face ruined credit ratings or even be blamed for criminal activities in which they had no part.

Other web attacks are aimed at obtaining control of (or compromising) a web site or the server on which it operates, or both. A hacker who gains control of a web site or server can use it to host unauthorized content, act as a proxy for content hosted on another web server, provide SMTP services to
send unsolicited bulk email, or provide DNS services to support such activities on other compromised
web servers. Most web sites that are hosted on compromised web servers promote questionable or
outright fraudulent businesses. For example, the majority of phishing web sites and child exploitation
web sites are hosted on compromised web servers.

Protecting your web sites and web services against these attacks requires a multilayered defense capa-
ble of both blocking known attacks with identifiable characteristics and protecting against unknown
attacks, which can often be detected because they look different from the normal traffic to your web
sites and web services.

**Known web attacks**

The first line of defense for your web sites is protection against the large number of attacks that are
known to exist and have been observed and analyzed by web security experts. Common types of
attacks against HTML-based web sites include:

- **Buffer overflow attacks.** Sending an extremely long URL, extremely long cookie, or other ex-
tremely long bit of information to a web server in hopes of causing it or the underlying operating
system to hang, crash, or provide the attacker with access to the underlying operating system. A
buffer overflow attack can be used to gain access to unauthorized information, to compromise
a web server, or both.
- **Cookie security attacks.** Sending a modified cookie to a web server, usually in hopes of ob-
taining access to unauthorized content by using falsified credentials.
- **Forceful browsing.** Accessing URLs on a web site directly, without navigating to the URLs by
means of hyperlinks on the home page or other common start URLs on the web site. Individual
instances of forceful browsing may simply indicate a user who bookmarked a page on your web
site, but repeated attempts to access nonexistent content, or content that users should never
access directly, often represent an attack on web site security. Forceful browsing is normally
used to gain access to unauthorized information, but can also be combined with a buffer over-
flow attack in an attempt to compromise your server.
- **Web form security attacks.** Sending inappropriate content to your web site in a web form. In-
appropriate content can include modified hidden fields, HTML or code in a field intended for
alphanumeric data only, an overly long string in a field that accepts only a short string, an al-
phanumeric string in a field that accepts only an integer, and a wide variety of other data that
your web site does not expect to receive in that web form. A web form security attack can be
used either to obtain unauthorized information from your web site or to compromise the web
site outright, usually when combined with a buffer overflow attack.

Two specialized types of attacks on web form security deserve special mention:

- **SQL injection attacks.** Sending an active SQL command or commands in a web form or as part
of a URL, with the goal of causing an SQL database to execute the command or commands. SQL
Injection attacks are normally used to obtain unauthorized information.

- **Cross-site scripting attacks.** Using a URL or a script on a web page to violate the same-origin policy, which forbids any script from obtaining properties from or modifying any content on a different web site. Since scripts can obtain information and modify files on your web site, allowing a script access to content on a different web site can provide an attacker the means to obtain unauthorized information, to compromise a web server, or both.

Attacks against XML-based web services normally fall into at least one of the following two categories: attempts to send inappropriate content to a web service, or attempts to breach security on a web service. Common types of attacks against XML-based web services include:

- **Malicious code or objects.** XML requests that contain code or objects that can either directly obtain sensitive information or can give an attacker control of the web service or underlying server.
- **Badly-formed XML requests.** XML requests that do not conform to the W3C XML specification, and that can therefore breach security on an insecure web service.
- **Denial of service (DoS) attacks.** XML requests that are sent repeatedly and in high volume, with the intent of overwhelming the targeted web service and denying legitimate users access to the web service.

In addition to standard XML-based attacks, XML web services and Web 2.0 sites are also vulnerable to SQL injection and cross-site scripting attacks, as described below:

- **SQL injection attacks.** Sending an active SQL command or commands in an XML-based request, with the goal of causing an SQL database to execute that command or commands. As with HTML SQL injection attacks, XML SQL injection attacks are normally used to obtain unauthorized information.
- **Cross-site scripting attacks.** Using a script included in an XML based application to violate the same-origin policy, which does not allow any script to obtain properties from or modify any content on a different application. Since scripts can obtain information and modify files by using your XML application, allowing a script access to content belonging to a different application can give an attacker the means to obtain unauthorized information, to compromise the application, or both.

Known web attacks can usually be stopped by filtering web site traffic for specific characteristics (signatures) that always appear for a specific attack and should never appear in legitimate traffic. This approach has the advantages of requiring relatively few resources and posing relatively little risk of false positives. It is therefore a valuable tool in fighting attacks on web sites and web services, and configuring basic signature protections that intercept most known web attacks is easy to do.
**Unknown web attacks**

The greatest threat against web sites and applications does not come from known attacks, but from unknown attacks. Most unknown attacks fall into one of two categories: newly-launched attacks for which security firms have not yet developed an effective defense (zero-day attacks), and carefully-targeted attacks on a specific web site or web service rather than many web sites or web services (spear attacks). These attacks, like known attacks, are usually intended to obtain sensitive private information, compromise the web site or web service and allow it to be used for further attacks, or both of those goals.

Zero-day attacks are a major threat to all users. These attacks are usually of the same types as known attacks; zero-day attacks often involve injected SQL, a cross-site script, a cross-site request forgery, or another type of attack similar to known attacks. In most cases, they target vulnerabilities that the developers of the targeted software, web site, or web service either are unaware of or have just learned about. Security firms have therefore usually not developed defenses against these attacks, and even if they have, users have usually not obtained and installed the patches or performed the workarounds necessary to protect against these attacks. The time between discovery of a zero-day attack and availability of a defense (the vulnerability window) is shrinking, but perpetrators can still count on hours or even days in which many web sites and web services lack any specific protection against the attack.

Spear attacks are a major threat, but to a more select group of users. A common type of spear attack, a spear phish, is usually targeted at customers of a specific bank or financial institution, or (less commonly) at employees of a specific company or organization. Unlike other phishes, which are often crudely written forgeries that a user with any familiarity with the actual communications of that bank or financial institution can recognize, spear phishes are letter perfect and extremely convincing. They can contain information specific to the individual that, at first look, no stranger should know or be able to obtain. The spear phisher is therefore able to convince his or her target to provide the requested information, which the phisher can then use to loot accounts, to process illegitimately obtained money from other sources, or to gain access to other, even more sensitive information.

Both of these types of attack have certain characteristics that can usually be detected, although not by using static patterns that look for specific characteristics, as do standard signatures. Detecting these types of attacks requires more sophisticated and more resource-intensive approaches, such as heuristic filtering and positive security model systems. Heuristic filtering looks, not for specific patterns, but for patterns of behaviors. Positive security model systems model the normal behavior of the web site or web service that they are protecting, and then block connections that do not fit within that model of normal use. URL based and web-form based security checks profile normal use of your web sites, and then control how users interact with your web sites, using both heuristics and positive security to block anomalous or unexpected traffic. Both heuristic and positive security, properly designed and deployed, can catch most attacks that signatures miss. However, they require considerably more resources than do signatures, and you must spend some time configuring them properly to avoid false positives. They are therefore usually used, not as the primary line of defense, but as...
backups to signatures or other less resource-intensive approaches.

By configuring these advanced protections in addition to signatures, you create a hybrid security model, which enables the App Firewall to provide comprehensive protection against both known and unknown attacks.

**How App Firewall works**

January 6, 2019

When you install the App Firewall, you create an initial security configuration, which consists of a policy, a profile, and a signatures object. The policy is a rule that identifies the traffic to be filtered, and the profile identifies the patterns and types of behavior to allow or block when the traffic is filtered. The simplest patterns, which are called signatures, are not specified within the profile, but in a signatures object that is associated with the profile.

A signature is a string or pattern that matches a known type of attack. The App Firewall contains over a thousand signatures in seven categories, each directed at attacks on specific types of web servers and web content. Citrix updates the list with new signatures as new threats are identified. During configuration, you specify the signature categories that are appropriate for the web servers and content that you need to protect. Signatures provide good basic protection with low processing overhead. If your applications have special vulnerabilities or you detect an attack against them for which no signature exists, you can add your own signatures.

The more advanced protections are called security checks. A security check is a more rigorous, algorithmic inspection of a request for specific patterns or types of behavior that might indicate an attack or constitute a threat to your protected web sites and web services. It can, for example, identify a request that attempts to perform a certain type of operation that might breach security, or a response that includes sensitive private information such as a social security number or credit card number. During configuration, you specify the security checks that are appropriate for the web servers and content that you need to protect. The security checks are restrictive. Many of them can block legitimate requests and responses if you do not add the appropriate exceptions (relaxations) when configuring them. Identifying the needed exceptions is not difficult if you use the adaptive learning feature, which observes normal use of your web site and creates recommended exceptions.

The App Firewall can be installed as either a Layer 3 network device or a Layer 2 network bridge between your servers and your users, usually behind your company’s router or firewall. It must be installed in a location where it can intercept traffic between the web servers that you want to protect and the hub or switch through which users access those web servers. You then configure the network to send requests to the App Firewall instead of directly to your web servers, and responses to the App Firewall instead of directly to your users. The App Firewall filters that traffic before forwarding it to its final destination, using both its internal rule set and your additions and modifications. It blocks
or renders harmless any activity that it detects as harmful, and then forwards the remaining traffic to
the web server. The following figure provides an overview of the filtering process.

**Note:**
The figure omits the application of a policy to incoming traffic. It illustrates a security configuration in which the policy is to process all requests. Also, in this configuration, a signatures object has been configured and associated with the profile, and security checks have been configured in the profile.

Figure 1. A Flowchart of App Firewall filtering

As the figure shows, when a user requests a URL on a protected web site, the App Firewall first examines the request to ensure that it does not match a signature. If the request matches a signature, the App Firewall either displays the error object (a web page that is located on the App Firewall appliance and which you can configure by using the imports feature) or forwards the request to the designated error URL (the error page). Signatures do not require as many resources as do security checks, so detecting and stopping attacks that are detected by a signature before running any of the security checks reduces the load on the server.

If a request passes signature inspection, the App Firewall applies the request security checks that have been enabled. The request security checks verify that the request is appropriate for your web site or web service and does not contain material that might pose a threat. For example, security checks examine the request for signs indicating that it might be of an unexpected type, request unexpected content, or contain unexpected and possibly malicious web form data, SQL commands, or scripts. If the request fails a security check, the App Firewall either sanitizes the request and then sends it back to the NetScaler appliance (or NetScaler virtual appliance), or displays the error object. If the request passes the security checks, it is sent back to the NetScaler appliance, which completes any other processing and forwards the request to the protected web server.

When the web site or web service sends a response to the user, the App Firewall applies the response security checks that have been enabled. The response security checks examine the response for leaks of sensitive private information, signs of web site defacement, or other content that should not be present. If the response fails a security check, the App Firewall either removes the content that should not be present or blocks the response. If the response passes the security checks, it is sent back to the NetScaler appliance, which forwards it to the user.

**App Firewall features**

The basic App Firewall features are policies, profiles, and signatures, which provide a hybrid security model as described in “Known Web Attacks,” “Unknown Web Attacks,” and “How the App Firewall Works.” Of special note is the learning feature, which observes traffic to your protected applications and recommends appropriate configuration settings for certain security checks.
The imports feature manages files that you upload to the App Firewall. These files are then used by the App Firewall in various security checks, or when responding to a connection that matches a security check.

You can use the logs, statistics, and reports features to evaluate the performance of the App Firewall and identify possible needs for additional protections.

**The App Firewall configuration interfaces**

January 6, 2019

All hardware and virtual versions of the NetScaler can be configured and managed from the NetScaler command line interface or the web-based GUI. All features of most NetScaler features can be configured using either of these tools. The NetScaler App Firewall is an exception: not all App Firewall configuration tasks can be performed at the command line. Inexperienced users also find the GUI easier to use. In particular, the App Firewall wizard considerably reduces the complexity of configuring the App Firewall. Unlike most NetScaler wizards, the App Firewall wizard can serve as your primary interface to the App Firewall.

The command line interface is a modified UNIX shell based on the FreeBSD bash shell. To configure the App Firewall from the command line interface, you type commands at the prompt and press the Enter key, just as you do with any other Unix shell. For instructions for using the command line interface, see [Command Reference](https://developer-docs.citrix.com/projects/netscaler-command-reference/en/12.0/appfw/application-firewall-commands/).

The GUI is a web-based GUI interface to the appliance. The App Firewall configuration section is found under **Security > App Firewall**. Figure 1 shows the navigation pane expanded to display the App Firewall screens, and in the detail pane the main ![App Firewall screen](/en-us/netscaler/media/cu-screenshot-labeled.png).

The GUI has two main areas on all screens. The panel on the left, called the navigation pane, contains a navigation tree, with which you navigate to the screens on which you configure the features that are installed on your appliance. The screens to which you navigate appear to the right of the navigation pane, in the details pane.

When you access the GUI, the details pane displays the System Overview screen. If, in the navigation pane, you click plus sign next to the App Firewall folder, the App Firewall node expands to include the main App Firewall elements that you can configure. If you click the first element, Profiles, the details pane displays the configured profiles, if any profiles have been configured. At the bottom of the details pane, you can click Add to configure a new profile. Other buttons at the bottom of the details pane are grayed out until you select an existing profile. Screens for the other elements work in the same way.

If, instead of expanding the App Firewall node, you click the node itself, the details pane displays different options, one of which is the App Firewall wizard, as shown in Figure 1. Citrix recommends that
you use the wizard for initial configuration, and many users use it almost exclusively. It includes most of the functionality that is available elsewhere in the GUI.

Configuring the App Firewall

September 18, 2018

You can configure the NetScaler App Firewall by using any of the following methods:

- **App Firewall Wizard.** A dialog box consisting of a series of screens that step you through the configuration process.
- **NetScaler App Interface AppExpert Template.** A NetScaler AppExpert template (a set of configuration settings) that are designed to provide appropriate protection for web sites. This App-Expert template contains appropriate App Firewall configuration settings for protecting many web sites.
- **NetScaler GUI.** The NetScaler web-based configuration interface.
- **NetScaler Command Line Interface.** The NetScaler command line configuration interface.

Citrix recommends that you use the App Firewall Wizard. Most users will find it the easiest method to configure the App Firewall, and it is designed to prevent mistakes. If you have a new NetScaler or VPX that you will use primarily to protect web sites, you may find the Web Interface AppExpert template a better option because it provides a good default configuration, not just for the App Firewall, but for the entire appliance. Both the GUI and the command line interface are intended for experienced users, primarily to modify an existing configuration or use advanced options.

The App Firewall wizard

The App Firewall wizard is a dialog box that consists of several screens that prompt you to configure each part of a simple configuration. The App Firewall then creates the appropriate configuration elements from the information that you give it. This is the simplest and, for most purposes, the best way to configure the App Firewall.

To use the wizard, connect to the GUI with the browser of your choice. When the connection is established, verify that the App Firewall is enabled, and then run the App Firewall wizard, which prompts you for configuration information. You do not have to provide all of the requested information the first time you use the wizard. Instead, you can accept default settings, perform a few relatively straightforward configuration tasks to enable important features, and then allow the App Firewall to collect important information to help you complete the configuration.

For example, when the wizard prompts you to specify a rule for selecting the traffic to be processed, you can accept the default, which selects all traffic. When it presents you with a list of signatures, you can enable the appropriate categories of signatures and turn on the collection of statistics for those
signatures. For this initial configuration, you can skip the advanced protections (security checks). The wizard automatically creates the appropriate policy, signatures object, and profile (collectively, the security configuration), and binds the policy to global. The App Firewall then begins filtering connections to your protected websites, logging any connections that match one or more of the signatures that you enabled and collecting statistics about the connections that each signature matches. After the App Firewall processes some traffic, you can run the wizard again and examine the logs and statistics to see if any of the signatures that you have enabled are matching legitimate traffic. After determining which signatures are identifying the traffic that you want to block, you can enable blocking for those signatures. If your website or web service is not complex, does not use SQL, and does not have access to sensitive private information, this basic security configuration will probably provide adequate protection.

You may need additional protection if, for example, your website is dynamic. Content that uses scripts may need protection against cross-site scripting attacks. Web content that uses SQL—such as shopping carts, many blogs, and most content management systems—may need protection against SQL injection attacks. Websites and web services that collect sensitive private information such as social security numbers or credit card numbers may require protection against unintentional exposure of that information. Certain types of web-server or XML-server software may require protection from types of attacks tailored to that software. Another consideration is that specific elements of your websites or web services may require different protection than do other elements. Examining the App Firewall logs and statistics can help you identify the additional protections that you might need.

After deciding which advanced protections are needed for your websites and web services, you can run the wizard again to configure those protections. Certain security checks require that you enter exceptions (relaxations) to prevent the check from blocking legitimate traffic. You can do so manually, but it is usually easier to enable the adaptive learning feature and allow it to recommend the necessary relaxation. You can use the wizard as many times as necessary to enhance your basic security configuration and/or create additional security configurations.

The wizard automates some tasks that you would have to perform manually if you did not use the wizard. It automatically creates a policy, a signatures object, and a profile, and assigns them the name that you provided when you were prompted for the name of your configuration. The wizard also adds your advanced-protection settings to the profile, binds the signatures object to the profile, associates the profile with the policy, and puts the policy into effect by binding it to Global.

A few tasks cannot be performed in the wizard. You cannot use the wizard to bind a policy to a bind point other than Global. If you want the profile to apply to only a specific part of your configuration, you must manually configure the binding. You cannot configure the engine settings or certain other global configuration options in the wizard. While you can configure any of the advanced protection settings in the wizard, if you want to modify a specific setting in a single security check, it may be easier to do so on the manual configuration screens in the GUI.

For more information on using the App Firewall Wizard, see “The App Firewall Wizard.”
**NetScaler app interface appExpert template**

AppExpert templates are a different and simpler approach to configuring and managing complex enterprise applications. The AppExpert display in the GUI consists of a table. Applications are listed in the left-most column, with the NetScaler features that are applicable to that application appearing each in its own column to the right. (In the AppExpert interface, those features that are associated with an application are called *application units.*) In the AppExpert interface, you configure the interesting traffic for each application, and turn on rules for compression, caching, rewrite, filtering, responder and the App Firewall, instead of having to configure each feature individually.

The Web interface AppExpert template contains rules for the following App Firewall signatures and security checks:

- **“Deny URL check.”** Detects connections to content that is known to pose a security risk, or to any other URLs that you designate.
- **“Buffer Overflow check.”** Detects attempts to cause a buffer overflow on a protected web server.
- **“Cookie Consistency check.”** Detects malicious modifications to cookies set by a protected web site.
- **“Form Field Consistency check.”** Detects modifications to the structure of a web form on a protected web site.
- **“CSRF Form Tagging check.”** Detects cross-site request forgery attacks.
- **“Field Formats check.”** Detects inappropriate information uploaded in web forms on a protected web site.
- **“HTML SQL Injection check.”** Detects attempts to inject unauthorized SQL code.
- **“HTML Cross-Site Scripting check.”** Detects cross-site scripting attacks.

For information on installing and using an AppExpert Template, see “AppExpert Applications and Templates.”

**The NetScaler GUI**

The GUI is a web-based interface that provides access to all configuration options for the App Firewall feature, including advanced configuration and management options that are not available from any other configuration tool or interface. Specifically, many advanced Signatures options can be configured only in the GUI. You can review recommendations generated by the learning feature only in the GUI. You can bind policies to a bind point other than Global only in the GUI.

For a description of the GUI, see “The App Firewall Configuration Interfaces.” For more information on using the GUI to configure the App Firewall, see “Manual Configuration By Using the GUI.”

For instructions on configuring the App Firewall by using the GUI, see “Manual Configuration By Using the GUI.” For information on the NetScaler GUI, see “The App Firewall Configuration Interfaces.”

© 1999-2018 Citrix Systems, Inc. All rights reserved.
NetScaler 12.0

The NetScaler command line interface

The NetScaler command line interface is a modified UNIX shell based on the FreeBSD bash shell. To configure the App Firewall from the command line interface, you type commands at the prompt and press the Enter key, just as you do with any other Unix shell. You can configure most parameters and options for the App Firewall by using the NetScaler command line. Exceptions are the signatures feature, many of whose options can be configured only by using the GUI or the App Firewall wizard, and the learning feature, whose recommendations can only be reviewed in the GUI.

For instructions on configuring the App Firewall by using the NetScaler command line, see “Manual Configuration By Using the Command Line Interface.”

Enabling App Firewall

September 18, 2018

Before you can create an App Firewall security configuration, you must make sure that the App Firewall feature is enabled.

- If you are configuring a dedicated NetScaler App Firewall appliance or are upgrading an existing NetScaler or VPX, the feature is already enabled. You do not have to perform either of the procedures described here.
- If you have a new NetScaler or VPX, you need to enable the App Firewall feature before you configure it.
- If you are upgrading a NetScaler or VPX from a previous version of the NetScaler operating system to the current version, you might need to enable the App Firewall feature before you configure it.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you are upgrading a NetScaler or VPX from a previous version, you might also need to update the licenses on your ADC or VPX before you can enable the App Firewall. Check with your Citrix representative or reseller to obtain the correct license.</td>
</tr>
</tbody>
</table>

You can enable the App Firewall by using the command line or the GUI.

To enable the App Firewall by using the command line interface

At the command prompt, type the following command:

```
enable ns feature AppFW
```
To enable the App Firewall by using the GUI

1. Navigate to System > Settings.
2. In the details pane, click Configure Basic Features.
3. In the Configure Basic Features dialog box, check the App Firewall check box.
4. Click OK.

The App Firewall wizard

November 14, 2018

Unlike most wizards, the NetScaler App App Firewall Wizard is designed not just to simplify the initial configuration process, but also to modify previously created configurations and to maintain your App Firewall setup. A typical user runs the wizard multiple times, skipping some of the screens each time.

The App Firewall Wizard automatically creates profiles, policies, and signatures.

Opening the Wizard

To run the App Firewall Wizard, open the GUI and follow these steps:

1. Navigate to Security > Application Firewall.
2. In the details pane, under Getting Started, click Application Firewall Wizard. The wizard opens.

For more information about the GUI, see The App Firewall Configuration Interfaces.

The Wizard screens

The App Firewall wizard displays the following screens on a tabular page:

1. Specify Name: on this screen, when creating a new security configuration, specify a meaningful name and the appropriate type (HTML, XML or WEB 2.0) for your profile. The default policy and signatures are auto-generated by using the same name.

Profile Name

The name can begin with a letter, number, or the underscore symbol, and can consist of from 1 to 31 letters, numbers, and the hyphen (-), period (.), pound (#), space ( ), at (@), equals (=), colon (:), and underscore (_) symbols. Choose a name that makes it easy for others to tell what content your new security configuration protects.
Note:
Because the wizard uses this name for both the policy and the profile, it is limited to 31 characters. Manually created policies can have names up to 127 characters in length.

When modifying an existing configuration, you select Modify Existing Configuration and then, in the Name drop-down list, select the name of the existing configuration that you want to modify.

Note:
Only policies that are bound to global or to a bind point appear in this list; you cannot modify an unbound policy by using the Application Firewall wizard. You must either manually bind it to Global or a bind point, or modify it manually. (For manual modification, in the GUI Application Firewall > Policies > Firewall pane, select the policy and click Open).

Profile Type

You also select a profile type on this screen. The profile type determines the types of advanced protection (security checks) that can be configured. Because certain kinds of content are not vulnerable to certain types of security threats, restricting the list of available checks saves time during configuration. The types of App Firewall profiles are:

- Web Application (HTML). Any HTML-based Web site that does not use XML or Web 2.0 technologies.
- Web 2.0 Application (HTML, XML, REST). Any Web 2.0 site that combines HTML and XML-based content, such as an ATOM-based site, a blog, an RSS feed, or a wiki.

Note: If you are unsure which type of content is used on your website, you can choose Web 2.0 Application to ensure that you protect all types of web application content.

2. Specify Rule: on this screen, you specify the policy rule (expression) that defines the traffic the current configuration examines. If you create an initial configuration to protect your websites and web services, you can accept the default value, true, which selects all web traffic.

If you want this security configuration to examine, not all HTTP traffic that is routed through the appliance, but specific traffic, you can write a policy rule specifying the traffic that you want it to examine. Rules are written in NetScaler expressions language, which is a fully functional object-oriented programming language. For more information, see Configure a Custom Policy Expression.

Note: In addition to the default expressions syntax, for backward compatibility the NetScaler operating system supports the NetScaler classic expressions syntax on NetScaler Classic and nCore appliances and virtual appliances. Classic expressions are not supported on NetScaler Cluster appliances and virtual appliances. Current users who want to migrate their existing configurations to the NetScaler cluster must migrate any policies that contain classic expressions to the default expressions syntax.
For a simple description of using the NetScaler expressions syntax to create App Firewall rules, and a list of useful rules, see “Firewall Policies.”
For a detailed explanation of how to create policy rules in NetScaler expressions syntax, see “Policies and Expressions.”

4. **Select Signatures:** on this screen, you select the categories of signatures that you want to use to protect your web sites and web services.

This is not a mandatory step, and you can skip it if you want to and go to the Specify Deep Protections screen. If the Select Signatures screen is skipped, only a profile and associated policies are created, and the signatures are not created.

You can select **Create New Signature** or **Select Existing Signature**.

If you are creating a new security configuration, the signature categories that you select are enabled, and by default they are recorded in a new signatures object. The new signatures object is assigned the same name that you entered on the Specify name screen as the name of the security configuration.

If you have previously configured signatures objects and want to use one of them as the signatures object associated with the security configuration that you are creating, click **Select Existing Signature** and select a signatures object from the Signatures list.

If you are modifying an existing security configuration, you can click Select Existing Signature and assign a different signatures object to the security configuration.

If you click Create New Signature, you can choose the edit mode as **Simple** or **Advanced**.

1. **Specify Signature Protections (Simple mode)**

The simple mode allows for easy configuration of the signature, with a preset list of protection definitions for common applications such as IIS (Internet Information Server), PHP and ActiveX. The default categories in Simple mode are:

- **CGI.** Protection against attacks on web sites that use CGI scripts in any language, including PERL scripts, Unix shell scripts, and Python scripts.
- **Cold Fusion.** Protection against attacks on web sites that use the Adobe Systems® ColdFusion® Web development platform.
- **FrontPage.** Protection against attacks on web sites that use the Microsoft® FrontPage® Web development platform.
- **PHP.** Protection against attacks on web sites that use the PHP open-source Web development scripting language.
- **Client side.** Protection against attacks on client-side tools used to access your protected web sites, such as Microsoft Internet Explorer, Mozilla Firefox, the Opera browser, and the Adobe Acrobat Reader.
• Microsoft IIS. Protection against attacks on Web sites that run the Microsoft Internet Information Server (IIS)

• Miscellaneous. Protection against attacks on other server-side tools, such as Web servers and database servers.

On this screen, you select the actions associated with the signature categories that you selected on the Select Signatures screen. The actions that you can configure are:

• Block
• Log
• Stats

By default the Log and Stats actions are enabled but not the Block action. To configure actions, click Settings. You can change the action settings of all the selected categories by using the Action drop-down menu.

1. **Specify Signature Protections (Advanced mode)**

The advanced mode allows for more granular control over the signature definitions and provides significantly more information. Use the advanced mode if you want complete control over signature definition.

The contents of this screen are the same as the contents of the Modify Signatures Object dialog box, as described in “Configuring or Modifying a Signatures Object.” In this screen, you can configure actions either by clicking the Actions drop-down menu or the actions menu, which appears as a circle with three dots.

7. **Specify Deep Protections:** on this screen, you choose the advanced protections (also called security checks or simply checks) that you want to use to protect your web sites and web services. Which checks are available depends on the profile type that you chose on the Specify Name screen. All checks are available for Web 2.0 Application profiles.

For more information, see Overview of Security Checks and see “Advanced Form Protections Checks.”

You configure the actions for the advanced protections that you have enabled. The actions that you can configure are:

• Block: blocks connections that match the signature. Disabled by default.
• Log: logs connections that match the signature for later analysis. Enabled by default.
• Stats: maintains statistics, for each signature, that show how many connections it matched and provide certain other information about the types of connections that were blocked. Disabled by default.
• Learn. Observe traffic to this website or web service, and use connections that repeatedly violate this check to generate recommended exceptions to the check, or new rules for the check. Available only for some checks. For more information about the learning feature see “Configur-
ing and Using the Learning Feature,” and how learning works and how to configure exceptions (relaxations) or deploy learned rules for a check, see “Manual Configuration By Using the GUI.”

To configure actions, select the protection by clicking the check box, and then click Action Settings to select the required actions. Select other parameters, if required, and then click OK to close the Action Settings window.

To view all logs for a specific check, select that check, and then click Logs to display the Syslog Viewer, as described in “App Firewall Logs.” If a security check is blocking legitimate access to your protected web site or web service, you can create and implement a relaxation for that security check by selecting a log that shows the unwanted blocking, and then clicking Deploy.

After you completing specifying Action Settings, click Finish to complete the wizard.

Following are four procedures that show how to perform specific types of configuration by using the App Firewall wizard.

Create a New Configuration

Follow these steps to create a new firewall configuration and signature objects, by using the Application Firewall wizard.

1. Navigate to Security > Application Firewall.
2. In the details pane, under Getting Started, click Application Firewall Wizard. **The wizard opens.
3. On the Specify Name screen, select Create New Configuration.
4. In the Name field, type a name, and then click Next.
5. In the Specify Rule screen, click Next again.
6. In the Select Signatures screen, select Create New Signature and Simple as the edit mode, and then click Next.
7. In the Specify Signature Protections screen, configure the required settings. For more information about which signatures to consider for blocking and how to determine when you can safely enable blocking for a signature, see “Signatures.”
8. In the Specify Deep Protections screen configure the required actions and parameters in Action Settings.
9. When you complete, click Finish to close the Application Firewall wizard.

Modify an Existing Configuration

Follow these steps to modify an existing configuration and existing signature categories.
1. Navigate to Security > Application Firewall.
2. In the details pane, under Getting Started, click Application Firewall Wizard. The wizard opens.
3. On the Specify Name screen, select Modify Existing Configuration and, in the Name drop-down list, choose the security configuration that you created during new configuration, and then click Next.
4. In the Specify Rule screen, click Next to keep the default value “true.” If you want to modify the rule, follow the steps described in “Configure a Custom Policy Expression.”
5. In the Select Signatures screen, click Select Existing Signature. From the Existing Signature drop-down menu, select the appropriate option, and then click Next. The advanced signature protection screen appears.
   • Note: If you select an existing signature, the default edit mode for signature protected is advanced.
6. In the Specify Signature Protections screen, configure the required settings and click Next. For more information about which signatures to consider for blocking and how to determine when you can safely enable blocking for a signature, see “Signatures.”
7. In the Specify Deep Protections screen, configure the settings and click Next.
8. After you complete, click Finish to close the App Firewall Wizard.

Create a New Configuration without Signatures

Follow these steps to use the Application Firewall Wizard to skip the Select Signatures screen and create a new configuration with just the profile and the associated policies but without any signatures.

1. Navigate to Security > Application Firewall.
2. In the details pane, under Getting Started, click Application Firewall Wizard. The wizard opens.
3. On the Specify Name screen, select Create New Configuration.
4. In the Name field, type a name, and then click Next.
5. In the Specify Rule screen, click Next again.
6. In the Select Signatures screen, click Skip.
7. In the Specify Deep Protections screen configure the required actions and parameters in Action Settings.
8. When you complete, click Finish to close the Application Firewall Wizard.

Configure a Custom Policy Expression

Follow these steps to use the Application Firewall Wizard to create a specialized security configuration to protect only specific content. In this case, you create a new security configuration instead of modifying the initial configuration. This type of security configuration requires a custom rule, so that the policy applies the configuration to only the selected Web traffic.
1. Navigate to **Security > Application Firewall**.
2. In the details pane, under **Getting Started**, click **Application Firewall Wizard**.
3. On the Specify Name screen, type a name for your new security configuration in the Name text box, select the type of security configuration from the Type drop-down list, and then click **Next**.
4. On the **Specify Rule** screen, enter a rule that matches only that content that you want this web application to protect. Use the **Frequently Used Expressions** drop-down list and the **Expression Editor** to create a custom expression. When you complete, click **Next**.
5. In the **Select Signatures** screen, select the edit mode, and then click **Next**.
6. In the **Specify Signature Protections** screen, configure the required settings.
7. In the **Specify Deep Protections** screen configure the required actions and parameters in **Action Settings**.
8. When you complete, click **Finish** to close the **Application Firewall Wizard**.

**Manual configuration**

September 18, 2018

If you want to bind a profile to a bind point other than Global, you must manually configure the binding. Also, certain security checks require that you either manually enter the necessary exceptions or enable the learning feature to generate the exceptions that your Web sites and Web services need. Some of these tasks cannot be performed by using the App Firewall wizard.

If you are familiar with how the App Firewall works and prefer manual configuration, you can manually configure a signatures object and a profile, associate the signatures object with the profile, create a policy with a rule that matches the web traffic that you want to configure, and associate the policy with the profile. You then bind the policy to Global, or to a bind point, to put it into effect, and you have created a complete security configuration.

For manual configuration, you can use the GUI (a graphical interface) or the command line. Citrix recommends that you use the GUI. Not all configuration tasks can be performed at the command line. Certain tasks, such as enabling signatures and reviewing learned data, must be done in the GUI. Most other tasks are easier to perform in the GUI.

**Replicating configuration**

When you use the GUI (GUI) or the command line interface (CLI) to manually configure the App Firewall, the configuration is saved in the /nsconfig/ns.conf file. You can use the commands in that file to replicate the configuration on another appliance. You can cut and paste the commands into the CLI one by one, or you can save multiple commands in a text file in the /var/tmp folder and run them as a batch file. Following is an example of running a batch file containing commands copied from the /nsconfig/ns.conf file of a different appliance:
NetScaler 12.0

> batch -f /var/tmp/appfw_add.txt

Warning
Import commands are not saved in the ns.conf file. Before running commands from the ns.conf file to replicate the configuration on another appliance, you must import all the objects used in the configuration (for example, signatures, error page, WSDL, and Schema) to the appliance on which you will replicate the configuration. The add command to add an App Firewall profile saved in an ns.conf file might include the name of an imported object, but such a command might fail when executed on another appliance if the referenced object does not exist on that appliance.

Manual configuration by using the GUI

December 7, 2018

If you need to configure the App Firewall feature manually, Citrix recommends that you use the GUI.

To create and configure a signatures object

Before you can configure the signatures, you must create a new signatures object from the appropriate default signatures object template. Assign the copy a new name, and then configure the copy. You cannot configure or modify the default signatures objects directly. The following procedure provides basic instructions for configuring a signatures object. For more detailed instructions, see “Manually Configuring the Signatures Feature.”

1. Navigate to Security > application firewall > Signatures.

2. In the details pane, select the signatures object that you want to use as a template, and then click Add.

Your choices are:

• *Default Signatures. Contains the signatures rules, the SQL injection rules, and the cross-site scripting rules.
• *XPath Injection. Contains all of the items in the *Default Signatures, and in addition, contains the XPath injection rules.

3. In the **Add Signatures Object **dialog box, type a name for your new signatures object, click OK, and then click Close. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 31 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), and underscore (_) symbols.

4. Select the signatures object that you created, and then click Open.
5. In the **Modify Signatures Object** dialog box, set the **Display Filter Criteria** options at the left to display the filter items that you want to configure.

As you modify these options, the results that you specify are displayed in the Filtered Results window at the right. For more information about the categories of signatures, see “**Signatures**.”

6. In the **Filtered Results** area, configure the settings for a signature by selecting and clearing the appropriate checkboxes.

7. When finished, finished, click **Close**.

**To create an App Firewall profile by using the GUI**

Creating an App Firewall profile requires that you specify only a few configuration details.

1. Navigate to **Security > application firewall > Profiles**.

2. In the details pane, click **Add**.

3. In the **Create App Firewall Profile** dialog box, type a name for your profile.

   The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 31 letters, numbers, and the hyphen (-), period (.), pound (#), space ( ), at (@), equals (=), colon (:), and underscore (_) symbols.

4. Choose the profile type from the drop-down list.

5. Click **Create**, and then click **Close**.

**To configure an App Firewall profile by using the GUI**

1. Navigate to **Security > application firewall > Profiles**.

2. In the details pane, select the profile that you want to configure, and then click **Edit**.

3. In the **Configure App Firewall Profile** dialog box, on the **Security Checks** tab, configure the security checks.

   • To enable or disable an action for a check, in the list, select or clear the checkbox for that action.

   • To configure other parameters for those checks that have them, in the list, click the blue chevron to the far right of that check. In the dialog box that appears, configure the parameters. These vary from check to check.

   You can also select a check and, at the bottom of the dialog box, click **Open** to display the Configure Relaxation dialog box or Configure Rule dialog box for that check. These dialog boxes also vary from check to check. Most of them include a Checks tab and a General
tab. If the check supports relaxations or user-defined rules, the Checks tab includes an Add button, which opens yet another dialog box, in which you can specify a relaxation or rule for the check. (A relaxation is a rule for exempting specified traffic from the check.) If relaxations have already been configured, you can select one and click Open to modify it.

- To review learned exceptions or rules for a check, select the check, and then click Learned Violations. In the Manage Learned Rules dialog box, select each learned exception or rule in turn.
  - To edit the exception or rule, and then add it to the list, click **Edit & Deploy**.
  - To accept the exception or rule without modification, click **Deploy**.
  - To remove the exception or rule from the list, click **Skip**.
- To refresh the list of exceptions or rules to be reviewed, click **Refresh**.
- To open the Learning Visualizer and use it to review learned rules, click **Visualizer**.
- To review the log entries for connections that matched a check, select the check, and then click **Logs**. You can use this information to determine which checks are matching attacks so that you can enable blocking for those checks. You can also use this information to determine which checks are matching legitimate traffic, so that you can configure an appropriate exemption to allow those legitimate connections. For more information about the logs, see “Logs, Statistics, and Reports.”
- To completely disable a check, in the list, clear all of the checkboxes to the right of that check.

4. On the **Settings** tab, configure the profile settings.

- To associate the profile with the set of signatures that you previously created and configured, under **Common Settings**, choose that set of signatures in the Signatures drop-down list.
  
  **Note:**
  
  You may need to use the scroll bar on the right of the dialog box to scroll down to display the Common Settings section.

- To configure an HTML or XML Error Object, select the object from the appropriate drop-down list.
  
  **Note:**
  
  You must first upload the error object that you want to use in the Import pane.

- To configure the default XML Content Type, type the content type string directly into the Default Request and Default Response text boxes, or click Manage Allowed Content Types to manage the list of allowed content types.
5. If you want to use the learning feature, click Learning, and configure the learning settings for
the profile. For more information, see Configure and Learning feature.
6. Click OK to save your changes and return to the Profiles pane.

Configuring an App Firewall rule or relaxation

You configure two different types of information in this dialog box, depending upon which security
check you are configuring. In the majority of cases, you configure an exception (or relaxation) to the
security check. If you are configuring the Deny URL check or the Field Formats check, you configure
an addition (or rule). The process for either of these is the same.

To configure a relaxation or rule by using the GUI

1. Navigate to Security > application firewall > Profiles.
2. In the Profiles pane, select the profile you want to configure, and then click Edit.
3. In the Configure App Firewall Profile dialog box, click the Security Checks tab. The Security Checks tab contains the complete list of App Firewall security checks, also called advanced protections in some places.
4. In the Security Checks tab, click the check that you want to configure, and then click Open. The Modify Check dialog box for the check that you chose is displayed, with the Checks tab selected. The Checks tab contains a list of existing relaxations or rules for this check. The list might be empty if you have not either manually added any relaxations or approved any relaxations that were recommended by the learning engine. Beneath the list is a row of buttons that allow you to add, modify, delete, enable, or disable the relaxations on the list.
5. To add or modify a relaxation or a rule, do one of the following:
   • To add a new relaxation, click Add.
   • To modify an existing relaxation, select the relaxation that you want to modify, and then
     click Open.
   The Add Check Relaxation or Modify Check Relaxation dialog box for the selected check is displayed. Except for the title, these dialog boxes are identical.
6. Fill in the dialog box as described below. The dialog boxes for each check are different; the list
below covers all elements that might appear in any dialog box.
   • Enabled check box—Select to place this relaxation or rule in active use; clear to deactivate
     it.
• **Attachment Content Type**—The Content-Type attribute of an XML attachment. In the text area, enter a regular expression that matches the Content-Type attribute of the XML attachments to allow.

• **Action URL**—In the text area, enter a PCRE-format regular expression that defines the URL to which data entered into the web form is delivered.

• **Cookie**—In the text area, enter a PCRE-format regular expression that defines the cookie.

• **Field Name**—A web form field name element may be labeled Field Name, Form Field, or another similar name. In the text area, enter a PCRE-format regular expression that defines the name of the form field.

• **Form Origin URL**—In the text area, enter a PCRE-format regular expression that defines the URL that hosts the web form.

• **Form Action URL**—In the text area, enter a PCRE-format regular expression that defines the URL to which data entered into the web form is delivered.

• **Name**—An XML element or attribute name. In the text area, enter a PCRE-format regular expression that defines the name of the element or attribute.

• **URL**—A URL element may be labeled Action URL, Deny URL, Form Action URL, Form Origin URL, Start URL, or simply URL. In the text area, enter a PCRE-format regular expression that defines the URL.

• **Format**—The format section contains multiple settings that include list boxes and text boxes. Any of the following can appear:
  - **Type**—Select a field type in the Type drop-down list. To add a new field type definition, click Manage—
  - **Minimum Length**—Type a positive integer that represents the minimum length in characters if you want to force users to fill in this field. Default: 0 (Allows field to be left blank.)
  - **Maximum length**—To limit the length of data in this field, type a positive integer that represents the maximum length in characters. Default: 65535

• **Location**—Choose the element of the request that your relaxation will apply to from the drop-down list. For HTML security checks, the choices are:
  - FORMFIELD—Form fields in web forms.
  - HEADER—Request headers.
  - COOKIE—Set-Cookie headers.

For XML security checks, the choices are:
  - ELEMENT—XML element.
  - ATTRIBUTE—XML attribute.
• **Maximum Attachment Size**—The maximum size in bytes allowed for an XML attachment.

• **Comments**—In the text area, type a comment. Optional.

**Note:** For any element that requires a regular expression, you can type the regular expression, use the Regex Tokens menu to insert regular expression elements and symbols directly into the text box, or click *Regex Editor* to open the Add Regular Expression dialog box, and use it to construct the expression.

7. To remove a relaxation or rule, select it, and then click **Remove**.

8. To enable a relaxation or rule, select it, and then click **Enable**.

9. To disable a relaxation or rule, select it, and then click **Disable**.

10. To configure the settings and relationships of all existing relaxations in an integrated interactive graphic display, click **Visualizer**, and use the display tools.

   **Note:**

   The **Visualizer** button does not appear on all check relaxation dialog boxes.

11. To review learned rules for this check, click **Learning** and perform the steps in *To configure and use the Learning feature*.

12. Click **OK**.

### To configure the Learning feature by using the GUI

1. Navigate to **Security > application firewall > Profiles**.

2. In the **Profiles** pane, select the profile, and then click **Edit**.

3. Click the **Learning** tab. At the top of the **Learning** tab is list of the security checks that are available in the current profile and that support the learning feature.

4. To configure the learning thresholds, select a security check, and then type the appropriate values in the following text boxes:

   • **Minimum number threshold.** Depending on which security check’s learning settings you are configuring, the minimum number threshold might refer to the minimum number of total user sessions that must be observed, the minimum number of requests that must be observed, or the minimum number of times a specific form field must be observed, before a learned relaxation is generated. Default: 1

   • **Percentage of times threshold.** Depending on which security check’s learning settings you are configuring, the percentage of times threshold might refer to the percentage of total observed user sessions that violated the security check, the percentage of requests,
or the percentage of times a form field matched a particular field type, before a learned relaxation is generated. Default: 0

5. To remove all learned data and reset the learning feature, so that it must start its observations again from the beginning, click Remove All Learned Data.

   **Note:**
   This button removes only learned recommendations that have not been reviewed and either approved or skipped. It does not remove learned relaxations that have been accepted and deployed.

6. To restrict the learning engine to traffic from a specific set of IPs, click Trusted Learning Clients, and add the IP addresses that you want to use to the list.
   a) To add an IP address or IP address range to the Trusted Learning Clients list, click Add.
   b) In the Add Trusted Learning Clients dialog box, Trusted Clients IP list box, type the IP address or an IP address range in CIDR format.
   c) In the Comments text area, type a comment that describes this IP address or range.
   d) Click Create to add your new IP address or range to the list.
   e) To modify an existing IP address or range, click the IP address or range, and then click Open. Except for the name, the dialog box that appears is identical to the Add Trusted Learning Clients dialog box.
   f) To disable or enable an IP address or range, but leave it on the list, click Disable or Enable, as appropriate.
   g) To remove an IP address or range completely, click the IP address or range, and then click Remove.

7. Click Close to return to the Configure application firewall Profile dialog box.

8. Click Close to close the Configure application firewall Profile dialog box, and return to the application firewall Profile screen.

**To create and configure a policy by using the GUI**

2. In the details pane, do one of the following:
   - To create a new firewall policy, click Add. The Create App Firewall Policy is displayed.
   - To edit an existing firewall policy, select the policy, and then click Edit.

   The Create App Firewall Policy or Configure App Firewall Policy is displayed.

3. If you are creating a new firewall policy, in the Create App Firewall Policy dialog box, Policy Name text box, type a name for your new policy.
The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 128 letters, numbers, and the hyphen (-), period (.), pound (#), space ( ), at (@), equals (=), colon (:), and underscore (_) symbols.

If you are configuring an existing firewall policy, this field is read-only. You cannot modify it.

4. Select the profile that you want to associate with this policy from the **Profile** drop-down list. You can create a new profile to associate with your policy by clicking **New**, and you can modify an existing profile by clicking **Modify**.

5. In the **Expression** text area, create a rule for your policy.
   - You can type a rule directly into the text area.
   - You can click **Prefix** to select the first term for your rule, and follow the prompts.
   - You can click **Add** to open the Add Expression dialog box, and use it to construct the rule.

6. Click **Create** or **OK**, and then click **Close**.

**To create or configure an App Firewall rule (expression)**

The policy rule, also called the *expression*, defines the web traffic that the App Firewall filters by using the profile associated with the policy. Like other NetScaler policy rules (or *expressions*), App Firewall rules use NetScaler expressions syntax. This syntax is powerful, flexible, and extensible. It is too complex to describe completely in this set of instructions. You can use the following procedure to create a simple firewall policy rule, or you can read it as an overview of the policy creation process.

1. If you have not already done so, navigate to the appropriate location in the App Firewall wizard or the NetScaler GUI to create your policy rule:
   - If you are configuring a policy in the App Firewall wizard, in the navigation pane, click **application firewall**, then in the details pane click **application firewall Wizard**, and then navigate to the **Specify Rule** screen.
   - If you are configuring a policy manually, in the navigation pane, expand **application firewall**, **Policies**, and then **Firewall**. In the details pane, to create a new policy, click **Add**. To modify an existing policy, select the policy, and then click **Open**.

2. On the **Specify Rule** screen, the Create application firewall Profile dialog box, or the Configure Application Firewall Profile dialog box, click **Prefix**, and then choose the prefix for your expression from the drop-down list. Your choices are:
   - **HTTP**. The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol.
   - **SYS**. The protected Web site(s). Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.
• **CLIENT.** The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.

• **SERVER.** The computer to which the request was sent. Choose this if you want to examine some aspect of the recipient of the request.

After you choose a prefix, the App Firewall displays a two-part prompt window that displays the possible next choices at the top, and a brief explanation of what the selected choice means at the bottom.

3. Choose your next term.

If you chose HTTP as your prefix, your only choice is REQ, which specifies the Request/Response pair. (The App Firewall operates on the request and response as a unit instead of on each separately.) If you chose another prefix, your choices are more varied. For help on a specific choice, click that choice once to display information about it in the lower prompt window.

When you have decided which term you want, double-click it to insert it into the Expression window.

4. Type a period after the term you just chose. You are then prompted to choose your next term, as described in the previous step. When a term requires that you type a value, fill in the appropriate value. For example, if you choose HTTP.REQ.HEADER(""), type the header name between the quotation marks.

5. Continue choosing terms from the prompts and filling in any values that are needed, until your expression is finished.

Following are some examples of expressions for specific purposes.

• **Specific web host.** To match traffic from a particular web host:

```
1 HTTP.REQ.HEADER("Host").EQ("shopping.example.com")
```

For shopping.example.com, substitute the name of the web host that you want to match.

• **Specific web folder or directory.** To match traffic from a particular folder or directory on a Web host:

```
1 HTTP.REQ.URL.STARTSWITH("https://www.example.com/folder")
```

For www.example.com, substitute the name of the web host. For folder, substitute the folder or path to the content that you want to match. For example, if your shopping cart is in a folder called /solutions/orders, you substitute that string for folder.

• **Specific type of content: GIF images.** To match GIF format images:

```
1 HTTP.REQ.URL.ENDSWITH(".gif")
```

© 1999-2018 Citrix Systems, Inc. All rights reserved.
To match other format images, substitute another string in place of .gif.

- **Specific type of content: scripts.** To match all CGI scripts located in the CGI-BIN directory:

  ```
  HTTP.REQ.URL.STARTSWITH("https://www.example.com/CGI-BIN")
  ```

To match all JavaScripts with .js extensions:

  ```
  HTTP.REQ.URL.ENDSWITH(".js")
  ```

For more information about creating policy expressions, see “Policies and Expressions.”

**Note:**
If you use the command line to configure a policy, remember to escape any double quotation marks within NetScaler expressions. For example, the following expression is correct if entered in the GUI:

  ```
  HTTP.REQ.HEADER("Host").EQ("shopping.example.com")
  ```

If entered at the command line, however, you must type this instead:

  ```
  HTTP.REQ.HEADER("Host").EQ("shopping.example.com")
  ```

---

To add a firewall rule (expression) by using the Add Expression dialog box

The **Add Expression** dialog box (also referred to as the Expression Editor) helps users who are not familiar with the NetScaler expressions language to construct a policy that matches the traffic that they want to filter.

1. If you have not already done so, navigate to the appropriate location in the App Firewall wizard or the NetScaler GUI:
   - If you are configuring a policy in the **App Firewall** wizard, in the navigation pane, click **App Firewall**, then in the details pane click **App Firewall Wizard**, and then navigate to the **Specify Rule** screen.
   - If you are configuring a policy manually, in the navigation pane, expand **App Firewall**, then **Policies**, and then **Firewall**. In the details pane, to create a new policy, click **Add**. To modify an existing policy, select the policy, and then click **Open**.
2. On the **Specify Rule** screen, in the **Create App Firewall Profile** dialog box, or in the **Configure App Firewall Profile** dialog box, click **Add**.
3. In the **Add Expression** dialog box, in the Construct Expression area, in the first list box, choose one of the following prefixes:
   - **HTTP.** The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol. The default choice.
• **SYS.** The protected Web site(s). Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.

• **CLIENT.** The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.

• **SERVER.** The computer to which the request was sent. Choose this if you want to examine some aspect of the recipient of the request.

4. In the second list box, choose your next term. The available terms differ depending on the choice you made in the previous step, because the dialog box automatically adjusts the list to contain only those terms that are valid for the context. For example, if you selected HTTP in the previous list box, the only choice is REQ, for requests. Because the App Firewall treats requests and associated responses as a single unit and filters both, you do not need to specify responses separately. After you choose your second term, a third list box appears to the right of the second. The Help window displays a description of the second term, and the Preview Expression window displays your expression.

5. In the third list box, choose the next term. A new list box appears to the right, and the Help window changes to display a description of the new term. The Preview Expression window updates to display the expression as you have specified it to that point.

6. Continue choosing terms, and when prompted filling in arguments, until your expression is complete. If you make a mistake or want to change your expression after you have already selected a term, you can simply choose another term. The expression is modified, and any arguments or additional terms that you added after the term that you modified are cleared.

7. When you have finished constructing your expression, click OK to close the Add Expression dialog box. Your expression is inserted into the Expression text area.

### To bind an App Firewall policy by using the GUI

1. Do one of the following:
   - Navigate to **Security > App Firewall**, and in the details pane, click **application firewall policy manager**.
   - Navigate to **Security > application firewall > Policies > Firewall Policies**, and in the details pane, click **Policy Manager**.

2. In the **Application Firewall Manager** dialog, choose the bind point to which you want to bind the policy from the drop-down list. The choices are:
   - **Override Global.** Policies that are bound to this bind point process all traffic from all interfaces on the NetScaler appliance, and are applied before any other policies.
   - **LB Virtual Server.** Policies that are bound to a load balancing virtual server are applied only to traffic that is processed by that load balancing virtual server, and are applied before any Default Global policies. After selecting LB Virtual Server, you must also select the specific load balancing virtual server to which you want to bind this policy.
- **CS Virtual Server.** Policies that are bound to a content switching virtual server are applied only to traffic that is processed by that content switching virtual server, and are applied before any Default Global policies. After selecting CS Virtual Server, you must also select the specific content switching virtual server to which you want to bind this policy.

- **Default Global.** Policies that are bound to this bind point process all traffic from all interfaces on the NetScaler appliance.

- **Policy Label.** Policies that are bound to a policy label process traffic that the policy label routes to them. The policy label controls the order in which policies are applied to this traffic.

- **None.** Do not bind the policy to any bind point.

3. Click **Continue.** A list of existing App Firewall policies appears.

4. Select the policy you want to bind by clicking it.

5. Make any additional adjustments to the binding.
   - To modify the policy priority, click the field to enable it, and then type a new priority. You can also select **Regenerate Priorities** to renumber the priorities evenly.
   - To modify the policy expression, double click that field to open the **Configure App Firewall Policy** dialog box, where you can edit the policy expression.
   - To set the Goto Expression, double click field in the **Goto Expression** column heading to display the drop-down list, where you can choose an expression.
   - To set the Invoke option, double click field in the Invoke column heading to display the drop-down list, where you can choose an expression.

6. Repeat steps 3 through 6 to add any additional App Firewall policies you want to globally bind.

7. Click **OK.** A message appears in the status bar, stating that the policy has been successfully bound.

### Manual configuration By using the command line interface

**November 14, 2018**

You can configure many App Firewall features from the NetScaler command line. There are important exceptions, however. You cannot enable signatures from the command line. There are over 1,000 default signatures in seven categories; the task is simply too complex for the command line interface. You can configure the check actions and parameters for security checks from the command line, but cannot enter manual relaxations. While you can configure the adaptive learning feature and enable learning from the command line, you cannot review learned relaxations or learned rules and approve or skip them. The command line interface is intended for advanced users who are thoroughly familiar with the NetScaler appliance and the App Firewall feature.

To manually configure the App Firewall by using the NetScaler command line, use a telnet or secure shell client of your choice to log on to the NetScaler command line.
To create a profile by using the command line interface

At the command prompt, type the following commands:

- `add appfw profile <name> [-defaults ( basic | advanced )]`
- `set appfw profile <name> -type ( HTML | XML | HTML XML )`
- `save ns config`

Example

The following example adds a profile named pr-basic, with basic defaults, and assigns a profile type of HTML. This is the appropriate initial configuration for a profile to protect an HTML Web site.

1. `add appfw profile pr-basic -defaults basic`
2. `set appfw profile pr-basic -type HTML`
3. `save ns config`

To configure a profile by using the command line interface

At the command prompt, type the following commands:

- `set appfw profile <name> <arg1> [ <arg2> ... ]` where `<arg1>` represents a parameter and `<arg2>` represents either another parameter or the value to assign to the parameter represented by `<arg1>`. For descriptions of the parameters to use when configuring specific security checks, see Advanced Protections and its subtopics. For descriptions of the other parameters, see “Parameters for Creating a Profile.”
- `save ns config`

Example

The following example shows how to configure an HTML profile created with basic defaults to begin protecting a simple HTML-based Web site. This example turns on logging and maintenance of statistics for most security checks, but enables blocking only for those checks that have extremely low false positive rates and require no special configuration. It also turns on transformation of unsafe HTML and unsafe SQL, which prevents attacks but does not block requests to your Web sites. With logging and statistics enabled, you can later review the logs to determine whether to enable blocking for a specific security check.

1. `set appfw profile -startURLAction log stats`
2. `set appfw profile -denyURLAction block log stats`
3. `set appfw profile -cookieConsistencyAction log stats`
To create and configure a policy

At the command prompt, type the following commands:

- `add appfw policy <name> <rule> <profile>
- `save ns config

Example

The following example adds a policy named pl-blog, with a rule that intercepts all traffic to or from the host blog.example.com, and associates that policy with the profile pr-blog. This is an appropriate policy to protect a blog hosted on a specific hostname.

```
add appfw policy pl-blog "HTTP.REQ.HOSTNAME.DOMAIN.EQ("blog.example.com")" pr-blog
```

To bind an App Firewall policy

At the command prompt, type the following commands:

- `bind appfw global <policyName> <priority>
- `save ns config

Example

The following example binds the policy named pl-blog and assigns it a priority of 10.

```
bind appfw global pl-blog 10
save ns config
```
To configure session limit per PE

At the command prompt, type the following commands:

- `set appfw settings <session limit>`

Example

The following example configures the session limit per PE.

```
1 > set appfw settings -sessionLimit 500000
2 Done
3
4 Default value:100000  Max value:500000 per PE
```

Signatures

December 14, 2018

The App Firewall signatures function provides specific, configurable rules to simplify the task of protecting your web sites against known attacks. A signature represents a pattern that is a component of a known attack on an operating system, web server, website, XML-based web service, or other resource. A rich set of preconfigured App Firewall built-in or Native rules offers an easy to use security solution, leveraging the power of pattern matching to detect attacks and protect against application vulnerabilities.

You can create your own signatures or use the signatures in the built-in templates. The App Firewall has two built-in templates:

- **Default Signatures**: This template contains a preconfigured list of over 1,300 signatures, in addition to a complete list of SQL injection keywords, SQL special strings, SQL transform rules, and SQL wildchar characters. It also contains denied patterns for cross-site scripting, and allowed attributes and tags for cross-site scripting. This is a read-only template. You can view the contents, but you cannot add, edit, or delete anything in this template. To use it, you must make a copy. In your own copy, you can enable the signature rules that you want to apply to your traffic, and specify the actions to be taken when the signature rules match the traffic.

The App Firewall signatures are derived from the rules published by Snort, which is an open source intrusion prevention system capable of performing real-time traffic analysis to detect a variety of attacks and probes.
- **Xpath Injection Patterns**: This template contains a preconfigured set of literal and PCRE keywords and special strings that are used to detect XPath (XML Path Language) injection attacks.

**Blank Signatures**: In addition to making a copy of the built-in *Default Signatures template, you can use a blank signatures template to create a new signature object. The signature object that you create with the blank signatures option does not have any native signature rules, but, just like the *Default template, it has all the SQL/XSS built-in entities.

**External-Format Signatures**: The App Firewall also supports the use of external format signatures. You can import the scan files of the third party scan tools by using the XSLT files that are supported by the NetScaler App Firewall. A set of built-in XSLT files are available for the following scan tools to translate these external format files to the Native format:

- Cenzic
- Deep Security for Web Apps
- IBM AppScan Enterprise
- IBM AppScan Standard
- Qualys
- Whitehat
- Hewlett Packard Enterprise WebInspect

**Protection options for your application**

Tighter security increases processing overhead. Signatures provide the following deployment options to help you to optimize the protection of your applications:

- **Negative Security Model**: With the negative security model, you use a rich set of preconfigured signature rules to leverage the power of pattern matching to detect attacks and protect against application vulnerabilities. You block only what you don’t want and allow the rest. You can add your own signature rules, based on the specific security needs of your applications, to design your own customized security solutions.

- **Hybrid security Model**: In addition to using signatures, you can use positive security checks to create a configuration ideally suited for your applications. Use signatures to block what you don’t want, and use positive security checks to enforce what is allowed.

To protect your application by using signatures, you must configure one or more profiles to use your signatures object. In a hybrid security configuration, the SQL injection and Cross-Site scripting patterns, and the SQL transformation rules, in your signatures object are used not only by the signature rules, but also by the positive security checks configured in the App Firewall profile that is using the signatures object.

The App Firewall examines the traffic to your protected web sites and web services to detect traffic that matches a signature. A match is triggered only when every pattern in the rule matches the traffic.
When a match occurs, the specified actions for the rule are invoked. You can display an error page or error object when a request is blocked. Log messages can help you to identify attacks being launched against your application. If you enable statistics, the App Firewall maintains data about requests that match an App Firewall signature or security check.

If the traffic matches both a signature and a positive security check, the more restrictive of the two actions is enforced. For example, if a request matches a signature rule for which the block action is disabled, but the request also matches an SQL Injection positive security check for which the action is block, the request is blocked. In this case, the signature violation might be logged as `<not blocked >`, although the request is blocked by the SQL injection check.

**Customization:** If necessary, you can add your own rules to a signatures object. You can also customize the SQL/XSS patterns. The option to add your own signature rules, based on the specific security needs of your applications, gives you the flexibility to design your own customized security solutions. You block only what you don’t want and allow the rest. A specific fast-match pattern in a specified location can significantly reduce processing overhead to optimize performance. You can add, modify, or remove SQL injection and cross-site scripting patterns. Built-in RegEx and expression editors help you configure your patterns and verify their accuracy.

**Auto-update:** You can manually update the signature object to get the latest signature rules, or you can leverage the auto-update feature so that the App Firewall can automatically update the signatures from the cloud-based App Firewall updates service.

**Note**

If new signature rules are added during auto-update, they are disabled by default. You should periodically review the updated signatures and enable the newly added rules that are pertinent for protecting your applications.

You must configure CORS to host signatures on IIS servers.

**Getting started**

Using Citrix signatures to protect your application is quite easy and can be accomplished in a few simple steps:

1. Add a signature object.

   - You can use the Wizard that prompts you to create the entire App Firewall configuration, including adding the profile and policy, selecting and enabling signatures, and specifying actions for signatures and positive security checks. The signatures object is created automatically.
   - You can create a copy of the signatures object from the *Default Signatures template, use a blank template to create a new signature with your own customized rules, or add an external format signature. Enable the rules and configure the actions that you want to apply.
2. Configure the target App Firewall profile to use this signatures object.

3. Send traffic to validate the functionality

**Highlights**

- The *Default signatures object is a template. It cannot be edited or deleted. To use it, you must create a copy. In your own copy, you can enable the rules and the desired action for each rule as required for your application. To protect the application, you must configure the target profile to use this signature.
- Processing signature patterns has overhead. Try to enable only those signatures that are applicable for protecting your application, rather than enabling all signature rules.
- Every pattern in the rule must match to trigger a signature match.
- You can add your own customized rules to inspect incoming requests to detect various types of attacks, such as SQL injection or cross-site scripting attacks. You can also add rules to inspect the responses to detect and block leakage of sensitive information such as credit card numbers.
- You can make a copy of an existing signatures object and tweak it, by adding or editing rules and SQL/XSS patterns, to protect another application.
- You can use auto-update to download the latest version of the App Firewall default rules without need for ongoing monitoring to check for the availability of the new update.
- A signature object can be used by more than one profile. Even after you have configured one or more profile(s) to use a signature object, you can still enable or disable signatures or change the action settings. You can manually create and modify your own custom signature rules. The changes will apply to all the profiles that are currently configured to use this signature object.
- You can configure signatures to detect violations in various types of payloads, such as HTML, XML, JSON, and GWT.
- You can export a configured signatures object and import it to another NetScaler appliance for easy replication of your customized signature rules.

Signatures are patterns that are associated with a known vulnerability. You can use signature protection to identify the traffic that attempts to exploit these vulnerabilities, and take specific actions.

Signatures are organized into categories. You can optimize the performance and reduce the processing overhead by enabling only the rules in the categories that are appropriate for protecting your application.

**Manually configuring the signatures feature**

September 18, 2018
To use signatures to protect your web sites, you must review the rules, and enable and configure the ones that you want to apply. The rules are disabled by default. Citrix recommends that you enable all rules that are applicable to the type of content that your web site uses.

To manually configure the signatures feature, use a browser to connect to the GUI. Then, create a signatures object from a built-in template, an existing signatures object, or by importing a file. Next, configure the new signatures object as explained in Configuring or Modifying a Signatures Object.

Adding or removing a signatures object

September 18, 2018

You can add a new signatures object to the App Firewall by:

• Copying a built-in template.
• Copying an existing signatures object.
• Importing a signatures object from an external file.

You must use the GUI to copy a template or existing signatures object. You can use either the GUI or the command line to import a signatures object. You can also use either the GUI or the command line to remove a signatures object.

To create a signatures object from a template

1. Navigate to Security > Application Firewall > Signatures.
2. In the details pane, select the signatures object that you want to use as a template.

   Your choices are:

   • Default Signatures. Contains the signatures rules, the SQL injection rules, and the cross-site scripting rules.
   • XPath Injection. Contains the XPath injection patterns.
   • Any existing signatures object.

   Attention:

   If you do not choose a signatures type to use as a template, the App Firewall will prompt you to create signatures from scratch.

3. Click Add.
4. In the Add Signatures Object dialog box, type a name for your new signatures object, and then click OK. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 31 letters, numbers, and the hyphen (-), period (.), pound (#), space ( ), at (@), equals (=), and underscore (_) symbols.
To create a signatures object by importing a file

1. Navigate to Security > Application Firewall > Signatures.
2. In the details pane, click Add.
3. In the Add Signatures Object dialog box, select the format of the signatures you want to import.
   - To import a NetScaler format signatures file, select the Native Format tab.
   - To import an external signatures format file, select the External Format tab.
4. Choose the file that you want to use to create your new signatures object.
   - To import a native NetScaler format signatures file, in the Import section select either Import from Local File or Import from URL, then type or browse to the path or URL to the file.
   - To import a Cenzic, IBM AppScan, Qualys, or Whitehat format file, in the XSLT section select Use Built-in XSLT File, Use Local File, or Reference from URL. Next, if you chose Use Built-in XSLT File, select the appropriate file format from the drop-down list. If you chose Use Local File or Reference from URL, then type or browse to the path or URL to the file.
5. Click Add, and then click Close.

To create a signatures object by importing a file by using the command line

At the command prompt, type the following commands:

```
import appfw signatures <src> <name> [-xslt <string>] [-comment <string>] [-overwrite] [-merge] [-sha1 <string>]
save ns config
```

Example #1

The following example creates a new signatures object from a file named signatures.xml and assigns it the name MySignatures.

```
1  import appfw signatures signatures.xml MySignatures
2  save ns config
```

To remove a signatures object by using the GUI

1. Navigate to Security > Application Firewall > Signatures.
2. In the details pane, select the signatures object that you want to remove.
3. Click Remove.
To remove a signatures object by using the command line

At the command prompt, type the following commands:

- `rm appfw signatures <name>`
- `save ns config`

Configuring or modifying a signatures object

September 18, 2018

You configure a signatures object after creating it, or modify an existing signatures object, to enable or disable signature categories or specific signatures, and configure how the App Firewall responds when a signature matches a connection.

To configure or modify a signatures object

1. Navigate to Security > Application Firewall > Signatures.
2. In the details pane, select the signatures object that you want to configure, and then click Open.
3. In the Modify Signatures Object dialog box, set the Display Filter Criteria options at the left to display the filter items that you want to configure.

As you modify these options, the results that you requested are displayed in the Filtered Results window at the right.

```
| 1 - To display only selected categories of signatures, check or clear the appropriate signature-category check boxes. The signature categories are: |
| 2 | Name | Type of Attack that this Signature Protects Against |
| 3 | ------- |-------------------------------------------------- |
| 4 |--------- |-------------------------------------------------- |
| 5 | cgi | CGI scripts. Includes Perl and UNIX shell scripts. |
| 6 | client | Browsers and other clients. |
| 7 | coldfusion | Web sites that use the Adobe Systems ColdFusion application server. |
| 8 | frontpage | Web sites that use Microsoft’s FrontPage server. |
```
To display only signatures that have specific check actions enabled, select the ON check box for each of those actions, clear the ON check boxes for the other actions, and clear all of the OFF check boxes. To display only signatures that have a specific check action disabled, select their respective OFF check boxes and clear all of the ON check boxes. To display signatures regardless of whether they have a check action enabled or disabled, select or clear both the ON and the OFF check boxes for that action. The check actions are:

<table>
<thead>
<tr>
<th>Criterion</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enabled</td>
<td>The signature is enabled. The App Firewall checks only for signatures that are enabled when it processes traffic.</td>
</tr>
<tr>
<td>Block</td>
<td>Connections that match this signature are blocked.</td>
</tr>
<tr>
<td>Log</td>
<td>A log entry is produced for any connection that matches this signature.</td>
</tr>
<tr>
<td>Stats</td>
<td>The App Firewall includes any connection that matches this signature in the statistics that it generates for that check.</td>
</tr>
</tbody>
</table>

To display only signatures that contain a specific string, type the string into the text box under the filter criteria, and then click Search.

To reset all display filter criteria to the default settings and display all signatures, click Show All.

1. For information about a specific signature, select the signature, and then click the blue double arrow in the More field. The Signature Rule Vulnerability Detail message box appears. It con-
tains information about the purpose of the signature and provides links to external web-based information about the vulnerability or vulnerabilities that this signature addresses. To access an external link, click the blue double arrow to the left of the description of that link.

2. Configure the settings for a signature by selecting the appropriate check boxes.

3. If you want to add a local signature rule to the signatures object, or modify an existing local signature rule, see “The Signatures Editor.”

4. If you have no need for SQL injection, cross-site scripting, or Xpath injection patterns, click OK, and then click Close. Otherwise, in the lower left-hand corner of the details pane, click Manage SQL/XSS Patterns.

5. In the Manage SQL/XSS Patterns dialog box, Filtered Results window, navigate to the pattern category and pattern that you want to configure. For information about the SQL injection patterns, see “HTML SQL Injection Check.” For information about the cross-site scripting patterns, see “HTML Cross-Site Scripting Check.”

6. To add a new pattern:
   a) Select the branch to which you want to add the new pattern.
   b) Click the Add button directly below the lower section of the Filtered Results window.
   c) In the Create Signature Item dialog box, fill in the Element text box with the pattern that you want to add. If you are adding a transformation pattern to the transform rules branch, under Elements, fill in the From text box with the pattern that you want to change and the To text box with the pattern to which you want to change the previous pattern.
   d) Click OK.

7. To modify an existing pattern:
   a) In the Filtered Results window, select the branch that contains the pattern that you want to modify.
   b) In the detail window beneath the Filtered Results window, select the pattern that you want to modify.
   c) Click Modify.
   d) In the Modify Signature Item dialog box, Element text box, modify the pattern. If you are modifying a transformation pattern, you can modify either or both patterns under Elements, in the From and the To text boxes.
   e) Click OK.

8. To remove a pattern, select the pattern that you want to remove, then click the Remove button below the details pane beneath the Filtered Results window. When prompted, confirm your choice by clicking Close.

9. To add the patterns category to the XSS branch:
   a) Select the branch to which you want to add the patterns category.
b) Click the Add button directly below the Filtered Results window.

Note: Currently you can add only one category, named patterns, to the XSS branch, so after you click Add, you must accept the default choice, which is patterns.

3. Click OK.

10. To remove a branch, select that branch, and then click the Remove button directly below the Filtered Results window. When prompted, confirm your choice by clicking OK.

Note: If you remove a default branch, you remove all of the patterns in that branch. Doing so can disable the security checks that use that information.

11. When you are finished modifying the SQL injection, cross-site scripting, and XPath injection patterns, click OK, and then click Close to return to the Modify Signatures Object dialog box.

12. Click OK at any point to save your changes, and when you are finished configuring the signatures object, click Close.

Protecting JSON applications using signatures

September 18, 2018

JavaScript Object Notation (JSON) is a text-based open standard derived from the JavaScript scripting language. JSON is preferred for human readable representation of simple data structures and associative arrays, called objects. It serves as an alternative to XML and is primarily used to transmit serialized data structures for communicating with web applications. The JSON files are typically saved with a .json extension.

The JSON payload is typically sent with the MIME type specified as application/json. The other “standard” content types for JSON are:

- application/x-javascript
- text/javascript
- text/x-javascript
- text/x-json

Using the NetScaler App Firewall signatures to protect JSON applications

To allow JSON requests, the appliance is preconfigured with the JSON content type as shown in the following show-command output:

```
1 > sh appfw jsonContentType
2 1) JSONContentTypevalue: ^application/json$ IsRegex: REGEX
3 Done
```
The NetScaler App Firewall processes the post body for the following content-types only:

- application/x-www-form-urlencoded
- multipart/form-data
- text/x-gwt-rpc

The requests that are received with other content-type headers including application/json (or any other allowed content type) are forwarded to the backend after header inspection. The post body in such requests is not inspected for security check violations even when the profile’s security checks such as SQL or XSS are enabled.

In order to protect JSON applications and detect violations, App Firewall signatures can be used. All requests that contain the allowed content-type header are processed by the App Firewall for signature match. You can add your own customized signature rules to process JSON payload to perform various security check inspections (for example, XSS, SQL, and Field Consistency), to detect violations in the headers as well as the post body, and take specified actions.

Tip

Unlike the other built-in defaults, the preconfigured JSON content type can be edited or removed by using the CLI or the GUI (GUI). If legitimate requests for JSON applications are getting blocked and triggering content-type violations, check to make sure that the content type value is configured accurately. For additional details regarding how App Firewall processes content-type header, see Content type protection

To add or remove JSON content-type by using the command line interface

At the command prompt, type one of the following commands:

```
add appfw jsonContentType ^application/json$ IsRegEx REGEX
rm appfw JSONContentType "^application/json$"
```

To managing JSON content types by using the GUI

Navigate to Security > App Firewall and, in the Settings section, select Manage JSON Content Types.

In the Configure App Firewall JSON Content Type panel, add, edit, or delete JSON content types to suit the needs of your applications.
Configuring signature protection to detect attacks in JSON payload

In addition to a valid JSON content type, you need to configure signatures to specify the pattern(s) that, when detected in a JSON request, indicate a security breach. The specified actions, such as block and log, are taken when an incoming request triggers a match for all the target patterns in the signature rule.

To add a customized signature rule, Citrix recommends that you use the GUI. Navigate to System > Security > App Firewall > Signatures. Double click the target signature object to access the Edit App Firewall Signatures panel. Click on the Add button to configure the actions, category, log string, rule patterns and so on. Although App Firewall inspects all allowed content-type payload for signature match, you can optimize the processing by specifying the JSON expression in the rule. When you Add a new rule pattern, select Expression in the drop-down options for Match and provide the target match expression from your JSON payload to identify the specific requests that need to be inspected. An expression must begin with a TEXT. prefix. You can add other rule patterns to specify additional match patterns to identify the attack.

The following example shows a signature rule. If any cross-site script tag is detected in the POST body of the JSON payload that matches the specified XPATH_JSON expression, a signature match is triggered.

Example of a signature to detect XSS in JSON payload

```
  <SignatureRule actions="log,stats" category="JSON" enabled="ON" id="1000001" severity="" source="" type="" version="1">
    <PatternList>
      <RequestPatterns>
        <Pattern>
          <Location area="HTTP_POST_BODY"/>
          <Match type="Expression">TEXT.XPATH_JSON(xp%/glossary/title%).CONTAINS("example glossary")</Match>
        </Pattern>
        <Pattern>
          <Location area="HTTP_METHOD"/>
        </Pattern>
      </RequestPatterns>
    </PatternList>
  </SignatureRule>
```
Example of the payload

The following payload triggers the signature match, because it includes the cross-site scripting tag <Gotcha!!>.

```json
{
  "glossary": {
    "title": "example glossary", "GlossDiv": {
      "title": "S", "GlossList": {
        "GlossEntry": {
            "para": "A meta-markup language, used to create markup languages such as DocBook.\"", "GlossSeeAlso": ["GML", "XML"]
          }, "GlossSee": "markup" 
        }
      }
    }
  }
}```
Example of the log message

```
1 Aug 21 12:21:42 <local0.info> 10.217.31.239 08/21/2015:23:21:42 GMT ns 0-PPE-1 : APPFW_APPFW_SIGNATURE_MATCH 1471 0 : 10.217.253.62 990-PPE0_NtJnVMNnvPeQJnaUzXYW/GTvAQsA010_prof1_http://10.217.31.212/FFC/login_post.php Signature violation rule ID 1000001: cross-site scripting violation detected in json payload <not blocked>
```

Note

If you send the same payload after removing the cross-site script tag (<Gotcha!!>), the signature rule match is not triggered.

Highlights

- To protect JSON payload, use App Firewall signatures to detect XSS, SQL and other violations.
- Verify that the JSON content type is configured on the appliance as the allowed content type.
- Make sure that the content type in the payload matches the configured JSON content type.
- Make sure that all the patterns configured in the signature rule match for the signature violation to be triggered.
- When you add a signature rule, it MUST have at least one Rule pattern to match the Expression in the JSON payload. All the PI expressions in signature rules must start with the prefix TEXT and must be Boolean.

Updating a signatures object

September 18, 2018

You should update your signatures objects frequently to ensure that your App Firewall is providing protection against current threats. You should regularly update both the default App Firewall signatures and any signatures that you import from a supported vulnerability scanning tool.

Citrix regularly updates the default signatures for the App Firewall. You can update the default signatures manually or automatically. In either case, ask your Citrix representative or Citrix reseller for the URL to access the updates. You can enable automatic updates of the Citrix native format signatures in the “Engine Settings” and “Signature Auto Update Settings” dialog boxes.

Most makers of vulnerability scanning tools regularly update the tools. Most web sites also change frequently. You should update your tool and rescan your web sites regularly, exporting the resulting signatures to a file and importing them into your App Firewall configuration.
**Tip**

When you update the App Firewall signatures from the NetScaler command line, you must first update the default signatures, and then issue additional update commands to update each custom signatures file that is based on the default signatures. If you do not update the default signatures first, a version mismatch error prevents updating of the custom signatures files.

**Note**

The following applies to merging a third-party signature object with a user-defined signature object with Native rules and user-added rules:

When a version 0 signatures is merged with a new imported file, the resultant signatures will remain as version 0.

This means all native (or built-in) rules in the imported file will be ignored after the merge. This is to ensure that the version 0 signatures are maintained as is after a merge.

In order to include the native rules in the imported file for merge, you should update the existing signatures from version 0 first before the merge. This means you need to abandon the version 0 nature of the existing signatures.

---

**To update the App Firewall signatures from the source by using the command line**

At the command prompt, type the following commands:

- `update appfw signatures <name> [-mergedefault]`
- `save ns config`

**Example**

The following example updates the signatures object named MySignatures from the default signatures object, merging new signatures in the default signatures object with the existing signatures. This command does not overwrite any user-created signatures or signatures imported from another source, such as an approved vulnerability scanning tool.

```
1 update appfw signatures MySignatures -mergedefault
2 save ns config
```

**Updating a signatures object from a Citrix format file**

Citrix regularly updates the signatures for the App Firewall. You should regularly update the signatures on your App Firewall to ensure that your App Firewall is using the most current list. Ask your Citrix representative or Citrix reseller for the URL to access the updates.
To update a signatures object from a Citrix format file by using the command line

At the command prompt, type the following commands:

- `update appfw signatures <name> [-mergeDefault]`
- `save ns config`

To update a signatures object from a Citrix format file by using the GUI

1. Navigate to Security > App Firewall > Signatures.
2. In the details pane, select the signatures object that you want to update.
3. In the Action drop-down list, select Merge.
4. In the Update Signatures Object dialog box, choose one of the following options.
   - Import from URL—Choose this option if you download signature updates from a web URL.
   - Import from Local File—Choose this option if you import signature updates from a file on your local hard drive, network hard drive, or other storage device.
5. In the text area, type the URL, or type or browse to the local file.
6. Click Update. The update file is imported, and the Update Signatures dialog box changes to a format nearly identical to that of the Modify Signatures Object dialog box. The Update Signatures Object dialog box displays all branches with new or modified signature rules, SQL injection or cross-site scripting patterns, and XPath injection patterns if there are any.
7. Review and configure the new and modified signatures.
8. When you are finished, click OK, and then click Close.

Updating a signatures object from a supported vulnerability scanning tool

**Note:** Before you update a signatures object from a file, you must create the file by exporting signatures from the vulnerability scanning tool.

To import and update signatures from a vulnerability scanning tool

1. Navigate to Security > App Firewall > Signatures.
2. In the details pane, select the signatures object that you want to update, and then click Merge.
3. In the Update Signatures Object dialog box, on the External Format tab, Import section, choose one of the following options.
   - Import from URL—Choose this option if you download signature updates from a Web URL.
   - Import from Local File—Choose this option if you import signature updates from a file on your local or a network hard drive or other storage device.
4. In the text area, type the URL, or browse or type the path to the local file.
5. In the XSLT section, choose one of the following options.
- **Use Built-in XSLT File**—Choose this option if you want to use a built-in XSLT file.
- **Use Local XSLT File**—Choose this option to use an XSLT file on your local computer.
- **Reference XSLT from URL**—Choose this option to import an XSLT file from a web URL.

6. If you chose Use Built-in XSLT File, in the Built-In XSLT drop-down list select the file that you want to use from the following options:
   - Cenzic.
   - Deep_Security_for_Web_Apps.
   - Hewlett_Packard_Enterprise_WebInspect.
   - IBM-AppScan-Enterprise.
   - IBM-AppScan-Standard.
   - Qualys.
   - Whitehat.

7. Click **Update**. The update file is imported, and the Update Signatures dialog box changes to a format nearly identical to that of the Modify Signatures Object dialog box, which is described in “Configuring or Modifying a Signatures Object.” The **Update Signatures Object** dialog box displays all branches with new or modified signature rules, SQL injection or cross-site scripting patterns, and XPath injection patterns if there are any.

8. Review and configure the new and modified signatures.

9. When you are finished, click **OK**, and then click **Close**.

---

**Exporting a signatures object to a file**

September 18, 2018

You export a signatures object to a file so that you can import it to another NetScaler.

**To export a signatures object to a file**

1. Navigate to **Security > Application Firewall > Signatures**.
2. In the details pane, select the signatures object that you want to configure.
3. In the **Actions** drop-down list, select **Export**.
4. In the **Export Signatures Object** dialog box, **Local File** text box, type the path and name of the file to which you want to export the signatures object, or use the **Browse** dialog to designate a path and name.
5. Click **OK**.
The Signatures editor

September 18, 2018

You can use the signatures editor, which is available in the GUI, to add a new user-defined (local) signature rule to an existing signatures object, or to modify a previously configured local signature rule. Except that it is defined by the user (you), a local signature rule has the same attributes as a default signature rule from Citrix, and it functions in the same way. You enable or disable it, and configure the signature actions for it, just as you do for a default signature.

Add a local rule if you need to protect your web sites and services from a known attack that the existing signatures do not match. For example, you might discover a new type of attack and determine its characteristics by examining the logs on your web server, or you might obtain third-party information about a new type of attack.

At the heart of a signature rule are the rule patterns, which collectively describe the characteristics of the attack that the rule is designed to match. Each pattern can consist of a simple string, a PCRE-format regular expression, or the built-in SQL injection or cross-site scripting patterns.

You might want to modify a signature rule by adding a new pattern or modifying an existing pattern to match an attack. For example, you might find out about changes to an attack, or you might determine a better pattern by examining the logs on your web server, or from third-party information.

To add or modify a local signature rule by using the Signatures Editor

1. Navigate to Security > Application Firewall > Signatures.
2. In the details pane, select the signatures object that you want to edit, and then click Open.
3. In the Modify Signatures Object dialog box, in the middle of the screen beneath the Filtered Results window, do one of the following:
   - To add a new local signature rule, click Add.
   - To modify an existing local signature rule, select that rule, and then click Open.
4. In the Add Local Signature Rule or the Modify Local Signature Rule dialog box, configure the actions for a signature by selecting the appropriate check boxes.
   - Enabled. Enables the new signature rule. If you do not select this, this new signature rule is added to your configuration, but is inactive.
   - Block. Blocks connections that violate this signature rule.
   - Log. Logs violations of this signature rule to the NetScaler log.
   - Stat. Includes violations of this signature rule in the statistics.
   - Remove. Strips information that matches the signature rule from the response. (Applies only to response rules.)
• **X-Out.** Masks information that matches the signature rule with the letter X. (Applies only to response rules.)

• **Allow Duplicates.** Allows duplicates of this signature rule in this signatures object.

5. Choose a category for the new signature rule from the **Category** drop-down list.

You can also create a new category by clicking the icon to the right of the list and using the Add Signature Rule Category dialog box to add a new category to the list. The rule you are modifying is automatically added to the new category. For instructions, see “To add a signature rule category.”

6. In the **LogString** text box, type a brief description of the signature rule to be used in the logs.

7. In the **Comment** text box, type a comment. (Optional)

8. Click More…, and modify the advanced options.

   a) To strip HTML comments before applying this signature rule, in the Strip Comments drop-down list choose All or Exclude Script Tag.

   b) To set CSRF Referer Header checking, in the CSRF Referer Header checking radio button array, select either the If Present or Always radio button.

   c) To manually modify the Rule ID assigned to this local signature rule, modify the number in the Rule ID text box. The ID must be a positive integer between 1000000 and 1999999 that has not already been assigned to a local signature rule.

   d) To assign a version number to the new signature rule, modify the number in the Version Number text box.

   e) To assign a Source ID, modify the string in the Source ID text box.

   f) To specify the source, choose Local or Snort from the Source drop-down list, or click the Add icon to the right of the list and add a new source.

   g) To assign a harm score to violations of this local signature rule, type a number between 1 and 10 in the Harm Score text box.

   h) To assign a severity rating to this local signature rule, in the Severity drop-down list choose High, Medium, or Low, or click the Add icon to the right of the list and add a new severity rating.

   i) To assign a violation type to this local signature rule, in the Type drop-down list choose Vulnerable or Warning, or click the Add icon to the right of the list and add a new violation type.

9. In the **Patterns** list, add or edit a pattern.

   • To add a pattern, click **Add**. In the Create New Signature Rule Pattern dialog box, add one or more patterns for your signature rule, and then click **OK**.

   • To edit a pattern, select the pattern, and then click **Open**. In the Edit Signature Rule Pattern dialog box, modify the pattern, and then click **OK**.

For more information about adding or editing patterns, see “Signature Rule Patterns.”
10. Click **OK**.

To add a signature rule category

September 18, 2018

Putting signature rules into a category enables you to configure the actions for a group of signatures instead of for each individual signature. You might want to do so for the following reasons:

- **Ease of selection.** For example, assume that all of signature rules in a particular group protect against attacks on a specific type of web server software or technology. If your protected web sites use that software or technology, you want to enable them all. If they do not, you do not want to enable any of them.
- **Ease of initial configuration.** It is easiest to set defaults for a group of signatures as a category, instead of one-by-one. You can then make any changes to individual signatures as needed.
- **Ease of ongoing configuration.** It is easier to configure signatures if you can display only those that meet specific criteria, such as belonging to a specific category.

1. Navigate to **Security > App Firewall > Signatures.**
2. In the details pane, select that signatures object that you want to configure, and then click **Open.**
3. In the Modify Signatures Object dialog box, in the middle of the screen, beneath the Filtered Results window, click **Add.**
4. In the Add Local Signature Rule dialog box, click the icon to the right of the Category dropdown list.
5. In the Add Signature Rule Category dialog box, **New Category** text box, type a name for your new signature category. The name can consist of from one to 64 characters.
6. Click **OK.**

Signature rule patterns

December 14, 2018

You can add a new pattern to a signature rule or modify an existing pattern of a signature rule to specify a string or expression that characterizes an aspect of the attack that the signature matches. To determine which patterns an attack exhibits, you can examine the logs on your web server, use a tool to observe connection data in real time, or obtain the string or expression from a third-party report about the attack.

**Caution:**

Any new pattern that you add to a signature rule is in an
AND relationship with the existing patterns. Do not add a new pattern to an existing signature rule if you do not want a potential attack to have to match all of the patterns in order to match the signature.

Each pattern can consist of a simple string, a PCRE-format regular expression, or the built-in SQL injection or cross-site scripting pattern. Before you attempt to add a pattern that is based on a regular expression, you should make sure that you understand PCRE-format regular expressions. PCRE expressions are complex and powerful; if you do not understand how they work, you can unintentionally create a pattern that matches something that you did not want (a false positive) or that fails to match something that you did want (a false negative).

If you are not already familiar with PCRE-format regular expressions, you can use the following resources to learn the basics, or for help with some specific issue:

- “Regular Expressions Cookbook”. Copyright (c) 2009 by Jan Goyvaerts and Steven Levithan. O’Reilly Media, ISBN: 9780596520687
- PCRE Mailing List (run by exim.org): http://lists.exim.org/mailman/listinfo/pcre-dev

If you need to encode non-ASCII characters in a PCRE-format regular expression, the NetScaler platform supports encoding of hexadecimal UTF-8 codes. For more information, see “PCRE Character Encoding Format.”

To configure a signature rule pattern

1. Navigate to Security > Application Firewall > Signatures.
2. In the details pane, select that signatures object that you want to configure, and then click Open.
3. In the Modify Signatures Object dialog box, in the middle of the screen beneath the Filtered Results window, either click Add to create a signature rule, or select an existing signature rule and click Open.

Note:
You can modify only signature rules that you added. You cannot modify the default signature rules.

Depending on your action, either the Add Local Signature Rule or the Modify Local Signature Rule dialog box appears. Both dialog boxes have the same contents.
4. Under the Patterns window in the dialog box, either click Add to add a new pattern, or select an existing pattern from the list beneath the Add button and click Open. Depending on your action, either the Create New Signature Rule Pattern or the Edit Signature Rule Pattern dialog box appears. Both dialog boxes have the same contents.

5. In the Pattern Type drop-down list, choose the type of connection that the pattern is intended to match.

   - If the pattern is intended to match request elements or features, such as injected SQL code, attacks on web forms, cross-site scripts, or inappropriate URLs, choose Request.
   - If the pattern is intended to match response elements or features, such as credit card numbers or safe objects, choose Response.

6. In the Location area, define the elements to examine with this pattern.

   The Location area describes what elements of the HTTP request or response to examine for this pattern. The choices that appear in the Location area depend upon the chosen pattern type. If you chose Request as the pattern type, items relevant to HTTP requests appear; if you chose Response, items relevant to HTTP responses appear.

   In addition, as you choose a value from the Area drop-down list, the remaining parts of the Location area change interactively. Following are all configuration items that might appear in this section.

   - Area Drop-down list of elements that describe a particular portion of the HTTP connection. The choices are as follows:
      - HTTP_ANY. All parts of the HTTP connection.
      - HTTP_COOKIE. All cookies in the HTTP request headers after any cookie transformations are performed.
        Note: Does not search HTTP response “Set-Cookie:” headers.
      - HTTP_FORM_FIELD. Form fields and their contents, after URL decoding, percent decoding, and removal of excess whitespace. You can use the <Location> tag to further restrict the list of form field names to be searched.
      - HTTP_HEADER. The value portions of the HTTP header after any cross-site scripting or URL decoding transformations.
      - HTTP_METHOD. The HTTP request method.
      - HTTP_ORIGIN_URL. The origin URL of a web form.
      - HTTP_POST_BODY. The HTTP post body and the web form data that it contains.
      - HTTP_RAW_COOKIE. All HTTP request cookie, including the “Cookie:” name portion.
        Note: Does not search HTTP response “Set-Cookie:” headers.
      - HTTP_RAW_HEADER. The entire HTTP header, with individual headers separated by linefeed characters (\n) or carriage return/line-feed strings (\r\n).
      - HTTP_RAW_RESP_HEADER. The entire response header, including the name and value parts of the response header after URL transformation has been done, and
the complete response status. As with HTTP_RAW_HEADER, individual headers are separated by linefeed characters (\n) or carriage return/line-feed strings (\r\n).

- **HTTP_RAW_SET_COOKIE.** The entire Set-Cookie header after any URL transformations have been performed
  Note: URL transformation can change both the domain and path parts of the Set-Cookie header.

- **HTTP_RAW_URL.** The entire request URL before any URL transformations are performed, including any query or fragment parts.

- **HTTP_RESP_HEADER.** The value part of the complete response headers after any URL transformations have been performed.

- **HTTP_RESP_BODY.** The HTTP response body

- **HTTP_SET_COOKIE.** All “Set-Cookie” headers in the HTTP response headers.

- **HTTP_STATUS_CODE.** The HTTP status code.

- **HTTP_STATUS_MESSAGE.** The HTTP status message.

- **HTTP_URL.** The value portion of the URL in the HTTP headers, excluding any query or fragment parts, after conversion to the UTF-* character set, URL decoding, stripping of whitespace, and conversion of relative URLs to absolute. Does not include HTML entity decoding.

• **URL**

  Examines any URLs found in the elements specified by the Area setting. Select one of the following settings.

  - **Any.** Checks all URLs.

  - **Literal.** Checks URLs that contain a literal string. After you select Literal, a text box is displayed. Type the literal string that you want in the text box.

  - **PCRE.** Checks URLs that match a PCRE-format regular expression. After you select this choice, the regular expression window is displayed. Type the regular expression in the window. You can use the **Regex Tokens** to insert common regular expression elements at the cursor, or you can click Regex Editor to display the Regular Expression Editor dialog box, which provides more assistance in constructing the regular expression that you want.

  - **Expression.** Checks URLs that match a NetScaler default expression.

• **Field Name**

  Examines any form field names found in the elements specified by the Area selection.

  - **Any.** Checks all URLs.

  - **Literal.** Checks URLs that contain a literal string. After you select Literal, a text box is displayed. Type the literal string that you want in the text box.

  - **PCRE.** Checks URLs that match a PCRE-format regular expression. After you select this choice, the regular expression window is displayed. Type the regular expression
in the window. You can use the **Regex Tokens** to insert common regular expression elements at the cursor, or you can click Regex Editor to display the Regular Expression Editor dialog box, which provides more assistance in constructing the regular expression that you want.

- **Expression**. Checks URLs that match a NetScaler default expression.

7. In the Pattern area, define the pattern. A pattern is a literal string or PCRE-format regular expression that defines the pattern that you want to match. The Pattern area contains the following elements:

  - **Match**
    
    A drop-down list of search methods that you can use for the signature. This list differs depending on whether the pattern type is Request or Response.

### Request Match Types

- **PCRE**. A PCRE-format regular expression.

  **NOTE**: When you choose PCRE, the regular expression tools beneath the Pattern window are enabled. These tools are not useful for most other types of patterns.

  - **Injection**. Directs the App Firewall to look for injected SQL in the specified location. The Pattern window disappears, because the App Firewall already has the patterns for SQL injection.
  
  - **CrossSiteScripting**. Directs the App Firewall to look for cross-site scripts in the specified location. The Pattern window disappears, because the App Firewall already has the patterns for cross-site scripts.
  
  - **Expression**. An expression in the NetScaler default expressions language. This is the same expressions language that is used to create App Firewall policies and other policies on the NetScaler appliance. Although the NetScaler expressions language was originally developed for policy rules, it is a highly flexible general purpose language that can also be used to define a signature pattern.

When you choose Expression, the NetScaler Expression Editor appears beneath Pattern window. For more information about the Expression Editor and instructions on how to use it, see "To add a firewall rule (expression) by using the Add Expression dialog box"

### Response Match Types:

- **Literal**. A literal string

- **PCRE**. A PCRE-format regular expression.

  **NOTE**:

  When you choose PCRE, the regular expression tools beneath the Pattern window are enabled. These tools are not useful for most other types of patterns.

  - **Credit Card**. A built-in pattern to match one of the six supported types of credit card number.
Note: The Expression match type is not available for Response-side signatures.

- Pattern Window (unlabeled)

In this window, type the pattern that you want to match, and fill in any additional data.

1 - Literal. Type the string you want to search for in the text area.
2 - PCRE. Type the regular expression in the text area. Use the **Regex Editor** for more assistance in constructing the regular expression that you want, or the Regex Tokens to insert common regular expression elements at the cursor. To enable UTF-8 characters, click UTF-8.
3 - Expression. Type the NetScaler advanced expression in the text area. Use Prefix to choose the first term in your expression, or Operator to insert common operators at the cursor. Click **Add** to open the Add Expression dialog box for more assistance in constructing the regular expression that you want. Click Evaluate to open the Advanced Expression Evaluator to help determine what effect your expression has.
4 - Offset. The number of characters to skip over before starting to match on this pattern. You use this field to start examining a string at some point other than the first character.
5 - Depth. How many characters from the starting point to examine for matches. You use this field to limit searches of a large string to a specific number of characters.
6 - Min-Length. The string to be searched must be at least the specified number of bytes in length. Shorter strings are not matched.
7 - Max-Length. The string to be searched must be no longer than the specified number of bytes in length. Longer strings are not matched.
8 - Search method. A check box labeled fastmatch. You can enable fastmatch only for a literal pattern, to improve performance.

1. Click OK.

2. Repeat the previous four steps to add or modify additional patterns.

3. When finished adding or modifying patterns, click OK to save your changes and return to the Signatures pane.

Caution:

Until you click OK in the Add Local Signature Rule or Modify Local Signature Rule dialog box, your changes are not saved. Do not close either of these dialog boxes without clicking OK unless you want to discard your changes.
To Import and merge rules

September 18, 2018

When using the signature editor to perform an import and merge operation from the GUI, you can now see the new, updated, duplicate, and invalid rules.

The signature editor displays the following four new rows:

1. New Rules
2. Updated Rules
3. Duplicate Rules
4. Invalid Rules

The output of the New Rules Only and Updated Rules Only filters also appears in the Category filter pane of the Edit window in signature editor.

You will need to import the files from GUI to see the corresponding links for New, duplicate, invalid and updated rules.

For example, you can use GUI to import the following signature files:

To import signature rules:

1. In the NetScaler web GUI, go to Configuration > Security > Application Firewall > Signatures. In the Signatures window, click Add. Then select File Format > Native, Import From > URL and in the URL field, add the above link. For example; <http://10.217.30.16/testsite/signatures/sig-3100000.xml>.

2. After you click Open, the signature file will open and you can see links for New Rule and Invalid Rules.

3. If you import a 3<sup>rd</sup> party signature rule from the following site, for example; <http://10.217.30.16/FFC/sig_validation/trendmicro_sample2.xml> as shown below, you can see 90 new Rules and 9 duplicate Rules in the imported .xml file.

Signature updates in high availability deployment and build upgrades

September 18, 2018

The signature update occurs on the primary node. While the signatures are updated on the primary node, in parallel the updated files are simultaneously synchronized with the secondary node.

The *Default signature is always updated first and then the rest of the user-defined signatures are updated.
**Connecting to Amazon AWS**

The default route NSIP is used to connect to the Amazon AWS. If there is a specific use case scenario where SNIP is used, and if there are multiple SNIPs, the first one to receive the ARP response from the hosting site will hold the route.

**Signature updates during version upgrades**

In case of an upgrade, if the NS has an older base version for the signatures, *Default signature is automatically updated if a newer signature version is available.*

If the schema has changed, the schema version of all the signature objects gets updated when the version is upgraded.

However, for the base version of the user-defined signatures, the behavior is different in release 10.5 versus release 11.0.

In release 10.5, only the default signature was updated and the base version of the rest of the signatures remained unchanged after the build upgrade.

In release 11.0, this behavior has changed. When the appliance is upgraded to install a new build, not only the *Default signature object but all the other user-defined signatures that currently exist in the appliance are also updated and will have the same version after the build upgrade.

In both 10.5 and 11.0 release builds, if auto-update is configured, the *Default Signatures as well as all non-zero version signatures get auto-updated to the latest released signature version and will have the same base version.*

**Overview of security checks**

September 18, 2018

The App Firewall advanced protections (security checks) are a set of filters designed to catch complex or unknown attacks on your protected web sites and web services. The security checks use heuristics, positive security, and other techniques to detect attacks that may not be detected by signatures alone. You configure the security checks by creating and configuring an App Firewall profile, which is a collection of user-defined settings that tell the App Firewall which security checks to use and how to handle a request or response that fails a security check. A profile is associated with a signatures object and with a policy to create a security configuration.

The App Firewall provides twenty security checks, which differ widely in the types of attacks that they target and how complex they are to configure. The security checks are organized into the following categories:
• **Common security checks.** Checks that apply to any aspect of web security that either does not involve content or is equally applicable to all types of content.

• **HTML security checks.** Checks that examine HTML requests and responses. These checks apply to HTML-based web sites and to the HTML portions of Web 2.0 sites, which contain mixed HTML and XML content.

• **XML security checks.** Checks that examine XML requests and responses. These checks apply to XML-based web services and to the XML portions of Web 2.0 sites.

The security checks protect against a wide range of types of attack, including attacks on operation system and web server software vulnerabilities, SQL database vulnerabilities, errors in the design and coding of web sites and web services, and failures to secure sites that host or can access sensitive information.

All security checks have a set of configuration options, the check actions, which control how the App Firewall handles a connection that matches a check. Three check actions are available for all security checks. They are:

- **Block.** Block connections that match the signature. Disabled by default.
- **Log.** Log connections that match the signature, for later analysis. Enabled by default.
- **Stats.** Maintain statistics, for each signature, that show how many connections it matched and provide certain other information about the types of connections that were blocked. Disabled by default.

A fourth check action, **Learn**, is available for more than half of the check actions. It observes traffic to a protected Web site or web service and uses connections that repeatedly violate the security check to generate recommended exceptions (relaxations) to the check, or new rules for the check. In addition to the check actions, certain security checks have parameters that control the rules that the check uses to determine which connections violate that check, or that configure the App Firewall’s response to connections that violate the check. These parameters are different for each check, and they are described in the documentation for each check.

To configure security checks, you can use the App Firewall wizard, as described in “The App Firewall Wizard,” or you can configure the security checks manually, as described in “Manual Configuration By Using the GUI.” Some tasks, such as manually entering relaxations or rules or reviewing learned data, can be done only by using the GUI, not the command line. Using the wizard is usually best configuration method, but in some cases manual configuration might be easier if you are thoroughly familiar with it and simply want to adjust the configuration for a single security check.

Regardless of which method you use to configure the security checks, each security check requires that certain tasks be performed. Many checks require that you specify exceptions (relaxations) to prevent blocking of legitimate traffic before you enable blocking for that security check. You can do this manually, by observing the log entries after a certain amount of traffic has been filtered and then creating the necessary exceptions. However, it is usually much easier to enable the learning feature and let it observe the traffic and recommend the necessary exceptions.
App Firewall uses packet engines (PE) during processing the transactions. Each packet engine has a limit of 100K sessions which is sufficient for most deployment scenarios. However, when App Firewall is processing heavy traffic and the session timeout is configured at a higher value, the sessions might get accumulated. If the number of alive App Firewall sessions exceed the 100K per PE limit, the App Firewall security check violations might not be sent to the Security Insight appliance. Lowering the session timeout to a smaller value, or using sessionless mode for the security checks with sessionless URL closure or sessionless field consistency might help in preventing the sessions getting accumulated. If this is not a viable option in scenarios where transactions might require longer sessions, upgrading to a higher-end platform with more packet engine is recommended.

Support for cached AppFirewall is added, and the max session setting through the CLI per core is set to 50K sessions.

**Top level protections**

November 19, 2018

Four of the App Firewall protections are especially effective against common types of Web attacks, and are therefore more commonly used than any of the others. They are:

- **HTML Cross-Site Scripting.** Examines requests and responses for scripts that attempt to access or modify content on a different Web site than the one on which the script is located. When this check finds such a script, it either renders the script harmless before forwarding the request or response to its destination, or it blocks the connection.

- **HTML SQL Injection.** Examines requests that contain form field data for attempts to inject SQL commands into an SQL database. When this check detects injected SQL code, it either blocks the request or renders the injected SQL code harmless before forwarding the request to the Web server.

  **Note:** If both of the following conditions apply to your configuration, you should make certain that your App Firewall is correctly configured:

  - If you enable the HTML Cross-Site Scripting check or the HTML SQL Injection check (or both), and
  - Your protected Web sites accept file uploads or contain Web forms that can contain large POST body data.

  For more information about configuring the App Firewall to handle this case, see “Configuring the Application Firewall.”

- **Buffer Overflow.** Examines requests to detect attempts to cause a buffer overflow on the Web server.
• **Cookie Consistency.** Examines cookies returned with user requests to verify that they match the cookies your Web server set for that user. If a modified cookie is found, it is stripped from the request before the request is forwarded to the Web server.

The Buffer Overflow check is simple; you can usually enable blocking for it immediately. The other three top-level checks are considerably more complex and require configuration before you can safely use them to block traffic. Citrix strongly recommends that, rather than attempting to configure these checks manually, you enable the learning feature and allow it to generate the necessary exceptions.

---

**HTML cross-site scripting check**

September 18, 2018

The HTML Cross-Site Scripting (XSS) check examines both the headers and the POST bodies of user requests for possible cross-site scripting attacks. If it finds a cross-site script, it either modifies (transforms) the request to render the attack harmless, or blocks the request.

To prevent misuse of the scripts on your protected web sites to breach security on your web sites, the HTML Cross-Site Scripting check blocks scripts that violate the *same origin rule*, which states that scripts should not access or modify content on any server but the server on which they are located. Any script that violates the same origin rule is called a cross-site script, and the practice of using scripts to access or modify content on another server is called cross-site scripting. The reason cross-site scripting is a security issue is that a web server that allows cross-site scripting can be attacked with a script that is not on that web server, but on a different web server, such as one owned and controlled by the attacker.

Unfortunately, many companies have a large installed base of JavaScript-enhanced web content that violates the same origin rule. If you enable the HTML Cross-Site Scripting check on such a site, you have to generate the appropriate exceptions so that the check does not block legitimate activity.

The App Firewall offers various action options for implementing HTML Cross-Site Scripting protection. In addition to the *Block, Log, Stats* and *Learn* actions, you also have the option to *Transform cross-site scripts* to render an attack harmless by entity encoding the script tags in the submitted request. You can configure the **Check complete URL’s for cross-site scripting** parameter to specify if you want to inspect not just the query parameters but the entire URL to detect XSS attack.

You can deploy relaxations to avoid false positives. The App Firewall learning engine can provide recommendations for configuring relaxation rules.

Following options are available for configuring an optimized HTML Cross-Site Scripting protection for your application:

- **Block**—If you enable block, the block action is triggered if the XSS tags are detected in the request.
- **Log**—If you enable the log feature, the HTML Cross-Site Scripting check generates log messages indicating the actions that it takes. If block is disabled, a separate log message is generated for each header or form field in which the XSS violation was detected. However, only one message is generated when the request is blocked. Similarly, one log message per request is generated for the transform operation, even when XSS tags are transformed in multiple fields. You can monitor the logs to determine whether responses to legitimate requests are getting blocked. A large increase in the number of log messages can indicate attempts to launch an attack.

- **Stats**—If enabled, the stats feature gathers statistics about violations and logs. An unexpected surge in the stats counter might indicate that your application is under attack. If legitimate requests are getting blocked, you might have to revisit the configuration to see if you need to configure new relaxation rules or modify the existing ones.

- **Learn**—If you are not sure which relaxation rules might be ideally suited for your application, you can use the learn feature to generate HTML Cross-Site Scripting rule recommendations based on the learned data. The App Firewall learning engine monitors the traffic and provides learning recommendations based on the observed values. To get optimal benefit without compromising performance, you might want to enable the learn option for a short time to get a representative sample of the rules, and then deploy the rules and disable learning.

- **Transform cross-site scripts**—If enabled, the App Firewall makes the following changes to requests that match the HTML Cross-Site Scripting check:
  - Left angle bracket (<) to HTML character entity equivalent (&lt;)
  - Right angle bracket (>) to HTML character entity equivalent (&gt;)

This ensures that browsers do not interpret unsafe html tags, such as `<script>`, and thereby execute malicious code. If you enable both request-header checking and transformation, any special characters found in request headers are also modified as described above. If scripts on your protected website contain cross-site scripting features, but your website does not rely upon those scripts to operate correctly, you can safely disable blocking and enable transformation. This configuration ensures that no legitimate web traffic is blocked, while stopping any potential cross-site scripting attacks.

- **Check complete URLs for cross-site scripting**—If checking of complete URLs is enabled, the App Firewall examines entire URLs for HTML cross-site scripting attacks instead of checking just the query portions of URLs.

- **Check Request headers**—If Request header checking is enabled, the App Firewall examines the headers of requests for HTML cross-site scripting attacks, instead of just URLs. If you use the GUI, you can enable this parameter in the Settings tab of the App Firewall profile.

---

**Important**

As part of the streaming changes, the App Firewall processing of the Cross-site Scripting tags has changed. This change is applicable to 11.0 builds onwards. This change is also pertinent for the enhancement builds of 10.5.e that support request side streaming. In earlier releases,
presence of either open bracket (<), or close bracket (>), or both open and close brackets (<>)
was flagged as Cross-site Scripting Violation. The behavior has changed in the builds that include
support for request side streaming. Only the close bracket character (>) is no longer considered
as an attack. Requests are blocked even when an open bracket character (<) is present, and is
considered as an attack. The Cross-site scripting attack gets flagged.

**XSS Fine grained Relaxations**

The App Firewall gives you an option to exempt a specific form field, header, or Cookie from cross-site
scripting inspection check. You can completely bypass the inspection for one or more of these fields
by configuring relaxation rules.

The App Firewall allows you to implement tighter security by fine tuning the relaxation rules. An ap-
plication might require the flexibility to allow specific patterns, but configuring a relaxation rule to
bypass the security inspection might make the application vulnerable to attacks, because the target
field is exempted from inspection for any cross-site scripting attack patterns. Cross-site scripting fine
gained relaxation provides the option to allow specific attributes, tags, and patterns. The rest of
the attributes, tags and patterns are blocked. For example, the App Firewall currently has a default
set of more than 125 denied patterns. Because hackers can use these patterns in Cross-site script at-
tacks, the App Firewall flags them as potential threats. You can relax one or more pattern(s) that are
considered safe for the specific location. The rest of the potentially dangerous XSS patterns are still
checked for the target location and continue to trigger the security check violations. You now have
much tighter control.

The commands used in relaxations have optional parameters for **Value Type** and **Value Expression**.
The value type can be left blank or you have an option to select **Tag** or **Attribute** or **Pattern**. If you
leave the value type blank, the configured field of the specified URL is exempted from the Cross-Site
Scripting check inspection. If you select a value type, you must provide a value expression. You
can specify whether the value expression is a regular expression or a literal string. When the input
is matched against the allowed and denied list, only the specified expressions configured in the relax-
ation rules are exempted.

The App Firewall has the following XSS built-in lists:

1. **XSS Allowed Attributes**: There are 52 default allowed attributes, such as, abbr, accesskey,
   align, alt, axis, bgcolor, border, cellpadding, cellspacing, char, charoff, charset etc.
2. **XSS Allowed Tags**: There are 47 default allowed tags, such as, address, basefont, bgsound,
   big, blockquote, bg, br, caption, center, cite, dd, del etc.
3. **XSS Denied Patterns**: There are 129 default denied patterns, such as, FSCommand, javascript::
   onAbort, onActivate etc.
Warning

App Firewall action URL's are regular expressions. When configuring HTML cross-site scripting relaxation rules, you can specify Name, and Value Expression to be literal or RegEx. Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the rule that you want to add as an exception, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (\.*) metacharacter/wildcard combination, can have results that you do not want, such as blocking access to web content that you did not intend to block or allowing an attack that the HTML Cross-Site Scripting check would otherwise have blocked.

Points to Consider:

- Value expression is an optional argument. A field name might not have any value expression.
- A field name can be bound to multiple value expressions.
- Value expressions should be assigned a value type. The XSS value type can be: 1) Tag, 2) Attribute, or 3) Pattern.
- You can have multiple relaxation rules per field name/URL combination
- The form field names and the action URL's are not case sensitive.

Using the Command Line to Configure the HTML Cross-Site Scripting check

To configure HTML Cross-Site Scripting check actions and other parameters by using the command line

If you use the command-line interface, you can enter the following commands to configure the HTML Cross-Site Scripting Check:

- set appfw profile "Parameter descriptions provided at bottom of the page.")
- <name> -crossSiteScriptingAction (([block] [learn] [log] [stats])| [** none**])
- set appfw profile "Parameter descriptions provided at bottom of the page.")
- <name> **-crossSiteScriptingTransformUnsafeHTML** (ON | OFF)
- set appfw profile Parameter descriptions provided at bottom of the page.
- <name> -crossSiteScriptingCheckCompleteURLs (ON | OFF)
- set appfw profile Parameter descriptions provided at bottom of the page.
- <name> -checkRequestHeaders (ON | OFF)

To configure a HTML Cross-Site Scripting check relaxation rule by using the command line

Use the bind or unbind command to add or delete binding, as follows:

- bind appfw profile <name> -crossSiteScripting <String> [isRegex (REGEX | NOTREGEX)] <formActionURL> [-location <location>] [-valueType (
Tag|Attribute|Pattern|\[<valueExpression>\] \[-isValueRegex (REGEX | NOTREGEX)]\]

- unbind appfw profile <name> -crossSiteScripting <String> <formActionURL > \[-location <location>] \[-valueType (Tag |Attribute|Pattern)|<valueExpression >\]]

### Using the GUI to configure the HTML Cross-Site scripting check

In the GUI, you can configure the HTML Cross-Site Scripting check in the pane for the profile associated with your application.

To configure or modify the HTML Cross-Site Scripting check by using the GUI:

1. Navigate to Application Firewall > Profiles, highlight the target profile, and click **Edit**.
2. In the Advanced Settings pane, click **Security Checks**.

The security check table displays the currently configured action settings for all the security checks. You have 2 options for configuration:

a. If you just want to enable or disable Block, Log, Stats, and Learn actions for the HTML Cross-Site Scripting, you can select or clear check boxes in the table, click **OK**, and then click **Save and Close** to close the Security Check pane.

b. If you want to configure additional options for this security check, double click **HTML Cross-Site Scripting**, or select the row and click **Action Settings**, to display the following options:

   - **Transform cross-site scripts**—Transform unsafe script tags.
   - **Check complete URLs for Cross-site scripting**—Instead of checking just the query part of the URL, check the complete URL for cross-site script violations.

After changing any of the above settings, click **OK** to save the changes and return to the Security Checks table. You can proceed to configure other security checks if needed. Click **OK** to save all the changes you have made in the Security Checks section, and then click **Save and Close** to close the Security Check pane.

To enable or disable the **Check request Header** setting, in the Advanced Settings pane, click **Profile Settings**. In Common Settings, Select or clear the **Check Request Headers** check box. Click **OK**. You can either use the X icon at the top right hand side of the Profile Settings pane to close this section or, if you have finished configuring this profile, you can click **Done** to return to the Application Firewall > Profile

To configure a HTML Cross-Site Scripting relaxation rule by using the GUI:

1. Navigate to Application Firewall > Profiles, highlight the target profile, and click **Edit**.
2. In the Advanced Settings pane, click **Relaxation Rules**.
3. In the Relaxation Rules table, double-click the **HTML Cross-Site Scripting** entry, or select it and click **Edit**.

4. In the **HTML Cross-Site Scripting Relaxation Rules** dialogue box, perform **Add**, **Edit**, **Delete**, **Enable**, or **Disable** operations for relaxation rules.

**Note**

When you add a new rule, the **Value Expression** field is not displayed unless you select **Tag** or **Attribute** or **Pattern** option in the **Value Type** Field.

To manage HTML Cross-Site Scripting relaxation rules by using the visualizer

For a consolidated view of all the relaxation rules, you can highlight the **HTML Cross-Site Scripting** row in the Relaxation Rules table, and click **Visualizer**. The visualizer for deployed relaxations offers you the option to **Add** a new rule or **Edit** an existing one. You can also **Enable** or **Disable** a group of rules by selecting a node and clicking the corresponding buttons in the relaxation visualizer.

To view or customize the Cross-Site Scripting patterns by using the GUI

You can use the GUI to view or customize the default list of XSS allowed attributes or allowed tags. You can also view or customize the default list of XSS denied Patterns.

The default lists are specified in **Application Firewall > Signatures > Default Signatures**. If you do not bind any signature object to your profile, the default XSS allowed and denied list specified in the Default Signatures object will be used by the profile for the Cross-Site Scripting security check processing. The Tags, Attributes, and Patterns, specified in the default signatures object, are read-only. You cannot edit or modify them. If you want to modify or change these, make a copy of the Default Signatures object to create a User-Defined signature object. Make changes in the allowed or denied lists in the new User-defined signature object and use this signature object in your profile that is processing the traffic for which you want to use these customized allowed and denied lists.

For more information about **Signatures**, see the following topic.

1. To view default XSS patterns:
   
   a. Navigate to **Application Firewall > Signatures**, select *Default Signatures*, and click **Edit**. Then click **Manage SQL/XSS Patterns**.

   The **Manage SQL/XSS Paths** table shows following three rows pertaining to XSS:

   - **xss/allowed/attribute**
   - **xss/allowed/tag**
   - **xss/denied/pattern**

   b. Select a row and click **Manage Elements** to display the corresponding XSS Elements (Tag, Attribute, Pattern) used by the App Firewall **Cross-Site Scripting** check.
1. **To customize XSS Elements**: You can edit the User-Defined signature object to customize the allowed Tag, allowed Attributes and denied Patterns. You can add new entries or remove the existing ones.

   a. Navigate to **Application Firewall > Signatures**, highlight the target User-defined signature, and click **Edit**. Click **Manage SQL/XSS Patterns** to display the **Manage SQL/XSS paths** table.

   b. Select the target XSS row.

   i. Click **Manage Elements**, to *Add, Edit or Remove* the corresponding XSS element.

   ii. Click **Remove** to remove the selected row.

   **Warning**

   You must be very careful before you remove or modify any default XSS element, or delete the XSS path to remove the entire row. The signature rules as well as the Cross-Site Scripting security check rely on these elements for detecting attacks to protect your applications. Customizing the XSS Elements can make your application vulnerable to Cross-Site Scripting attacks if the required pattern is removed during editing.

**Using the Learn Feature with the HTML Cross-Site Scripting Check**

When the learn action is enabled, the App Firewall learning engine monitors the traffic and learns the triggered violations. You can periodically inspect these learned rules. After due consideration, you can deploy the learned rule as a HTML Cross-Site Scripting relaxation rule.

**HTML Cross-Site Scripting Learning enhancement**—An App Firewall learning enhancement was introduced in release 11.0 of the NetScaler software. To deploy fine grained HTML Cross-Site Scripting relaxation, the App Firewall offers fine grained HTML Cross-Site Scripting learning. The learning engine makes recommendations regarding the observed Value Type (Tag, Attribute, Pattern) and the corresponding Value expression observed in the input fields. In addition to checking the blocked requests to determine whether the current rule is too restrictive and needs to be relaxed, you can review the rules generated by the learning engine to determine which value type and value expressions are triggering violations and need to be addressed in relaxation rules.

**Note**

The App Firewall’s learning engine can distinguish only the first 128 bytes of the name. If a form has multiple fields with names that match for the first 128 bytes, the learning engine might not be able to distinguish between them. Similarly, the deployed relaxation rule might inadvertently relax all such fields from HTML Cross-Site Scripting inspection.

**Tip**

XSS tags which are longer than 12 characters are not learned or logged correctly.
If you need a larger taglength for learning, you can add a large non-appearing tag in the AS_XSS_ALLOWED_TAGS_LIST for length `x`.

To view or use learned data by using the command line interface

At the command prompt, type one of the following commands:

- `show appfw learningdata <profilename> crossSiteScripting`
- `rm appfw learningdata <profilename> -crossSiteScripting <string> <formActionURL> [<location>] [<valueType> <valueExpression>]`
- `export appfw learningdata <profilename> **crossSiteScripting**`

To view or use learned data by using the GUI

1. Navigate to Application Firewall > Profiles, highlight the target profile, and click Edit.
2. In the Advanced Settings pane, click Learned Rules. You can select the HTML Cross-Site Scripting entry in the Learned Rules table and double-click it to access the learned rules. The table displays the Field Name, Action URL, Value Type, Value and Hits columns. You can deploy the learned rules or edit a rule before deploying it as a relaxation rule. To discard a rule, you can select it and click the Skip button. You can edit only one rule at a time, but you can select multiple rules to deploy or skip.

You also have the option to show a summarized view of the learned relaxations by selecting the HTML Cross-Site Scripting entry in the Learned Rules table and clicking Visualizer to get a consolidated view of all the learned violations. The visualizer makes it very easy to manage the learned rules. It presents a comprehensive view of the data on one screen and facilitates taking action on a group of rules with one click. The biggest advantage of the visualizer is that it recommends regular expressions to consolidate multiple rules. You can select a subset of these rules, based on the delimiter and Action URL. You can display 25, 50, or 75 rules in the visualizer, by selecting the number from a drop-down list. The visualizer for learned rules offers the option to edit the rules and deploy them as relaxations. Or you can skip the rules to ignore them.

#### Using the Log Feature with the HTML Cross-Site Scripting Check

When the log action is enabled, the HTML Cross-Site Scripting security check violations are logged in the audit log as APPFW_XSS violations. The App Firewall supports both Native and CEF log formats. You can also send the logs to a remote syslog server.

To access the log messages by using the command line

Switch to the shell and tail the ns.logs in the /var/log/ folder to access the log messages pertaining to the HTML Cross-Site Scripting violations:
Example of a Cross-Site Scripting security check violation log message in CEF log format

```
1 Jul 11 00:45:51 <local0.info> 10.217.31.98 CEF:0|Citrix|NetScaler|NS11.0|APPFW|APPFW_XSS|6|src=10.217.253.62 geolocation=Unknown spt=4840 method=GET request=http://aaron.stratum8.net/FFC/CreditCardMind.html?abc\=%3Cdef\=%3E**Cross-site script check failed for field abc="Bad tag: def"** cn1=133 cn2=294 cs1=pr_ffc cs2=PPE1 cs3=eUljsvLa0BbashfGVE52Sewg9U0001 cs4=ALERCT cs5=2015 act=**not blocked**
```

Example of a Cross-Site Scripting security check violation log message in Native log format showing transform action

```
1 Jul 11 01:00:28 <local0.info> 10.217.31.98 07/11/2015:01:00:28 GMT ns 0-PPE-0 : default APPFW |**APPFW_XSS** 132 0 : 10.217.253.62 392-PPE0 eUljsvLa0BbashfGVE52Sewg9U0001 pr_ffc http://aaron.stratum8.net/FFC/login.php?login_name=%3CBDB%3E&password=&drinking_pref=on &text_area=&loginButton=ClickToLogin&as_sfid=AAAAAVFqmYL68IGvkrcn2pzehfIfkm5E6E9FL8YLV41AvAATuKYe9N7uGThSpEAxbboIbX5jFC4wF **Cross-site script special characters seen in fields <transformed>>
```

To access the log messages by using the GUI

The NetScaler GUI includes a useful tool (Syslog Viewer) for analyzing the log messages. You have multiple options for accessing the Syslog Viewer:

- Navigate to the **Application Firewall > Profiles**, select the target profile, and click **Security Checks**. Highlight the **HTML Cross-Site Scripting** row and click **Logs**. When you access the logs directly from the HTML Cross-Site Scripting check of the profile, the GUI filters out the log messages and displays only the logs pertaining to these security check violations.

- You can also access the Syslog Viewer by navigating to **NetScaler > System > Auditing**. In the Audit Messages section, click the **Syslog messages** link to display the Syslog Viewer, which displays all log messages, including other security check violation logs. This is useful for debugging when multiple security check violations might be triggered during request processing.

- Navigate to **Application Firewall > policies > Auditing**. In the Audit Messages section, click the **Syslog messages** link to display the Syslog Viewer, which displays all log messages, including other security check violation logs.

The HTML based Syslog Viewer provides various filter options for selecting only the log messages that are of interest to you. To select log messages for the **HTML Cross-Site Scripting** check, filter by selecting **APPFW** in the dropdown options for **Module**. The **Event Type** list offers a rich set of options to
further refine your selection. For example, if you select the APPFW_XSS check box and click the Apply button, only log messages pertaining to the HTML Cross-Site Scripting security check violations appear in the Syslog Viewer.

If you place the cursor in the row for a specific log message, multiple options, such as Module, EventType, EventID, ClientIP etc. appear below the log message. You can select any of these options to highlight the corresponding information in the log message.

**Click to Deploy** functionality is available only in the GUI. You can use the Syslog Viewer to not only view the logs but also to deploy HTML Cross-Site Scripting relaxation rules based on the log messages for the App Firewall security check violations. The log messages must be in CEF log format for this operation. Click to deploy functionality is available only for log messages that are generated by the block (or not block) action. You cannot deploy a relaxation rule for a log message about the transform operation.

To deploy a relaxation rule from the Syslog Viewer, select the log message. A check box appears in the upper right corner of the Syslog Viewer box of the selected row. Select the check box, and then select an option from the Action list to deploy the relaxation rule. **Edit & Deploy**, **Deploy**, and **Deploy All** are available as Action options.

The HTML Cross-Site Scripting rules that are deployed by using the **Click to Deploy** option do not include the fine grain relaxation recommendations.

To use Click to Deploy functionality in the GUI:

1. In the Syslog Viewer, select APPFW in the Module options.
2. Select the APP_XSS as the Event Type to filter corresponding log messages.
3. Select the check box to identify the rule to deploy.
4. Use the Action drop-down list of options to deploy the relaxation rule.
5. Verify that the rule appears in the corresponding relaxation rule section.

**Statistics for the HTML Cross-Site Scripting violations**

When the stats action is enabled, the counter for the HTML Cross-Site Scripting check is incremented when the App Firewall takes any action for this security check. The statistics are collected for Rate and Total count for Traffic, Violations, and Logs. The size of an increment of the log counter can vary depending on the configured settings. For example, if the block action is enabled, the request for a page that contains 3 HTML Cross-Site Scripting violations increments the stats counter by one, because the page is blocked as soon as the first violation is detected. However, if block is disabled, processing the same request increments the statistics counter for violations and the logs by three, because each violation generates a separate log message.

To display HTML Cross-Site Scripting check statistics by using the command line:

At the command prompt, type:
> `sh appfw stats`

To display stats for a specific profile, use the following command:

> `**stat appfw profile** <profile name>`

To display HTML Cross-Site Scripting statistics by using the GUI

1. Navigate to **Security > Application Firewall > Profiles > Statistics**.
2. In the right pane, access the **Statistics** Link.
3. Use the scroll bar to view the statistics about HTML Cross-Site Scripting violations and logs. The statistics table provides real-time data and is updated every 7 seconds.

**Highlights**

Note the following points about the HTML Cross-Site Scripting check:

- **Built-in Support for HTML Cross-Site Scripting attack Protection**—The NetScaler App App Firewall protects against Cross-Site Scripting attacks by monitoring a combination of allowed attributes and tags, as well as denied patterns in the received payload. All the built-in default allowed tags, allowed attributes and denied patterns used by the XSS check are specified in the `/netscaler/default_custom_settings.xml` file.

- **Customization**—You can change the default list of tags, attributes, and patterns to customize the Cross-Site Scripting security check inspection for the specific needs of your application. Make a copy of the default signature object, modify existing entries, or add new ones. Bind this signature object to your profile to make use of the customized configuration.

- **Hybrid Security Model**—Both signatures and deep security protections use the SQL/XSS patterns specified in the signature object that is bound to the profile. If no signature object is bound to the profile, the SQL/XSS patterns present in the default signature object are used.

- **Transform**—Note the following about the transform operation:

  The transform operation works independently of the other Cross-Site Scripting action settings. If transform is enabled and block, log, stats, and learn are all disabled, XSS tags will be transformed.

  If the block action is enabled, it takes precedence over the transform action.

- **Fine Grained Relaxation and Learning**—Fine tune the relaxation rule to relax a subset of XSS elements from security check inspection but detect the rest. The learning engine recommends a specific value type and value expressions based on the observed data.

- **Click to Deploy**—Select one, or multiple XSS violation log messages in the syslog viewer and deploy them as relaxation rules.

- **Charset**—The default charset for the profile should be set based on the need of the application. By default, the profile charset is set to English US (ISO-8859-1). If a request is received without the specified charset, the App Firewall processes the request as if it is ISO-8859-1.
open bracket character (<) or the close bracket character (>) will not get interpreted as XSS tags if these characters are encoded in other charsets. For example, if a request contains a UTF-8 character string “%uфф1csрrс%uфф1e” but the charset is not specified on the request page, the XSS violation might not get triggered unless the default charset for the profile is specified as Unicode.

**HTML SQL injection check**

December 13, 2018

Many web applications have web forms that use SQL to communicate with relational database servers. Malicious code or a hacker can use an insecure web form to send SQL commands to the web server. The App Firewall HTML SQL Injection check provides special defenses against injection of unauthorized SQL code that might break security. If the App Firewall detects unauthorized SQL code in a user request, it either transforms the request, to render the SQL code inactive, or blocks the request. The App Firewall examines the request payload for injected SQL code in three locations: 1) POST body, 2) headers, and 3) cookies.

A default set of keywords and special characters provides known keywords and special characters that are commonly used to launch SQL attacks. You can add new patterns, and you can edit the default set to customize the SQL check inspection. The App Firewall offers various action options for implementing SQL Injection protection. In addition to the **Block**, **Log**, **Stats**, and **Learn** actions, the App Firewall profile also offers the option to **transform SQL special characters** to render an attack harmless.

In addition to actions, there are several parameters that can be configured for SQL injection processing. You can check for **SQL wildcard characters**. You can change the SQL injection type and select one of the 4 options (SQLKeyword, SQLSplChar, SQLSplCharANDKeyword, SQLSplCharORKeyword) to indicate how to evaluate the SQL keywords and SQL special characters when processing the payload. The **SQL Comments Handling parameter** gives you an option to specify the type of comments that need to be inspected or exempted during SQL Injection detection.

You can deploy relaxations to avoid false positives. The App Firewall learning engine can provide recommendations for configuring relaxation rules.

Following options are available for configuring an optimized SQL Injection protection for your application:

**Block**—If you enable block, the block action is triggered only if the input matches the SQL injection type specification. For example, if SQLSplCharANDKeyword is configured as the SQL injection type, a request is not blocked if it contains no key words, even if SQL special characters are detected in the input. Such a request is blocked if the SQL injection type is set to either SQLSplChar, or SQL-SplCharORKeyword.
Log—If you enable the log feature, the SQL Injection check generates log messages indicating the actions that it takes. If block is disabled, a separate log message is generated for each input field in which the SQL violation was detected. However, only one message is generated when the request is blocked. Similarly, one log message per request is generated for the transform operation, even when SQL special characters are transformed in multiple fields. You can monitor the logs to determine whether responses to legitimate requests are getting blocked. A large increase in the number of log messages can indicate attempts to launch an attack.

Stats—If enabled, the stats feature gathers statistics about violations and logs. An unexpected surge in the stats counter might indicate that your application is under attack. If legitimate requests are getting blocked, you might have to revisit the configuration to see if you need to configure new relaxation rules or modify the existing ones.

Learn—If you are not sure which SQL relaxation rules might be ideally suited for your application, you can use the learn feature to generate recommendations based on the learned data. The App Firewall learning engine monitors the traffic and provides SQL learning recommendations based on the observed values. To get optimal benefit without compromising performance, you might want to enable the learn option for a short time to get a representative sample of the rules, and then deploy the rules and disable learning.

Transform SQL special characters—The App Firewall considers three characters, Single straight quote (‘), Backslash (), and Semicolon (;) as special characters for SQL security check processing. The SQL Transformation feature modifies the SQL injection code in an HTML request to ensure that the request is rendered harmless. The modified HTML request is then sent to the server. All default transformation rules are specified in the /netscaler/default_custom_settings.xml file.

The transform operation renders the SQL code inactive by making the following changes to the request:

- Single straight quote (‘) to double straight quote (“).  
- Backslash (\) to double backslash (\\).  
- Semicolon (;) is dropped completely.

These three characters (special strings) are necessary to issue commands to an SQL server. Unless an SQL command is prefaced with a special string, most SQL servers ignore that command. Therefore, the changes that the App Firewall performs when transformation is enabled prevent an attacker from injecting active SQL. After these changes are made, the request can safely be forwarded to your protected web site. When web forms on your protected web site can legitimately contain SQL special strings, but the web forms do not rely on the special strings to operate correctly, you can disable blocking and enable transformation to prevent blocking of legitimate web form data without reducing the protection that the App Firewall provides to your protected web sites.

The transform operation works independently of the SQL Injection Type setting. If transform is enabled and the SQL Injection type is specified as SQL keyword, SQL special characters are transformed
even if the request does not contain any keywords.

**Tip**

You normally enable either transformation or blocking, but not both. If the block action is enabled, it takes precedence over the transform action. If you have blocking enabled, enabling transformation is redundant.

**Check for SQL Wildcard Characters**—Wild card characters can be used to broaden the selections of a structured query language (SQL-SELECT) statement. These wild card operators can be used in conjunction with **LIKE** and **NOT LIKE** operators to compare a value to similar values. The percent (%), and underscore (_) characters are frequently used as wild cards. The percent sign is analogous to the asterisk (*) wildcard character used with MS-DOS and to match zero, one, or multiple characters in a field. The underscore is similar to the MS-DOS question mark (?) wildcard character. It matches a single number or character in an expression.

For example, you can use the following query to do a string search to find all customers whose names contain the D character.

```sql
SELECT * from customer WHERE name like "%D%"
```

The following example combines the operators to find any salary values that have 0 in the second and third place.

```sql
SELECT * from customer WHERE salary like '_00%'
```

Different DBMS vendors have extended the wildcard characters by adding extra operators. The NetScaler App Firewall can protect against attacks that are launched by injecting these wildcard characters. The 5 default Wildcard characters are percent (%), underscore (_), caret (^), opening square bracket ([]), and closing square bracket (]). This protection applies to both HTML and XML profiles.

The default wildcard chars are a list of literals specified in the **Default Signatures**:

- `<wildchar type="LITERAL" >%<\wildchar>`
- `<wildchar type="LITERAL" >_<\wildchar>`
- `<wildchar type="LITERAL" >^<\wildchar>`
- `<wildchar type="LITERAL" >[<\wildchar>`
- `<wildchar type="LITERAL" >]<\wildchar>`

Wildcard characters in an attack can be PCRE, like `[\^A-F]`. The App Firewall also supports PCRE wildcards, but the literal wildcard chars above are sufficient to block most attacks.

**Note**

The SQL wildcard character check is different from the SQL special character check. This option must be used with caution to avoid false positives.
Check Request Containing SQL Injection Type—The App Firewall provides 4 options to implement the desired level of strictness for SQL injection inspection, based on the individual need of the application. The request is checked against the injection type specification for detecting SQL violations. The 4 SQL injection type options are:

- **SQL Special Character and Keyword**—Both an SQL keyword and an SQL special character must be present in the input to trigger SQL violation. This least restrictive setting is also the default setting.
- **SQL Special Character**—At least one of the special characters must be present in the input to trigger SQL violation.
- **SQL keyword**—At least one of the specified SQL keywords must be present in the input to trigger an SQL violation. Do not select this option without due consideration. To avoid false positives, make sure that none of the keywords are expected in the inputs.
- **SQL Special Character or Keyword**—Either the keyword or the special character string must be present in the input to trigger the security check violation.

**Tip**

If you configure the App Firewall to check for inputs that contain an SQL special character, the App Firewall skips web form fields that do not contain any special characters. Since most SQL servers do not process SQL commands that are not preceded by a special character, enabling this option can significantly reduce the load on the App Firewall and speed up processing without placing your protected web sites at risk.

**SQL comments handling**—By default, the App Firewall checks all SQL comments for injected SQL commands. Many SQL servers ignore anything in a comment, however, even if preceded by an SQL special character. For faster processing, if your SQL server ignores comments, you can configure the App Firewall to skip comments when examining requests for injected SQL. The SQL comments handling options are:

- **ANSI**—Skip ANSI-format SQL comments, which are normally used by UNIX-based SQL databases. For example:
  - -- (Two Hypens) - This is a comment that begins with two hyphens and ends with end of line.
  - {} - Braces (Braces enclose the comment. The { precedes the comment, and the } follows it. Braces can delimit single- or multiple-line comments, but comments cannot be nested)
  - /***/: C style comments (Does not allow nested comments). Please note **/!!! comment that begin with slash followed by asterisk and exclamation mark is not a comment > ***/**
  - MySQL Server supports some variants of C-style comments. These enable you to write code that includes MySQL extensions, but is still portable, by using comments of the following form: /! MySQL-specific code /
  - . # : Mysql comments : This is a comment that begins with # character and ends with end
of the line

- **Nested**—Skip nested SQL comments, which are normally used by Microsoft SQL Server. For example; – (Two Hypens), and /** */ (Allows nested comments)
- **ANSI/Nested**—Skip comments that adhere to both the ANSI and nested SQL comment standards. Comments that match only the ANSI standard, or only the nested standard, are still checked for injected SQL.
- **Check all Comments**—Check the entire request for injected SQL without skipping anything. This is the default setting.

**Tip**

In most cases, you should not choose the Nested or the ANSI/Nested option unless your back-end database runs on Microsoft SQL Server. Most other types of SQL server software do not recognize nested comments. If nested comments appear in a request directed to another type of SQL server, they might indicate an attempt to breach security on that server.

**Check Request headers**—Enable this option if, in addition to examining the input in the form fields, you want to examine the request headers for HTML SQL Injection attacks. If you use the GUI, you can enable this parameter in the Advanced Settings -> Profile Settings pane of the App Firewall profile.

**Note**

If you enable the Check Request header flag, you might have to configure relaxation rule for the **User-Agent** header. Presence of the SQL keyword `like` and SQL special character semi-colon (`;`) might trigger false positive and block requests that contain this header.

**Warning**

If you enable both request header checking and transformation, any SQL special characters found in headers are also transformed. The Accept, Accept-Charset, Accept-Encoding, Accept-Language, Expect, and User-Agent headers normally contain semicolons (`;`). Enabling both Request header checking and transformation simultaneously might cause errors.

**SQL fine grained relaxations**

The App Firewall gives you an option to exempt a specific form field, header, or Cookie from SQL Injection inspection check. You can completely bypass the inspection for one or more of these fields by configuring relaxation rules for the SQL Injection check.

The App Firewall allows you to implement tighter security by fine tuning the relaxation rules. An application might require the flexibility to allow specific patterns, but configuring a relaxation rule to bypass the security inspection might make the application vulnerable to attacks, because the target field is exempted from inspection for any SQL attack patterns. SQL fine grained relaxation provides the option to allow specific patterns and block the rest. For example, the App Firewall currently has
a default set of more than 100 SQL keywords. Because hackers can use these keywords in SQL Injection attacks, the App Firewall flags them as potential threats. You can relax one or more keyword(s) that are considered safe for the specific location. The rest of the potentially dangerous SQL keywords are still checked for the target location and continue to trigger the security check violations. You now have much tighter control.

The commands used in relaxations have optional parameters for **Value Type** and **Value Expression**. You can specify whether the value expression is a regular expression or a literal string. The value type can be left blank or you have an option to select **Keyword** or **SpecialString** or **WildChar**.

**Warning**

Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the URL that you want to add as an exception, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (.* ) metacharacter/wildcard combination, can have results that you do not want, such as blocking access to web content that you did not intend to block or allowing an attack that the HTML SQL Injection check would otherwise have blocked.

**Points to Consider:**

- Value expression is an optional argument. A field name might not have any value expression.
- A field name can be bound to multiple value expressions.
- Value expressions should be assigned a value type. The SQL value type can be: 1) Keyword, 2) SpecialString, or 3) WildChar.
- You can have multiple relaxation rules per field name/URL combination.

### Using the command line to configure the SQL injection check

**To configure SQL Injection actions and other parameters by using the command line:**

In the command line interface, you can use either the `set appfw profile` command or the `add appfw profile` command to configure the SQL Injection protections. You can enable the block, learn, log, stats action(s) and specify whether you want to transform the special characters used in SQL Injection attack strings to disable the attack. Select the type of SQL attack pattern (key words, wildcard characters, special strings) you want to detect in the payloads, and indicate whether you want the App Firewall to also inspect the request Headers for SQL Injection violations. Use the `unset appfw profile` command to revert the configured settings back to their defaults. Each of the following commands sets only one parameter, but you can include multiple parameters in a single command:

- `set appfw profile "Parameter descriptions provided at bottom of the page."`
- `<name> -SQLInjectionAction (([block] [learn] [log] [stats])| [none])`
- `set appfw profile "Parameter descriptions provided at bottom of the page."`
- `<name> -SQLInjectionTransformSpecialChars (**ON** | OFF)`
• set appfw profile “Parameter descriptions provided at bottom of the page.”
• <name> -**SQLInjectionCheckSQLWildChars** (**ON** | **OFF**)
• set appfw profile “Parameter descriptions provided at bottom of the page.”
• **<name> -**SQLInjectionType** (**SQLKeyword** | **SQLSplChar** | **SQLSplCharANDKeyword** | **SQLSplCharORKeyword**)
• set appfw profile “Parameter descriptions provided at bottom of the page.”
• <name> -**SQLInjectionParseComments** (**checkall** | **ansi|nested** | **ansinested**)
• **set appfw profile “Parameter descriptions provided at bottom of the page.”
• <name> -CheckRequestHeaders (ON | OFF)

To configure a SQL Injection relaxation rule by using the command line

Use the bind or unbind command to add or delete binding, as follows:

- bind appfw profile <name> -SQLInjection <String> [isRegex(REGEX NOTREGE)] <formActionURL> [-location <location>] [-valueType (Keyword|SpecialString|Wildchar)[<valueExpression>][-isValueRegex (REGEX | NOTREGEX)]
- unbind appfw profile <name> -SQLInjection <String> <formActionURL> [-location <location>] [-valueTyp (Keyword|SpecialString|Wildchar)[<valueExpression>]]

**Note**

You can find the list of SQL keywords from default signature file contents by viewing the view signature object, which has list of sql key words and sql special characters.

**Using the GUI to configure the SQL injection security check**

In the GUI, you can configure the SQL Injection security check in the pane for the profile associated with your application.

To configure or modify the SQL Injection check by using the GUI

1. Navigate to Application Firewall > Profiles, highlight the target profile, and click Edit.
2. In the Advanced Settings pane, click Security Checks.

The security check table displays the currently configured action settings for all the security checks. You have 2 options for configuration:

a. If you just want to enable or disable Block, Log, Stats, and Learn actions for HTML SQL Injection, you can select or clear check boxes in the table, click OK, and then click Save and Close to close the Security Check pane.
b. If you want to configure additional options for this security check, double click HTML SQL Injection, or select the row and click Action Settings, to display the following options:

- **Transform SQL Special character**—Transform any SQL Special characters in the request.
- **Check for SQL Wildcard Characters**—Consider SQL Wildcard characters in the payload to be attack patterns.
- **Check Request Containing**—Type of SQL injection (SQLKeyword, SQLSplChar, SQLSplCharANDKeyword, or SQLSplCharORKeyword) to check.
- **SQL Comments Handling**—Type of comments (Check All Comments, ANSI, Nested, or ANSI/Nested) to check.

After changing any of the above settings, click **OK** to save the changes and return to the Security Checks table. You can proceed to configure other security checks if needed. Click **OK** to save all the changes you have made in the Security Checks section, and then click **Save and Close** to close the Security Check pane.

1. To enable or disable the **Check request Header** setting, in the Advanced Settings pane, click **Profile Settings**. In **Common Settings**, Select or clear the **Check Request Headers** check box. Click **OK**. You can either use the X icon at the top right hand side of the Profile Settings pane to close this section or, if you have finished configuring this profile, you can click **Done** to return to the **App Firewall > Profile**.

To configure an SQL Injection relaxation rule by using the GUI

- Navigate to **Application Firewall > Profiles**, highlight the target profile, and click **Edit**.
- In the **Advanced Settings** pane, click **Relaxation Rules**.
- In the Relaxation Rules table, double-click the **HTML SQL Injection** entry, or select it and click **Edit**.
- In the **HTML SQL Injection Relaxation Rules** dialogue box, perform **Add**, **Edit**, **Delete**, **Enable**, or **Disable** operations for relaxation rules.

**Note**

When you add a new rule, the **Value Expression** field is not displayed unless you select **Keyword** or **SpecialString** or **WildChar** option in the **Value Type** Field.

To manage SQL Injection relaxation rules by using the visualizer

For a consolidated view of all the relaxation rules, you can highlight the **HTML SQL Injection** row and click **Visualizer**. The visualizer for deployed relaxations offers you the option to **Add** a new rule or **Edit** an existing one. You can also **Enable** or **Disable** a group of rules by selecting a node and clicking the corresponding buttons in the relaxation visualizer.

To view or customize the SQL Injection patterns by using the GUI

You can use the GUI to view or customize the SQL patterns.
The default SQL patterns are specified in Application Firewall > Signatures > Default Signatures. If you do not bind any signature object to your profile, the default SQL patterns specified in the Default Signatures object will be used by the profile for the SQL Injection security check processing. The rules and patterns, specified in the default signatures object, are read-only. You cannot edit or modify them. If you want to modify or change these patterns, make a copy of the Default Signatures object to create a User-Defined signature object. Make changes in the SQL patterns in the new User-defined signature object and use this signature object in your profile that is processing the traffic for which you want to use these customized SQL patterns.

For more information, see Signatures

1. **To view default SQL patterns:**
   a. Navigate to Application Firewall > Signatures, select *Default Signatures*, and click **Edit**.
   Then click **Manage SQL/XSS patterns**.

   The **Manage SQL/XSS paths** table shows following four rows pertaining to SQL Injection:
   - Injection (not_alphanum, SQL)/ Keyword
   - Injection (not_alphanum, SQL)/ specialstring
   - Injection (not_alphanum, SQL)/ transformrules/transform
   - Injection (not_alphanum, SQL)/ wildchar

   b. Select a row and click **Manage Elements** to display the corresponding SQL patterns (keywords, special strings, transformation rules or the wildcard characters) used by the App Firewall SQL injection check.

2. **To customize SQL patterns:** You can edit the User-Defined signature object to customize the SQL key words, special strings, and wildcard characters. You can add new entries or remove the existing ones. You can modify the transformation rules for the SQL special strings.
   
   a. **Navigate to Application Firewall > Signatures**, highlight the target User-defined signature, and click **Edit**. Click **Manage SQL/XSS patterns** to display the **Manage SQL/XSS paths** table.
   b. Select the target SQL injection row.
   i. Click **Manage Elements**, to **Add**, **Edit** or **Remove** the corresponding SQL element.
   ii. Click **Remove** to remove the selected row.

   **Warning**
   You must be very careful before you remove or modify any default SQL element, or delete the SQL path to remove the entire row. The signature rules as well as the SQL Inject security check rely on these elements for detecting SQL Injection attacks to protect your applications. Customizing the SQL patterns can make your application vulnerable to SQL attacks if the required pattern is
Using the Learn feature with the SQL injection check

When the learn action is enabled, the App Firewall learning engine monitors the traffic and learns the triggered violations. You can periodically inspect these learned rules. After due consideration, you can deploy the learned rule as an SQL Injection relaxation rule.

SQL Injection Learning enhancement—An App Firewall learning enhancement was introduced in release 11.0 of the NetScaler software. To deploy fine grained SQL Injection relaxation, the App Firewall offers fine grained SQL Injection learning. The learning engine makes recommendations regarding the observed Value Type (keyword, SpecialString, Wildchar) and the corresponding Value expression observed in the input fields. In addition to checking the blocked requests to determine whether the current rule is too restrictive and needs to be relaxed, you can review the rules generated by the learning engine to determine which value type and value expressions are triggering violations and need to be addressed in relaxation rules.

Important

The App Firewall’s learning engine can distinguish only the first 128 bytes of the name. If a form has multiple fields with names that match for the first 128 bytes, the learning engine might not be able to distinguish between them. Similarly, the deployed relaxation rule might inadvertently relax all such fields from SQL Injection inspection.

Note To bypass SQL check in User-Agent header, use the following relaxation rule:

bind appfw profile your_profile_name -SQLInjection User-Agent ".*" -location HEADER

To view or use learned data by using the command line interface

At the command prompt, type one of the following commands:

- show appfw learningdata <profilename> SQLInjection
- rm appfw learningdata <profilename> -SQLInjection <string> <formActionURL> [ <location>] [ <valueType> <valueExpression>]
- export appfw learningdata <profilename> SQLInjection

To view or use learned data by using the GUI

1. Navigate to Application Firewall > Profiles, highlight the target profile, and click Edit.

2. In the Advanced Settings pane, click Learned Rules. You can select the HTML SQL Injection entry in the Learned Rules table and double-click it to access the learned rules. You can deploy the learned rules or edit a rule before deploying it as a relaxation rule. To discard a rule, you can select it and click the Skip button. You can edit only one rule at a time, but you can select multiple rules to deploy or skip.
You also have the option to show a summarized view of the learned relaxations by selecting the HTML SQL Injection entry in the Learned Rules table and clicking Visualizer to get a consolidated view of all the learned violations. The visualizer makes it very easy to manage the learned rules. It presents a comprehensive view of the data on one screen and facilitates taking action on a group of rules with one click. The biggest advantage of the visualizer is that it recommends regular expressions to consolidate multiple rules. You can select a subset of these rules, based on the delimiter and Action URL. You can display 25, 50, or 75 rules in the visualizer, by selecting the number from a drop-down list. The visualizer for learned rules offers the option to edit the rules and deploy them as relaxations. Or you can skip the rules to ignore them.

Using the log feature with the SQL injection check

When the log action is enabled, the HTML SQL Injection security check violations are logged in the audit log as APPFW_SQL violations. The App Firewall supports both Native and CEF log formats. You can also send the logs to a remote syslog server.

To access the log messages by using the command line

Switch to the shell and tail the ns.logs in the /var/log/ folder to access the log messages pertaining to the SQL Injection violations:

```
> Shell
```

```
## tail -f /var/log/ns.log | grep APPFW_SQL
```

Example of a HTML SQL Injection log message when the request is transformed

```
login_name=%27+or+passwd=\=and+%3B&drinking
  prefer=on&text_area=select++from+%5C+&loginButton=ClickToLogin&as_sfid=
AAAAAAAxjgN5gLH-hvToPiySEiqE57BjFRsSmqWvPp-3ZHDi5yWLRWBy0cVbMyy-Ens2vaaiULK0cUri40D4kbXWwSY5s7I3QkdsrvqIgCYMC9BmVwY2wNc5QcWk52lfE8k%3D&as_fid=-feec8758b41740edeeb6b35b85dfe3d5def30c msg= Special characters seen in fields cn1=74 cn2=762 cs1=pr_ffc cs2=PPE1 cs3=9 ztIlfpr1Hp6Xtzn6NMygTv/QM0002 cs4=ALERT cs5=2015 act=transformed
```

Example of a HTML SQL Injection log message when the post request is blocked

```
1 Jun 26 21:30:34 <local0.info> 10.217.31.98 CEF:0|Citrix|NetScaler|NS11.0|APPFW|APPFW_SQL|6|src=10.217.253.62 geolocation=Unknown spt=9459 method=POST request=http://aaron.stratum8.net/FFC/login_post.php msg=SQL Keyword check failed for field text_area="(')" cn1=78 cn2=834 cs1=pr_ffc cs2=PPE1 cs3=eVJMMPltt2ZGyGrHjx3ZLBFCl002 cs4=ALERT cs5=2015 act=blocked
```

© 1999-2018 Citrix Systems, Inc. All rights reserved.
Note

As part of the streaming changes in 10.5.e build (enhancement builds) as well as 11.0 build onwards, we now process the input data in blocks. RegEx pattern matching is now restricted to 4K for contiguous character string matching. With this change, the SQL violation log messages might include different information compared to the earlier builds. The keyword and special character in the input could be separated by a large number of bytes. We now keep track of the SQL keywords and special strings when processing the data, instead of buffering the entire input value. In addition to the field name, the log message now includes the SQL keyword, or the SQL special character, or both the SQL keyword and the SQL special character, as determined by the configured setting. The rest of the input is no longer included in the log message, as shown in the following example:

Example:

In 10.5, when the App Firewall detects the SQL violation, the entire input string might be included in the log message, as shown below:

```
SQL Keyword check failed for field text="select a name from testbed1 ;(;)".*<blocked>
```

In enhancement builds of 10.5.e that support request side streaming as well as 11.0 build onwards, we log only the field name, keyword and special character (if applicable) in the log message, as shown below:

```
SQL Keyword check failed for field **text="select(;)"<blocked>
```

This change is applicable to requests that contain application/x-www-form-urlencoded, or multipart/form-data, or text/x-gwt-rpc content-types. Log messages generated during processing of JSON or XML payloads are not affected by this change.

To access the log messages by using the GUI

The NetScaler GUI includes a useful tool (Syslog Viewer) for analyzing the log messages. You have multiple options for accessing the Syslog Viewer:

- Navigate to the Application Firewall > Profiles, select the target profile, and click Security Checks. Highlight the HTML SQL Injection row and click Logs. When you access the logs directly from the HTML SQL Injection check of the profile, the GUI filters out the log messages and displays only the logs pertaining to these security check violations.
- You can also access the Syslog Viewer by navigating to NetScaler > System > Auditing. In the Audit Messages section, click the Syslog messages link to display the Syslog Viewer, which displays all log messages, including other security check violation logs. This is useful for debugging when multiple security check violations might be triggered during request processing.
• Navigate to Application Firewall > policies > Auditing. In the Audit Messages section, click the Syslog messages link to display the Syslog Viewer, which displays all log messages, including other security check violation logs.

The HTML based Syslog Viewer provides various filter options for selecting only the log messages that are of interest to you. To select log messages for the HTML SQL Injection check, filter by selecting APPFW in the dropdown options for Module. The Event Type list offers a rich set of options to further refine your selection. For example, if you select the APPFW_SQL check box and click the Apply button, only log messages pertaining to the SQL Injection security check violations appear in the Syslog Viewer.

If you place the cursor in the row for a specific log message, multiple options, such as Module, EventType, EventID, ClientIP etc. appear below the log message. You can select any of these options to highlight the corresponding information in the log message.

Click to Deploy functionality is available only in the GUI. You can use the Syslog Viewer to not only view the logs but also to deploy HTML SQL Injection relaxation rules based on the log messages for the App Firewall security check violations. The log messages must be in CEF log format for this operation. Click to deploy functionality is available only for log messages that are generated by the block (or not block) action. You cannot deploy a relaxation rule for a log message about the transform operation.

To deploy a relaxation rule from the Syslog Viewer, select the log message. A check box appears in the upper right corner of the Syslog Viewer box of the selected row. Select the check box, and then select an option from the Action list to deploy the relaxation rule. Edit & Deploy, Deploy, and Deploy All are available as Action options.

The SQL Injection rules that are deployed by using the Click to Deploy option do not include the fine grain relaxation recommendations.

To use Click to Deploy functionality in the GUI:

1. In the Syslog Viewer, select Application Firewall in the Module options.
2. Select the APP_SQL as the Event Type to filter corresponding log messages.
3. Select the check box to identify the rule to deploy.
4. Use the Action drop-down list of options to deploy the relaxation rule.
5. Verify that the rule appears in the corresponding relaxation rule section.

Statistics for the SQL Injection violations

When the stats action is enabled, the counter for the SQL Injection check is incremented when the App Firewall takes any action for this security check. The statistics are collected for Rate and Total count for Traffic, Violations, and Logs. The size of an increment of the log counter can vary depending on the configured settings. For example, if the block action is enabled, the request for a page that contains 3 SQL Injection violations increments the stats counter by one, because the page is blocked as soon as
the first violation is detected. However, if block is disabled, processing the same request increments the statistics counter for violations and the logs by three, because each violation generates a separate log message.

**To display SQL Injection check statistics by using the command line:**

At the command prompt, type:

```
sh appfw stats
```

To display stats for a specific profile, use the following command:

```
> stat appfw profile <profile name>
```

To display HTML SQL Injection statistics by using the GUI

1. Navigate to **System > Security > Application Firewall**.
2. In the right pane, access the **Statistics** Link.
3. Use the scroll bar to view the statistics about HTML SQL Injection violations and logs. The statistics table provides real-time data and is updated every 7 seconds.

**Highlights**

**Note the following points about the SQL Injection check:**

- **Built-in Support for SQL Injection Protection**—The NetScaler App App Firewall protects against SQL Injection by monitoring a combination of SQL keywords and special characters in the form parameters. All SQL keywords, special characters, wildcard characters, and default transformation rules are specified in the `/netscaler/default_custom_settings.xml` file.

- **Customization**—You can change the default key words, special characters, wildcard characters and transformation rules to customize the SQL security check inspection for the specific needs of your application. Make a copy of the default signature object, modify existing entries, or add new ones. Bind this signature object to your profile to make use of the customized configuration.

- **Hybrid Security Model**—Both signatures and deep security protections use the SQL/XSS patterns specified in the signature object that is bound to the profile. If no signature object is bound to the profile, the SQL/XSS patterns present in the default signature object are used.

- **Transform**—Note the following about the transform operation:
  - The transform operation works independently of the other SQL Injection action settings. If transform is enabled and block, log, stats, and learn are all disabled, SQL special characters will be transformed.
  - When SQL Transformation is enabled, user requests are sent to the backend servers after the SQL special characters are transformed in non-block mode. If the block action is enabled, it takes precedence over the transform action. If the injection type is specified as...
SQL special character and block is enabled, the request is blocked despite the transform action.

- **Fine Grained Relaxation and Learning**—Fine tune the relaxation rule to relax a subset of SQL elements from security check inspection but detect the rest. The learning engine recommends a specific value type and value expressions based on the observed data.

- **Click to Deploy**—Select one, or multiple SQL violation log messages in the syslog viewer and deploy them as relaxation rules.

### Buffer overflow check

September 18, 2018

The Buffer Overflow check detects attempts to cause a buffer overflow on the web server. If the App Firewall detects that the URL, cookies, or header are longer than the specified maximum length in a request, it blocks that request because it might be an attempt to cause a buffer overflow.

The Buffer Overflow check prevents attacks against insecure operating-system or web-server software that can crash or behave unpredictably when it receives a data string that is larger than it can handle. Proper programming techniques prevent buffer overflows by checking incoming data and either rejecting or truncating overlong strings. Many programs, however, do not check all incoming data and are therefore vulnerable to buffer overflows. This issue especially affects older versions of web-server software and operating systems, many of which are still in use.

The Buffer Overflow security check allows you to configure the **Block**, **Log**, and **Stats** actions. In addition, you can also configure the following parameters:

- **Maximum URL Length.** The maximum length the App Firewall allows in a requested URL. Requests with longer URLs are blocked. **Possible Values**: 0-65535. **Default**: 1024

- **Maximum Cookie Length.** The maximum length the App Firewall allows for all cookies in a request. Requests with longer cookies trigger the violations. **Possible Values**: 0-65535. **Default**: 4096

- **Maximum Header Length.** The maximum length the App Firewall allows for HTTP headers. Requests with longer headers are blocked. **Possible Values**: 0-65535. **Default**: 4096

### Using the command line to configure the Buffer Overflow security check

To configure Buffer Overflow security check actions and other parameters by using the command line, you can add the following Buffer Overflow Check arguments to the `set appfw profile <profileName>` command:

- `-bufferOverflowAction [[ block] [ log] [stats]] | [none]`

© 1999-2018 Citrix Systems, Inc. All rights reserved.
Using the GUI to Configure the Buffer Overflow Security Check

In the GUI, you can configure the Buffer Overflow security check in the pane for the profile associated with your application.

To configure or modify the Buffer Overflow security check by using the GUI

1. Navigate to Application Firewall > Profiles, highlight the target profile, and click Edit.
2. In the Advanced Settings pane, click Security Checks.

The security check table displays the currently configured action settings for all the security checks. You have 2 options for configuration:

a. If you just want to enable or disable Block, Log, and Stats actions for Buffer Overflow, you can select or clear check boxes in the table, click OK, and then click Save and Close to close the Security Check pane.

b. If you want to configure additional options for this security check, double click Buffer Overflow, or select the row and click Action Settings, to display the following options:

   - **Maximum URL Length**.
   - **Maximum Cookie Length**.
   - **Maximum Header Length**.

After changing any of the above settings, click OK to save the changes and return to the Security Checks table. You can proceed to configure other security checks if needed. Click OK to save all the changes you have made in the Security Checks section, and then click Save and Close to close the Security Check pane.

Using the Log Feature with the Buffer Overflow Security Check

When the log action is enabled, the Buffer Overflow security check violations are logged in the audit log as APPFW_BUFFEROVERFLOW_URL, APPFW_BUFFEROVERFLOW_COOKIE, and APPFW_BUFFEROVERFLOW_HDR violations. The App Firewall supports both Native and CEF log formats. You can also send the logs to a remote syslog server.

If you use the GUI to review the logs, you can use the click-to-deploy feature to apply relaxations indicated by the logs.

To access the log messages by using the command line
Switch to the shell and tail the ns.logs in the /var/log/ folder to access the log messages pertaining to the Buffer overflow violations:

```
1  > **Shell**
2  > **tail -f /var/log/ns.log | grep APPFW_BUFFEROVERFLOW**
```

Example of a CEF log message showing bufferOverflowMaxCookieLength violation in non-block mode

```
Oct 22 17:35:20 <local0.info> 10.217.31.98 CEF:0|Citrix|NetScaler|NS11.0|APPFW|APPFW_BUFFEROVERFLOW_COOKIE|6|src=10.217.253.62 geolocation=Unknown spt=41198 method=GET request=http://aaron.stratum8.net/FFC/sc11.html msg=Cookie header length(43) is greater than maximum allowed(16). cn1=119 cn2=465 cs1=owa_profile cs2=PPE1 cs3=wv000b+cJ2ZRbztZpyeNXIqLj7Y0001 cs4=ALERT cs5=2015 act=not blocked
```

Example of a CEF log message showing bufferOverflowMaxURLLength violation in non-block mode

```
Oct 22 18:39:56 <local0.info> 10.217.31.98 CEF:0|Citrix|NetScaler|NS11.0|APPFW|APPFW_BUFFEROVERFLOW_URL|6|src=10.217.253.62 geolocation=Unknown spt=19171 method=GET request=http://aaron.stratum8.net/FFC/sc11.html **msg=URL length(39) is greater than maximum allowed(20). cn1=707 cn2=402 cs1=owa_profile cs2=PPE0 cs3=kW49GcKbnwKBByyi3+jeNzfgWa80000 cs4=ALERT cs5=2015 act=not blocked
```

Example of a Native Format Log message showing bufferOverflowMaxHeaderLength violation in block mode

```
Oct 22 18:44:00 <local0.info> 10.217.31.98 10/22/2015:18:44:00 GMT ns 0-PPE-2 : default APPFW APPFW_BUFFEROVERFLOW_HDR 155 0 : 10.217.253.62 374-PPE2 khhBeeY4DB8V2D3H2sMLkXmWnA0002 owa_profile Header(User-Agent) length(82) is greater than maximum allowed(10)** http://aaron.stratum8.net/ <blocked>
```

To access the log messages by using the GUI

The NetScaler GUI includes a useful tool (Syslog Viewer) for analyzing the log messages. You have multiple options for accessing the Syslog Viewer:

- Navigate to the Application Firewall > Profiles, select the target profile, and click Security Checks. Highlight the Buffer Overflow row and click Logs. When you access the logs directly from the Buffer Overflow Security Check of the profile, the GUI filters out the log messages and displays only the logs pertaining to these security check violations.

- You can also access the Syslog Viewer by navigating to NetScaler > System > Auditing. In the Audit Messages section, click the Syslog messages link to display the Syslog Viewer, which dis-
plays all log messages, including other security check violation logs. This is useful for debugging when multiple security check violations might be triggered during request processing.

- Navigate to Application Firewall > policies > Auditing. In the Audit Messages section, click the Syslog messages link to display the Syslog Viewer, which displays all log messages, including other security check violation logs.

The XML based Syslog Viewer provides various filter options for selecting only the log messages that are of interest to you. To select log messages for the Buffer Overflow check, filter by selecting APPFW in the dropdown options for Module. The Event Type list offers three options, APPFW_BUFFEROVERFLOW_URL, APPFW_BUFFEROVERFLOW_COOKIE, and APPFW_BUFFEROVERFLOW_HDR, to view all the log messages pertaining to buffer overflow security check. You can select one or more options to further refine your selection. For example, if you select the APPFW_BUFFEROVERFLOW_COOKIE check box and click the Apply button, only log messages pertaining to the Buffer Overflow security check violations for the Cookie header appear in the Syslog Viewer. If you place the cursor in the row for a specific log message, multiple options, such as Module, Event Type, Event ID, and Client IP, appear below the log message. You can select any of these options to highlight the corresponding information in the log message.

Click-to-Deploy: The GUI provides click-to-deploy functionality, which is currently supported only for the buffer overflow log messages pertaining to the URL Length violations. You can use the Syslog Viewer to not only view the triggered violations, but also execute informed decisions based on the observed lengths of the blocked messages. If the current value is too restrictive and is triggering false positives, you can select a message and deploy it to replace the current value with the URL length value seen in the message. The log messages must be in CEF log format for this operation. If the relaxation can be deployed for a log message, a check box appears at the right edge of the Syslog Viewer box in the row. Select the check box, and then select an option from the Action list to deploy the relaxation. Edit & Deploy, Deploy, and Deploy All are available as Action options. You can use the APPFW_BUFFEROVERFLOW_URL filter to isolate all the log messages pertaining to the configured URL length violations.

If you select an individual log message, all three action options Edit & Deploy, Deploy, and Deploy All are available. If you select Edit & Deploy, the Buffer Overflow settings dialogue is displayed. The new URL length that was observed in the request is inserted into the Maximum URL length input field. If you click Close without any edits, the current configured values remain unchanged. If you click the OK button, the new value of the Maximum URL length replaces the previous value.

**Note**

The block, log and stats action check boxes are unchecked in the displayed Buffer Overflow settings dialogue, and need to be reconfigured if you select the Edit & Deploy option. Make sure to enable these check boxes before clicking OK, otherwise the new URL length will get configured but the actions will be set to none.
If you select the check boxes for multiple log messages, you can use the **Deploy** or **Deploy All** option. If the deployed log messages have different URL lengths, the configured value gets replaced by the highest URL Length value observed in the selected messages. Deploying the rule results only in changing the `bufferOverflowMaxURLLength` value. Configured actions are retained and remain unchanged.

To use Click-to-Deploy functionality in the GUI

1. In the Syslog Viewer, select **APPFW** in the **Module** options.
2. Enable the **APPFW_BUFFEROVERFLOW_URL** check box as the **EventType** to filter corresponding log messages.
3. Enable the check box to select the rule.
4. Use the **Action** drop-down list of options to deploy the relaxation.
5. Navigate to **Application Firewall > Profiles**, select the target profile, and click **Security Checks** to access the **Buffer Overflow** settings pane to verify that the **Maximum URL Length** value is updated.

**Statistics for the Buffer Overflow violations**

When the stats action is enabled, the counter for the Buffer Overflow Security Check is incremented when the App Firewall takes any action for this security check. The statistics are collected for Rate and Total count for Traffic, Violations, and Logs. The size of an increment of the log counter can vary depending on the configured settings. For example, if the block action is enabled, a request for a page that contains three Buffer Overflow violations increments the stats counter by one, because the page is blocked as soon as the first violation is detected. However, if block is disabled, processing the same request increments the statistics counter for violations and the logs by three, because each violation generates a separate log message.

To display Buffer Overflow Security Check statistics by using the command line

At the command prompt, type:

```
> sh appfw stats
```

To display stats for a specific profile, use the following command:

```
> stat appfw profile <profile name>
```

To display Buffer Overflow statistics by using the GUI

1. Navigate to **System > Security > Application Firewall**.
2. In the right pane, access the **Statistics** Link.
3. Use the scroll bar to view the statistics about Buffer Overflow violations and logs. The statistics table provides real-time data and is updated every 7 seconds.
NetScaler 12.0

**Highlights**

- The buffer overflow security check allows you to configure limits to enforce the maximum length of allowed URLs, Cookies and Headers.

- **Block, Log and Stats** actions enable you to monitor the traffic and configure optimal protection for your application.

- Syslog viewer enables you to filter and view all the log messages pertaining to buffer overflow violations.

- **Click-to-Deploy** functionality is supported for the `bufferOverflowMaxURLLength` violations. You can select and deploy an individual rule, or you can select multiple log messages to tweak and relax the current configured value of the maximum allowed length of the URL. The highest value of the URL from the selected group is set as the new value, to allow all these requests that are currently flagged as violations.

- The App Firewall now evaluates individual cookies when inspecting the incoming request. If length of any one cookie received in the Cookie header exceeds the configured `BufferOverflowMaxCookieLength`, the Buffer Overflow violation is triggered.

**Important**

In release 10.5.e (in a few interim enhancement builds prior to 59.13xx.e build) as well as in the 11.0 release (in builds prior to 65.x), App Firewall processing of the Cookie header was changed. In those releases, every cookie is evaluated individually, and if the length of any one cookie received in the Cookie header exceeds the configured `BufferOverflowMaxCookieLength`, the Buffer Overflow violation is triggered. As a result of this change, requests that were blocked in 10.5 and earlier release builds might be allowed, because the length of the entire cookie header is not calculated for determining the cookie length. **In some situations, the total cookie size forwarded to the server might be larger than the accepted value, and the server might respond with “400 Bad Request”.**

**Note** that this change has been reverted. The behavior in the 10.5.e -`59.13xx.e and subsequent 10.5.e enhancement builds as well as in the 11.0 release 65.x and subsequent builds is now similar to that of the non-enhancement builds of release 10.5. The entire raw Cookie header is now considered when calculating the length of the cookie. Surrounding spaces and the semicolon (:) characters separating the name-value pairs are also included in determining the cookie length.**

**Cookie consistency check**

September 18, 2018
The Cookie Consistency check examines cookies returned by users, to verify that they match the cookies that your web site set for that user. If a modified cookie is found, it is stripped from the request before the request is forwarded to the web server. You can also configure the Cookie Consistency check to transform all of the server cookies that it processes, by encrypting the cookies, proxying the cookies, or adding flags to the cookies. This check applies to requests and responses.

An attacker would normally modify a cookie to gain access to sensitive private information by posing as a previously authenticated user, or to cause a buffer overflow. The Buffer Overflow check protects against attempts to cause a buffer overflow by using a very long cookie. The Cookie Consistency check focuses on the first scenario.

If you use the wizard or the GUI, in the
Modify Cookie Consistency Check dialog box, on the
General tab you can enable or disable the following actions:

- Block
- Log
- Learn
- Statistics
- Transform. If enabled, the Transform action modifies all cookies as specified in the following settings:
  - **Encrypt Server Cookies.** Encrypt cookies set by your web server, except for any listed in the Cookie Consistency check relaxation list, before forwarding the response to the client. Encrypted cookies are decrypted when the client sends a subsequent request, and the decrypted cookies are reinserted into the request before it is forwarded to the protected web server. Specify one of the following types of encryption:
    * **None.** Do not encrypt or decrypt cookies. The default.
    * **Decrypt only.** Decrypt encrypted cookies only. Do not encrypt cookies.
    * **Encrypt session only.** Encrypt session cookies only. Do not encrypt persistent cookies. Decrypt any encrypted cookies.
    * **Encrypt all.** Encrypt both session and persistent cookies. Decrypt any encrypted cookies.
  
  **Note:** When encrypting cookies, the App Firewall adds the
HttpOnly flag to the cookie. This flag prevents scripts from accessing and parsing the cookie. The flag therefore prevents a script-based virus or trojan from accessing a decrypted cookie and using that information to breach security. This is done regardless of the Flags to Add in Cookies parameter settings, which are handled independently of the Encrypt Server Cookies parameter settings.
- **Proxy Server Cookies.** Proxy all non-persistent (session) cookies set by your web server, except for any listed in the Cookie Consistency check relaxation list. Cookies are proxied by using the existing App Firewall session cookie. The App Firewall strips session cookies set by the pro-
tected web server and saves them locally before forwarding the response to the client. When the client sends a subsequent request, the App Firewall reinserts the session cookies into the request before forwarding it to the protected web server. Specify one of the following settings:

- **None.** Do not proxy cookies. The default.
- **Session only.** Proxy session cookies only. Do not proxy persistent cookies

  Note: If you disable cookie proxying after having enabled it (set this value to None after it was set to Session only), cookie proxying is maintained for sessions that were established before you disabled it. You can therefore safely disable this feature while the App Firewall is processing user sessions.

- **Flags to Add in Cookies.** Add flags to cookies during transformation. Specify one of the following settings:

  - **None.** Do not add flags to cookies. The default.
  - **HTTP only.** Add the HttpOnly flag to all cookies. Browsers that support the HttpOnly flag do not allow scripts to access cookies that have this flag set.
  - **Secure.** Add the Secure flag to cookies that are to be sent only over an SSL connection. Browsers that support the Secure flag do not send the flagged cookies over an insecure connection.
  - **All.** Add the HttpOnly flag to all cookies, and the Secure flag to cookies that are to be sent only over an SSL connection.

If you use the command-line interface, you can enter the following commands to configure the Cookie Consistency Check:

- set appfw profile <name> -cookieConsistencyAction [**block**] [**learn**] [**log**] [**stats**] [**none**]
- set appfw profile <name> -cookieTransforms ([**ON**] | [**OFF**])
- set appfw profile <name> -cookieEncryption ([**none**] | [**decryptOnly**] | [**encryptSession**] | [**encryptAll**])
- set appfw profile <name> -cookieProxying ([**none**] | [**sessionOnly**] | [**secure**] | [**all**])

To specify relaxations for the Cookie Consistency check, you must use the GUI. On the Checks tab of the Modify Cookie Consistency Check dialog box, click Add to open the Add Cookie Consistency Check Relaxation dialog box, or select an existing relaxation and click Open to open the Modify Cookie Consistency Check Relaxation dialog box. Either dialog box provides the same options for configuring a relaxation.

Following are examples of Cookie Consistency check relaxations:

- **Logon Fields.** The following expression exempts all cookie names beginning with the string
logon_ followed by a string of letters or numbers that is at least two characters long and no more than fifteen characters long:

```
1   ^logon_[0-9A-Za-z]{2,15 } $
```

- **Logon Fields (special characters).** The following expression exempts all cookie names beginning with the string türkçe-logon_ followed by a string of letters or numbers that is at least two characters long and no more than fifteen characters long:

```
1   ^txC3xBCrkxC3xA7e-logon_[0-9A-Za-z]{2,15 } $
```

- **Arbitrary strings.** Allow cookies that contain the string sc-item_, followed by the ID of an item that the user has added to his shopping cart ([0-9A-Za-z]+), a second underscore (_), and finally the number of these items he wants ([1-9][0-9]?), to be user-modifiable:

```
1   ^sc-item_[0-9A-Za-z]+_\[1-9][0-9]?$ $
```

Caution: Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the URL you want to add as an exception, and nothing else. Careless use of wildcards, and especially the dot-asterisk ( . *) metacharacter/wildcard combination, can have results you do not want or expect, such as blocking access to web content that you did not intend to block or allowing an attack that the Cookie Consistency check would otherwise have blocked.

**Important**

In release 10.5.e (in a few interim enhancement builds prior to 59.13xx.e build) as well as in the 11.0 release (in builds prior to 65.x), App Firewall processing of the Cookie header was changed. In those releases, every cookie is evaluated individually, and if the length of any one cookie received in the Cookie header exceeds the configured BufferOverflowMaxCookieLength, the Buffer Overflow violation is triggered. As a result of this change, requests that were blocked in 10.5 and earlier release builds might be allowed, because the length of the entire cookie header is not calculated for determining the cookie length. In some situations, the total cookie size forwarded to the server might be larger than the accepted value, and the server might respond with “400 Bad Request”.

**Note** that this change has been reverted. The behavior in the 10.5.e ->59.13xx.e and subsequent 10.5.e enhancement builds as well as in the 11.0 release 65.x and subsequent builds is now simi-
lar to that of the non-enhancement builds of release 10.5. The entire raw Cookie header is now considered when calculating the length of the cookie. Surrounding spaces and the semicolon (;) characters separating the name-value pairs are also included in determining the cookie length.**

Note

Sessionless Cookie Consistency: The cookie consistency behavior has changed in release 11.0. In earlier releases, the cookie consistency check invokes sessionization. The cookies are stored in the session and signed. A “wlt_” suffix is appended to transient cookies and a “wlf_” suffix is appended to the persistent cookies before they are forwarded to the client. Even if the client does not return these signed wlf/wlt cookies, the App Firewall uses the cookies stored in the session to perform the cookie consistency check.

In release 11.0, the cookie consistency check is sessionless. The App Firewall now adds a cookie that is a hash of all the cookies tracked by the App Firewall. If this hash cookie or any other tracked cookie is missing or tampered with, the App Firewall strips the cookies before forwarding the request to the back end server and triggers a cookie-consistency violation. The server treats the request as a new request and sends new Set-Cookie header(s).

App Firewall support for Google web toolkit

September 18, 2018

Note: This feature is available in NetScaler release 10.5.e.

Web servers following Google Web Toolkit (GWT) Remote Procedure Call (RPC) mechanisms can be secured by the NetScaler App App Firewall without a need for any specific configuration to enable the GWT support.

What is GWT

The GWT is used for building and optimizing complex high-performance web applications by people who do not have expertise in XMLHttpRequest, and JavaScript. This open source, free development toolkit is used extensively for developing small and large scale applications and is quite frequently used for displaying browser based data such as search results for flights, hotels, and so on. The GWT provides a core set of Java APIs and widgets for writing optimized JavaScript scripts that can run on most browsers and mobile devices. The GWT RPC framework makes it easy for the client and server components of the web application to exchange Java objects over HTTP. GWT RPC services are not the same as web services based on SOAP or REST. They are simply a lightweight method for transferring data between the server and the GWT application on the client. GWT handles serialization of the Java objects exchanging the arguments in the method calls and the return value.

For popular websites that use GWT, see
How a GWT request works

The GWT RPC request is pipe delimited and has variable number of arguments. It is carried as a payload of HTTP POST and has the following values:

1. Content-type = text/x-gwt-rpc. Charset can be any value.
2. Method = POST.

The following example shows a valid payload for a GWT request:

```
1 5|0|8|http://localhost:8080/test/|16878339F02B83818D264AE430C20468| com.
 Integer| myInput1|java.lang.Integer|3438268394|1|2|3|4|2|5|6|7|8|1|
```

The request can be divided into three parts:

**a) Header: 5|0|8**

<table>
<thead>
<tr>
<th>The first 3 digits “5”</th>
<th>0</th>
<th>8</th>
</tr>
</thead>
</table>

” in the above request, represent “version, subversion, and size of table”, respectively. These must be positive integers.

**b) String Table:**

```
client.TestService|testMethod|java.lang.String|java.lang.Integer|myInput1|
java.lang.Integer|3438268394|
```

The members of the above pipe delimited string table contain the user-provided inputs. These inputs are parsed for the App Firewall checks and are identified as follows:

- 1st: `http://localhost:8080/test/`
  
  This is the Request URL. It should not contain the query part, because the GET method is not allowed.

- 2nd: `16878339F02B83818D264AE430C20468`
  
  Unique HEX identifier. A request is considered malformed if this string has non-hex characters.
NetScaler 12.0

- rd : com.test.client.TestService
  Service Class name
- 4th : testMethod
  Service method name

<table>
<thead>
<tr>
<th>5th onwards:</th>
<th>java.lang.Integer</th>
<th>myInput1</th>
<th>java.lang.Integer/3438268394</th>
</tr>
</thead>
<tbody>
<tr>
<td>java.lang.String</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- Data-types and data. Non-primitive data-types are specified as
  `<container>.<sub-cntnr>.name/<integer><identifier>`

**c) Payload: 1|2|3|4|2|5|6|7|8|1**

The payload consists of references to the elements in the string table. These integer values cannot be larger than the number of elements in the string table.

**App Firewall protection for GWT applications**

The App Firewall understands and interprets GWT RPC requests, inspects the payload for security check violations, and takes specified actions.

The App Firewall headers and cookies checks for GWT requests are similar to those for other request formats. After appropriate URL decoding and charset conversion, all the parameters in the string table are inspected. The GWT request body does not contain field names, just the field values. The input values can be validated against the specified format by using the App Firewall Field Format check, which can also be used to control the length of the input. The Cross-site Scripting and SQL Injection attacks in the inputs can be easily detected and thwarted by the App Firewall.

**Learning and relaxation rules:** Learning and deployment of relaxation rules are supported for GWT requests. App Firewall rules are in the form of `<actionURL> <fieldName>` mapping. The GWT request format does not have the field names and thus requires special handling. The App Firewall inserts dummy field names in the learned rules that can be deployed as relaxation rules. The `-isRegex` flag works as it does for non-GWT rules.

- Action URL:

  Multiple services responding to an RPC can be configured on the same web server. The HTTP request has the URL of the web server, not of the actual service handling the RPC. Therefore, relaxation is not applied on the basis of the HTTP request URL, because that would relax all the services on that URL for the target field. For GWT requests, the App Firewall uses the URL of the actual service found in the GWT payload, in the fourth field in the string table.
Field name:

Since the GWT request body contains only field values, the App Firewall inserts dummy field names such as 1, 2, and so on when recommending learned rules.

**Example of a GWT learned rule**

```
1 POST /abcd/def/gh HTTP/1.1
2 Content-type: text/x-gwt-rpc
3 Host: 10.217.222.75
4 Content-length: 157

5 |0|8| http://localhost:8080/acdtest/|16878339
   F02Baf83818D264AE430C20468|
   lang.Integer|onblur|
8
9 The learn data will be as follows:
10 sh learningdata pr1 crossSiteScripting
11 Profile: pr1 SecurityCheck: crossSiteScripting
13  Field: 10
14  Hits: 1
15  Done
```

**Example of a GWT relaxation rule**

```
bind appfw profile pr1 -crossSiteScripting 1 abcd -isregex NOTREGEX
```

**Log Messages:** The App Firewall generates log messages for the security check violations that are detected in the GWT requests. A log message generated by a malformed GWT request contains the string “GWT” for easy identification.

**Example of a Log message for malformed GWT request:**

Dec 5 21:48:02 <local0.notice> 10.217.31.247 12/05/2014:21:48:02 GMT ns
0-PPE=0 : APPFW Message 696 0 : "GWT RPC request with malformed payload. <
blocked>"

**Difference in processing of GWT vs non-GWT requests:**

The same payload can trigger different App Firewall security check violations for different Content-types. Consider the following example:

```
   test.client.TestService|testMethod|java.lang.String|java.lang.Integer|
   select|
```

**Content-type: application/x-www-form-urlencoded:**
A request sent with this content type results in a SQL violation if the SQL Injection Type is configured to use any of the four available options: SQLSplCharANDKeyword, SQLSplCharORKeyword, SQLKeyword, or SQLSplChar. The App Firewall considers ‘&’ to be the field separator and ‘=’ to be the name-value separator when processing the above payload. Since neither of these characters appears anywhere in the post body, the entire content is treated as a single field name. The field name in this request contains both an SQL special character (;) and an SQL Keyword (select). Therefore violations are caught for all four SQL Injection type options.

Content-type: text/x-gwt-rpc:

A request sent with this content type triggers an SQL violation only if the SQL injection type is set to one of the following three options: SQLSplCharORKeyword, SQLKeyword, or SQLSplChar. No violation is triggered if the SQL injection type is set to SQLSplCharANDKeyword, which is the default option. The App Firewall considers the vertical bar ‘|’ to be the field separator for the above payload in the GWT request. Therefore, the post body is divided into various form-field values, and form-field names are added (in accordance with the convention described earlier). Because of this splitting, the SQL special character and SQL keyword become parts of separate form fields.

Form field 8: java.lang.String%3b -> %3b is the (;) char

Form Field 10: select

As a result, when SQL Injection Type is set to SQLSplChar, field 8 indicates the SQL violation. For SQLKeyword, field 10 indicates the violation. Either of these two fields can indicate a violation if the SQL Inject type is configured with the SQLSplCharORKeyword option, which looks for the presence of either a keyword or a special character. No violation is caught for the default SQLSplCharANDKeyword option, because there is no single field that has a value that contains both SQLSplChar and SQLKeyword together.

Tips:

- No special App Firewall configuration is needed to enable GWT support.
- The Content-type must be text/x-gwt-rpc.
- Learning and deploying of the relaxation rules for all the pertinent App Firewall security checks applied to GWT payload works the same as it does for the other supported content-types.
- Only POST requests are considered valid for GWT. All other request methods are blocked if the content-type is text/x-gwt-rpc.
- GWT requests are subject to the configured POST body limit of the profile.
- The sessionless setting for the security checks is not applicable and will be ignored.
- CEF log format is supported for the GWT log messages.
Data leak prevention checks

September 18, 2018

The data-leak-prevention checks filter responses to prevent leaks of sensitive information, such as credit card numbers and social security numbers, to unauthorized recipients.

Credit card check

September 18, 2018

If you have an application that accepts credit cards, or your websites have access to database servers that store credit card numbers, you must use Data Leak Prevention (DLP) measures and configure protection for each type of credit card that you accept.

The NetScaler App App Firewall Credit Card check prevents attackers from exploiting Data Leak Prevention flaws to obtain credit card numbers of your customers. By following simple configuration steps, you can enforce protection of one or more of the following credit cards: 1) Visa, 2) Master Card, 3) Discover, 4) American Express (Amex), 5) JCB, and 6) Diners Club.

The Credit Card security check examines server responses to identify instances of the target credit card numbers, and applies a specified action when such a number is found. The action can be to transform the response by X'ing out all but the last group of digits in the credit card number, or to block the response if it contains more than a specified number of credit card numbers. If you specify both, the block action takes precedence. The Maximum credit cards allowed per page setting determines when the block action is invoked. The default setting, 0 (no credit card numbers allowed on the page), is the safest, but you can allow up to 255. Depending on where the violation is detected in the response and the block action gets triggered, you might get fewer than the maximum allowed number of credit cards in the response.

To avoid false positives, you can apply relaxations to exempt specific numbers from the Credit Card check. For example, a social security number, purchase order number, or Google account number might be similar to a credit card number. You can specify individual numbers or use a regular expression to indicate the string of digits to be bypassed when processing the response URL for credit card inspection.

If you’re not sure which credit card numbers to exempt, you can use the learn feature to generate recommendations based on the learned data. To get optimal benefit without compromising performance, you might want to enable this option for a short time to get a representative sample of the rules, and then deploy the relaxations and disable learning.

If you enable the log feature, the Credit Card check generates log messages indicating the actions that it takes. You can monitor the logs to determine whether responses to legitimate requests are
getting blocked. A large increase in the number of log messages can indicate thwarted attempts to gain access. By default, the doSecureCreditCardLogging parameter is ON, so the credit card number is not included in the log message generated by the safe commerce (Credit Card) violation.

The stats feature gathers statistics about violations and logs. An unexpected surge in the stats counter might indicate that your application is under attack.

To configure the Credit Card security check for protecting your application, configure the profile that governs inspecting the traffic to and from this application.

**Note:**

A website that does not access a SQL database usually does not have access to sensitive private information such as credit card numbers.

### Using the command line to configure the credit card check

In the command line interface, you can use either the set appfw profile command or the add appfw profile command to activate credit-card checking and specify which actions to perform. You can use the unset appfw profile command to revert back to the default settings. To specify relaxations, use the bind appfw command to bind credit card numbers to the profile.

To configure a credit card check by using the command line

Use either the set appfw profile command or the add appfw profile command, as follows:

- `set appfw profile <name> -creditCardAction ([block][learn] [log][stats]) [none])`
- `set appfw profile <name> -creditCard (VISA | MASTERCARD | DISCOVER | AMEX | JCB | DINERSCLUB)`
- `set appfw profile <name> -creditCardMaxAllowed <integer>`
- `set appfw profile <name> -creditCardXOut ([ON] [OFF])<name> -doSecureCreditCardLogging ([ON] [OFF])`

  - To configure a Credit Card relaxation rule by using the command line

Use the bind command to bind the credit card number to the profile. To remove a credit card number from a profile, use the unbind command, with the same arguments that you used for the bind command. You can use the show command to display the credit card numbers bound to a profile.

To bind a credit card number a profile

```bash
bind appfw profile <profile-name> -creditCardNumber <any number/regex> "<url>"
```

© 1999-2018 Citrix Systems, Inc. All rights reserved. 1556
**Example**: bind appfw profile test_profile -creditCardNumber 378282246310005 'http://www.example.com/credit\_card\_test.html'

- To unbind a credit card number from a profile
  
  'unbind appfw profile <profile-name> -creditCardNumber <credit card number / regex> "<url>"'

- To show the list of credit card numbers bound to a profile.

```
3 show appfw profile <profile>
```

**Using the GUI to configure the credit card check**

In the GUI, you configure the credit card security check in the pane for the profile associated with your application.

To add or modify the Credit Card security check by using the GUI

1. Navigate to **App Firewall > Profiles**, highlight the target profile, and click **Edit**.

2. In the **Advanced Settings** pane, click **Security Checks**.

   The security check table displays the currently configured action settings for all the security checks. You have 2 options for configuration:

   a) If you just want to enable or disable Block, Log, Stats, and Learn actions for Credit Card, you can select or clear check boxes in the table, click **OK**, and then click **Save and Close** to close the **Security Check** pane.

   b) If you want to configure additional options for this security check, double click Credit Card, or select the row and click **Action Settings** to display additional options as follows:

   - **Out**—Mask any credit card number detected in a response by replacing each digit, except the digits in the final group, with the letter “X.

   - **Maximum credit cards allowed per page**—Specify the number of credit cards that can be forwarded to the client without triggering a block action.

   - **Protected Credit Cards.** Select or clear a check box to enable or disable protection for each type of credit card.

   - You can also edit the Block, Log, Stats and Learn actions in the Credit Card Settings pane.

   After making any of the above changes, click **OK** to save the changes and return to the Security Checks table. You can proceed to configure other security checks if needed. Click **OK** to save all the changes you have made in the Security Checks section and then click **Save and Close** to close the Security Check pane.
3. In the Advanced Settings pane, click Profile settings. To enable or disable secure logging of credit card Numbers, select or clear the Secure Credit Card Logging check box. (By default, it is selected).

Click OK to save the changes.

• To configure a Credit Card relaxation rule by using the GUI

1. Navigate to App Firewall > Profiles, highlight the target profile, and click Edit.
2. In the Advanced Settings pane, click Relaxation Rules. The Relaxation Rules table has a Credit Card entry. You can double click, or select this row and click Edit to access the Credit Card Relaxation Rules dialogue. You can perform Add, Edit, Delete, Enable, or Disable operations for relaxation rules.

**Using the learn feature with the credit card check**

When the learn action is enabled, the App Firewall learning engine monitors the traffic and learns the triggered violations. You can periodically inspect these learned rules. After due consideration, if you want to exempt a specific string of digits from the Credit Card security check, you can by deploy the learned rule as a relaxation rule.

• To view or use learned data by using the command line interface

```
show appfw learningdata <profilename> creditCardNumber
rm appfw learningdata <profilename> -creditcardNumber <credit card number> "<url>"
export appfw learningdata <profilename> creditCardNumber
```

• To view or use learned data by using the GUI

1. Navigate to App Firewall > Profiles, highlight the target profile, and click Edit.
2. In the Advanced Settings pane, click Learned Rules. You can select the Credit Card entry in the Learned Rules table and double-click it to access the learned rules. You can deploy the learned rules or edit a rule before deploying it as a relaxation rule. To discard a rule, you can select it and click the Skip button. You can edit only one rule at a time, but you can select multiple rules to deploy or skip.

You also have the option to show a summarized view of the learned relaxations by selecting the Credit Card entry in the Learned Rules table and clicking Visualizer to get a consolidated view of all the learned violations. The visualizer makes it very easy to manage the learned rules. It presents a comprehensive view of the data on one screen and facilitates taking action on a group of rules with one click. The biggest advantage of the visualizer is that it recommends regular expressions to consolidate multiple rules. You can select a subset of these rules, based on the delimiter and Action URL. You can display 25, 50, or 75 rules in the visualizer, by selecting
the number from a drop-down list. The visualizer for learned rules offers the option to edit the rules and deploy them as relaxations. Or you can skip the rules to ignore them.

**Using the log feature with the credit card check**

When the log action is enabled, the Credit Card security check violations are logged in the audit log as APPFW_SAFECOMMERCE or APPFW_SAFECOMMERCE_XFORM violations. The App Firewall supports both Native and CEF log formats. You can also send the logs to a remote syslog server.

The default setting for doSecureCreditCardLogging is ON. If you change it to OFF, both credit card number and type are included in the log message.

Depending on the settings configured for the Credit Card checks, the application-firewall generated log messages might include the following information:

- Response was blocked or not blocked.
- Credit card numbers were transformed (X’d out). A separate log message is generated for each transformed credit card number, so multiple log messages might be generated during processing of a single response.
- Response contained the maximum number of potential credit card numbers.
- Credit card numbers and their corresponding types.
- To access the log messages by using the command line

Switch to the shell and tail the ns.log in the /var/log/ folder to access the log messages pertaining to the Credit Card violations:

```
Shell

tail -f /var/log/ns.log  grep SAFECOMMERCE
```

- To access the log messages by using the GUI

1. The NetScaler GUI includes a very useful tool (Syslog Viewer) for analyzing the log messages. You have a couple of options for accessing the Syslog Viewer: Navigate to the **target profile > Security Checks**. Highlight the Credit Card row and click Logs. When you access the logs directly from the Credit Card security check of the profile, it filters out the log messages and displays only the logs pertaining to these security check violations.

2. You can also access the Syslog Viewer by navigating to **NetScaler > System > Auditing**. In the Audit Messages section, click the **Syslog messages** link to display the Syslog Viewer,
which displays all log messages, including other security check violation logs. This is useful for debugging when multiple security check violations might be triggered during request processing.

The HTML based Syslog Viewer provides various filter options for selecting only the log messages that are of interest to you. To access Credit Card security check violation log messages, filter by selecting APPFW in the dropdown options for Module. The Event Type displays a rich set of options to further refine your selection. For example, if you select the APPFWSAFECOMMERCE and APPFWSAFECOMMERCE_XFORM check boxes and click the Apply button, only log messages pertaining to the Credit Card security check violations appear in the Syslog Viewer.

If you place the cursor in the row for a specific log message, multiple options, such as Module and EventType, appear below the log message. You can select any of these options to highlight the corresponding information in the logs.

Example of a Native format log message when the response is not blocked

```
1 May 29 01:26:31 <local0.info> 10.217.31.98 05/29/2015:01:26:31 GMT ns 0-PPE-0 :

2 CEF:0|Citrix|NetScaler|NS11.0|APPFW|APPFWSAFECOMMERCE|6|src=10.217.253.62
3 spt=25314 method=GET request=http://aaron.stratum8.net/FFC/CreditCardMind.html
```
Statistics for the credit card violations

When the stats action is enabled, the corresponding counter for the Credit Card check is incremented when the App Firewall takes any action for this security check. The statistics are collected for Rate and Total count for Traffic, Violations, and Logs. The increment of the log counter can vary depending on the configured settings. For example, if the block action is enabled and the Max Allowed credit card setting is 0, the request for a page that contains 20 credit card numbers increments the stats counter by one when the page is blocked as soon as the first credit card number is detected. However, if block is disabled and transform is enabled, processing the same request increments the statistics counter for logs by 20, because each credit card transformation generates a separate log message.

- To display Credit Card statistics by using command line

  At the command prompt, type:

  `sh appfw stats`

  To display stats for a specific profile, use the following command:

  `stat appfw profile <profile name>`

- To display Credit Card statistics by using GUI

  1. Navigate to **System > Security > App Firewall**.
  2. In the right pane, access the **Statistics** Link.
  3. Use the scroll bar to view the statistics about Credit Card violations and logs. The statistics table provides real-time data and is updated every 7 seconds.

**Highlights**

Note the following points about the Credit Card security check:

- The App Firewall enables you to protect credit card information and detect any attempts to access this sensitive data.

- To use the Credit Card protection check, you must specify at least one type of credit card and an action. The check is then applied to HTML, XML, and Web 2.0 profiles.
You can pipe the output of `sh appfw profile` command and `grep` for CreditCard to see all the Credit Card specific configuration. For example, `sh appfw profile my_profile` displays the configured settings of various parameters as well as the relaxation rules pertaining to the Credit Card check for the App Firewall profile named `my_profile`.

- You can exclude specific numbers from Credit Card inspection without bypassing the security check inspection for the rest of the credit card numbers.

- Relaxation is available for all App Firewall protected credit card patterns. In the GUI, you can use the visualizer to specify Add, Edit, Delete, Enable, or Disable operations on relaxation rules.

- The App Firewall learning engine can monitor the outgoing traffic to recommend rules based on observed violations. Visualizer support is also available for managing the learned credit card rules in the GUI. You can edit and deploy the learned rules, or skip them after careful inspection.

- The setting for number of allowed credit cards applies to each response. It does not pertain to the cumulative total of credit card numbers observed during the entire user session.

- The number of X’d out digits depends on the length of the credit card numbers. Ten digits are X’d out for credit cards that have 13 through 15 digits. Twelve digits are X’d out for credit cards that have 16 digits. If your application does not require sending the entire credit card number in the response, Citrix recommends that you enable this action to mask the digits in the credit card numbers.

- The X-out operation transforms all the credit cards and works independently of the configured settings for the maximum number of allowed credit cards. For example, if there are 4 credit cards in the response and the `creditCardMaxAllowed` parameter is set to 10, all 4 credit cards are X’d-out, but they are not blocked. If the credit card numbers are spread out in the document, a partial response with X’d-out numbers might be sent to the client before the response is blocked.

- Do not disable the `doSecureCreditCardLogging` parameter before due consideration. When this parameter is turned off, the credit card numbers are displayed and are accessible in the log messages. These numbers are not masked in the logs, even if the X-out action is enabled. If you are sending logs to a remote syslog server, and the logs are compromised, the credit card numbers can be exposed.

- When the response page is blocked because of a Credit Card violation, the App Firewall does not redirect to the error page.
**Safe object check**

September 18, 2018

The Safe Object check provides user-configurable protection for sensitive business information, such as customer numbers, order numbers, and country-specific or region-specific telephone numbers or postal codes. A user-defined regular expression or custom plug-in tells the App Firewall the format of this information and defines the rules to be used to protect it. If a string in a user request matches a safe object definition, the App Firewall either blocks the response, masks the protected information, or removes the protected information from the response before sending it to the user, depending on how you configured that particular safe object rule.

The Safe Object check prevents attackers from exploiting a security flaw in your web server software or on your web site to obtain sensitive private information, such as company credit card numbers or social security numbers. If your web sites do not have access to these types of information, you do not need to configure this check. If you have a shopping cart or other application that can access such information, or your web sites have access to database servers that contain such information, you should configure protection for each type of sensitive private information that you handle and store.

---

**Note:**

A web site that does not access an SQL database usually does not have access to sensitive private information.

---

The Safe Object Check dialog box is unlike that for any other check. Each safe object expression that you create is the equivalent of a separate security check, similar to the Credit Card check, for that type of information. If you use the wizard or the GUI, you add a new expression by clicking Add and configuring the expression in the Add Safe Object dialog box. You modify an existing expression by selecting it, then clicking Open, and then configuring the expression in the Modify Safe Object dialog box.

In the Safe Object dialog box for each safe object expression, you can configure the following:

- **Safe Object Name.** A name for your new safe object. The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 255 letters, numbers, and the hyphen (-), period (.), pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) symbols.

- **Actions.** Enable or disable the
  Block,
  Log, and
  Statistics actions, and the following actions:
    - **X-Out.** Mask any information that matches the safe object expression with the letter “X”.
    - **Remove.** Remove any information that matches the safe object expression.
**Regular Expression.** Enter a PCRE-compatible regular expression that defines the safe object. You can create the regular expression in one of three ways: by typing the regular expression directly into the text box, by using the **Regex Tokens** menu to enter regular expression elements and symbols directly into the text box, or by opening the Regular Expressions Editor and using it to construct the expression. The regular expression must consist of ASCII characters only. Do not cut and paste characters that are not part of the basic 128-character ASCII set. If you want to include non-ASCII characters, you must manually type those characters in PCRE hexadecimal character encoding format.

Note: Do not use start anchors (ˆ) at the beginning of Safe Object expressions, or end anchors ($) at the end of Safe Object expressions. These PCRE entities are not supported in Safe Object expressions, and if used, will cause your expression not to match what it was intended to match.

**Maximum Match Length.** Enter a positive integer that represents the maximum length of the string that you want to match. For example, if you want to match U.S. social security numbers, enter the number eleven (11) in this field. That allows your regular expression to match a string with nine numerals and two hyphens. If you want to match California driver’s license numbers, enter the number eight (8).

**Caution:**

If you do not enter a maximum match length in this field, the App Firewall uses a default value of one (1) when filtering for strings that match your safe object expressions. As a result, most safe object expressions fail to match their target strings.

You cannot use the command-line interface to configure the Safe Object check. You must configure it by using either the App Firewall wizard or the GUI.

Following are examples of Safe Object check regular expressions:

- Look for strings that appear to be U.S. social security numbers, which consist of three numerals (the first of which must not be zero), followed by a hyphen, followed by two more numerals, followed by a second hyphen, and ending with a string of four more numerals:

```
1 \[1-9\]\[0-9\]\{2,2\} -\[0-9\]\{2,2\} -\[0-9\]\{4,4\}
```

- Look for strings that appear to be California driver’s license IDs, which start with a letter and are followed by a string of exactly seven numerals:

```
1 \[A-Za-z\]\[0-9\]\{7,7\}
```
• Look for strings that appear to be Example Manufacturing customer IDs which, consist of a string of five hexadecimal characters (all the numerals and the letters A through F), followed by a hyphen, followed by a three-letter code, followed by a second hyphen, and ending with a string of ten numerals:

```
1  \[0-9A-Fa-f]\{5,5\}
2  \-[A-Za-z]\{3,3\}
3  \-[0-9]\{10,10\}
```

Caution: Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write to ensure that they define exactly the type of string you want to add as a safe object definition, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (\*\*) metacharacter/wildcard combination, can have results you did not want or expect, such as blocking access to web content that you did not intend to block.

Advanced form protection checks

September 18, 2018

The advanced Form Protection checks examine web form data to prevent attackers from compromising your system by modifying the web forms on your web sites or sending unexpected types and quantities of data to your web site in a form.

Note

SQL, XSS, FFC, and FieldFormat protection checks are applied if the Exclude Upload Files From Security Checks is unset.

A file upload is also a form element that has control-name name field that is submitted as part of form submission.

Refer to this page, for more information: Forms

Field formats check

January 6, 2019
The Field Formats check verifies the data that users send to your websites in web forms. It examines both the length and type of data to ensure that it is appropriate for the form field in which it appears. If the App Firewall detects inappropriate web form data in a user request, it blocks the request.

By preventing an attacker from sending inappropriate web form data to your website, the Field Formats check prevents certain types of attacks on your website and database servers. For example, if a particular field expects the user to enter a phone number, the Field Formats check examines the user-submitted input to ensure that the data matches the format of a phone number. If a particular field expects a first name, the Field Formats check ensures that the data in that field is of a type and length appropriate for a first name. It does the same thing for each form field that you configure it to protect.

This check applies to HTML requests only. It does not apply to XML requests. You can configure Field Format Checks in HTML profiles or Web 2.0 profiles to inspect HTML payload for protecting your applications. The App Firewall also supports Field Format Check protection for Google Web Toolkit (GWT) applications.

The Field Formats check requires that you enable one or more actions. The App Firewall examines the submitted inputs and applies the specified actions.

Note
Field format rules are tightening rules. Adding them to relaxation list from learned data acts as a blocking rule.
To relax field format rules, please remove particular “fieldname” from the fieldformat relaxations list.

You have the option to set the default field formats to specify Field Type and the minimum and maximum length of data expected in each form field on each web form that you want to protect. You can deploy relaxation rules to configure a Field Format for an individual field of a specific form. Multiple rules can be added to specify the field name, the action URL, and Field Formats. Specify Field Formats to accept different types of inputs in different form fields. The learning feature can provide recommendations for the relaxation rules.

Field Format Actions—You can enable Block, Log, Stats, and Learn actions. At least one of these actions must be enabled to engage the Field Format Check protection.

- **Block.** If you enable block, the block action is triggered if the input does not conform to the specified Field Format. If a rule was configured for the target field, the input is checked against the specified rule. Otherwise, it is checked against the default field format specification. Any mismatch in the Field Type or min/max length specification results in blocking the request.
- **Log.** If you enable the log feature, the Field Format check generates log messages indicating the actions that it takes. You can monitor the logs to determine whether responses to legitimate requests are getting blocked. A large increase in the number of log messages can indicate malicious attempts to launch an attack.
• **Stats.** If enabled, the stats feature gathers statistics about violations and logs. An unexpected surge in the stats counter might indicate that your application is under attack, or you might have to revisit the configuration to see if the specified field format is too restrictive.

• **Learn.** If you are not sure which Field Types or minimum and maximum length values might be ideally suited for your application, you can use the learn feature to generate recommendations based on the learned data. The App Firewall learning engine monitors the traffic and provides field format recommendations based on the observed values. To get optimal benefit without compromising performance, you might want to enable the learn option for a short time to get a representative sample of the rules, and then deploy the rules and disable learning.

Note: The App Firewall’s learning engine can distinguish only the first 128 bytes of the name. If a form has multiple fields with names that match for the first 128 bytes, the learning engine might not be able to distinguish between them. Similarly, the deployed relaxation rule might inadvertently relax all such fields.

**Default Field Format**—In addition to configuring the actions, you can configure the default Field Format to specify the type of data expected in all the form fields for your application. A Field Type can be selected as the Field Format type. Minimum length and Maximum length parameters can be used to specify the length of the allowed inputs. As an alternative to Field Types, you can use Character Maps to specify what’s allowed in a field (except in cluster deployments).

• **Field Type**—Field Types are named expression to which you assign assigned priority values. Field Type expressions specify the allowed inputs and are matched against the submitted data to determine whether the received values are consistent with the allowed values. The Field Types are checked in the order of their priority numbers. A lower number indicates a higher priority. The App Firewall gives you the option to add your own Field Types and assign them the priorities you want. The priority value can range from 0 through 64000. The following built-in Field Types are provided to help simplify the configuration process:

```
1  > sh appfw fieldtype
2  1) Name: integer  Regex: "^[+-]?[0-9]+$"  Comment: Integer
3       Priority: 30
4       Builtin: IMMUTABLE
5  2) Name: alpha  Regex: "^[a-zA-Z]+$"  Comment: "Alpha characters"
6       Priority: 40
7       Builtin: IMMUTABLE
8  3) Name: alphanum  Regex: "^[a-zA-Z0-9]+$"  Comment: "Alpha-numeric characters"
9       Priority: 50
10      Builtin: IMMUTABLE
11  4) Name: nohtml  Regex: "^[^&<>]+$"  Comment: "Not HTML"
12       Priority: 60
13       Builtin: IMMUTABLE
```
<table>
<thead>
<tr>
<th>Name</th>
<th>Regex</th>
</tr>
</thead>
<tbody>
<tr>
<td>any</td>
<td>&quot;^.*$&quot;</td>
</tr>
</tbody>
</table>

**Priority:** 70  
**Comment:** Anything  
**Builtin:** IMMUTABLE

**Note:** The built-in Field Types are IMMUTABLE. They cannot be modified or removed. Any Field Types that you add are MODIFIABLE. You can edit them or remove them.

Configuring a Field Type as a default Field Format might be useful when you have a PCRE expression that can identify the valid inputs in all or most of the form fields for your application and exclude the invalid inputs. For example, if all the inputs in your application forms are expected to contain only numbers and letters, you might want to use the built-in Field Type alphanum as the default Field Type. Any non-alphanumeric character such as a backslash (\) or semicolon (;) in the input will trigger a violation. You can also add your own customized Field Types and use them to configure default Field Formats. For example, if you want to make the lowercase “x”, “y”, and “z” the only allowed alpha characters, you can configure a customized Field Type with regular expression “^[x-z]+$”. You could assign it a higher priority (lower priority number) then the built-in Field Types and use it as the default Field Type.

- **Minimum Length** — The default minimum data length assigned to form fields in web forms that do not have an explicit setting. This parameter is set to 0 by default, which allows the user to leave the field blank. Any higher setting forces users to fill in the field.

  **Caution:** If the minimum length value is 0 but the Field Type is integer, alpha, or alphanum, a request is blocked if any input field is left empty, despite the minimum length setting. That is because the regEx for these Field Types contains a + character, which means one or more characters. Distinguishing an integer from an alpha character requires at least one character.

- **Maximum Length** — The default maximum data length assigned to form fields in web forms that do not have an explicit setting. This parameter is set to 65535 by default.

  **Note:** Characters vs bytes. The minimum and the maximum lengths for the field formats represent the number of bytes, not the number of characters. Languages that have greater than one-byte character representation can cause the limit to be exceeded with fewer characters than the number configured for the maximum value. For example, with double-byte character representation, the maximum value of 9 allows no more than 4 characters.

  **Tip:** The GUI allows you to cut and paste UTF-8 characters directly into the GUI without having to convert them to hex.

- **Character Maps** — In addition to recommending the Field Types, the App Firewall learning engine offers you an additional option, Use Character Maps, to deploy the Format Check rules. A Character Map is a set of all the characters allowed in a particular form field. You can fine tune the Field format specification to allow or disallow specific characters by using Character Maps.
A separate Character Map is generated for each form field. The alpha and numeric characters are treated differently in Character Maps. If any alpha character is seen in the input, all alpha characters [A-Za-z] will be allowed by the recommended PCRE expression in the Character Map. Similarly, if any digit is included, all digits [0-9] will be allowed. Non-printable characters are specified by using the x construct. Only single Byte characters with values between 0-255 are considered for Character Map recommendations.

A Character Map can be more specific than the corresponding Field Type recommendation. In some situations, Character Maps might be a better option, because they give you tighter control over the set of characters allowed as inputs. The deployed character maps are displayed as strings that start with prefix “CM” followed by digits. The priority for the Character Maps starts at 10000. As with user-added Field Types, you can add, edit or remove a Character Map. Character Maps that are currently used in deployed rules cannot be modified or removed.

**Note:** Character Maps are not supported in cluster deployments.

**Note**

When you add a field formats rule with any built-in Field Type and use character map instead of Field Type and save it, the changes do not get saved and rule still shows with Field Type.

When the character map matches one of the built-in type, the field type is reused instead of creating a new character map.

### Using the command line to configure the field format check

In the command line interface, you can use the `add appfw fieldType` command to add a new Field Type. You can use either the `set appfw profile` command or the `add appfw profile` command to configure the Field Format check and specify which actions to perform. You can use the `unset appfw profile` command to revert the configured settings back to their defaults. To specify a Field Format rule, use the `bind appfw` command to bind a Field Type to a form Field and the action URL, along with the minimum and maximum length specifications.

**To add, remove or view a Field Type by using the command line:**

Use the `add` command to add a Field Type. You must specify the Name, Regular expression and Priority when adding a new Field Type. You also have the option to add a Comment. You can use the `show` command to display the configured Field Types. You can also delete a Field Type by using the `remove` command, which requires only the Name of the Field Type.

```
add [appfw] fieldType <name> <regex> <priority> [-comment <string>]
```

where:

- `<regex>` is a regular expression
- `<priority>` is a positive_integer
Example:

```
add fieldType "Cust_Zipcode" "^[0-9]{5}[-][0-9]{4}$" 4

- show [appfw] fieldType [<name>]
  Example: sh fieldType
  sh appfw fieldType
  sh appfw fieldType cust_zipcode
  - `rm [appfw] fieldType <name>`
  Example: rm fieldType cust_zipcode
  `rm appfw fieldType cust_zipcode`
```

**Note:** As shown above, use of “appfw” in the command is optional. For example, “Add FieldType” or “Add appfw fieldType” are both valid options. The names of the Field Types are case insensitive due to normalization. As shown in the above examples, Cust_Zipcode, cust_zipcode, and cUsT_ziPcode refer to the same Field Type.

To configure a Field Format check by using the command line

Use either the set appfw profile command or the add appfw profile command, as follows:

- `set appfw profile <name> -fieldFormatAction ([block] [learn] [log] [stats]) [none]`
- `set appfw profile <name> -defaultFieldFormatType <string>`
- `set appfw profile <name> -defaultFieldFormatMinLength <integer>`
- `set appfw profile <name> -defaultFieldFormatMaxLength <integer>`

To configure a Field Format relaxation rule by using the command line

```
bind appfw profile <name> (-fieldFormat <string> <formActionURL> <fieldType>
  [-fieldFormatMinLength <positive_integer>] [-fieldFormatMaxLength <positive_integer>]
  [-isRegex (REGEX | NOTREGEX)])
```

Example:
Using the GUI to Configure the field formats security check

In the GUI, you can manage the Field Types. You can also configure the Field Formats security check in the pane for the profile associated with your application.

To add, modify or remove a Field Type using the GUI

1. Navigate to Application Firewall node. In the Settings, click Manage Field Types to display the Configure Application Firewall Field Type dialogue box.
2. Click Add to add a new Field Type. Follow the instructions in this pane and click Create. You can also edit or delete any user-added Field Type if it is currently not being used by a deployed rule.

To add or modify the Field Formats security check by using the GUI

1. Navigate to Application Firewall > Profiles, highlight the target profile, and click Edit.
2. In the Advanced Settings pane, click Security Checks.

The security check table displays the currently configured action settings for all the security checks. You have 2 options for configuration:

a) If you just want to enable or disable Block, Log, Stats, and Learn actions for Field Formats, you can select or clear check boxes in the table, click OK, and then click Save and Close to close the Security Check pane.

b) If you want to configure additional options for this security check, double click Field Formats, or select the row and click Action Settings, to display the following options for Default Field Format:

- Field Type—Select the Field Type that you want to configure as the default Field Type. You can select the built-in and user-defined Field Types. The deployed Character Maps are also included in the list and can be selected.
- Minimum Length—Specify the minimum number of characters that must be in each field. Possible values: 0-65535.
- Maximum Length—Specify the maximum number of characters that must be in each field. Possible values: 1-65535.

You can also edit the Block, Log, Stats and Learn actions in the Field Formats Settings pane.

After making any of the above changes, click OK to save the changes and return to the Security Checks table. You can proceed to configure other security checks if needed. Click OK **to save all the changes you have made in the Security Checks section, and then click **Save and Close to close the Security Check pane.

```bash
1 bind appfw profile pr_ffc -fieldFormat "login_name" \n   integer -fieldformatMinLength 3 -fieldformatMaxlength 6
```
To configure a Field Formats relaxation rule by using the GUI

1. Navigate to Application Firewall > Profiles, highlight the target profile, and click Edit.

2. In the Advanced Settings pane, click Relaxation Rules. The Relaxation Rules table has a Field Formats entry. You can double click, or select this row and click the Edit button, to access the Field Formats Relaxation Rules dialogue. You can perform Add, Edit, Delete, Enable, or Disable operations for relaxation rules.

   For a consolidated view of all the relaxation rules, you can highlight the Field Formats row and click Visualizer. The visualizer for deployed relaxations offers you the option to Add a new rule or Edit an existing one. You can also Enable or Disable a group of rules by selecting a node and clicking the corresponding buttons in the relaxation visualizer.

Using the learn feature with the Field Formats Check

When the learn action is enabled, the App Firewall learning engine monitors the traffic and learns the triggered violations. You can periodically inspect these learned rules. After due consideration, you can deploy the learned rule as a Field Format relaxation rule.

Field formats learning enhancement—An App Firewall learning enhancement was introduced in release 11.0. In the previous releases, once the learned field format recommendation is deployed, the App Firewall learning engine stops monitoring the valid requests for the purpose of recommending new rules on the basis of the new data points. This limits the configured security protection, because the learning database does not include any representations of the new data seen in the valid requests processed by the security check.

Violations are no longer coupled with learning. The learning engine learns and makes recommendations for the field formats regardless of the violations. In addition to checking the blocked requests to determine whether the current field format is too restrictive and needs to be relaxed, the learning engine also monitors the allowed requests to determine whether the current field format is too permissive, and allows elevating the security by deploying a more restrictive rule.

Following is a summary of the Field Formats learning behavior:

No Field format is bound—The behavior remains unchanged in this scenario. All learn data is sent to the aslearn engine. The learning engine suggests a field format rule based on the data set.

Field format is bound: In the previous releases, observed data is sent to the aslearn engine only in the case of a violation. The learning engine suggests a field format rule based on the data set. In the 11.0 release, all data is sent to aslearn engine even if no violation is triggered. The learning engine suggests a field format rule based on the entire data set of all received inputs.

Use Case for learning enhancement:
If the initial field format learned rules are based on a small sample of data, a few non-typical values might result in a recommendation that is too lenient for the target field. The ongoing learning allows the App Firewall to observe data points from every request to collect a representative sample for the learned recommendations. This is helpful in further tightening the security to deploy the optimal input format with an adequate range value.

The field format learning makes use of the priority of the Field Types as well as the configured settings of the following learning thresholds:

- **FieldFormatMinThreshold**—Minimum number of times a specific form field must be observed before a learned relaxation is generated. Default: 1.
- **FieldFormatPercentThreshold**—Percentage of times a form field matched a particular Field Type, before a learned relaxation is generated. Default: 0.

The field format rule recommendations are based on the following criteria:

- **Field Type recommendations**—The Field Type recommendations are determined by the assigned priorities of the existing Field Types and the specified Field Format thresholds. The priorities determine the order in which the Field Types are matched against the inputs. A lower number specifies a higher priority. For example, Field Type integer has the higher priority (30) and is therefore evaluated before Field Type alphanum (50). The thresholds determine the number of inputs evaluated to collect a representative sample for the data point. Assigning the right priority to the configured Field Types, and configuring an appropriate learning setting value for the fieldFormatPercentThreshold and fieldFormatMinThreshold parameters, is essential for getting the correct Field Format recommendation. The Field Type with the highest priority, based on the configured thresholds, is matched first against the inputs. If there is a match, this Field Type is suggested without considering the other Field Types. For example, three default Field Types, integer, alphanum, and any will match if all the inputs contain only numbers. However, integer will be recommended since it has the highest priority.

- **Minimum and Maximum length recommendations**—Calculations for the minimum and maximum lengths for the Field Format are done independently of the determination for the Field Type. The field format length calculations are based on the average length of all the observed inputs. Half of this calculated average is suggested as the min value, and twice the value of this average is suggested as the max value. The range for the Minimum Length is 0-65535 and the range for the Maximum Length is 1-65535. The configured value for the minimum length cannot exceed the maximum length.

- **Handling of space character**—The Field Format check counts every space character when checking for the Field Formats length. Leading or trailing spaces are not stripped, and multiple consecutive spaces in the middle of the input string are no longer consolidated to a single space during input processing.

Example to illustrate the Field Format recommendations:
**Total requests**: 100

**Number of Req with Field Type**:

1. **Int**: 22 (22 int values) - 22%
2. **Alpha**: 44 (44 alpha values) - 44%
3. **Alphanum**: 14 (14 + 44 + 22 = 80 alphanum values) = 80%
4. **noHTML**: 10 (80 + 10 = 90 noHTML values) = 90%
5. **any**: 10 (90 + 10 = 100 any values) = 100%

**% threshold**

- **0-22**: int
- **23-44**: alpha
- **45-80**: alphanum
- **81-90**: noHTML
- **91-100**: any

---

To view or use learned data by using the command line interface:

1. `show appfw learningdata <profilename> FieldFormat`
2. `rm appfw learningdata <profilename> -fieldFormat <string> <formActionURL>`
3. `export appfw learningdata <profilename> FieldFormat`

---

To view or use learned data by using the GUI:

1. Navigate to **Application Firewall > Profiles**, highlight the target profile, and click **Edit**.

2. In the **Advanced Settings** pane, click **Learned Rules**. You can select the Field Formats entry in the Learned Rules table and double-click it to access the learned rules. You can deploy the learned rules or edit a rule before deploying it as a relaxation rule. To discard a rule, you can select it and click the **Skip** button. You can edit only one rule at a time, but you can select multiple rules to deploy or skip.

You also have the option to show a summarized view of the learned relaxations by selecting the Field Formats entry in the Learned Rules table and clicking Visualizer to get a consolidated view of all the learned violations. The visualizer makes it very easy to manage the learned rules. It presents a comprehensive view of the data on one screen and facilitates taking action on a group of rules with one click. The biggest advantage of the visualizer is that it recommends regular expressions to consolidate multiple rules. You can select a subset of these rules, based on the delimiter and Action URL. You can display 25, 50, or 75 rules in the visualizer, by selecting the number from a drop-down list. The visualizer for learned rules offers the option to edit the rules and deploy them as relaxations. Or you can skip the rules to ignore them.
Using the log feature with the field formats check

When the log action is enabled, the Field Formats security check violations are logged in the audit log as APPFW_FIELDFORMAT violations. The App Firewall supports both Native and CEF log formats. You can also send the logs to a remote syslog server.

To access the log messages by using the command line

Switch to the shell and tail the ns.logs in the /var/log/ folder to access the log messages pertaining to the Field Formats violations:

• Shell
  tail -f /var/log/ns.log | grep APPFW_FIELDFORMAT

To access the log messages by using the GUI

The NetScaler GUI includes a very useful tool (Syslog Viewer) for analyzing the log messages. You have multiple options for accessing the Syslog Viewer:

• Navigate to the Application Firewall > Profiles, select the target profile, and click Security Checks. Highlight the Field Formats row and click Logs. When you access the logs directly from the Field Formats security check of the profile, it filters out the log messages and displays only the logs pertaining to these security check violations.

• You can also access the Syslog Viewer by navigating to NetScaler > System > Auditing. In the Audit Messages section, click the Syslog messages link to display the Syslog Viewer, which displays all log messages, including other security check violation logs. This is useful for debugging when multiple security check violations might be triggered during request processing.

• Navigate to Application Firewall > policies > Auditing. In the Audit Messages section, click the Syslog messages link to display the Syslog Viewer, which displays all log messages, including other security check violation logs.

The HTML based Syslog Viewer provides various filter options for selecting only the log messages that are of interest to you. To access Field Formats security check violation log messages, filter by selecting APPFW in the dropdown options for Module. The Event Type displays a rich set of options to further refine your selection. For example, if you select the APPFW_FIELDFORMAT check box and click the Apply button, only log messages pertaining to the Field Formats security check violations appear in the Syslog Viewer.

If you place the cursor in the row for a specific log message, multiple options, such as Module and EventType, appear below the log message. You can select any of these options to highlight the corresponding information in the logs.

Example of a Native format log message when the request is not blocked

```
1 Jun 10 22:32:26 <local0.info> 10.217.31.98 06/10/2015:22:32:26 GMT ns 0-PPE-0 :
```
Statistics for the field formats violations

When the stats action is enabled, the corresponding counter for the Field Formats check is incremented when the App Firewall takes any action for this security check. The statistics are collected for Rate and Total count for Traffic, Violations, and Logs. The increment of the log counter can vary depending on the configured settings. For example, if the block action is enabled, the request for a page that contains 3 Field Format violations increments the stats counter by one, because the page is blocked as soon as the first Field Formats violation is detected. However, if block is disabled, processing the same request increments the statistics counter for violations and the logs by 3, because each Field Formats violation generates a separate log message.

To display Field Formats statistics by using command line

At the command prompt, type:

sh appfw stats

To display stats for a specific profile, use the following command:

stat appfw profile <profile name>

To display Field Formats statistics by using GUI

1. Navigate to System > Security > Application Firewall.
2. In the right pane, access the Statistics Link.
3. Use the scroll bar to view the statistics about Field Formats violations and logs. The statistics table provides real-time data and is updated every 7 seconds.

Deployment tip

- Enable Field format actions log, learn and stats.
- After running a representative sample of the traffic to your application, review the learned recommendations.
- If a Field Type is recommended by most of the learned rules, configure that Field Type as the Default Field Type. For minimum and maximum lengths, use the widest range suggested by these rules.
- Deploy rules for other fields for which different Field Types or different minimum/maximum lengths are better suited.
- Enable blocking and disable learning.
- Monitor stats and logs. If a significant number of violations are still being triggered, you might want to review the log messages to confirm that the violations represent malicious requests that should have been blocked. If valid requests are being flagged as violations, you can either edit the configured Field Format rule to further relax it or enable learning again to get recommendations based on the new data points.

**Note:** You can fine tune your configuration by getting new learning recommendations.

**Highlights**

Note the following points about the Field Format security check:

- **Protection**—By configuring optimal field format rules, you can protect against many attacks. For example, if you specify that a field can only have integers, hackers will not be able to launch SQL Injection or XSS attacks by using this field, because the inputs required to launch such attacks will not meet the configured field format requirement.
- **Performance**—You can limit the minimum and the maximum allowed length for the inputs in the field format rules. This can prevent a malicious user from entering excessively large input strings in an attempt to add processing overhead to the server, or worse, cause the server to dump core because of stack overflow. By limiting the input size, you can shorten the time required for processing legitimate requests.
- **Configuring Field Formats**—You must enable one of the actions (block, log, stats, learn) to engage the field Format protection. You can also specify the Field format rules to identify the allowed inputs in your form fields.
- **Selecting Character Maps vs. Field Types**—Both Character Maps and Field Types use regular expressions. However, a Character Map provides a more specific expression by narrowing down the list of allowed characters. For example, for an input such as janedoe@citrix.com, the learning engine might recommend the Field Type nohtml but the Character Map [.@-Za-z] might be more specific, because it narrows down the allowed set of non-alpha characters. The Character Map option allows, in addition to alpha characters, only two non-alpha characters: period (.) and at (@).
- **Ongoing Learning**—The App Firewall monitors and takes into account all the incoming data (violations as well as allowed inputs) to build a learning table for recommending rules. The rules
are revised and updated as new incoming data arrives. New field format rules are suggested for a field even if it already has a bound field format rule. If the configured Field Formats are too restrictive and are blocking the valid requests, you can deploy a more relaxed Field Format. Similarly, if the current Field Formats are too generic, you can further refine and tighten the security by deploying a more restrictive Field Format.

- **Overwriting Rules**—If a rule has already been deployed for a field/URL combination, the GUI allows the user to update the field format. A dialog box asks for confirmation to replace the existing rule. If you are using the command line interface, you have to explicitly unbind the previous binding and then bind the new rule.

- **Multiple match**—If multiple field formats match a given field name and its action URL, the App Firewall arbitrarily selects one of them to apply.

- **Buffer boundary**—If a field value extends across multiple streaming buffers, and the format for these two parts of the field value is different, a field format corresponding to “any” is sent to the learn database.

- **Field Format vs. Field Consistency Check**—Both the Field Format check and the Field Consistency check are form-based protection checks. The Field Formats check provides a different type of protection than does the Form Field Consistency check. The Form Field Consistency check verifies that the structure of the web forms returned by users is intact, that data format restrictions configured in the HTML are respected, and that data in hidden fields has not been modified. It can do this without any specific knowledge about your web forms other than what it derives from the web form itself. The Field Formats check verifies that the data in each form field matches the specific formatting restrictions that you configured manually, or that the learning feature generated and you approved. In other words, the Form Field Consistency check enforces general web form security, while the Field Formats check enforces the specific rules for the allowed inputs for your web forms.

## Form field consistency check

September 18, 2018

The Form Field Consistency check examines the web forms returned by users of your web site, and verifies that web forms were not modified inappropriately by the client. This check applies only to HTML requests that contain a web form, with or without data. It does not apply to XML requests.

The Form Field Consistency check prevents clients from making unauthorized changes to the structure of the web forms on your web site when they fill out and submit a form. It also ensures that the data a user submits meets the HTML restrictions for length and type, and that data in hidden fields is not modified. This prevents an attacker from tampering with a web form and using the modified form to gain unauthorized access to web site, redirect the output of a contact form that uses an insecure script and thereby send unsolicited bulk email, or exploit a vulnerability in your web server software.
to gain control of the web server or the underlying operating system. Web forms are a weak link on many web sites and attract a wide range of attacks.

The Form Field Consistency check verifies all of the following:

- If a field is sent to the user, the check ensures that it is returned by the user.
- The check enforces HTML field lengths and types.

**Note:** The Form Field Consistency check enforces HTML restrictions on data type and length but does not otherwise validate the data in web forms. You can use the Field Formats check to set up rules that validate data returned in specific form fields on your web forms.

- If your web server does not send a field to the user, the check does not allow the user to add that field and return data in it.
- If a field is a read-only or hidden field, the check verifies that the data has not changed.
- If a field is a list box or radio button field, the check verifies that the data in the response corresponds to one of the values in that field.

If a web form returned by a user violates one or more of the Form Field consistency checks, and you have not configured the App Firewall to allow that web form to violate the Form Field Consistency checks, the request is blocked.

If you use the wizard or the GUI, in the Modify Form Field Consistency Check dialog box, on the General tab you can enable or disable the Block, Log, Learn, and Statistics actions.

You also configure Sessionless Field Consistency in the General tab. If Sessionless Field Consistency is enabled, the App Firewall checks only the web form structure, dispensing with those parts of the Form Field Consistency check that depend upon maintaining session information. This can speed the Form Field Consistency check with little security penalty for web sites that use many forms. To use Sessionless Field Consistency on all web forms, select On. To use it only for forms submitted with the HTTP POST method, select postOnly.

If you use the command-line interface, you can enter the following command to configure the Form Field Consistency Check:

```
set appfw profile <name> -fieldConsistencyAction [block] [learn] [log] [stats] [none]
```

To specify relaxations for the Form Field Consistency check, you must use the GUI. On the Checks tab of the Modify Form Field Consistency Check dialog box, click Add to open the Add Form Field Consistency Check Relaxation dialog box, or select an existing relaxation and click Open to open the Modify Form Field Consistency Check Relaxation dialog box. Either dialog box provides the same options for configuring a relaxation, as described in “Manual Configuration By Using the GUI.”

Following are examples of Form Field Consistency check relaxations:
Form Field Names:

- Choose form fields with the name UserType:

  ```
  ^UserType$
  ```

- Choose form fields with names that begin with UserType_ and are followed by a string that begins with a letter or number and consists of from one to twenty-one letters, numbers, or the apostrophe or hyphen symbol:

  ```
  ^UserType_[0-9A-Za-z][0-9A-Za-z\'-]{0,20} $
  ```

- Choose form fields with names that begin with Turkish-UserType_ and are otherwise the same as the previous expression, except that they can contain Turkish special characters throughout:

  ```
  ^T\xC3\xBCrk\xC3\xA7e-UserType_([^0-9A-Za-z]\\[0-9A-Fa-f][0-9A-Fa-f])+$
  ```

  **Note:** See “PCRE Character Encoding Format” for a complete description of supported special characters and how to encode them properly.

- Choose form field names that begin with a letter or number, consist of a combination of letters and/or numbers only, and that contain the string Num anywhere in the string:

  ```
  ^[0-9A-Za-z]*Num[0-9A-Za-z]+$ 
  ```

Form Field Action URLs:

- Choose URLs beginning with http://www.example.com/search.pl? and containing any string after the query except for a new query:

  ```
  ^http://www[.]example[.]com/search[.]pl?[^?]*$
  ```

- Choose URLs that begin with http://www.example-español.com and have paths and filenames that consist of upper-case and lower-case letters, numbers, non-ASCII special characters, and selected symbols in the path. The ñ character and any other special characters are represented as encoded UTF-8 strings containing the hexadecimal code assigned to each special character in the UTF-8 charset:

  ```
  ^http://www[.]example-espa\xC3\xB1ol[.]com/(((0-9A-Za-z)\\[0-9A-Fa-f]([0-9A-Za-z_-])\\[0-9A-Fa-f][0-9A-Fa-f])+)((0-9A-Za-z_-)\\[0-9A-Fa-f])((0-9A-Za-z_-)\\[0-9A-Fa-f])\[.]\[asp|htp|php|s?html?\]+$ 
  ```
Choose all URLs that contain the string /search.cgi?:

```
^[^<>]*/search(\.[^<>]?[^<>]*)*$
```

**Caution:** Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the URL you want to add as an exception, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (*) metacharacter/wildcard combination, can have results you do not want or expect, such as blocking access to web content that you did not intend to block or allowing an attack that the Cookie Consistency check would otherwise have blocked.

---

**CSRF form tagging check**

November 19, 2018

The Cross Site Request Forgery (CSRF) Form Tagging check tags each web form sent by a protected web site to users with a unique and unpredictable FormID, and then examines the web forms returned by users to ensure that the supplied FormID is correct. This check protects against cross-site request forgery attacks. This check applies only to HTML requests that contain a web form, with or without data. It does not apply to XML requests.

The CSRF Form Tagging check prevents attackers from using their own web forms to send high volume form responses with data to your protected web sites. This check requires relatively little CPU processing capacity compared to certain other security checks that analyze web forms in depth. It is therefore able to handle high volume attacks without seriously degrading the performance of the protected web site or the App Firewall itself.

Before you enable the CSRF Form Tagging check, you should be aware of the following:

- You need to enable form tagging. The CSRF check depends on form tagging and does not work without it.
- You should disable the NetScaler Integrated Caching feature for all web pages containing forms that are protected by that profile. The Integrated Caching feature and CSRF form tagging are not compatible.
- You should consider enabling Referer checking. Referer checking is part of the Start URL check, but it prevents cross-site request forgeries, not Start URL violations. Referer checking also puts less load on the CPU than does the CSRF Form Tagging check. If a request violates Referer checking, it is immediately blocked, so the CSRF Form Tagging check is not invoked.
- The CSRF Form Tagging check does not work with web forms that use different domains in the form-origin URL and form-action URL. For example, CSRF Form Tagging cannot protect a web
form with a form-origin URL of http://www.example.com and a form action URL of http://www.example.org/form.pl, because example.com and example.org are different domains.

If you use the wizard or the GUI, in the Modify CSRF Form Tagging Check dialog box, on the General tab you can enable or disable the Block, Log, Learn and Statistics actions.

If you use the command-line interface, you can enter the following command to configure the CSRF Form Tagging Check:

- `set appfw profile <name> -fieldConsistencyAction [block] [log] [learn] [stats] [none]`

To specify relaxations for the CSRF Form Tagging check, you must use the GUI. On the Checks tab of the Modify CSRF Form Tagging Check dialog box, click Add to open the Add CSRF Form Tagging Check Relaxation dialog box, or select an existing relaxation and click Open to open the Modify CSRF Form Tagging Check Relaxation dialog box. Either dialog box provides the same options for configuring a relaxation.

An alert is generated when you set the NetScaler Appfirewall session limit to a value of 0 or lower, because such a setting affects advanced protection check functionality that requires a properly functioning App Firewall session.

Following are examples of CSRF Form Tagging check relaxations:

**Note:** The following expressions are URL expressions that can be used in both the Form Origin URL and Form Action URL roles.

**Choose URLs beginning with http://www.example.com/search.pl?**

```
1 ^http://www[.].example[.].com/search
2 [.].pl?[^?]*$
```

**Choose URLs that begin with http://www.example-español.com and have paths and filenames that consist of upper-case and lower-case letters, numbers, non-ASCII special characters, and selected symbols in the path. The ñ character and any other special characters are represented as encoded UTF-8 strings containing the hexadecimal code assigned to each special character in the UTF-8 charset:**

```
1 http://www[.].example-español.com/(([0-9A-Za-z]\\x[0-9A-Fa-f][0-9A-Fa-f])
2 (([0-9A-Za-z_]\\x[0-9A-Fa-f][0-9A-Fa-f])\*[([0-9A-Za-z]\\x[0-9A-Fa-f][0-9A-Fa-f])\*[([0-9A-Za-z_]\\x[0-9A-Fa-f][0-9A-Fa-f]))\*[.]\(asp|htp|php|s?html?)$}
```

**Choose all URLs that contain the string /search.cgi?**:

© 1999-2018 Citrix Systems, Inc. All rights reserved.
**Important**

Regular expressions are powerful. If you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the URL that you want to add as an exception, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (\.*) metacharacter/wildcard combination, can have results you do not want, such as blocking access to web content that you did not intend to block or allowing an attack that the check would otherwise have blocked.

**Tip**

When enableValidate referrer header is enabled under the Start URL Action, ensure that the Referrer Header URL is added to StartURL as well.

**Note**

When NetScaler reaches the `appfw_session_limit` and CSRF checks are enabled, the web application freezes.

To prevent web application freeze, decrease the session timeout and increase the session limit by using the following commands:

```bash
1  > From CLI: set appfw settings -sessiontimeout 300
2  > From shell: root@ns# nsapimgr_wr.sh -s appfw_session_limit=200000
```

Logging and generating SNMP alarms when `appfw_session_limit` is reached assists you in troubleshooting and debugging issues.

**Managing CSRF form tagging check relaxations**

September 18, 2018

You configure an exception (or relaxation) to the CSRF Form Tagging security check in the Add Cross-Site Request Forgery Tagging Check Relaxation dialog box or the Modify Cross-Site Request Forgery Tagging Check Relaxation dialog box.

**To configure a CSRF form tagging check relaxation by using the GUI**

1. Navigate to Security > Application Firewall > Profiles.
2. In the Profiles pane, select the profile you want to configure, and then click Open.
3. In the **Configure App Firewall Profile** dialog box, click the **Security Checks** tab. The **Security Checks** tab contains the list of App Firewall security checks.

4. To add or modify a CSRF relaxation, do one of the following:
   - To add a new relaxation, click **Add**.
   - To modify an existing relaxation, select the relaxation that you want to modify, and then click **Open**.

   The **Add Cross-Site Request Forgery Tagging Check Relaxation** or **Modify Cross-Site Request Forgery Tagging Check Relaxation** dialog box is displayed. Except for the title, these dialog boxes are identical.

5. Fill in the dialog box as described below.
   - **Enabled check box**—Select to place this relaxation or rule in active use; clear to deactivate it.
   - **Form Origin URL**—In the text area, enter a PCRE-format regular expression that defines the URL that hosts the form.
   - **Form Action URL**—In the text area, enter a PCRE-format regular expression that defines the URL to which data entered into the form is delivered.
   - **Comments**—In the text area, type a comment. Optional.

   **Note**: For any element that requires a regular expression, you can type the regular expression, use the **Regex Tokens** menu to insert regular expression elements and symbols directly into the text box, or click **Regex Editor** to open the **Add Regular Expression** dialog box, and use it to construct the expression.

6. Click **OK**. The **Add Cross-Site Request Forgery Tagging Check Relaxation** or **Modify Cross-Site Request Forgery Tagging Check Relaxation** dialog box closes and you return to the **Modify Cross-Site Request Forgery Tagging Check** dialog box.

7. To remove a relaxation or rule, select it, and then click **Remove**.

8. To enable a relaxation or rule, select it, and then click **Enable**.

9. To disable a relaxation or rule, select it, and then click **Disable**.

10. To configure the settings and relationships of all existing relaxations in an integrated interactive graphic display, click **Visualizer**, and use the display tools.

11. To review and configure learned rules for the CSRF check, click **Learning** and perform the steps in “To configure and use the Learning feature.”

12. Click **OK**.
**URL protection checks**

September 18, 2018

The URL Protection checks examine request URLs to prevent attackers from aggressively attempting to access multiple URLs (forceful browsing) or using a URL to trigger a known security vulnerability in web server software or web site scripts.

**Start URL check**

September 20, 2018

The Start URL check examines the URLs in incoming requests and blocks the connection attempt if the URL does not meet the specified criteria. To meet the criteria, the URL must match an entry in the Start URL list, unless the Enforce URL Closure parameter is enabled. If you enable this parameter, a user who clicks a link on your Web site is connected to the target of that link.

The primary purpose of the Start URL check is to prevent repeated attempts to access random URLs on a Web site, (forceful browsing) through bookmarks, external links, or jumping to pages by manually typing in the URLs to skip the pages required to reach that part of the website. Forceful browsing can be used to trigger a buffer overflow, find content that users were not intended to access directly, or find a back door into secure areas of your Web server. The App Firewall enforces a website’s given traversal or logic path by allowing access to only the URL’s that are configured as start URLs.

If you use the wizard or the GUI, in the Modify Start URL Check dialog box, on the General tab you can enable or disable Block, Log, Statistics, Learn actions, and the following parameters:

- **Enforce URL Closure.** Allow users to access any web page on your web site by clicking a hyperlink on any other page on your web site. Users can navigate to any page on your web site that can be reached from the home page or any designated start page by clicking hyperlinks.
  
  Note: The URL closure feature allows any query string to be appended to and sent with the action URL of a web form submitted by using the HTTP GET method. If your protected web sites use forms to access an SQL database, make sure that you have the SQL injection check enabled and properly configured.

- **Sessionless URL Closure.** From the client’s point of view, this type of URL closure functions in exactly the same way as standard, session-aware URL Closure, but uses a token embedded in the URL instead of a cookie to track the user’s activity, which consumes considerably fewer resources. When sessionless URL closure is enabled, the App Firewall appends a “as_url_id” tag to all the URL’s that are in URL closure.
  
  **Note:** When enabling sessionless (Sessionless URL Closure), you must also enable regular URL closure (Enforce URL Closure) or sessionless URL closure does not work.
• **Validate Referer Header.** Verify that the Referer header in a request that contains web form data from your protected web site instead of another web site. This action verifies that your web site, not an outside attacker, is the source of the web form. Doing so protects against cross-site request forgeries (CSRF) without requiring form tagging, which is more CPU-intensive than header checks. The App Firewall can handle the HTTP Referer header in one of the following four ways, depending on which option you select in the drop-down list:
  - **Off**—Do not validate the Referer header.
  - **If-Present**—Validate the Referer header if a Referer header exists. If an invalid Referer header is found, the request generates a referer-header violation. If no Referer header exists, the request does not generate a referer-header violation. This option enables the App Firewall to perform Referer header validation on requests that contain a Referer header, but not block requests from users whose browsers do not set the Referer header or who use web proxies or filters that remove that header.
  - **Always Except Start URLs**—Always validate the Referer header. If there is no Referer header and the requested URL is not exempted by the startURL relaxation rule, the request generates a referer-header violation. If the Referer header is present but it is invalid, the request generates a referer-header violation.
  - **Always Except First Request**—Always validate the referer header. If there is no referer header, only the URL that is accessed first is allowed. All other URL’s are blocked without a valid referer header. If the Referer header is present but it is invalid, the request generates a referer-header violation.

One Start URL setting, **Exempt Closure URLs from Security Checks**, is not configured in the Modify Start URL Check dialog box, but is configured in the Settings tab of the Profile. If enabled, this setting directs the App Firewall not to run further form based checks (such as Cross-Site Scripting and SQL Injection inspection) on URLs that meet the URL Closure criteria.

**Note**
Although the referer header check and Start URL security check share the same action settings, it is possible to violate the referer header check without violating the Start URL check. The difference is visible in the logs, which log referer header check violations separately from Start URL check violations.

The Referer header settings (OFF, if-Present, AlwaysExceptStartURLs, and AlwaysExceptFirstRequest) are arranged in order of least restrictive to most restrictive and work as follows:

**OFF:**
- Referer Header Not checked.

**If-Present:**
- Request has no referer header -> Request is allowed.
- Request has referer header and the referer URL is in URL closure -> Request is allowed.
- Request has referer header and the referer URL is **not** in URL closure -> Request is blocked.

**AlwaysExceptStartURLs:**
- Request has no referer header and the request URL is a start URL -> Request is allowed.
- Request has no referer header and the request URL is not a start URL -> Request is blocked.
- Request has referer header and the referer URL is in URL closure -> Request is allowed.
- Request has referer header and the referer URL is **not** in URL closure -> Request is blocked.

**AlwaysExceptFirstRequest:**
- Request has no referer header and is the first request URL of the session -> Request is allowed.
- Request has no referer header and is **not** the first request URL of the session -> Request is blocked.
- Request has referer header and is either the first request URL of the session or is in URL closure -> Request is allowed.
- Request has referer header and is neither the first request URL of the session nor is in URL closure -> Request is blocked.

If you use the command-line interface, you can enter the following commands to configure the Start URL Check:

- `set appfw profile <name> -startURLAction [block] [learn] [log] [stats] [none]`
- `set appfw profile <name> -startURLClosure ([ON] | [OFF])`
- `set appfw profile <name> -sessionlessURLClosure ([ON] | [OFF])`
- `set appfw profile <name> -exemptClosureURLsFromSecurityChecks ([ON] | [OFF])`
- `set appfw profile <name> -RefererHeaderCheck ([OFF] | [if-present] | [AlwaysExceptStartURLs] | [AlwaysExceptFirstRequest])`

To specify relaxations for the Start URL check, you must use the GUI. On the Checks tab of the Modify Start URL Check dialog box, click Add to open the Add Start URL Check Relaxation dialog box, or select an existing relaxation and click Open to open the Modify Start URL Check Relaxation dialog box. Either dialog box provides the same options for configuring a relaxation.

Following are examples of Start URL check relaxations:

- Allow users to access the home page at `www.example.com`:

  ```plaintext
  ^http://www[.]example[.]com$
  ```

- Allow users to access all static HTML (.htm and .html), server-parsed HTML (.htp and .shtml), PHP (.php), and Microsoft ASP (.asp) format web pages at `www.example.com`:

  ```plaintext
  ^http://www[.]example[.]com/([0-9A-Za-z][0-9A-Za-z-_]*/)*([0-9A-Za-z][0-9A-Za-z-_]*[.])(asp|htp|php)s?html?$
  ```

© 1999-2018 Citrix Systems, Inc. All rights reserved.
Allow users to access web pages with pathnames or file names that contain non-ASCII characters at www.example-español.com:

```
^http://www[.].example-espaxC3xB1ol[.].com/(([0-9A-Za-z][0-9A-Fa-f][0-9A-Za-z-_][0-9A-Za-z-][0-9A-Fa-f])*/x)
```

Note: In the above expression, each character class has been grouped with the string `x[0-9A-Fa-f][0-9A-Fa-f]`, which matches all properly-constructed character encoding strings but does not allow stray backslash characters that are not associated with a UTF-8 character encoding string. The double backslash (`\`) is an escaped backslash, which tells the App Firewall to interpret it as a literal backslash. If you included only one backslash, the App Firewall would instead interpret the following left square bracket `[` as a literal character instead of the opening of a character class, which would break the expression.

Allow users to access all GIF (.gif), JPEG (.jpg and .jpeg), and PNG (.png) format graphics at www.example.com:

```
^http://www[.].example[.].com/([0-9A-Za-z][0-9A-Za-z-][0-9A-Za-z-_][0-9A-Za-z-][0-9A-Fa-f])*hash
```

Allow users to access CGI (.cgi) and PERL (.pl) scripts, but only in the CGI-BIN directory:

```
^http://www[.].example[.].com/CGI-BIN/[0-9A-Za-z][0-9A-Za-z-][0-9A-Za-z-][0-9A-Fa-f]*[.]((cgi|pl))
```

Allow users to access Microsoft Office and other document files in the docsarchive directory:

```
^http://www[.].example[.].com/docsarchive/[0-9A-Za-z][0-9A-Za-z-][0-9A-Za-z-][0-9A-Fa-f]*[.]((doc|xls|pdf|ppt))
```

Note

By default, all App Firewall URLs are considered to be regular expressions.

Caution: Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions that you write. Make sure that they define exactly the URL you want to add as an exception, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (`.*`) metacharacter/wildcard combination, can have results you do
not want, such as blocking access to web content that you did not intend to block or allowing an attack that the Start URL check would otherwise have blocked.

Tip
You can add the -and- to the allowed list of SQL keywords for URL naming scheme. For example, example https://FQDN/bread-and-butter.

Deny URL check

September 20, 2018

The Deny URL check examines and blocks connections to URLs that are commonly accessed by hackers and malicious code. This check contains a list of URLs that are common targets of hackers or malicious code and that rarely if ever appear in legitimate requests. You can also add URLs or URL patterns to the list. The Deny URL check prevents attacks against various security weaknesses known to exist in web server software or on many web sites.

The Deny URL check takes priority over the Start URL check, and thus denies malicious connection attempts even when a Start URL relaxation would normally allow a request to proceed.

In the Modify Deny URL Check dialog box, on the General tab you can enable or disable the Block, Log, and Statistics actions.

If you use the command-line interface, you can enter the following command to configure the Deny URL Check:

```plaintext
set appfw profile <name> -denyURLAction [block] [log] [stats] [none]
```

To create and configure your own deny URLs, you must use the GUI. On the Checks tab of the Modify Deny URL Check dialog box, click Add to open the Add Deny URL dialog box, or select an existing user-defined deny URL and click Open to open the Modify Deny URL dialog box. Either dialog box provides the same options for creating and configuring a deny URL.

Following are examples of Deny URL expressions:

- Do not allow users to access the image server at images.example.com directly:

  ```plaintext
  ^http://images[.]example[.]com$
  ```

- Do not allow users to access CGI (.cgi) or PERL (.pl) scripts directly:

  ```plaintext
  ^http://www[.]example[.]com/([0-9A-Za-z][0-9A-Za-z_-]*)*/
  ^http://www[.]example[.]com/([0-9A-Za-z][0-9A-Za-z_-]*)*/(.)(cgi|pl)$
  ```

- Here is the same deny URL, modified to support non-ASCII characters:
XML protection checks

September 18, 2018

The XML Protection checks examine requests for XML-based attacks of all types.

Caution: The XML security checks apply only to content that is sent with an HTTP content-type header of text/xml. If the content-type header is missing, or is set to a different value, all XML security checks are bypassed. If you plan to protect XML or Web 2.0 web applications, the webmasters of each web server that hosts those applications should ensure that the proper HTTP content-type header is sent.

XML format check

September 18, 2018

The XML Format check examines the XML format of incoming requests and blocks those requests that are not well formed or that do not meet the criteria in the XML specification for properly-formed XML documents. Some of those criteria are:

- An XML document must contain only properly-encoded Unicode characters that match the Unicode specification.
- No special XML syntax characters—such as <, > and &—can be included in the document except when used in XML markup.
- All begin, end, and empty-element tags must be correctly nested, with none missing or overlapping.
- XML element tags are case-sensitive. All beginning and end tags must match exactly.
A single root element must contain all the other elements in the XML document.

A document that does not meet the criteria for well-formed XML does not meet the definition of an XML document. Strictly speaking, it is not XML. However, not all XML applications and web services enforce the XML well-formed standard, and not all handle poorly-formed or invalid XML correctly. Inappropriate handling of a poorly-formed XML document can cause security breaches. The purpose of the XML Format check is to prevent a malicious user from using a poorly-formed XML request to breach security on your XML application or web service.

If you use the wizard or the GUI, in the Modify XML Format Check dialog box, on the General tab you can enable or disable the Block, Log, and Statistics actions.

If you use the command-line interface, you can enter the following command to configure the XML Format Check:

```
set appfw profile <name> -xmlFormatAction [block] [log] [stats] [none]
```

You cannot configure exceptions to the XML Format check. You can only enable or disable it.

**XML denial-of-service check**

September 20, 2018

The XML Denial of Service (XML DoS or XDoS) check examines incoming XML requests to determine whether they match the characteristics of a denial-of-service (DoS) attack, and blocks those requests that do. The purpose of the XML DoS check is to prevent an attacker from using XML requests to launch a denial-of-service attack on your web server or web site.

If you use the wizard or the GUI, in the Modify XML Denial-of-Service Check dialog box, on the General tab you can enable or disable the Block, Log, Statistics, and Learn actions:

If you use the command-line interface, you can enter the following command to configure the XML Denial-of-Service check:

```
set appfw profile <name> -xmlDoSAction [block] [log] [learn] [stats] [none]
```

To configure individual XML Denial-of-Service rules, you must use the GUI. On the Checks tab of the Modify XML Denial-of-Service Check dialog box, select a rule and click Open to open the Modify XML Denial-of-Service dialog box for that rule. The individual dialog boxes differ for the different rules but are extremely simple. Some only allow you to enable or disable the rule; others allow you to modify a number by typing a new value in a text box.

The individual XML denial-of-service rules are:

- Maximum Element Depth
Restrict the maximum number of nested levels in each individual element to 256. If this rule is enabled, and the App Firewall detects an XML request with an element that has more than the maximum number of allowed levels, it blocks the request. You can modify the maximum number of levels to any value from one (1) to 65,535.

- **Maximum Element Name Length**

Restrict the maximum length of each element name to 128 characters. This includes the name within the expanded namespace, which includes the XML path and element name in the following format:

```plaintext
{ http://prefix.example.com/path/ } target_page.xml
```

The user can modify the maximum name length to any value between one (1) character and 65,535.

- **Maximum # Elements**

Restrict the maximum number of any one type of element per XML document to 65,535. You can modify the maximum number of elements to any value between one (1) and 65,535.

- **Maximum # Element Children**

Restrict the maximum number of children (including other elements, character information, and comments) each individual element is allowed to have to 65,535. You can modify the maximum number of element children to any value between one (1) and 65,535.

- **Maximum # Attributes**

Restrict the maximum number of attributes each individual element is allowed to have to 256. You can modify the maximum number of attributes to any value between one (1) and 256.

- **Maximum Attribute Name Length**

Restrict the maximum length of each attribute name to 128 characters. You can modify the maximum attribute name length to any value between one (1) and 2,048.

- **Maximum Attribute Value Length**

Restrict the maximum length of each attribute value to 2048 characters. You can modify the maximum attribute name length to any value between one (1) and 2,048.

- **Maximum Character Data Length**

Restrict the maximum character data length for each element to 65,535. You can modify the length to any value between one (1) and 65,535.
• Maximum File Size
  Restrict the size of each file to 20 MB. You can modify the maximum file size to any value.

• Minimum File Size
  Require that each file be at least 9 bytes in length. You can modify the minimum file size to any positive integer representing a number of bytes.

• Maximum # Entity Expansions
  Limit the number of entity expansions allowed to the specified number. Default: 1024.

• Maximum Entity Expansion Depth
  Restrict the maximum number of nested entity expansions to no more than the specified number. Default: 32.

• Maximum # Namespaces
  Limit the number of namespace declarations in an XML document to no more than the specified number. Default: 16.

• Maximum Namespace URI Length
  Limit the URL length of each namespace declaration to no more than the specified number of characters. Default: 256.

• Block Processing Instructions
  Block any special processing instructions included in the request. This rule has no user-modifiable values.

• Block DTD
  Block any document type definitions (DTD) included with the request. This rule has no user-modifiable values.

• Block External Entities
  Block all references to external entities in the request. This rule has no user-modifiable values.

• SOAP Array Check
  Enable or disable the following SOAP array checks:

  – **Maximum SOAP Array Size.** The maximum total size of all SOAP arrays in an XML request before the connection is blocked. You can modify this value. Default: 20000000.

  – **Maximum SOAP Array Rank.** The maximum rank or dimensions of any single SOAP array in an XML request before the connection is blocked. You can modify this value. Default: 16.
XML cross-site scripting check

September 20, 2018

The XML Cross-Site Scripting check examines the user requests for possible cross-site scripting attacks in the XML payload. If it finds a possible cross-site scripting attack, it blocks the request.

To prevent misuse of the scripts on your protected web services to breach security on your web services, the XML Cross-Site Scripting check blocks scripts that violate the same origin rule, which states that scripts should not access or modify content on any server but the server on which they are located. Any script that violates the same origin rule is called a cross-site script, and the practice of using scripts to access or modify content on another server is called cross-site scripting. The reason cross-site scripting is a security issue is that a web server that allows cross-site scripting can be attacked with a script that is not on that web server, but on a different web server, such as one owned and controlled by the attacker.

The App Firewall offers various action options for implementing XML Cross-Site Scripting protection. You have the option to configure Block, Log, and Stats actions.

The App Firewall XML XSS check is performed on the payload of the incoming requests and attack strings are identified even if they are spread over multiple lines. The check looks for XSS attack strings in the element and the attribute values. You can apply relaxations to bypass security check inspection under specified conditions. The logs and statistics can help you identify needed relaxations.

The CDATA section of the XML payload might be an attractive area of focus for the hackers because the scripts are not executable outside the CDATA section. A CDATA section is used for content that is to be treated entirely as character data. HTML mark up tag delimiters “<”, “>”, and “/” will not cause the parser to interpret the code as HTML elements. The following example shows a CDATA Section with XSS attack string:

```xml
1  <![CDATA[rn
2  <script language="Javascript" type="text/javascript">alert ("Got you")</script>rn
3  ]]>]
```

**Action Options**

An action is applied when the XML Cross-Site Scripting check detects an XSS attack in the request. The following options are available for optimizing XML Cross-Site Scripting protection for your application:

- **Block**—Block action is triggered if the XSS tags are detected in the request.
- **Log**—Generate log messages indicating the actions taken by the XML Cross-Site Scripting check. If block is disabled, a separate log message is generated for each location (ELEMENT,
ATTRIBUTE) in which the XSS violation is detected. However, only one message is generated when the request is blocked. You can monitor the logs to determine whether responses to legitimate requests are getting blocked. A large increase in the number of log messages can indicate attempts to launch an attack.

- **Stats**—Gather statistics about violations and logs. An unexpected surge in the stats counter might indicate that your application is under attack. If legitimate requests are getting blocked, you might have to revisit the configuration to see if you need to configure new relaxation rules or modify the existing ones.

**Relaxation Rules**

If your application requires you to bypass the Cross-Site Scripting check for a specific ELEMENT or ATTRIBUTE in the XML payload, you can configure a relaxation rule. The XML Cross-Site Scripting check relaxation rules have the following parameters:

- **Name**—You can use literal strings or regular expressions to configure the name of the ELEMENT or the Attribute. The following expression exempts all ELEMENTS beginning with the string name_ followed by a string of uppercase or lowercase letters, or numbers, that is at least two and no more than fifteen characters long:

```
^name_[0-9A-Za-z]{2,15}$
```

**Note**

The names are case sensitive. Duplicate entries are not allowed, but you can use capitalization of the names and differences in location to create similar entries. For example, each of the following relaxation rules is unique:

1) XMLXSS: ABC IsRegex: NOTREGEX Location: ATTRIBUTE State: ENABLED
2) XMLXSS: ABC IsRegex: NOTREGEX Location: ELEMENT State: ENABLED
3) XMLXSS: abc IsRegex: NOTREGEX Location: ELEMENT State: ENABLED
4) XMLXSS: abc IsRegex: NOTREGEX Location: ATTRIBUTE State: ENABLED

- **Location**—You can specify the Location of the Cross-site Scripting Check exception in your XML payload. The option ELEMENT is selected by default. You can change it to ATTRIBUTE.
- **Comment**—This is an optional field. You can use up to a 255 character string to describe the purpose of this relaxation Rule.
Warning

Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the name that you want to add as an exception, and nothing else. Careless use of Regular Expressions can have results that you do not want, such as blocking access to web content that you did not intend to block or allowing an attack that the XML Cross-Site Scripting check would otherwise have blocked.

Using the command line to configure the XML cross-site scripting check

To configure XML Cross-Site Scripting check actions and other parameters by using the command line

If you use the command-line interface, you can enter the following commands to configure the XML Cross-Site Scripting Check:

```bash
> set appfw profile <name> -XMLXSSAction (\[\{block\} [\{log\} [\{stats\}]] | \{none\})
```

To configure a XML Cross-Site Scripting check relaxation rule by using the command line

You can add relaxation rules to bypass inspection of XSS script attack inspection in a specific location.

Use the bind or unbind command to add or delete the relaxation rule binding, as follows:

```bash
> bind appfw profile <name> -XMLXSS <String> [isRegex (\{REGEX\} | \{NOTREGEX\})] [-location (\{ELEMENT\} | \{ATTRIBUTE\})] -comment <string> [-state (\{ENABLED\} | \{DISABLED\})]
```

```bash
> unbind appfw profile <name> -XMLXSS <String>
```

Example:

```bash
> bind appfw profile test_pr -XMLXSS ABC
```

After executing the above command, the following relaxation rule is configured. The rule is enabled, the name is treated as a literal (NOTREGEX), and ELEMENT is selected as the default location:

```
1)  XMLXSS:  ABC  IsRegex:  NOTREGEX
2   Location:  ELEMENT  State:  ENABLED
3
4  ‘> unbind appfw profile test_pr -XMLXSS abc‘
5
6  ERROR:  No such XMLXSS check
7
8  ‘> unbind appfw profile test_pr -XMLXSS ABC‘
9
10 Done
```
Using the GUI to configure the XML cross-site scripting check

In the GUI, you can configure the XML Cross-Site scripting check in the pane for the profile associated with your application.

To configure or modify the XML Cross-Site Scripting check by using the GUI

1. Navigate to App Firewall > Profiles, highlight the target profile, and click Edit.
2. In the Advanced Settings pane, click Security Checks.

The security check table displays the currently configured action settings for all the security checks. You have 2 options for configuration:

a) If you just want to enable or disable Block, Log, and Stats actions for the XML Cross-Site Scripting check, you can select or clear check boxes in the table, click OK, and then click Save and Close to close the Security Check pane.

b) You can double click XML Cross-Site Scripting, or select the row and click Action Settings, to display the action options. After changing any of the action settings, click OK to save the changes and return to the Security Checks table.

You can proceed to configure other security checks if needed. Click OK to save all the changes you have made in the Security Checks section, and then click Save and Close to close the Security Check pane.

To configure a XML Cross-Site Scripting relaxation rule by using the GUI

1. Navigate to App Firewall > Profiles, highlight the target profile, and click Edit.
2. In the Advanced Settings pane, click Relaxation Rules.
3. In the Relaxation Rules table, double-click the XML Cross-Site Scripting entry, or select it and click Edit.
4. In the XML Cross-Site Scripting Relaxation Rules dialogue box, perform Add, Edit, Delete, Enable, or Disable operations for relaxation rules.

To manage XML Cross-Site Scripting relaxation rules by using the visualizer

For a consolidated view of all the relaxation rules, you can highlight the XML Cross-Site Scripting row in the Relaxation Rules table, and click Visualizer. The visualizer for deployed relaxations offers you the option to Add a new rule or Edit an existing one. You can also Enable or Disable a group of rules by selecting a node and clicking the corresponding buttons in the relaxation visualizer.

To view or customize the Cross-Site Scripting patterns by using the GUI

You can use the GUI to view or customize the default list of XSS allowed attributes or allowed tags. You can also view or customize the default list of XSS denied Patterns.

The default lists are specified in App Firewall > Signatures > Default Signatures. If you do not bind any signature object to your profile, the default XSS Allowed and Denied list specified in the Default
Signatures object will be used by the profile for the Cross-Site Scripting security check processing. The Tags, Attributes, and Patterns, specified in the default signatures object, are read-only. You cannot edit or modify them. If you want to modify or change these, make a copy of the Default Signatures object to create a User-Defined signature object. Make changes in the Allowed or Denied lists in the new user-defined signature object and use this signature object in the profile that is processing the traffic for which you want to use these customized allowed and denied lists.

For more information about signatures, see Signatures.

To view default XSS patterns:

1. Navigate to App Firewall > Signatures, select Default Signatures, and click Edit. Then click Manage SQL/XSS Patterns.

The Manage SQL/XSS Paths table shows following three rows pertaining to XSS:

|   |  
|---|---|
| 1 | xss/allowed/attribute |
| 2 |  |
| 3 | xss/allowed/tag |
| 4 |  |
| 5 | xss/denied/pattern |

Select a row and click Manage Elements to display the corresponding XSS Elements (Tag, Attribute, Pattern) used by the App Firewall Cross-Site Scripting check.

To customize XSS Elements: You can edit the user-defined signature object to customize the allowed Tag, allowed Attributes and denied Patterns. You can add new entries or remove the existing ones.

1. Navigate to App Firewall > Signatures, highlight the target user-defined signature, and click Edit. Click Manage SQL/XSS Patterns to display the Manage SQL/XSS paths table.
2. Select the target XSS row.

a) Click Manage Elements, to Add, Edit or Remove the corresponding XSS element.

b) Click Remove to remove the selected row.

Warning

Be very careful when you remove or modify any default XSS element, or delete the XSS path to remove the entire row. The signatures, HTML Cross-Site Scripting security check, and XML Cross-Site Scripting security check rely on these Elements for detecting attacks to protect your applications. Customizing the XSS Elements can make your application vulnerable to Cross-Site Scripting attacks if the required pattern is removed during editing.
Using the log feature with the XML cross-site scripting check

When the log action is enabled, the XML Cross-Site Scripting security check violations are logged in the audit log as `APPFW_XML_XSS` violations. The App Firewall supports both Native and CEF log formats. You can also send the logs to a remote syslog server.

To access the log messages by using the command line

Switch to the shell and tail the ns.log in the `/var/log/` folder to access the log messages pertaining to the XML Cross-Site Scripting violations:

```
1 > Shell
2 > **tail -f /var/log/ns.log | grep APPFW_XML_XSS**
```

Example of a XML Cross-Site Scripting security check violation log message in Native log format showing `<blocked>` action

```
```

Example of a XML Cross-Site Scripting security check violation log message in CEF log format showing `<not blocked>` action

```
1 Oct  7 01:46:52 <local0.warn> 10.217.31.98 CEF:0|Citrix|NetScaler|NS11.0|APPFW|APPFW_XML_XSS|4|src=10.217.30.17 geolocation=Unknown spt=33141 method=GET request=http://10.217.31.101/FFC/login.html msg=Cross-site script check failed for field script="Bad tag: script" cn1=1607 cn2=3538 cs1=owa_profile cs2=PPE0 cs4=ERROR cs5=2015 act=** not blocked**
```

To access the log messages by using the GUI

The NetScaler GUI includes a useful tool (Syslog Viewer) for analyzing the log messages. You have multiple options for accessing the Syslog Viewer:

- Navigate to the App Firewall > Profiles, select the target profile, and click Security Checks. Highlight the XML Cross-Site Scripting row and click Logs. When you access the logs directly from the XML Cross-Site Scripting check of the profile, the GUI filters out the log messages and displays only the logs pertaining to these security check violations.

- You can also access the Syslog Viewer by navigating to NetScaler > System > Auditing. In the Audit Messages section, click the Syslog messages link to display the Syslog Viewer, which dis-
plays all log messages, including other security check violation logs. This is useful for debugging when multiple security check violations might be triggered during request processing.

- Navigate to App Firewall > policies > Auditing. In the Audit Messages section, click the Syslog messages link to display the Syslog Viewer, which displays all log messages, including other security check violation logs.

The XML based Syslog Viewer provides various filter options for selecting only the log messages that are of interest to you. To select log messages for the XML Cross-Site Scripting check, filter by selecting APPFW in the dropdown options for Module. The Event Type list offers a rich set of options to further refine your selection. For example, if you select the APPFW_XML_XSS check box and click the Apply button, only log messages pertaining to the XML Cross-Site Scripting security check violations appear in the Syslog Viewer.

If you place the cursor in the row for a specific log message, multiple options, such as Module, EventType, Event ID, Client IP etc. appear below the log message. You can select any of these options to highlight the corresponding information in the log message.

Statistics for the XML cross-site scripting violations

When the stats action is enabled, the counter for the XML Cross-Site Scripting check is incremented when the App Firewall takes any action for this security check. The statistics are collected for Rate and Total count for Traffic, Violations, and Logs. The size of an increment of the log counter can vary depending on the configured settings. For example, if the block action is enabled, a request for a page that contains three XML Cross-Site Scripting violations increments the stats counter by one, because the page is blocked as soon as the first violation is detected. However, if block is disabled, processing the same request increments the statistics counter for violations and the logs by three, because each violation generates a separate log message.

To display XML Cross-Site Scripting check statistics by using the command line

At the command prompt, type:

```
sh appfw stats
```

To display stats for a specific profile, use the following command:

```
stat appfw profile <profile name>
```

To display XML Cross-Site Scripting statistics by using the GUI

1. Navigate to System > Security > App Firewall.
2. In the right pane, access the Statistics Link.
3. Use the scroll bar to view the statistics about XML Cross-Site Scripting violations and logs. The statistics table provides real-time data and is updated every 7 seconds.
The XML SQL injection check examines the user requests for possible XML SQL Injection attacks. If it finds injected SQL in XML payloads, it blocks the requests.

A XML SQL attack can inject source code into a web application such that it can be interpreted and executed as a valid SQL query to perform a database operation with malicious intent. For example, XML SQL attacks can be launched to gain unauthorized access to the contents of a database or to manipulate the stored data. XML SQL Injection attacks are not only common, but can also be very harmful and costly.

Compartmentalizing the privileges of the database users can assist in protecting the database to some extent. All database users should be given only the required privileges to complete their intended tasks, so that they cannot execute SQL queries to perform other tasks. For example, a read-only user should not be allowed to write or manipulate data tables. The App Firewall XML SQL Injection check inspects all XML requests to provide special defenses against injection of unauthorized SQL code that might break security. If the App Firewall detects unauthorized SQL code in any XML request of any user, it can block the request.

The NetScaler App App Firewall inspects the presence of SQL keywords and special characters to identify the XML SQL Injection attack. A default set of keywords and special characters provides known keywords and special characters that are commonly used to launch XML SQL attacks. The App Firewall considers three characters, single straight quote (’), backslash (\), and semicolon (;) as special characters for SQL security check processing. You can add new patterns, and you can edit the default set to customize the XML SQL check inspection.

The App Firewall offers various action options for implementing XML SQL Injection protection. You can Block the request, Log a message in the ns.log file with details regarding the observed violations, and collect Stats to keep track of the number of observed attacks.

In addition to actions, there are several parameters that can be configured for XML SQL injection processing. You can check for SQL wildcard characters. You can change the XML SQL Injection type and select one of the 4 options (SQLKeyword, SQLSplChar, SQLSplCharANDKeyword, SQLSplCharORKeyword) to indicate how to evaluate the SQL keywords and SQL special characters when processing the XML payload. The XML SQL Comments Handling parameter gives you an option to specify the type of comments that need to be inspected or exempted during XML SQL Injection detection.

You can deploy relaxations to avoid false positives. The App Firewall XML SQL check is performed on the payload of the incoming requests, and attack strings are identified even if they are spread over multiple lines. The check looks for SQL Injection strings in the element and the attribute values. You can apply relaxations to bypass security check inspection under specified conditions.
statistics can help you identify needed relaxations.

**Action options**

An action is applied when the XML SQL Injection check detects an SQL Injection attack string in the request. The following actions are available for configuring an optimized XML SQL Injection protection for your application:

**Block**—If you enable block, the block action is triggered only if the input matches the XML SQL injection type specification. For example, if `SQLSplCharANDKeyword` is configured as the XML SQL injection type, a request is not blocked if it does not contain any key words, even if SQL special characters are detected in the payload. Such a request is blocked if the XML SQL injection type is set to either `SQLSplChar`, or `SQLSplCharORKeyword`.

**Log**—If you enable the log feature, the XML SQL Injection check generates log messages indicating the actions that it takes. If block is disabled, a separate log message is generated for each location (ELEMENT, ATTRIBUTE) in which the XML SQL violation was detected. However, only one message is generated when the request is blocked. You can monitor the logs to determine whether responses to legitimate requests are getting blocked. A large increase in the number of log messages can indicate attempts to launch an attack.

**Stats**—If enabled, the stats feature gathers statistics about violations and logs. An unexpected surge in the stats counter might indicate that your application is under attack. If legitimate requests are getting blocked, you might have to revisit the configuration to see if you need to configure new relaxation rules or modify the existing ones.

**XML SQL parameters**

In addition to the block, log and stats actions, you can configure the following parameters for XML SQL Injection check:

**Check for XML SQL wildcard Characters**—Wild card characters can be used to broaden the selections of a structured query language (SQL-SELECT) statement. These wild card operators can be used in conjunction with LIKE and NOT LIKE operators to compare a value to similar values. The percent (%), and underscore (_) characters are frequently used as wild cards. The percent sign is analogous to the asterisk (*) wildcard character used with MS-DOS and to match zero, one, or multiple characters in a field. The underscore is similar to the MS-DOS question mark (?) wildcard character. It matches a single number or character in an expression.

For example, you can use the following query to do a string search to find all customers whose names contain the D character.

```sql
SELECT * from customer WHERE name like "%D%"
```
The following example combines the operators to find any salary values that have 0 as the second and third character.

```sql
SELECT * FROM customer WHERE salary LIKE '%_00%
```

Different DBMS vendors have extended the wildcard characters by adding extra operators. The NetScaler App App Firewall can protect against attacks that are launched by injecting these wildcard characters. The 5 default Wildcard characters are percent (%), underscore (_), caret (^), opening square bracket ([), and closing square bracket (]). This protection applies to both HTML and XML profiles.

The default wildcard chars are a list of literals specified in the `*Default Signatures`:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><code>&lt;wildchar type=&quot;LITERAL&quot; &gt;%&lt;wildchar&gt;</code></td>
</tr>
<tr>
<td>2</td>
<td><code>&lt;wildchar type=&quot;LITERAL&quot; &gt;_&lt;wildchar&gt;</code></td>
</tr>
<tr>
<td>3</td>
<td><code>&lt;wildchar type=&quot;LITERAL&quot; &gt;^&lt;wildchar&gt;</code></td>
</tr>
<tr>
<td>4</td>
<td><code>&lt;wildchar type=&quot;LITERAL&quot; &gt;[&lt;wildchar&gt;</code></td>
</tr>
<tr>
<td>5</td>
<td><code>&lt;wildchar type=&quot;LITERAL&quot; &gt;]&lt;wildchar&gt;</code></td>
</tr>
</tbody>
</table>

Wildcard characters in an attack can be PCRE, like `^[A-F]`. The App Firewall also supports PCRE wildcards, but the literal wildcard chars above are sufficient to block most attacks.

**Note**

The XML SQL **wildcard character** check is different from the XML SQL **special character** check. This option must be used with caution to avoid false positives.

**Check Request Containing SQL Injection Type**—The App Firewall provides 4 options to implement the desired level of strictness for SQL Injection inspection, based on the individual need of the application. The request is checked against the injection type specification for detecting SQL violations. The 4 SQL injection type options are:

- **SQL Special Character and Keyword**—Both an SQL keyword and an SQL special character must be present in the inspected location to trigger SQL violation. This least restrictive setting is also the default setting.
- **SQL Special Character**—At least one of the special characters must be present in the processed payload string to trigger SQL violation.
- **SQL keyword**—At least one of the specified SQL keywords must be present in the processed payload string to trigger an SQL violation. Do not select this option without due consideration. To avoid false positives, make sure that none of the keywords are expected in the inputs.
- **SQL Special Character or Keyword**—Either the keyword or the special character string must be present in the payload to trigger the security check violation.

**Tip**

If you select the SQL Special Character option, the App Firewall skips strings that do not contain
any special characters. Since most SQL servers do not process SQL commands that are not preceded by a special character, enabling this option can significantly reduce the load on the App Firewall and speed up processing without placing your protected web sites at risk.

**SQL comments handling**—By default, the App Firewall parses and checks all comments in XML data for injected SQL commands. Many SQL servers ignore anything in a comment, even if preceded by an SQL special character. For faster processing, if your XML SQL server ignores comments, you can configure the App Firewall to skip comments when examining requests for injected SQL. The XML SQL comments handling options are:

- **ANSI**—Skip ANSI-format SQL comments, which are normally used by UNIX-based SQL databases.
- **Nested**—Skip nested SQL comments, which are normally used by Microsoft SQL Server.
- **ANSI/Nested**—Skip comments that adhere to both the ANSI and nested SQL comment standards. Comments that match only the ANSI standard, or only the nested standard, are still checked for injected SQL.
- **Check all Comments**—Check the entire request for injected SQL, without skipping anything. This is the default setting.

**Tip**

In most cases, you should not choose the Nested or the ANSI/Nested option unless your back-end database runs on Microsoft SQL Server. Most other types of SQL server software do not recognize nested comments. If nested comments appear in a request directed to another type of SQL server, they might indicate an attempt to breach security on that server.

**Relaxation rules**

If your application requires you to bypass the XML SQL Injection inspection for a specific ELEMENT or ATTRIBUTE in the XML payload, you can configure a relaxation rule. The XML SQL Injection inspection relaxation rules have the following parameters:

- **Name**: You can use literal strings or regular expressions to configure the name of the ELEMENT or the ATTRIBUTE. The following expression exempts all ELEMENTS beginning with the string `PurchaseOrder_` followed by a string of numbers that is at least two and no more than ten characters long:

  Comment: “Exempt XML SQL Check for Purchase Order Elements”

  ```
  1  XMLSQLInjection: "PurchaseOrder_[0-9A-Za-z]{2,10}"
  2  "  
  3  
  4  
  5  IsRegex: REGEX     Location: ELEMENT
  ```
Note: The names are case sensitive. Duplicate entries are not allowed, but you can use capitalization of the names and differences in location to create similar entries. For example, each of the following relaxation rules is unique:

<table>
<thead>
<tr>
<th></th>
<th>XMLSQLInjection:</th>
<th>Location:</th>
<th>State:</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>XYZ</td>
<td>ELEMENT</td>
<td>ENABLED</td>
</tr>
<tr>
<td>2</td>
<td>xy</td>
<td>ELEMENT</td>
<td>ENABLED</td>
</tr>
<tr>
<td>3</td>
<td>xyz</td>
<td>ATTRIBUTE</td>
<td>ENABLED</td>
</tr>
<tr>
<td>4</td>
<td>XYZ</td>
<td>ATTRIBUTE</td>
<td>ENABLED</td>
</tr>
</tbody>
</table>

- **Location**: You can specify the Location of the XML SQL Inspection exception in your XML payload. The option **ELEMENT** is selected by default. You can change it to **ATTRIBUTE**.
- **Comment**: This is an optional field. You can use up to a 255 character string to describe the purpose of this relaxation Rule.

**Warning**

Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the name that you want to add as an exception, and nothing else. Careless use of Regular Expressions can have results that you do not want, such as blocking access to web content that you did not intend to block or allowing an attack that the XML SQL Injection inspection would otherwise have blocked.

**Using the command line to configure the XML SQL Injection Check**

**To configure XML SQL Injection actions and other parameters by using the command line:**

In the command line interface, you can use either the `set appfw profile` command or the `add appfw profile` command to configure the XML SQL Injection protections. You can enable the block, log, and stats action(s). Select the type of SQL attack pattern (key words, wildcard characters, special strings)
you want to detect in the payloads. Use the `unset appfw profile` command to revert the configured settings back to their defaults. Each of the following commands sets only one parameter, but you can include multiple parameters in a single command:

- `set appfw profile <name> **-XMLSQLInjectionAction** ([block] [log] [stats]) [none])`
- `set appfw profile <name> -XMLSQLInjectionCheckSQLWildChars (ON |OFF)`
- `set appfw profile <name> -XMLSQLInjectionType ([SQLKeyword] | [SQLSplChar] | [SQLSplCharANDKeyword] | [SQLSplCharORKeyword])`
- `set appfw profile <name> -XMLSQLInjectionParseComments ([checkall] | [ansi|nested] | [ansinested])`

To configure a SQL Injection relaxation rule by using the command line

Use the `bind` or `unbind` command to add or delete relaxation rules, as follows:

```
1 - bind appfw profile <name> -XMLSQLInjection <string> [isRegex (REGEX | NOTREGEX)] [-location (ELEMENT | ATTRIBUTE)] -comment <string> [-state (ENABLED | DISABLED )]
2 - unbind appfw profile <name> -XMLSQLInjection <String>
```

Example:

```
1 > bind appfw profile test_profile -XMLSQLInjection "PurchaseOrder_[0-9A-Za-z]{{2,15}"
2 2,15 }
3 " -isregex REGEX -location ATTRIBUTE
4
5 > unbind appfw profile test_profile -XMLSQLInjection "PurchaseOrder_[0-9A-Za-z]{{2,15}"
6 2,15 }
7 " -location ATTRIBUTE
```

**Using the GUI to configure the XMLSQL injection security check**

In the GUI, you can configure the XML SQL Injection security check in the pane for the profile associated with your application.

To configure or modify the XML SQL Injection check by using the GUI

1. Navigate to **App Firewall > Profiles**, highlight the target profile, and click **Edit**.
2. In the Advanced Settings pane, click **Security Checks**.

The security check table displays the currently configured action settings for all the security checks. You have 2 options for configuration:
a. If you just want to enable or disable Block, Log, and Stats actions for XML SQL Injection, you can select or clear check boxes in the table, click OK, and then click Save and Close to close the Security Check pane.

b. If you want to configure additional options for this security check, double click XML SQL Injection, or select the row and click **Action Settings**, to display the following options:

Check for SQL Wildcard Characters—Consider SQL Wildcard characters in the payload to be attack patterns.

Check Request Containing—Type of SQL injection (SQLKeyword, SQLSplChar, SQLSplCharANDKeyword, or SQLSplCharORKeyword) to check.

SQL Comments Handling—Type of comments (Check All Comments, ANSI, Nested, or ANSI/Nested) to check.

After changing any of the above settings, click **OK** to save the changes and return to the Security Checks table. You can proceed to configure other security checks if needed. Click **OK** to save all the changes you have made in the Security Checks section, and then click **Save** and **Close** to close the Security Check pane.

To configure a XML SQL Injection relaxation rule by using the GUI:

1. Navigate to **App Firewall > Profiles**, highlight the target profile, and click **Edit**.
2. In the **Advanced Settings** pane, click **Relaxation Rules**.
3. In the Relaxation Rules table, double-click the **XML SQL Injection** entry, or select it and click **Edit**.
4. In the **XMLSQLInjectionRelaxationRules** dialogue box, perform **Add**, **Edit**, **Delete**, **Enable**, or **Disable** operations for relaxation rules.

To manage XML SQL Injection relaxation rules by using the visualizer

For a consolidated view of all the relaxation rules, you can highlight the **XML SQL Injection** row in the Relaxation Rules table, and click **Visualizer**. The visualizer for deployed relaxations offers you the option to **Add** a new rule or **Edit** an existing one. You can also **Enable** or **Disable** a group of rules by selecting a node and clicking the corresponding buttons in the relaxation visualizer.

**To view or customize the SQL Injection patterns by using the GUI:**

You can use the GUI to view or customize the SQL patterns.

The default SQL patterns are specified in **App Firewall > Signatures > *Default Signatures**. If you do not bind any signature object to your profile, the default SQL patterns specified in the Default Signatures object will be used by the profile for XML SQL Injection security check processing. The rules and patterns in the Default Signatures object are read-only. You cannot edit or modify them. If you want to modify or change these patterns, create a user-defined signature object by making a copy of the Default Signatures object and changing the SQL patterns. Use the user-defined signature object in the profile that processes the traffic for which you want to use these customized SQL patterns.
For more information, see Signatures.

To view default SQL patterns:

a. Navigate to App Firewall > Signatures, select *Default Signatures*, and click Edit. Then click Manage SQL/XSS Patterns.

The Manage SQL/XSS Paths table shows following four rows pertaining to SQL Injection:

<table>
<thead>
<tr>
<th></th>
<th>Injection (not_alphanum, SQL)/ Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>Injection (not_alphanum, SQL)/ specialstring</td>
</tr>
<tr>
<td>4</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>Injection (not_alphanum, SQL)/ transformrules/transform</td>
</tr>
<tr>
<td>6</td>
<td></td>
</tr>
<tr>
<td>7</td>
<td>Injection (not_alphanum, SQL)/ wildcard</td>
</tr>
</tbody>
</table>

b. Select a row and click Manage Elements to display the corresponding SQL patterns (keywords, special strings, transformation rules or the wildcard characters) used by the App Firewall SQL injection check.

To customize SQL Patterns: You can edit a user-defined signature object to customize the SQL key words, special strings, and wildcard characters. You can add new entries or remove the existing ones. You can modify the transformation rules for the SQL special strings.

a. Navigate to App Firewall > Signatures, highlight the target user-defined signature, and click Edit. Click Manage SQL/XSS Patterns to display the Manage SQL/XSS paths table.

b. Select the target SQL row.

i. Click Manage Elements, to Add, Edit or Remove the corresponding SQL element.

ii. Click Remove to remove the selected row.

Warning

You must be very careful when removing or modifying any default SQL element, or deleting the SQL path to remove the entire row. The signature rules as well as the XML SQL Injection security check rely on these elements for detecting SQL Injection attacks to protect your applications. Customizing the SQL patterns can make your application vulnerable to XML SQL attacks if the required pattern is removed during editing.

Using the log feature with the XML SQL injection check

When the log action is enabled, the XML SQL Injection security check violations are logged in the audit log as APPFW_XML_SQL violations. The App Firewall supports both Native and CEF log formats. You can also send the logs to a remote syslog server.
To access the log messages by using the command line:

Switch to the shell and tail the ns.logs in the /var/log/ folder to access the log messages pertaining to the XML Cross-Site Scripting violations:

1 > Shell
2 > tail -f /var/log/ns.log | grep APPFW_XML_SQL

To access the log messages by using the GUI

The NetScaler GUI includes a useful tool (Syslog Viewer) for analyzing the log messages. You have multiple options for accessing the Syslog Viewer:

- Navigate to App Firewall > Profiles, select the target profile, and click Security Checks. Highlight the XML SQL Injection row and click Logs. When you access the logs directly from the XML SQL Injection check of the profile, the GUI filters out the log messages and displays only the logs pertaining to these security check violations.

- You can also access the Syslog Viewer by navigating to System > Auditing. In the Audit Messages section, click the Syslog messages link to display the Syslog Viewer, which displays all log messages, including other security check violation logs. This is useful for debugging when multiple security check violations might be triggered during request processing.

- Navigate to App Firewall > Policies > Auditing. In the Audit Messages section, click the Syslog messages link to display the Syslog Viewer, which displays all log messages, including other security check violation logs.

The XML based Syslog Viewer provides various filter options for selecting only the log messages that are of interest to you. To select log messages for the XML SQL Injection check, filter by selecting APPFW in the dropdown options for Module. The Event Type list offers a rich set of options to further refine your selection. For example, if you select the APPFW_XML_SQL check box and click the Apply button, only log messages pertaining to the XML SQL Injection security check violations appear in the Syslog Viewer.

If you place the cursor in the row for a specific log message, multiple options, such as Module, Event Type, Event ID, and Client IP appear below the log message. You can select any of these options to highlight the corresponding information in the log message.

Statistics for the XML SQL injection violations

When the stats action is enabled, the counter for the XML SQL Injection check is incremented when the App Firewall takes any action for this security check. The statistics are collected for Rate and Total count for Traffic, Violations, and Logs. The size of an increment of the log counter can vary depending on the configured settings. For example, if the block action is enabled, a request for a page that
NetScaler 12.0

contains three XML SQL Injection violations increments the stats counter by one, because the page is blocked as soon as the first violation is detected. However, if block is disabled, processing the same request increments the statistics counter for violations and the logs by three, because each violation generates a separate log message.

To display XML SQL Injection check statistics by using the command line

At the command prompt, type:

> sh appfw stats

To display stats for a specific profile, use the following command:

> stat appfw profile <profile name>

To display XML SQL Injection statistics by using the GUI

1. Navigate to System > Security > App Firewall.
2. In the right pane, access the Statistics Link.
3. Use the scroll bar to view the statistics about XML SQL Injection violations and logs. The statistics table provides real-time data and is updated every 7 seconds.

XML attachment check

September 20, 2018

The XML Attachment check examines incoming requests for malicious attachments, and it blocks those requests that contain attachments that might breach applications security. The purpose of the XML Attachment check is to prevent an attacker from using an XML attachment to breach security on your server.

If you use the wizard or the GUI, in the Modify XML Attachment Check dialog box, on the General tab you can enable or disable the Block, Learn, Log, Statistics, and Learn actions:

If you use the command-line interface, you can enter the following command to configure the XML Attachment Check:

• `set appfw profile <name> -xmlAttachmentAction [block] [learn] [log] [stats] [none]`

You must configure the other XML Attachment check settings in the GUI. In the Modify XML Attachment Check dialog box, on the Checks tab, you can configure the following settings:

• Maximum Attachment Size. Allow attachments that are no larger than the maximum attachment size you specify. To enable this option, first select the Enabled check box, and then type the maximum attachment size in bytes in the Size text box.
• **Attachment Content Type.** Allow attachments of the specified content type. To enable this option, first select the Enabled check box, and then enter a regular expression that matches the Content-Type attribute of the attachments that you want to allow.
  - You can type the URL expression directly in the text window. If you do so, you can use the Regex Tokens menu to enter a number of useful regular expressions at the cursor instead of typing them manually.
  - You can click Regex Editor to open the Add Regular Expression dialog box and use it to construct the URL expression.

**Web services interoperability check**

September 18, 2018

The Web Services Interoperability (WS-I) check examines both requests and responses for adherence to the WS-I standard, and blocks those requests and responses that do not adhere to this standard. The purpose of the WS-I check is to block requests that might not interact with other XML appropriately. An attacker can use inconsistencies in interoperability to launch an attack on your XML application.

If you use the wizard or the GUI, in the Modify Web Services Interoperability Check dialog box, on the General tab you can enable or disable the Block, Log, Statistics, and Learn actions.

If you use the command-line interface, you can enter the following command to configure the Web Services Interoperability check:

```
set appfw profile <name> -xmlWSIAction [block] [log] [learn] [stats] [none]
```

To configure individual Web Services Interoperability rules, you must use the GUI. On the Checks tab of the Modify Web Services Interoperability Check dialog box, select a rule and click Enable or Disable to enable or disable the rule. You can also click Open to open the Web Services Interoperability Detail message box for that rule. The message box displays read-only information about the rule. You cannot modify or make other configuration changes to any of these rules.

The WS-I check uses the rules listed in WS-I Basic Profile 1.0. WS-I delivers best practices for developing interoperable Web Services solutions. WS-I checks are performed only on SOAP Messages.

Description of each WSI standard rule is provided below:

<table>
<thead>
<tr>
<th>Rule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BP1201</td>
<td>Message body should be a soap:envelope with namespace.</td>
</tr>
<tr>
<td>Rule</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>R1000</td>
<td>When an ENVELOPE is a Fault, the soap:Fault element MUST NOT have element children other than faultcode, faultstring, faultactor and detail.</td>
</tr>
<tr>
<td>R1001</td>
<td>When an ENVELOPE is a Fault, the element children of the soap:Fault element MUST be unqualified.</td>
</tr>
<tr>
<td>R1003</td>
<td>A RECEIVER MUST accept fault messages that have any number of qualified or unqualified attributes, including zero, appearing on the detail element. The namespace of qualified attributes can be anything other than the namespace of the qualified document element Envelope.</td>
</tr>
<tr>
<td>R1004</td>
<td>When an ENVELOPE contains a faultcode element, the content of that element SHOULD be either one of the fault codes defined in SOAP 1.1 (supplying additional information if necessary in the detail element), or a QName whose namespace is controlled by the fault’s specifying authority (in that order of preference).</td>
</tr>
<tr>
<td>R1005</td>
<td>An ENVELOPE MUST NOT contain soap:encodingStyle attribute on any of the elements whose namespace is the same as the namespace of the qualified document element Envelope.</td>
</tr>
<tr>
<td>R1006</td>
<td>An ENVELOPE MUST NOT contain soap:encodingStyle attributes on any element that is a child of soap:Body.</td>
</tr>
<tr>
<td>R1007</td>
<td>An ENVELOPE described in an rpc-literal binding MUST NOT contain soap:encodingStyle attribute on any element that is a grandchild of soap:Body.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Rule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>R1011</td>
<td>An ENVELOPE MUST NOT have any element children of soap:Envelope following the soap:Body element.</td>
</tr>
<tr>
<td>R1012</td>
<td>A MESSAGE MUST be serialized as either UTF-8 or UTF-16.</td>
</tr>
<tr>
<td>R1013</td>
<td>An ENVELOPE containing a soap:mustUnderstand attribute MUST only use the lexical forms 0 and 1.</td>
</tr>
<tr>
<td>R1014</td>
<td>The children of the soap:Body element in an ENVELOPE MUST be namespace qualified.</td>
</tr>
<tr>
<td>R1015</td>
<td>A RECEIVER MUST generate a fault if they encounter an envelope whose document element is not soap:Envelope.</td>
</tr>
<tr>
<td>R1031</td>
<td>When an ENVELOPE contains a faultcode element the content of that element SHOULD NOT use of the SOAP 1.1 dot notation to refine the meaning of the fault.</td>
</tr>
<tr>
<td>R1032</td>
<td>The soap:Envelope, soap:Header, and soap:Body elements in an ENVELOPE MUST NOT have attributes in the same namespace as that of the qualified document element Envelope.</td>
</tr>
<tr>
<td>R1109</td>
<td>The value of the SOAPAction HTTP header field in a HTTP request MESSAGE MUST be a quoted string.</td>
</tr>
<tr>
<td>R1111</td>
<td>An INSTANCE SHOULD use a 200 OK HTTP status code on a response message that contains an envelope that is not a fault.</td>
</tr>
<tr>
<td>R1126</td>
<td>An INSTANCE MUST return a 500 Internal Server Error HTTP status code if the response envelope is a Fault.</td>
</tr>
</tbody>
</table>
## NetScaler 12.0

<table>
<thead>
<tr>
<th>Rule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>R1132</td>
<td>A HTTP request MESSAGE MUST use the HTTP POST method.</td>
</tr>
<tr>
<td>R1140</td>
<td>A MESSAGE SHOULD be sent using HTTP/1.1.</td>
</tr>
<tr>
<td>R1141</td>
<td>A MESSAGE MUST be sent using either HTTP/1.1 or HTTP/1.0.</td>
</tr>
<tr>
<td>R2113</td>
<td>An ENVELOPE MUST NOT include the soapenc:arrayType attribute.</td>
</tr>
<tr>
<td>R2211</td>
<td>An ENVELOPE described with an rpc-literal binding MUST NOT have the xsi:nil attribute with a value of 1 or true on the part accessors.</td>
</tr>
<tr>
<td>R2714</td>
<td>For one-way operations, an INSTANCE MUST NOT return a HTTP response that contains an envelope. Specifically, the HTTP response entity-body must be empty.</td>
</tr>
<tr>
<td>R2729</td>
<td>An ENVELOPE described with an rpc-literal binding that is a response MUST have a wrapper element whose name is the corresponding wsdl:operation name suffixed with the stringResponse.</td>
</tr>
<tr>
<td>R2735</td>
<td>An ENVELOPE described with an rpc-literal binding MUST place the part accessor elements for parameters and return value in no namespace.</td>
</tr>
<tr>
<td>R2738</td>
<td>An ENVELOPE MUST include all soapbind:headers specified on a wsdl:input or wsdl:output of a wsdl:operation of a wsdl:binding that describes it.</td>
</tr>
<tr>
<td>R2740</td>
<td>A wsdl:binding in a DESCRIPTION SHOULD contain a soapbind:fault describing each known fault.</td>
</tr>
<tr>
<td>R2744</td>
<td>A HTTP request MESSAGE MUST contain a SOAPAction HTTP header field with a quoted value equal to the value of the soapAction attribute of soapbind:operation, if present in the corresponding WSDL description.</td>
</tr>
</tbody>
</table>
XML message validation check

September 20, 2018

The XML Message Validation check examines requests that contain XML messages to ensure that they are valid. If a request contains an invalid XML message, the App Firewall blocks the request. The purpose of the XML Validation check is to prevent an attacker from using specially constructed invalid XML messages to breach the security of your application.

If you use the wizard or the GUI, in the Modify XML Message Validation Check dialog box, on the General tab you can enable or disable the Block, Log, and Statistics actions.

If you use the command-line interface, you can enter the following command to configure the XML Message Validation Check:

```bash
set appfw profile <name> -xmlValidationAction [block] [log] [stats] [none]
```

You must use the GUI to configure the other XML Validation check settings. In the Modify XML Message Validation Check dialog box, on the Checks tab, you can configure the following settings:

- **XML Message Validation.** Use one of the following options to validate the XML message:
  - **SOAP Envelope.** Validate only the SOAP envelope of XML messages.
  - **WSDL.** Validate XML messages by using an XML SOAP WSDL. If you choose WSDL validation, in the WSDL Object drop-down list you must choose a WSDL. If you want to validate against a WSDL that has not already been imported to the App Firewall, you can click the Import button to open the Manage WSDL Imports dialog box and import your WSDL. See “WSDL topic” for more information.
    * If you want to validate the entire URL, leave the Absolute radio button in the End Point Check button array selected. If you want to validate only the portion of the URL after the host, select the Relative radio button.
    * If you want the App Firewall to enforce the WSDL strictly, and not allow any additional XML headers not defined in the WSDL, you must clear the Allow additional headers not defined in the WSDL check box.
  Caution: If you uncheck the Allow Additional Headers not defined in the WSDL check box, and your WSDL does not define all XML headers that your protected XML application or Web 2.0 application expects or that a client sends, you may block legitimate access to your protected service.
  - **XML Schema.** Validate XML messages by using an XML schema. If you choose XML schema validation, in the XML Schema Object drop-down list you must choose an XML schema. If you want to validate against an XML schema that has not already been imported to the App
Firewall, you can click the Import button to open the Manage XML Schema Imports dialog box and import your WSDL. See WSDL for more information.

- **Response Validation.** By default, the App Firewall does not attempt to validate responses. If you want to validate responses from your protected application or Web 2.0 site, select the Validate Response check box. When you do, the Reuse the XML Schema specified in request validation check box and the XML Schema Object drop-down list are activated.
  - Check the Reuse XML Schema check box to use the schema you specified for request validation to do response validation as well.
  - If you want to use a different XML schema for response validation, use the XML Schema Object drop-down list to select or upload that XML schema.

**XML SOAP fault filtering check**

September 18, 2018

The XML SOAP fault filtering check examines responses from your protected web services and filters out XML SOAP faults. This prevents leaking of sensitive information to attackers.

If you use the wizard or the GUI, in the Modify XML SOAP Fault Filtering Check dialog box, on the General tab you can enable or disable the Block, Log, and Statistics actions, and the Remove action, which removes SOAP faults before forwarding the response to the user.

If you use the command-line interface, you can enter the following command to configure the XML SOAP Fault Filtering Check:

```
set appfw profile <name> -XMLSOAPFaultAction [block] [log] [stats] [none]
```

You cannot configure exceptions to the XML SOAP Fault Filtering check. You can only enable or disable it.

**Managing content types**

October 4, 2018

Web servers usually add a Content-Type header that contains a MIME/type definition for the type of content in each file that the web server serves to users. Web servers serve many different types of content. For example, standard HTML is assigned the “text/html” MIME type. JPG images are assigned the “image/jpeg” or “image/jpg” content type. A normal web server can serve dozens or hundreds of different types of content, all defined in the Content Type header by an assigned MIME/type.
Many App Firewall filtering rules are designed to filter specific types of content. Because filtering rules that apply to one type of content (such as HTML) are often inappropriate when filtering a different type of content (such as images), the App Firewall attempts to determine the content type of requests and responses before it filters them. When a web server or browser does not add a Content-Type header to a request or response, the App Firewall applies a default content type to the connection and filters the content accordingly.

The default content type is normally “application/octet-stream”, the most generic MIME/type definition. This MIME/type is appropriate for any type of content that a web server is likely to serve, but also does not provide much information to the App Firewall to allow it to choose appropriate filtering. If a protected web server on your network is configure to add accurate content type headers to the content it serves, or serves only one type of content, you can create a profile for that web server and assign a different default content type to it to improve both the speed and the accuracy of filtering.

You can also configure a list of allowed request content types for a specific profile. When this feature is configured, if the App Firewall filters a request that does not match one of the allowed content types, it blocks the request. After upgrade from release 10.5 to 11.0, unknown content-types which are not in the default allowed content-type list do not bind. You can add other content-types which you want to be allowed to the relaxed rules.

Requests must always be of either the “application/x-www-form-urlencoded”, “multipart/form-data”, or “text/x-gwt-rpc” types. The App Firewall blocks any request that has any other content type designated.

**Note**

You cannot include the “application/x-www-form-urlencoded” or “multipart/form-data” content types on the allowed response content types list.

### To set the default request content type by using the command line interface

At the command prompt, type the following commands:

- `set appfw profile <name> -requestContentType <type>`
- `save ns config`

**Example**

The following example sets the “text/html” content type as the default for the specified profile:

```
1 set appfw profile profile1 -requestContentType "text/html"
2 save ns config
```
To remove the user-defined default request content type by using the command line interface

At the command prompt, type the following commands:

- `unset appfw profile <name> -requestContentType <type>`
- `save ns config`

Example

The following example unsets the default content type of “text/html” for the specified profile, allowing the type to revert to “application/octet-stream”:

```
1  unset appfw profile profile1 -requestContentType "text/html"
2  save ns config
```

Note

Always use last content-type header for processing and remove remaining content-type headers if any that ensures that the backend server receives a request with only one content-type.

To block requests that can be bypassed, add an App Firewall policy with rule as HTTP.REQ.HEADER (“content-type”).COUNT.GT(1)’ and profile as appfw_block.

If a request is received without a Content-Type header or if the request has Content-Type header without any value, App Firewall applies the configured RequestContentType value and processes the request accordingly.

To set the default response content type by using the command line interface

At the command prompt, type the following commands:

- `set appfw profile <name> -responseContentType <type>`
- `save ns config`

Example

The following example sets the “text/html” content type as the default for the specified profile:

```
1  set appfw profile profile1 -responseContentType "text/html"
2  save ns config
```
To remove the user-defined default response content type by using the command line interface

At the command prompt, type the following commands:

- `unset appfw profile <name> -responseContentType <type>`
- `save ns config`

**Example**

The following example unsets the default content type of “text/html” for the specified profile, allowing the type to revert to “application/octet-stream”:

```
1 unset appfw profile profile1 -responseContentType "text/html"
2 save ns config
```

To add a content type to the allowed content types list by using the command line interface

At the command prompt, type the following commands:

- `bind appfw profile <name> -ContentType <contentTypeName>`
- `save ns config`

**Example**

The following example adds the “text/shtml” content type to the allowed content types list for the specified profile:

```
1 bind appfw profile profile1 -contentType "text/shtml"
2 save ns config
```

To remove a content type from the allowed content types list by using the command line interface

At the command prompt, type the following commands:

- `unbind appfw profile <name> -ContentType <contentTypeName>`
- `save ns config`
Example

The following example removes the “text/shtml” content type from the allowed content types list for the specified profile:

```
1  unbind appfw profile profile1 -contentType "text/shtml"
2  save ns config
```

To manage the default and allowed content types by using the GUI

1. Navigate to Security > App Firewall > Profiles.
2. In the details pane, select the profile that you want to configure, and then click Edit. The Configure App Firewall Profile dialog box is displayed.
3. The Configure App Firewall Profile dialog box, click the Settings tab.
4. On the Settings tab, scroll down about halfway to the Content Type area.
5. In the Content Type area, configure the default request or response content type:
   - To configure the default request content type, type the MIME/type definition of the content type you want to use in the Default Request text box.
   - To configure the default response content type, type the MIME/type definition of the content type you want to use in the Default Response text box.
   - To create a new allowed content type, click Add. The Add Allowed Content Type dialog box is displayed.
   - To edit an existing allowed content type, select that content type, and then click Open. The Modify Allowed Content Type dialog box is displayed.
6. To manage the allowed content types, click Manage Allowed Content Types.
7. To add a new content type or modify an existing content type, click Add or Open, and in the Add Allowed Content Type or Modify Allowed Content Type dialog box, do the following steps.
   a) Select/clear the Enabled check box to include the content type in, or exclude it from, the list of allowed content types.
   b) In the Content Type text box, type a regular expression that describes the content type that you want to add, or change the existing content type regular expression. Content types are formatted exactly as MIME type descriptions are.
      
      **Note:** You can include any valid MIME type on the allowed contents type list. Since many types of document can contain active content and therefore could potentially contain malicious content, you should exercise caution when adding MIME types to this list.
   c) In the Comments text box, add an optional comment that describes the reason for adding this particular MIME type to the allowed contents type list.
   d) Click Create or OK to save your changes.
8. Click **Close** to close the Manage Allowed Content Types dialog box and return to the **Settings** tab.
9. Click **OK** to save your changes.

Profiles

September 18, 2018

A profile is a collection of security settings that are used to protect specific types of web content or specific parts of your web site. In a profile, you determine how the App Firewall applies each of its filters (or checks) to requests to your web sites, and responses from them. The App Firewall supports two types of profile: four built-in (default) profiles that do not require further configuration, and user-defined profiles that do require further configuration.

Built-in profiles

The four App Firewall built-in profiles provide simple protection for applications and web sites that either do not require protection, or that should not be directly accessed by users at all. These profile types are:

- **APPFW_BYPASS.** Skips all App Firewall filtering and sends the unmodified traffic to the protected application or web site, or to the client.
- **APPFW_RESET.** Resets the connection, requiring that the client re-establish his or her session by visiting a designated start page.
- **APPFW_DROP.** Drops all traffic to or from the protected application or web site, and sends no response of any kind to the client.
- **APPFW_BLOCK.** Blocks traffic to or from the protected application or web site.

You use the built-in profiles exactly as you do user-defined profiles, by configuring a policy that selects the traffic to which you want to apply the profile and then associating the profile with your policy. Since you do not have to configure a built-in policy, it provides a quick way to allow or block specified types of traffic or traffic that is sent to specific applications or web sites.

User-defined profiles

User-defined profiles are profiles that are build and configured by users. Unlike the default profiles, you must configure a user-defined profile before it will be of use filtering traffic to and from your protected applications.

There are three types of user-defined profile:
• **HTML.** Protects HTML-based web pages.
• **XML.** Protects XML-based web services and web sites.
• **Web 2.0.** Protects Web 2.0 content that combines HTML and XML content, such as ATOM feeds, blogs, and RSS feeds.

The App Firewall has a number of security checks, all of which can be enabled or disabled, and configured in a number of ways in each profile. Each profile also has a number of settings that control how it handles different types of content. Finally, rather than manually configuring all of the security checks, you can enable and configure the learning feature. This feature observes normal traffic to your protected web sites for a period of time, and uses those observations to provide you with a tailored list of recommended exceptions (*relaxations*) to some security checks, and additional rules for other security checks.

During initial configuration, whether by using the App Firewall Wizard or manually, you normally create one general purpose profile to protect all content on your web sites that is not covered by a more specific profile. After that, you can create as many specific profiles as you want to protect more specialized content.

The Profiles pane consists of a table that contains the following elements:

**Name.** Displays all the App Firewall profiles configured in the appliance.

**Bound signature.** Displays the signatures object that is bound to the profile in the previous column, if any.

**Policies.** Displays the App Firewall policy that invokes the profile in the leftmost column of that row, if any.

**Comments.** Displays the comment associated with the profile in the leftmost column of that row, if any.

**Profile Type.** Displays the type of profile. Types are Built-In, HTML, XML, and Web 2.0.

Above the table is a row of buttons and a drop-down list that allow you to create, configure, delete, and view information about your profiles:

• **Add.** Add a new profile to the list.
• **Edit.** Edit the selected profile.
• **Delete.** Delete the selected profile from the list.
• **Statistics.** View the statistics for the selected profile.
• **Action.** Drop-down list that contains additional commands. Currently allows you to import a profile that was exported from another App Firewall configuration.

## Creating App Firewall profiles

September 20, 2018
You can create an App Firewall profile in one of two ways: by using the command line, and by using the GUI. Creating a profile by using the command line requires that you specify options on the command line. The process is similar to that of configuring an existing profile, and with a few exceptions the two commands take the same parameters.

Creating a profile by using the GUI requires that you specify only two options. You specify basic or advanced defaults, the default configuration for the various security checks and settings that are part of a profile, and choose the profile type to match the type of content that the profile is intended to protect. You can also, optionally, add a comment. After you create the profile, you must then configure it by selecting it in the data pane, and then clicking Edit.

If you plan to use the learning feature or to enable and configure a large number of advanced protections, you should choose advanced defaults. In particular, if you plan to configure either of the SQL injection checks, either of the cross-site scripting checks, any check that provides protection against Web form attacks, or the cookie consistency check, you should plan to use the learning feature. Unless you include the proper exceptions for your protected Web sites when configuring these checks, they can block legitimate traffic. Anticipating all of the necessary exceptions without creating any that are too broad is difficult. The learning feature makes this task much easier. Otherwise, basic defaults are quick and should provide the protection that your web applications need.

There are three profile types:

- **HTML.** Protects standard HTML-based web sites.
- **XML.** Protects XML-based web services and web sites.
- **Web 2.0 (HTML XML).** Protects sites that contain both HTML and XML elements, such as ATOM feeds, blogs, and RSS feeds.

There are also a few restrictions on the name that you can give to a profile. A profile name cannot be the same as the name assigned to any other profile or action in any feature on the NetScaler appliance. Certain action or profile names are assigned to built-in actions or profiles, and can never be used for user profiles. A complete list of disallowed names can be found in the App Firewall Profile Supplemental Information. If you attempt to create a profile with a name that has already been used for an action or a profile, an error message is displayed and the profile is not created.

**To create an App Firewall profile by using the command line interface**

At the command prompt, type the following commands:

- `add appfw profile <name> [-defaults ( basic | advanced )]`
- `set appfw profile <name> -type ( HTML | XML | HTML XML )`
- `set appfw profile <name> -comment "<comment>"`
- `save ns config`
Example

The following example adds a profile named pr-basic, with basic defaults, and assigns a profile type of HTML. This is the appropriate initial configuration for a profile to protect an HTML Web site.

```
1  add appfw profile pr-basic -defaults basic -comment "Simple profile for web sites."
2  set appfw profile pr-basic -type HTML
3  save ns config
```

To create an App Firewall profile by using the GUI

Creating an App Firewall profile requires that you specify only a few configuration details.

1. Navigate to Security > Application Firewall > Profiles.
2. In the details pane, click Add.
3. In the Create App Firewall Profile dialog box, type a name for your profile.
   The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 31 letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at (@), equals (=), colon (:), and underscore (_) symbols.
4. Choose the profile type from the drop-down list.
5. Click Create, and then click Close.

Configuring App Firewall profiles

September 18, 2018

To configure a user-defined App Firewall profile, first configure the security checks, which are called deep protections or advanced protections in the App Firewall wizard. Certain checks require configuration if you are to use them at all. Others have default configurations that are safe but limited in scope; your web sites might need or benefit from a different configuration that takes advantage of additional features of certain security checks.

After you have configured the security checks, you can also configure a number of other settings that control the behavior, not of a single security check, but the App Firewall feature. The default configuration is sufficient to protect most web sites, but you should review them to make sure that they are right for your protected web sites.

For more information about the App Firewall security checks, see “Advanced Protections.”
To configure an App Firewall profile by using the command line

At the command prompt, type the following commands:

- `set appfw profile <name> <arg1> [<arg2> ...]`

  where:
  - `<arg1>` = a parameter and any associated options.
  - `<arg2>` = a second parameter and any associated options.
  - `...` = additional parameters and options.

  For descriptions of the parameters to use when configuring specific security checks, see “Advanced Protections.”

- `save ns config`

Example

The following example shows how to enable blocking for the HTML SQL Injection and HTML Cross-Site Scripting checks in a profile named pr-basic. This command enables blocking for those actions while making no other changes to the profile.

```
set appfw profile pr-basic -crossSiteScriptingAction block -SQLInjectionAction block
```

To configure an App Firewall profile by using the GUI

1. Navigate to Security > Application Firewall > Profiles.
2. In the details pane, select the profile that you want to configure, and then click Edit.
3. In the Configure App Firewall Profile dialog box, on the Security Checks tab, configure the security checks.

   - To enable or disable an action for a check, in the list, select or clear the check box for that action.
   - To configure other parameters for those checks that have them, in the list, click the blue chevron to the far right of that check. In the dialog box that appears, configure the parameters. These vary from check to check.

You can also select a check and, at the bottom of the dialog box, click Open to display the Configure Relaxation dialog box or Configure Rule dialog box for that check. These dialog boxes also vary from check to check. Most of them include a Checks tab and a General tab. If the check supports relaxations or user-defined rules, the Checks tab includes an...
Add button, which opens yet another dialog box, in which you can specify a relaxation or rule for the check. (A relaxation is a rule for exempting specified traffic from the check.) If relaxations have already been configured, you can select one and click Open to modify it.

• To review learned exceptions or rules for a check, select the check, and then click Learned Violations. In the Manage Learned Rules dialog box, select each learned exception or rule in turn.
  – To edit the exception or rule, and then add it to the list, click Edit & Deploy.
  – To accept the exception or rule without modification, click Deploy.
  – To remove the exception or rule from the list, click Skip.

• To refresh the list of exceptions or rules to be reviewed, click Refresh.

• To review the log entries for connections that matched a check, select the check, and then click Logs. You can use this information to determine which checks are matching attacks, so that you can enable blocking for those checks. You can also use this information to determine which checks are matching legitimate traffic, so that you can configure an appropriate exemption to allow those legitimate connections. For more information about the logs, see “Logs, Statistics, and Reports.”

• To refresh the list of exceptions or rules to be reviewed, click Refresh.

• To completely disable a check, in the list, clear all of the check boxes to the right of that check.

4. On the Settings tab, configure the profile settings.

• To associate the profile with the set of signatures that you previously created and configured, under Common Settings, choose that set of signatures in the Signatures drop-down list.
  Note: You may need to use the scroll bar on the right of the dialog box to scroll down to display the Common Settings section.

• To configure an HTML or XML Error Object, select the object from the appropriate drop-down list.
  Note: You must first upload the error object that you want to use in the Imports pane. For more information about importing error objects, see Imports.

• To configure the default XML Content Type, type the content type string directly into the Default Request and Default Response text boxes, or click Manage Allowed Content Types to manage the list of allowed content types. “More…”

5. If you want to use the learning feature, click Learning, and configure the learning settings for the profile, as described in “Configuring and Using the Learning Feature.”

6. Click OK to save your changes and return to the Profiles pane.

Changing an App Firewall profile type

September 20, 2018
If you chose the wrong profile type for an App Firewall profile, or the type of content on the protected web site has changed, you can change the profile type.

**Note:** When you change the profile type, you lose all configuration settings and learned relaxations or rules for the features that the new profile type does not support. For example, if you change the profile type from Web 2.0 to XML, you lose any configuration options for Start URL, Form Field Consistency Check, and the other HTML-specific security checks. The configuration for any options that is supported by both the old and the new profile types remains unchanged.

**To change an App Firewall profile type by using the command line interface**

At the command prompt, type the following commands:

- `set appfw profile <name> -type ( HTML | XML | HTML XML )`
- `save ns config`

**Example**

The following example changes the type of a profile named pr-basic, from HTML to HTML XML, which is equivalent to the Web 2.0 type in the GUI.

```
1 set appfw profile pr-basic -type HTML XML
2 save ns config
```

**To change an App Firewall profile type by using the GUI**

1. Navigate to **Security > Application Firewall > Policies**.
2. In the details pane, click **Action**, and then **Change Profile Type**.
3. In the **Change App Firewall Profile Type** dialog box, **Profile Type** drop-down list, select a new profile type.
4. Click **OK** to save your changes and return to the **Profiles** pane.

**Exporting and importing an App Firewall profile**

September 20, 2018

You can replicate the entire configuration of an App Firewall profile (including all bound objects, such as HTML error object, XML error object, WSDL or XML schema, signatures, and so on) across multiple appliances. You can select a target profile and export the configuration to save it in your computer’s local file system, or you can transfer the archived configuration to store it on a server. Similarly, you can
browse your computer’s local file system or import the archive from the server to select a previously exported profile and import it into your NetScaler appliance.

The option to export the entire profile configuration and then import it into another appliance can be useful in various use cases. For example, you might want to configure an App Firewall profile in a test bed set-up to test and validate that it is working as expected. Once you are satisfied, you can export the profile and import the profile configuration to your production NetScaler appliances. This functionality is also useful for backing up your configuration. You can export the profile before making changes, so that you can easily roll back the configuration to a known state if necessary.

Note

App Firewall profiles that are exported and archived from one build cannot be restored to a system running a different build, because changes introduced in the newer releases can lead to compatibility issues. If you attempt to restore an archived profile to a different build than the one from which it was exported, an error message is logged in ns.log.

The export and import profile functionality is available in both the GUI (GUI) and the command line interface (CLI). The GUI is recommended, because it offers easy to use Action options. With a click of a button you can Export or Import the entire configuration of a profile.

Exporting App Firewall profiles with the CLI

If you use CLI to export a profile, you must archive the configuration and then export it. To import a profile, you must import the archive into the NetScaler appliance and then execute the restore command to extract the configuration. The following set of CLI commands can be used for exporting, importing and managing the profile configurations.

CLI commands to export archives:

• archive appfw profile <name> <archivename> [-comment <string>]
• export appfw archive <name> <target>

CLI commands to import archives:

• import appfw archive <src> <name> [-comment <string>]
• restore appfw profile <archivename>

CLI commands to manage archives:

• show appfw archive
• rm appfw archive <name>

Exporting a profile from one appliance and importing it to another requires five steps in CLI. The first 3 steps are performed on the source appliance on which profile configuration is originally created, and the next 2 steps are performed on the target appliance on which the profile configuration is to be replicated.
Export profile from the source NetScaler appliance:

**Step 1:** Create an archive of the configured profile.

**Step 2:** Export the archive to the NetScaler file system.

**Step 3:** Use a file transfer utility such as scp to transfer the exported archive file from NetScaler appliance A to the target NetScaler appliance.

Import profile to the target NetScaler appliance:

**Step 4:** Execute the import command to import the archived file. You can import the archive from your NetScaler’s local file system, or you can use HTTP or HTTPS protocol to import the archive from a server by using the URL.

**Step 5:** Execute the restore command to restore the profile configuration from the imported archive.

To export an App Firewall profile by using the command line interface:

First, **archive** the profile’s configuration, and then **export** the archive to a target location. At the command prompt, type the following commands:

```
archive appfw profile <profileName> <archiveName>
```

where:

- `<profileName>` is the name of the profile to archive.
- `<archiveName>` is the name of the archive file to create.

Execution of the above command creates 2 instances of the archive file. One in `/var/tmp` folder and another in the `/var/archive/appfw` folder.

```
export appfw archive <archiveName> <target>
```

where:

- `<archiveName>` is the name of the archive to export. (The same name as in the previous command.
- `<target>` is a file path starting with local: as the prefix, followed by `<archiveName>`.

Execution of the export command saves the exported archive file on the file system of your NetScaler appliance in the `/var/tmp` folder.

**Examples:**

```
> archive appfw profile test_pr archived_test_pr
> export appfw archive archived_test_pr local:dutA_test_pr
```

After the above two commands are executed, the `/var/tmp` folder contains the archived_test_pr file and the exported copy, dutA_test_pr, which are identical in size. From the CLI, you can drop into the shell to navigate to the folder to verify that these files are there.
After exporting the archive file, you can use scp or some other such file transfer utility to transfer a copy of the archive file from the NetScaler appliance on which they were created to your target NetScaler appliance.

**Importing App Firewall profiles with the CLI**

After you have successfully scp’d the archived file from the source appliance to the target appliance, you are ready to import the profile’s archive, and then execute the restore command to replicate the profile’s configuration on the target appliance.

Log onto the target appliance. Drop into the shell and cd to the /var/tmp folder to verify that the size of the scp'd file on this appliance matches the size of the original archived file on the source appliance. Exit the shell to return to the command line.

**To import a profile by using the CLI:**

At the command prompt, type the following commands:

```
import appfw archive <src> <name> [-comment <string>]
```

where

- `<src>` is the location of the archive file after it has been transferred from the source appliance on which it was created. You can use a local file system and file name. If you have placed the archive on a server, you can use a URL to import the archived file. If the path or file name contains spaces, enclose the URL in straight double quotation marks.
- `<name>` is the name of the archive file to be imported.
- `<string>` is an optional description of the purpose of the Archive.

```
restore appfw profile <archiveName>
```

**Examples:**

**A. Import from local file followed by restore:**

```
> import appfw archive local:dutA_test_pr dut2_test_pr
> restore appfw profile dut2_test_pr
```

**B. Import from URL followed by restore:**

```
import appfw archive http://10.217.30.16/FFC/Profile_IMPORT_EXPORT/dutA_test_pr.tgz my_archive
restore appfw profile my_archive
```

This example restores the test_pr profile along with all bound objects (such as signatures, html error page, relaxation rules and so on) on the target NetScaler appliance.

You can use the following CLI commands to access man pages for additional details.
NetScaler 12.0

- man archive appfw profile
- man export appfw archive
- man import appfw archive
- man restore appfw profile
- man show appfw archive
- man rm appfw archive

**Exporting and importing App Firewall profiles with the GUI**

The GUI is easier to use than the CLI. The utility performs both archive and export operations when you click **Export**. Similarly it executes both import and restore when you click **Import**. The GUI can access the local file system of the computer from which you access the utility. You can export a copy of the archive and save it on your local computer. You can then import this copy directly in the target appliance without having to manually transfer the archive file from one appliance to the other(s).

**To export an App Firewall profile by using the GUI:**

1. Navigate to **Configuration > Security > App Firewall > Profiles**.
2. In the details pane, select a profile to export. Click **Actions** and select **Export** to download and save a copy in your computer’s local file system.

**To import an App Firewall profile by using the GUI:**

1. Navigate to **Configuration > Security > App Firewall > Profiles**.
2. In the details pane, click **Actions** and select **Import**. In the Import App Firewall Profile pane, the Import From* selection box gives you 2 options:

- **URL**: You can choose to import an archive by specifying a **URL**. When this option is selected, you must provide an absolute path for the archived file in the **URL** input box.
- **File**: You can choose to import an archive from the local **File**. When this option is selected, a **Local File** selection field is displayed. You can browse your computer’s local files to select the target archive file.

Click **Create** to import the specified archive. Successful completion of the import operation creates the profile configuration on the target appliance.

**Highlights**

- You can replicate the entire configuration (including all import objects as well as configured relaxation rules for the profile) on multiple appliances, without needing to repeat configuration steps, by using export and import profile functionality.
- The imported objects, such as signatures, WSDL, Schema, error page and so on, are included in the archived tar file and replicated on the target appliance.
• Customized field types are included in the archived tar file and replicated on the target appliance.
• The policy bindings of the archived profile are not replicated when the configuration is restored. You must configure the policy and bind it to the profile after importing the profile to the appliance.
• The name of the archive file can be up to 31 character long. As with profile names, an archive name must begin with an alphanumeric character or underscore and contain only alphanumeric and underscore (_), number (#), period (.), space ( ), colon (:), at (@), equals (=) or hyphen (-) characters.
• Comments associated with the archive should be descriptive enough to convey the purpose of the archived configuration. The maximum allowed length for a comment is 255 characters.
• The “clear config –force basic” command does not remove the archived profiles.
• The import and export profile functionality is supported in high availability (HA) deployments.

Debugging tips

• Monitor the /var/log/ns.log during command executions to see if there are any ERROR messages.
• Additional logs (_restore.log, remove.log, import.log) are generated in the /var/tmp/folder. They can help debug issues during the corresponding operations. When these logs reach one MB in size, the log messages are purged to shrink the log file to one fourth of the original size.
• If the import command fails when you are using the URL option instead of the local file system, verify that DNS name server and route settings are accurately configured.
• If you are using the HTTPS protocol to import the archive, the command might fail if the HTTPS server requires client certificate authentication.

Configuring and using the Learning feature

September 18, 2018

The learning feature is a repetitive pattern filter that observes activity on a web site or application protected by the App Firewall, to determine what constitutes normal activity on that web site or application. It then generates a list of up to 2,000 suggested rules or exceptions (relaxations) for each security checks that includes support for the learning feature. Users normally find it easier to configure relaxations by using the learning feature than by entering the necessary relaxations manually.

The security checks that support the learning feature are:

• Start URL check
• Cookie Consistency check
- Form Field Consistency check
- Field Formats check
- CSRF Form Tagging check
- HTML SQL Injection check
- HTML Cross-Site Scripting check
- XML Denial-of-Service check
- XML Attachment check
- Web Services Interoperability check

You perform two different types of activities when using the learning feature. First, you enable and configure the feature to use it. You can use learning on all traffic to your protected web applications, or you can configure a list of IPs (called the Add Trusted Learning Clients list) from which the learning feature should generate recommendations. Second, after the feature has been enabled and has processed a certain amount of traffic to your protected web sites, you review the list of suggested rules and relaxations (learned rules) and mark each with one of the following designations:

- **Edit & Deploy.** The rule is pulled into the Edit dialog box so that you can modify it, and the modified form is deployed.
- **Deploy.** The unmodified learned rule is placed on the list of rules or relaxations for this security check.
- **Skip.** The learned rule is placed on a list of rules or relaxations that are not deployed. The learned rule is removed when skipped. However, as they are not added to relaxations, they might get learned again.

Learning is not performed only when relaxations are in place, except for field format rules. When rules are skipped, they are only removed from learned database. As relaxations are not added, they might get learned again. When rules are deployed, they are removed from learned database and also relaxations are added for the rules. As relaxations are added, they would not be learned again. For field format protection, learning is performed irrespective of relaxations.

Although you can use the command line interface for basic configuration of the learning feature, the feature is designed primarily for configuration through the App Firewall wizard or the GUI. You can perform only limited configuration of the learning feature by using the command line.

The wizard integrates configuration of learning features with configuration of the App Firewall as a whole, and is therefore the easiest method for configuring this feature on a new NetScaler appliance or when managing a simple App Firewall configuration. The GUI visualizer and manual interface both provide direct access to all learned rules for all security checks, and are therefore often preferable when you must review learned rules for a large number of security checks.

The learning database is limited to 20 MB in size, which is reached after approximately 2,000 learned rules or relaxations are generated per security check for which learning is enabled. If you do not regularly review and either approve or ignore learned rules and this limit is reached, an error is logged to
the NetScaler log and no more learned rules are generated until you review the existing learned rules and relaxations.

If learning stops because the database has reached its size limit, you can restart learning either by reviewing the existing learned rules and relaxations or by resetting the learning data. After learned rules or relaxations are approved or ignored, they are removed from the database. After you reset the learning data, all existing learning data is removed from the database and it is reset to its minimum size. When the database falls below 20 MB in size, learning restarts automatically.

To configure the learning settings by using the command line interface

Specify the App Firewall profile to be configured and, for each security check that you want to include in that profile, specify the minimum threshold or the percent threshold. The minimum threshold is an integer representing the minimum number of user sessions that the App Firewall must process before it learns a rule or relaxation (default: 1). The percent threshold is an integer representing the percentage of user sessions in which the App Firewall must observe a particular pattern (URL, cookie, field, attachment, or rule violation) before it learns a rule or relaxation (default: 0). Use the following commands:

```
• save ns config
```

Example

The following example enables and configures the learning settings in the profile pr-basic for the HTML SQL Injection security check. This is an appropriate initial test bed learning configuration, where you have complete control over the traffic that is sent to the App Firewall.

```
1 set appfw learningsettings pr-basic -SQLInjectionMinThreshold 10
```
To reset learning settings to their defaults by using the command line interface

To remove any custom configuration of the learning settings for the specified profile and security check, and return the learning settings to their defaults, at the command prompt type the following commands:

- save ns config

To display the learning settings for a profile by using the command line interface

At the command prompt, type the following command:

show appfw learningsettings <profileName>

To display unreviewed learned rules or relaxations for a profile by using the command line interface

At the command prompt, type the following command:

show appfw learningdata <profileName> <securityCheck>

To remove specific unreviewed learned rules or relaxations from the learning database by using the command line interface

At the command prompt, type the following command:
rm appfw learningdata <profileName> (-startURL <expression> | -cookieConsistency <string> | (-fieldConsistency <string> <formActionURL>)| (-crossSiteScripting <string> <formActionURL>)| (-SQLInjection <string> <formActionURL>)| (-fieldFormat <string><formActionURL>)| (-CSRFTag <expression> <CSRFFormOriginURL>)| -XMLDoSCheck <expression> | -XMLWSICheck <expression> | -XMLAttachmentCheck <expression>)[-TotalXMLRequests]

Example

The following example removes all unreviewed learned relaxations for the pr-basic profile, HTML SQL Injection security check, that apply to the LastName form field.

```
rm appfw learningdata pr-basic -SQLInjection LastName
```

To remove all unreviewed learned data by using the command line interface

At the command prompt, type the following command:

```
reset appfw learningdata
```

To export learning data by using the command line interface

At the command prompt, type the following command:

```
export appfw learningdata <profileName> <securitycheck>[-target <string>]
```

Example

The following example exports learned relaxations for the pr-basic profile and the HTML SQL Injection security check to a comma-separated values (CSV) format file in the /var/learnt_data/ directory under the filename specified in the -target parameter.

```
export appfw learningdata pr-basic SQLInjection -target sqli_ld
```

To configure the Learning feature by using the GUI

1. Navigate to Security > App Firewall > Profiles.
2. In the Profiles pane, select the profile, and then click Edit.
3. Click the Learning tab. At the top of the Learning tab is list of the security checks that are available in the current profile and that support the learning feature.

4. To configure the learning thresholds, select a security check, and then type the appropriate values in the following text boxes:

   **Minimum number threshold.** Depending on which security check’s learning settings you are configuring, the minimum number threshold might refer to the minimum number of total user sessions that must be observed, the minimum number of requests that must be observed, or the minimum number of times a specific form field must be observed, before a learned relaxation is generated. Default: 1

   - **Percentage of times threshold.** Depending on which security check’s learning settings you are configuring, the percentage of times threshold might refer to the percentage of total observed user sessions that violated the security check, the percentage of requests, or the percentage of times a form field matched a particular field type, before a learned relaxation is generated. Default: 0

5. To remove all learned data and reset the learning feature, so that it must start its observations again from the beginning, click **Remove All Learned Data.**
   Note: This button removes only learned recommendations that have not been reviewed and either approved or skipped. It does not remove learned relaxations that have been accepted and deployed.

6. To restrict the learning engine to traffic from a specific set of IPs, click **Trusted Learning Clients,** and add the IP addresses that you want to use to the list.
   a) To add an IP address or IP address range to the Trusted Learning Clients list, click **Add.**
   b) In the **Add Trusted Learning Clients** dialog box, Trusted Clients IP list box, type the IP address or an IP address range in CIDR format.
   c) In the Comments text area, type a comment that describes this IP address or range.
   d) Click **Create** to add your new IP address or range to the list.
   e) To modify an existing IP address or range, click the IP address or range, and then click **Open.** Except for the name, the dialog box that appears is identical to the **Add Trusted Learning Clients** dialog box.
   f) To disable or enable an IP address or range, but leave it on the list, click **Disable or Enable,** as appropriate.
   g) To remove an IP address or range completely, click the IP address or range, and then click **Remove.**

7. Click **Close** to return to the Configure App Firewall Profile dialog box.

8. Click **Close** to close the **Configure App Firewall Profile** dialog box, and return to the **App Firewall Profile** screen.
To review learned rules or relaxations by using the GUI

1. Navigate to Security > App Firewall > Profiles.
2. Select the security check for which you want to review learned rules or relaxations, and then click Manage Rules.
3. In the Manage Learned Rules dialog box, choose how you want to review the learned rules.
   - To review the actual learned patterns as displayed in the window, do nothing and proceed to the next step.
   - To review the learned data hierarchically as a branching tree, enabling you to choose general patterns that match many of the learned patterns, click **Visualizer**.
4. If you have chosen to review actual learned patterns, perform the following steps.
5. Select the first learned relaxation and choose how to handle it.
   - To modify and then accept the relaxation, click **Edit & Deploy**, edit the relaxation regular expression, and then click **OK**.
   - To accept the relaxation without modifications, click **Deploy**.
   - To remove the relaxation from the list without deploying it, click **Skip**.
     a) Repeat the previous step to review each additional learned relaxation.
6. If you have chosen to use the Learning Visualizer, perform the following steps.
   a) In the branching hierarchical display, select a node that contains a learned pattern, and choose how to handle it.
      The screen area beneath the tree structure, under Regex of Selected Node, displays a generalized expression that matches all of the patterns in that node. If you want to display an expression that matches just one of the branches or just one of the leaves, select that branch or leaf.
      - To modify and then accept the learned relaxation, click Edit & Deploy, edit the relaxation regular expression, and then click **OK**.
      - To accept the relaxation without modifications, click Deploy.
      - To remove the modification from the list without deploying it, click **Skip**.
     b) Repeat the previous step to review other portions of the display.
7. Click **Close** to return to the Manage Learned Rules dialog box.
8. Click **Close** to return to the Configure App Firewall Profile dialog box.
9. Click **Close** to close the Configure App Firewall Profile dialog box, and return to the App Firewall Profile screen.
Supplemental Information about profiles

September 20, 2018

Following is supplemental information about particular aspects of App Firewall profiles. This information explains how to include special characters in a security check rule or relaxation, and how to use variables when configuring profiles.

Configuration variable support

Instead of using static values, to configure the App Firewall’s security checks and settings, you can now use standard NetScaler named variables. By creating variables, you can more easily export and then import configurations to new NetScaler appliances, or update existing NetScaler appliances from a single set of configuration files. This simplifies updates when you use a test bed setup to develop a complex App Firewall configuration that is tuned for your local network and servers and then transfer that configuration to your production NetScaler appliances.

You create App Firewall configuration variables in the same manner as you do any other NetScaler named variables, following standard NetScaler conventions. To create a named expression variable by using the GUI, you use the [Add Expression dialog box](http://docs.citrix.com/en-us/netscaler/ns-gen-NetScaler11-wrapper-con/ns-gen-appsec-wrapper-10-con/appfw-wrapper-con-10/appfw-policies-con/appfw-policies-firewall-tsk/appfw-policies-firewall-configuring-tsk.html). To create a named expression variable by using the NetScaler command line, you use the add expression command followed by the appropriate parameter.

The following URLs and expressions can be configured with variables instead of static values:

- **Start URL** (-starturl)
- **Deny URL** (-denyurl)
- **Form Action URL** for **Form Field Consistency Check** (-fieldconsistency)
- **Action URL** for **XML SQL Injection Check** (-xmlSQLInjection)
- **Action URL** for **XML Cross-Site Scripting Check** (-xmlXSS)
- **Form Action URL** for **HTML SQL Injection Check** (-sqlInjection)
- **Form Action URL** for **Field Format Check** (-fieldFormat)
- **Form Origin URL** and **Form Action URL** for **Cross-Site Request Forgery (CSRF) Check** (-csrfTag)
- **Form Action URL** for **HTML Cross-Site Scripting Check** (-crossSiteScripting)
- **Safe Object** (-safeObject)
- **Action URL** for **XML Denial-of-Service (XDoS) check** (-XMLDoS)
- **URL** for **Web Services Interoperability check** (-XMLWSIURL)
- **<URL** for **XML Validation check** (-XMLValidationURL)
- **URL** for **XML Attachment check** (-XMLAttachmentURL)
For more information, see “Policies and Expressions.”

To use a variable in the configuration, you enclose the variable name between two at (@) symbols and then use it exactly as you would the static value that it replaces. For example, if you are configuring the Deny URL check by using the GUI and want to add the named expression variable myDenyURL to the configuration, you would type @myDenyURL@ into the Add Deny URL dialog box, Deny URL text area. To do the same task by using the NetScaler command line, you would type add appfw profile <name> -denyURLAction @myDenyURL@.

PCRE character encoding format

The NetScaler operating system supports direct entry of characters in the printable ASCII character set only—characters with hexadecimal codes between HEX 20 (ASCII 32) and HEX 7E (ASCII 127). To include a character with a code outside that range in your App Firewall configuration, you must enter its UTF-8 hexadecimal code as a PCRE regular expression.

A number of character types require encoding using a PCRE regular expression if you include them in your App Firewall configuration as a URL, form field name, or Safe Object expression. They include:

- **Upper-ASCII characters.** Characters with encodings from HEX 7F (ASCII 128) to HEX FF (ASCII 255). Depending on the character map used, these encodings can refer to control codes, ASCII characters with accents or other modifications, non-Latin alphabet characters, and symbols not included in the basic ASCII set. These characters can appear in URLs, form field names, and safe object expressions.

- **Double-Byte characters.** Characters with encodings that use two 8-byte words. Double-byte characters are used primarily for representing Chinese, Japanese, and Korean text in electronic format. These characters can appear in URLs, form field names, and safe object expressions.

- **ASCII control characters.** Non-printable characters used to send commands to a printer. All ASCII characters with hexadecimal codes less than HEX 20 (ASCII 32) fall into this category. These characters should never appear in a URL or form field name, however, and would rarely if ever appear in a safe object expression.

The NetScaler appliance does not support the entire UTF-8 character set, but only the characters found in the following eight charsets:

- **English US (ISO-8859-1).** Although the label reads, “English US,” the App Firewall supports all characters in the ISO-8859-1 character set, also called the Latin-1 character set. This character set fully represents most modern western European languages and represents all but a few uncommon characters in the rest.

- **Chinese Traditional (BIG5).** The App Firewall supports all characters in the BIG5 character set, which includes all of the Traditional Chinese characters (ideographs) commonly used in modern
Chinese as spoken and written in Hong Kong, Macau, Taiwan, and by many people of Chinese ethnic heritage who live outside of mainland China.

- **Chinese Simplified (GB2312).** The App Firewall supports all characters in the GB2312 character set, which includes all of the Simplified Chinese characters (ideographs) commonly used in modern Chinese as spoken and written in mainland China.

- **Japanese (SJIS).** The App Firewall supports all characters in the Shift-JIS (SJIS) character set, which includes most characters (ideographs) commonly used in modern Japanese.

- **Korean (EUC-KR).** The App Firewall supports all characters in the EUC-KR character set, which includes all characters (ideographs) commonly used in modern Korean.

- **Turkish (ISO-8859-9).** The App Firewall supports all characters in the ISO-8859-9 character set, which includes all letters used in modern Turkish.

- **Unicode (UTF-8).** The App Firewall supports certain additional characters in the UTF-8 character set, including those used in modern Russian.

When configuring the App Firewall, you enter all non-ASCII characters as PCRE-format regular expressions using the hexadecimal code assigned to that character in the UTF-8 specification. Symbols and characters within the normal ASCII character set, which are assigned single, two-digit codes in that character set, are assigned the same codes in the UTF-8 character set. For example, the exclamation point (!), which is assigned hex code 21 in the ASCII character set, is also hex 21 in the UTF-8 character set. Symbols and characters from another supported character set have a paired set of hexadecimal codes assigned to them in the UTF-8 character set. For example, the letter a with an acute accent (á) is assigned UTF-8 code C3 A1.

The syntax you use to represent these UTF-8 codes in the App Firewall configuration is “xNN” for ASCII characters; “\xNN\xNN” for non-ASCII characters used in English, Russian, and Turkish; and “\xNN\xNN\xNN” for characters used in Chinese, Japanese, and Korean. For example, if you want to represent a ! in an App Firewall regular expression as a UTF-8 character, you would type \x21. If you want to include an á, you would type \xC3\xA1.

**Note:**

Normally you do not need to represent ASCII characters in UTF-8 format, but when those characters might confuse a web browser or an underlying operating system, you can use the character’s UTF-8 representation to avoid this confusion. For example, if a URL contains a space, you might want to encode the space as x20 to avoid confusing certain browsers and web server software.

Below are examples of URLs, form field names, and safe object expressions that contain non-ASCII characters that must be entered as PCRE-format regular expressions to be included in the App Firewall...
configuration. Each example shows the actual URL, field name, or expression string first, followed by a PCRE-format regular expression for it.

- A URL containing extended ASCII characters.
  Actual URL: http://www.josénuñez.com
  Encoded URL: ^http://www\.José\xA9nuñez\.com$

- Another URL containing extended ASCII characters.
  Actual URL: http://www.example.de/trömsos.html
  Encoded URL: ^http://www\.example\.de/tr\xC3\xA9msos[.]html$

- A form field name containing extended ASCII characters.
  Actual Name: nome_do_usuário
  Encoded Name: ^nome_do_usuário$

- A safe object expression containing extended ASCII characters.
  Unencoded Expression: [A-Z][3,6]¥[1-9][0-9][6,6]
  Encoded Expression: [A-Z][3,6]\xC2\xA5[1-9][0-9][6,6]

You can find a number of tables that include the entire Unicode character set and matching UTF-8 encodings on the Internet. A useful web site that contains this information is located at the following URL:

1 http://www.utf8-chartable.de/unicode-utf8-table.pl

For the characters in the table on this web site to display correctly, you must have an appropriate Unicode font installed on your computer. If you do not, the visual display of the character may be in error. Even if you do not have an appropriate font installed to display a character, however, the description and the UTF-8 and UTF-16 codes on this set of web pages will be correct.

**Inverted PCRE Expressions**

In addition to matching content that contains a pattern, you can match content that does not contain a pattern by using an inverted PCRE expression. To invert an expression, you simply include an exclamation point (!) followed by white space as the first character in the expression.

**Note:** If an expression consists only of an exclamation point with nothing following, the exclamation point is treated as a literal character, not syntax indicating an inverted expression.

The following App Firewall commands support inverted PCRE expressions:

- Start URL (URL)
• Deny URL (URL)
• Form Field Consistency (form action URL)
• Cookie Consistency (form action URL)
• Cross Site Request Forgery (CSRF) (form action URL)
• HTML Cross-site Scripting (form action URL)
• Field Format (form action URL)
• Field Type (type)
• Confidential Field (URL)

Note: If the security check contains an isRegex flag or check box, it must be set to YES or checked to enable regular expressions in the field. Otherwise the contents of that field are treated as literal and no regular expressions (inverted or not) are parsed.

**Disallowed names for App Firewall profiles**

The following names are assigned to built-in actions and profiles on the NetScaler appliance, and cannot be used as names for a user-created App Firewall profile.

• AGGRESSIVE
• ALLOW
• BASIC
• CLIENTAUTH
• COMPRESS
• CSSMINIFY
• DEFLATE
• DENY
• DNS-NOP
• DROP
• GZIP
• HTMLMINIFY
• IMG OPTIMIZE
• JS MINIFY
• MODERATE
• NO CLIENT AUTH
• NO COMPRESS
• NONE
• NOOP
• NOREWRITE
• RESET
• SETASLEARNNSLOG_ACT
• SETNSLOGPARAMS_ACT
• SETSYSLOGPARAMS_ACT
• SETTMSESSPARAMS_ACT
  • SETVPNPARAMS_ACT
• SET_PREAUTHPARAMS_ACT
• default_DNS64_action
• dns_default_act_Cachebypass
• dns_default_act_Drop
• nshttp_default_profile
• nshttp_default_strict_validation
• nstcp_default_Mobile_profile
• nstcp_default_XA_XD_profile
• nstcp_default_profile
• nstcp_default_tcp_interactive_stream
• nstcp_default_tcp_lan
• nstcp_default_tcp_lan_thin_stream
• nstcp_default_tcp_lfp
• nstcp_default_tcp_lfp_thin_stream
• nstcp_default_tcp_lnp
• nstcp_default_tcp_lnp_thin_stream
• nstcp_internal_apps

Policy labels

September 18, 2018
A policy label consists of a set of policies, other policy labels, and virtual server-specific policy banks. The App Firewall evaluates each policy bound to the policy label in order of priority. If the policy matches, it filters the connection as specified in the associated profile. Then it does whatever the Goto parameter specifies, which can be to terminate policy evaluation, go to the next policy, or go to the policy with the specified priority. If the Invoke parameter is set, it terminates processing of the current policy label and begins to process the specified policy label or virtual server.

To create an App Firewall policy label by using the command line

At the command prompt, type the following commands:

- add appfw policylabel <labelName> http_req
- save ns config

Example

The following example creates a policy label named policylbl1.

```
1 add appfw policylabel policylbl1 http_req
2 save ns config
```

To bind a policy to a policy label by using the command line

At the command prompt, type the following commands:

- bind appfw policylabel <labelName> <policyName> <priority> [goToPriorityExpression] [-invoke (<labelType> <labelName>)]
- save ns config

Example

The following example binds the policy policy1 to the policy label policylbl1 with a priority of 1.

```
1 bind appfw policylabel policylbl1 policy1 1
2 save ns config
```

To configure an App Firewall policy label by using the GUI

1. Navigate to Security > Application Firewall > Policy Labels.
2. In the details pane, do one of the following:
   • To add a new policy label, click **Add**.
   • To configure an existing policy label, select the policy label and the click **Open**.

   The **Create App Firewall Policy Label** or the **Configure App Firewall Policy Label** dialog box opens. The dialog boxes are nearly identical.

3. If you are creating a new policy label, in the Create App Firewall Policy Label dialog box, type a name for your new policy label.

   The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 127 letters, numbers, and the hyphen (-), period (.), pound (#), space ( ), at (@), equals (=), colon (:), and underscore (_) symbols.

4. Select **Insert Policy** to insert a new row and display a drop-down list with all existing App Firewall policies.

5. Select the policy you want to bind to the policy label, or select New Policy to create a new policy and follow the instructions in **To create and configure a policy by using the GUI**. The policy that you selected or created is inserted into the list of globally bound App Firewall policies.

6. Make any additional adjustments.
   • To modify the policy priority, click the field to enable it, and then type a new priority. You can also select Regenerate Priorities to renumber the priorities evenly.
   • To modify the policy expression, double click that field to open the Configure App Firewall Policy dialog box, where you can edit the policy expression.
   • To set the Goto Expression, double click field in the Goto Expression column heading to display the drop-down list, where you can choose an expression.
   • To set the Invoke option, double click field in the Invoke column heading to display the drop-down list, where you can choose an expression.

7. Repeat steps 5 through 7 to bind any additional App Firewall policies you want to the policy label.

8. Click **Create** or **OK**, and then click **Close**. A message appears in the status bar, stating that you have successfully created or modified the policy label.

**Policies**

September 18, 2018

The App Firewall uses two types of policies: firewall policies and auditing policies. Firewall policies control which traffic is sent to the App Firewall. Auditing policies control the log server to which App Firewall logs are sent.
Firewall policies can be complex because the policy rule can consist of multiple expressions in the NetScaler expressions language, which is a full-fledged object oriented programming language capable of defining with extreme precision exactly which connections to filter. Because firewall policies operate within the context of the App Firewall, they must meet certain criteria that are connected to how the App Firewall functions and what traffic is appropriately filtered by it. As long as you keep these criteria in mind, however, firewall policies are similar to policies for other NetScaler features. The instructions here do not attempt to cover all aspects of writing firewall policies, but only provide an introduction to policies and cover those criteria that are unique to the App Firewall.

Auditing policies are simple because the policy rule is always ns_true. You need only specify the log server that you want to send logs to, the logging levels that you want to use, and a few other criteria that are explained in detail.

**App Firewall Policies**

September 18, 2018

A firewall policy is a rule associated with a profile. The rule is an expression or group of expressions that define the types of request/response pairs that the App Firewall is to filter by applying the profile. Firewall policy expressions are written in the NetScaler expressions language, an object-oriented programming language with special features to support specific NetScaler functions. The profile is the set of actions that the App Firewall is to use to filter request/response pairs that match the rule.

Firewall policies enable you to assign different filtering rules to different types of web content. Not all web content is alike. A simple web site that uses no complex scripting and accesses and handles no private data might require only the level of protection provided by a profile created with basic defaults. Web content that contains JavaScript-enhanced web forms or accesses an SQL database probably requires more tailored protection. You can create a different profile to filter that content and create a separate firewall policy that can determine which requests are attempting to access that content. You then associate the policy expression with a profile you created and globally bind the policy to put it into effect.

The App Firewall processes only HTTP connections, and therefore uses a subset of the overall NetScaler expressions language. The information here is limited to topics and examples that are likely to be useful when configuring the App Firewall. Following are links to additional information and procedures for firewall policies:

- For procedures that explain how to create and configure a policy, see Creating and Configuring App Firewall Policies.
- For a procedure that explains in detail how to create a policy rule (expression), see To create or configure an App Firewall rule (expression).
• For a procedure that explains how to use the Add Expression dialog box to create a policy rule, see To add a firewall rule (expression) by using the Add Expression dialog box.

• For a procedure that explains how to view the current bindings for a policy, see Viewing a Firewall Policy's Bindings.

• For procedures that explain how to bind an App Firewall policy, see Binding App Firewall Policies.

• For detailed information about the NetScaler expressions language, see Policies and Expressions.

Note

App Firewall evaluates the policies based on the configured priority and goto expressions. At the end of the policy evaluation, the last policy that evaluates to true is used and the security configuration of the corresponding profile is invoked for processing the request.

For example, Consider a scenario where there are 2 policies.

• Policy_1 is a generic policy with Expression=ns_true and has a corresponding profile_1 which is a basic profile. The priority is set to 100.

• Policy_2 is more specific with Expression=HTTP.REQ.URL.CONTAINS("XYZ") and has a corresponding profile_2 which is an advance profile. The GoTo Expression is set to NEXT and the priority is set to 95 which is a higher priority compared to Policy_1.

In this scenario, if the target string “XYZ” is detected in the URL of the processed request, Policy_2 match is triggered as it has a higher priority even though Policy_1 is also a match. However, as per the GoTo expression configuration of Policy_2, the policy evaluation continues and the next policy Policy_1 is also processed. At the end of the policy evaluation, Policy_1 evaluates as true and the basic security checks configured in Profile_1 are invoked.

If the Policy_2 is modified and the GoTo Expression is changed from NEXT to END, the processed request that has the target string “XYZ”, triggers the Policy_2 match due to priority consideration and as per the GoTo expression configuration, the policy evaluation ends at this point. Policy_2 evaluates as true and the advanced security checks configured in Profile_2 are invoked.

NEXT
END

Policy evaluation is completed in one pass. Once the policy evaluation is completed for the request and the corresponding profile actions are invoked, the request does not go through another round of policy evaluation.
Creating and configuring App Firewall policies

November 14, 2018

A firewall policy consists of two elements: a rule, and an associated profile. The rule selects the HTTP traffic that matches the criteria that you set, and sends that traffic to the App Firewall for filtering. The profile contains the filtering criteria that the App Firewall uses.

The policy rule consists of one or more expressions in the NetScaler expressions language. The NetScaler expressions syntax is a powerful, object-oriented programming language that enables you to precisely designate the traffic that you want to process with a specific profile. For users who are not completely familiar with the NetScaler expressions language syntax, or who prefer to configure their NetScaler appliance by using a web-based interface, the GUI provides two tools: the Prefix menu and the Add Expression dialog box. Both help you to write expressions that select exactly the traffic that you want to process. Experienced users who are thoroughly familiar with the syntax may prefer to use the NetScaler command line to configure their NetScaler appliances.

Note: In addition to the default expressions syntax, for backward compatibility the NetScaler operating system supports the NetScaler classic expressions syntax on NetScaler Classic and nCore appliances and virtual appliances. Classic expressions are not supported on NetScaler Cluster appliances and virtual appliances. Current NetScaler users who want to migrate existing configurations to the NetScaler Cluster must migrate any policies that contain classic expressions to the default expressions syntax.

For detailed information about the NetScaler expressions languages, see “Policies and Expressions.”

You can create a firewall policy by using the GUI or the NetScaler command line.

To create and configure a policy by using the command line interface

At the command prompt, type the following commands:

- `add appfw policy <name><rule> <profileName>`
- `save ns config`

Example

The following example adds a policy named pl-blog, with a rule that intercepts all traffic to or from the host blog.example.com, and associates that policy with the profile pr-blog. This is an appropriate policy to protect a blog hosted on a specific hostname.

```
1 add appfw policy pl-blog "HTTP.REQ.HOSTNAME.DOMAIN.EQ("blog.example.com ")" pr-blog
```
To create and configure a policy by using the GUI

2. In the details pane, do one of the following:
   - To create a new firewall policy, click Add. The Create App Firewall Policy is displayed.
   - To edit an existing firewall policy, select the policy, and then click Edit.

The Create App Firewall Policy or Configure App Firewall Policy is displayed.

3. If you are creating a new firewall policy, in the Create App Firewall Policy dialog box, Policy Name text box, type a name for your new policy.
   The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 128 letters, numbers, and the hyphen (-), period (.), pound (#), space ( ), at (@), equals (=), colon (:), and underscore (_) symbols.
   If you are configuring an existing firewall policy, this field is read-only. You cannot modify it.
4. Select the profile that you want to associate with this policy from the Profile drop-down list. You can create a new profile to associate with your policy by clicking New, and you can modify an existing profile by clicking Modify.
5. In the Expression text area, create a rule for your policy.
   - You can type a rule directly into the text area.
   - You can click Prefix to select the first term for your rule, and follow the prompts.
   - You can click Add to open the Add Expression dialog box, and use it to construct the rule.
6. Click Create or OK, and then click Close.

To create or configure an App Firewall rule

The policy rule, also called the expression, defines the web traffic that the App Firewall filters by using the profile associated with the policy. Like other NetScaler policy rules (or expressions), App Firewall rules use NetScaler expressions syntax. This syntax is powerful, flexible, and extensible. It is too complex to describe completely in this set of instructions. You can use the following procedure to create a simple firewall policy rule, or you can read it as an overview of the policy creation process.

1. If you have not already done so, navigate to the appropriate location in the App Firewall wizard or the NetScaler GUI to create your policy rule:
   - If you are configuring a policy in the App Firewall wizard, in the navigation pane, click App Firewall, then in the details pane click App Firewall Wizard, and then navigate to the Specify Rule screen.
• If you are configuring a policy manually, in the navigation pane, expand **App Firewall**, then **Policies**, and then **Firewall**. In the details pane, to create a new policy, click **Add**. To modify an existing policy, select the policy, and then click **Open**.

2. On the **Specify Rule** screen, the **Create App Firewall Profile** dialog box, or the **Configure App Firewall Profile** dialog box, click **Prefix**, and then choose the prefix for your expression from the drop-down list. Your choices are:

   - **HTTP**. The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol.
   - **SYS**. The protected Web site(s). Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.
   - **CLIENT**. The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.
   - **SERVER**. The computer to which the request was sent. Choose this if you want to examine some aspect of the recipient of the request.

   After you choose a prefix, the App Firewall displays a two-part prompt window that displays the possible next choices at the top, and a brief explanation of what the selected choice means at the bottom.

3. Choose your next term.

   If you chose HTTP as your prefix, your only choice is **REQ**, which specifies the Request/Response pair. (The App Firewall operates on the request and response as a unit instead of on each separately.) If you chose another prefix, your choices are more varied. For help on a specific choice, click that choice once to display information about it in the lower prompt window.

   When you have decided which term you want, double-click it to insert it into the **Expression** window.

4. Type a period after the term you just chose. You are then prompted to choose your next term, as described in the previous step. When a term requires that you type a value, fill in the appropriate value. For example, if you choose HTTP.REQ.HEADER(""), type the header name between the quotation marks.

5. Continue choosing terms from the prompts and filling in any values that are needed, until your expression is finished.

   Following are some examples of expressions for specific purposes.

   - **Specific web host**. To match traffic from a particular web host:

     ```
     HTTP.REQ.HEADER("Host").EQ("shopping.example.com")
     ```

     For shopping.example.com, substitute the name of the web host that you want to match.
**Specific web folder or directory.** To match traffic from a particular folder or directory on a Web host:

```plaintext
HTTP.REQ.URL.STARTSWITH("https://www.example.com/folder")
```

For www.example.com, substitute the name of the web host. For folder, substitute the folder or path to the content that you want to match. For example, if your shopping cart is in a folder called /solutions/orders, you substitute that string for folder.

**Specific type of content: GIF images.** To match GIF format images:

```plaintext
HTTP.REQ.URL.ENDSWITH(".gif")
```

To match other format images, substitute another string in place of .gif.

**Specific type of content: scripts.** To match all CGI scripts located in the CGI-BIN directory:

```plaintext
HTTP.REQ.URL.STARTSWITH("https://www.example.com/CGI-BIN")
```

To match all JavaScripts with .js extensions:

```plaintext
HTTP.REQ.URL.ENDSWITH(".js")
```

For more information about creating policy expressions, see “Policies and Expressions.”

**Note:** If you use the command line to configure a policy, remember to escape any double quotation marks within NetScaler expressions. For example, the following expression is correct if entered in the GUI:

```plaintext
HTTP.REQ.HEADER("Host").EQ("shopping.example.com")
```

If entered at the command line, however, you must type this instead:

```plaintext
HTTP.REQ.HEADER("Host").EQ("shopping.example.com")
```

### To add a firewall rule (expression) by using the Add Expression dialog box

The Add Expression dialog box (also referred to as the Expression Editor) helps users who are not familiar with the NetScaler expressions language to construct a policy that matches the traffic that they want to filter.

1. If you have not already done so, navigate to the appropriate location in the **App Firewall** wizard or the NetScaler GUI:
If you are configuring a policy in the App Firewall wizard, in the navigation pane, click App Firewall, then in the details pane click App Firewall Wizard, and then navigate to the Specify Rule screen.

If you are configuring a policy manually, in the navigation pane, expand App Firewall, then Policies, and then Firewall. In the details pane, to create a new policy, click Add. To modify an existing policy, select the policy, and then click Open.

2. On the Specify Rule screen, in the Create App Firewall Profile dialog box, or in the Configure App Firewall Profile dialog box, click Add.

3. In the Add Expression dialog box, in the Construct Expression area, in the first list box, choose one of the following prefixes:
   - HTTP. The HTTP protocol. Choose this if you want to examine some aspect of the request that pertains to the HTTP protocol. The default choice.
   - SYS. The protected Web site(s). Choose this if you want to examine some aspect of the request that pertains to the recipient of the request.
   - CLIENT. The computer that sent the request. Choose this if you want to examine some aspect of the sender of the request.
   - SERVER. The computer to which the request was sent. Choose this if you want to examine some aspect of the recipient of the request.

4. In the second list box, choose your next term. The available terms differ depending on the choice you made in the previous step, because the dialog box automatically adjusts the list to contain only those terms that are valid for the context. For example, if you selected HTTP in the previous list box, the only choice is REQ, for requests. Because the App Firewall treats requests and associated responses as a single unit and filters both, you do not need to specify responses separately. After you choose your second term, a third list box appears to the right of the second. The Help window displays a description of the second term, and the Preview Expression window displays your expression.

5. In the third list box, choose the next term. A new list box appears to the right, and the Help window changes to display a description of the new term. The Preview Expression window updates to display the expression as you have specified it to that point.

6. Continue choosing terms, and when prompted filling in arguments, until your expression is complete. If you make a mistake or want to change your expression after you have already selected a term, you can simply choose another term. The expression is modified, and any arguments or additional terms that you added after the term that you modified are cleared.

7. When you have finished constructing your expression, click OK to close the Add Expression dialog box. Your expression is inserted into the Expression text area.

Binding App Firewall policies

September 18, 2018
After you have configured your App Firewall policies, you bind them to Global or a bind point to put them into effect. After binding, any request or response that matches an App Firewall policy is transformed by the profile associated with that policy.

When you bind a policy, you assign a priority to it. The priority determines the order in which the policies you define are evaluated. You can set the priority to any positive integer. In the NetScaler OS, policy priorities work in reverse order - the higher the number, the lower the priority.

Because the App Firewall feature implements only the first policy that a request matches, not any additional policies that it might also match, policy priority is important for achieving the results that you intend. If you give your first policy a low priority (such as 1000), you configure the App Firewall to perform it only if other policies with a higher priority do not match a request. If you give your first policy a high priority (such as 1), you configure the App Firewall to perform it first, and skip any other policies that might also match. You can leave yourself plenty of room to add other policies in any order, without having to reassign priorities, by setting priorities with intervals of 50 or 100 between each policy when you bind your policies.

For more information about binding policies on the NetScaler appliance, see “Policies and Expressions.”

To bind an App Firewall policy by using the command line interface

At the command prompt, type the following commands:

- `bind appfw global <policyName>`
- `save ns config`
- `bind appfw profile <profile_name> -crossSiteScripting data`

**Example**

The following example binds the policy named pl-blog and assigns it a priority of 10.

```
bind appfw global pl-blog 10 save ns config
```

To bind an App Firewall policy by using the GUI

1. Do one of the following:
   - Navigate to **Security > App Firewall**, and in the details pane, click App Firewall policy manager.
   - Navigate to **Security > App Firewall > Policies > Firewall Policies**, and in the details pane, click **Policy Manager**.
2. In the **App Firewall Policy Manager** dialog, choose the bind point to which you want to bind the policy from the drop-down list. The choices are:
   - **Override Global.** Policies that are bound to this bind point process all traffic from all interfaces on the NetScaler appliance, and are applied before any other policies.
   - **LB Virtual Server.** Policies that are bound to a load balancing virtual server are applied only to traffic that is processed by that load balancing virtual server, and are applied before any Default Global policies. After selecting LB Virtual Server, you must also select the specific load balancing virtual server to which you want to bind this policy.
   - **CS Virtual Server.** Policies that are bound to a content switching virtual server are applied only to traffic that is processed by that content switching virtual server, and are applied before any Default Global policies. After selecting CS Virtual Server, you must also select the specific content switching virtual server to which you want to bind this policy.
   - **Default Global.** Policies that are bound to this bind point process all traffic from all interfaces on the NetScaler appliance.
   - **Policy Label.** Policies that are bound to a policy label process traffic that the policy label routes to them. The policy label controls the order in which policies are applied to this traffic.
   - **None.** Do not bind the policy to any bind point.

3. Click **Continue**. A list of existing App Firewall policies appears.
4. Select the policy you want to bind by clicking it.
5. Make any additional adjustments to the binding.
   - To modify the policy priority, click the field to enable it, and then type a new priority. You can also select Regenerate Priorities to renumber the priorities evenly.
   - To modify the policy expression, double click that field to open the **Configure App Firewall Policy** dialog box, where you can edit the policy expression.
   - To set the Goto Expression, double click **field** in the Goto Expression column heading to display the drop-down list, where you can choose an expression.
   - To set the Invoke option, double click **field** in the Invoke column heading to display the drop-down list, where you can choose an expression.
6. Repeat steps 3 through 6 to add any additional App Firewall policies you want to globally bind.
7. Click **OK**. A message appears in the status bar, stating that the policy has been successfully bound.

### Viewing a policy bindings

September 18, 2018

You can quickly check to determine what bindings are in place for any firewall policy by viewing the bindings in the GUI.
To view bindings for an App Firewall policy

1. Navigate to Security > Application Firewall > Policies > Firewall Policies
2. In the details pane, select the policy that you want to check, and then click Show Bindings. The Binding Details for Policy: Policy message box is displayed, with a list of bindings for the selected policy.
3. Click Close.

Supplemental information about App Firewall policies

September 18, 2018

Following is supplemental information about particular aspects of App Firewall policies that system administrators who manage the App Firewall might need to know.

Correct but unexpected behavior

Web application security and modern web sites are complex. In a number of scenarios, a NetScaler policy might cause the App Firewall to behave differently in certain situations than a user who is familiar with policies would normally expect. Following are a number of cases where the App Firewall may behave in an unexpected fashion.

- Request with a missing HTTP Host header and an absolute URL. When a user sends a request, in the majority of cases the request URL is relative. That is, it takes as its starting point the Referer URL, the URL where the user’s browser is located when it sends the request. If a request is sent without a Host header, and with a relative URL, the request is normally blocked both because it violates the HTTP specification and because a request that fails to specify the host could under some circumstances constitute an attack. If a request is sent with an absolute URL, however, even if the Host header is missing, the request bypasses the App Firewall and is forwarded to the web server. Although such a request violates the HTTP specification, it poses no possible threat because an absolute URL contains the host.

Auditing policies

September 18, 2018

Auditing policies determine the messages that are generated and logged during an App Firewall session. These messages are logged in SYSLOG format to the local NSLOG server or to an external logging server. Different types of messages are logged on the basis of the level of logging selected.
To create an auditing policy, you must first create either an NSLOG server or a SYSLOG server. After specifying the server, you create the policy and specify the type of log and the server to which logs are sent.

To create an auditing server by using the command line interface

You can create two different types of auditing server: an NSLOG server or a SYSLOG server. The command names are different, but the parameters for the commands are the same.

To create an auditing server, at the command prompt, type the following commands:

- `add audit syslogAction <name> <serverIP> [-serverPort <port>] -logLevel <logLevel> ... [-dateFormat ( **MMDDYYYY** | **DDMMYYYY** )] [-logFacility <logFacility>] [-tcp ( **NONE** | **ALL** )] [-acl ( **ENABLED** | **DISABLED** )] [-userDefinedAuditlog ( **YES** | **NO** )] [-appflowExport ( **ENABLED** | **DISABLED** )]

- `save ns config`

Example

The following example creates a syslog server named syslog1 at IP 10.124.67.91, with loglevels of emergency, critical, and warning, log facility set to LOCAL1, that logs all TCP connections:

```
1 add audit syslogAction syslog1 10.124.67.91 -logLevel emergency critical warning -logFacility LOCAL1 -tcp ALL
2 save ns config
```

To modify or remove an auditing server by using the command line interface

- To modify an auditing server, type the `set audit <type>` command, the name of the auditing server, and the parameters to be changed, with their new values.
- To remove an auditing server, type the `rm audit <type>` command and the name of the auditing server.

Example

The following example modifies the syslog server named syslog1 to add errors and alerts to the log level:
To create or configure an auditing server by using the GUI

2. In the details pane, click Application the Server tab.
3. Do one of the following:
   • To add a new auditing server, click Add.
   • To modify an existing auditing server, select the server, and then click Edit.
4. In the Create Auditing Server or Configure Auditing Server dialog box, set the following parameters:
   • Name
   • Auditing Type
   • IP Address
   • Port
   • Log Levels
   • Log Facility
   • TCP Logging
   • ACL Logging
   • User-Configurable Log Messages
   • AppFlow Logging
   • Date Format
   • Time Zone
5. Click Create or OK.

To create an auditing policy by using the command line interface

You can create an NSLOG policy or a SYSLOG policy. The type of policy must match the type of server. The command names for the two types of policy are different, but the parameters for the commands are the same.

At the command prompt, type the following commands:

• add audit syslogPolicy <name> <-rule > <action>
• save ns config
Example

The following example creates a policy named syslogP1 that logs App Firewall traffic to a syslog server named syslog1.

```
1 add audit syslogPolicy syslogP1 rule "ns_true" action syslog1
2 save ns config
```

To configure an auditing policy by using the command line interface

At the command prompt, type the following commands:

- `set audit syslogPolicy <name> [-rule <expression>] [-action <string>]`
- `save ns config`

Example

The following example modifies the policy named syslogP1 to log App Firewall traffic to a syslog server named syslog2.

```
1 set audit syslogPolicy syslogP1 rule "ns_true" action syslog2
2 save ns config
```

To configure an auditing policy by using the GUI

1. Navigate to Security > Application Firewall > Policies > Auditing.
2. In the details pane, do one of the following:
   - To add a new policy, click Add.
   - To modify an existing policy, select the policy, and then click Edit.
3. In the Create Auditing Policy or Configure Auditing Policy dialog box, set the following parameters:
   - Name
   - Auditing Type
   - Server
4. Click Create or OK.

Imports

September 18, 2018
NetScaler 12.0

Several App Firewall features make use of external files that you upload to the App Firewall when configuring it. Using the GUI, you manage those files in the Imports pane, which has four tabs corresponding to the four types of files you can import: HTML error objects, XML error objects, XML schemas, and Web Services Description Language (WSDL) files. Using the NetScaler command line, you can import these types of files, but you cannot export them.

**HTML error object**

When a user’s connection to an HTML or Web 2.0 page is blocked, or a user asks for a non-existent HTML or Web 2.0 page, the App Firewall sends an HTML-based error response to the user’s browser. When configuring which error response the App Firewall should use, you have two choices:

- You can configure a redirect URL, which can be hosted on any Web server to which users also have access. For example, if you have a custom error page on your Web server, 404.html, you can configure the App Firewall to redirect users to that page when a connection is blocked.
- You can configure an HTML error object, which is an HTML-based Web page that is hosted on the App Firewall itself. If you choose this option, you must upload the HTML error object to the App Firewall. You do that in the Imports pane, on the HTML Error Object tab.

The error object must be a standard HTML file that contains no non-HTML syntax except for App Firewall error object customization variables. It cannot contain any CGI scripts, server-parsed code, or PHP code. The customization variables enable you to embed troubleshooting information in the error object that the user receives when a request is blocked. While most requests that the App Firewall blocks are illegitimate, even a properly configured App Firewall can occasionally block legitimate requests, especially when you first deploy it or after you make significant changes to your protected Web sites. By embedding information in the error page, you provide the user with the information that he or she needs to give to the technical support person so that any issues can be fixed.

The App Firewall error page customization variables are:

- ${NS_TRANSACTION_ID}. The transaction ID that the App Firewall assigned to this transaction.
- ${NS_APPFW_SESSION_ID}. The App Firewall session ID.
- ${NS_APPFW_VIOLATION_CATEGORY}. The specific App Firewall security check or rule that was violated.
- ${NS_APPFW_VIOLATION_LOG}. The detailed error message associated with the violation.
- {$COOKIE The contents of the specified cookie. For `<CookieName>` substitute the name of the specific cookie that you want to display on the error page. If you have multiple cookies whose contents you want to display for troubleshooting, you can use multiple instances of this customization variable, each with the appropriate cookie name.

**Note:** If you have blocking enabled for the Cookie Consistency Check, any blocked cookies are not displayed on the error page because the App Firewall blocks them.

© 1999-2018 Citrix Systems, Inc. All rights reserved.
To use these variables, you embed them in the HTML or XML of the error page object as if they were an ordinary text string. When the error object is displayed to the user, for each customization variable the App Firewall substitutes the information to which the variable refers. An example HTML error page that uses custom variables is shown below.

```
<!doctype html public "/-//w3c//dtd html 4.0//en"> <html> <head> <title>Page Not Accessible</title> </head> <body> <h1>Page Not Accessible</h1> <p>The page that you accessed is not available. You can:</p> <ul> <li>Return to the <a href="[homePage]">home page</a> or by calling [<helpDeskEmailAddress]>. </li> <li>If you contact the help desk, please provide the following information:</li> </ul> <table cellpadding=8 width=80%> <tr><th align="right" width=30%>Transaction ID</th><td align="left" valign="top" width=70%>{NS_TRANSACTION_ID}</td></tr> <tr><th align="right" width=30%>Session ID</th><td align="left" valign="top" width=70%>{NS_APPFW_SESSION_ID}</td></tr> <tr><th align="right" width=30%>Violation Category</th><td align="left" valign="top" width=70%>{NS_APPFW_VIOLATION_CATEGORY}</td></tr> <tr><th align="right" width=30%>Violation Log</th><td align="left" valign="top" width=70%>{NS_APPFW_VIOLATION_LOG}</td></tr> <tr><th align="right" width=30%>Cookie Name</th><td align="left" valign="top" width=70%>{COOKIE("[cookieName]")}</td></tr> </table>
</body> </html>
```

To use this error page, copy it into a text or HTML editor. Substitute the appropriate local information for the following variables, which are enclosed in square brackets to distinguish them from the NetScaler variables. (Leave those unchanged):

- [homePage]. The URL for your web site’s home page.
- [helpDeskEmailAddress]. The email address that you want users to use to report blocking incidents.
- [helpDeskPhoneNumber]. The phone number that you want users to call to report blocking incidents.
- [cookieName]. The name of the cookie whose contents you want to display on the error page.
**XML error object**

When a user’s connection to an XML page is blocked, or a user asks for a nonexistent XML application, the App Firewall sends an XML-based error response to the user’s browser. You configure the error response by uploading an XML-based error page to the App Firewall in the Imports Pane, on the XML Error Object tab. All XML error responses are hosted on the App Firewall. You cannot configure a redirect URL for XML applications.

*Note:*
You can use the same customization variables in an XML error object as in an HTML error object.

**XML Schema**

When the App Firewall performs a validation check on a user’s request for an XML or Web 2.0 application, it can validate the request against the XML schema or design type document (DTD) for that application and reject any request that does not follow the schema or DTD. Both an XML schema and a DTD are standard XML configuration files that describe the structure of a specific type of XML document.

**WSDL**

When the App Firewall performs a validation check on a user’s request for an XML SOAP-based web service, it can validate the request against the web services type definition (WSDL) file for that web service. A WSDL file is a standard XML SOAP configuration file that defines the elements of a specific XML SOAP web service.

**Importing and exporting files**

September 18, 2018

You can import HTML or XML error objects, XML schemas, DTDs, and WSDLs to the App Firewall by using the GUI or the command line. You can edit any of these files in a web-based text area after importing them, to make small changes directly on the NetScaler instead of having to make them on your computer and then reimport them. Finally, you can export any of these files to your computer, or delete any of these files, by using the GUI.

*Note:*
You cannot delete or export an imported file by using the command line.
To import a file by using the command line interface

At the command prompt, type the following commands:

- `import appfw htmlerrorpage <src> <name>`
- `<save> ns config`

Example

The following example imports an HTML error object from a file named error.html and assigns it the name HTMLError.

```
1 import htmlerrorpage error.html HTMLError
2 save ns config
```

To import a file by using the GUI

Before you attempt to import an XML schema, DTD, or WSDL file, or an HTML or XML error object from a network location, verify that the NetScaler can connect to the Internet or LAN computer where the file is located. Otherwise, you cannot import the file or object.

1. Navigate to Security > Application Firewall > Imports.
2. Navigate to Application Firewall > Imports.
3. In the Application Firewall Imports pane, select the tab for the type of file you want to import, and then click Add.

   The tabs are HTML Error Page, XML Error Page, XML Schema or WSDL. The upload process is identical on all four tabs from the user point of view.

4. Fill in the dialog fields.
   - **Name**—A name for the imported object.
   - **Import From**—Choose the location of the HTML file, XML file, XML schema or WSDL that you want to import in the drop-down list:
     - **URL**: A web URL on a website accessible to the appliance.
     - **File**: A file on a local or networked hard disk or other storage device.
     - **Text**: Type or paste the text of the custom response directly into a text field in the GUI.

   The third text box changes to the appropriate value. The three possible values are provided below.
   - **URL**—Type the URL into the text box.
- **File**—Type the path and filename to the HTML file directly, or click Browse and browse to the HTML file.
- **Text**—The third field is removed, leaving a blank space.

5. Click **Continue**. The File Contents dialog is displayed. If you chose URL or File, the File Contents text box contains the HTML file that you specified. If you chose Text, the File Contents text box is empty.

6. If you chose Text, type or copy and paste the custom response HTML that you want to import.

7. Click **Done**.

8. To delete an object, select the object, and then click **Delete**.

### To export a file by using the GUI

Before you attempt to export an XML schema, DTD, or WSDL file, or an HTML or XML error object, verify that the App Firewall appliance can access the computer where the file is to be saved. Otherwise, you cannot export the file.

1. Navigate to **Security > App Firewall > Imports**.
2. In the **App Firewall Imports** pane, select the tab for the type of file you want to export.
   
The export process is identical on all four tabs from the user point of view.
3. Select the file that you want to export.
4. Expand the Action drop-down list, and select **Export**.
5. In the dialog box, choose **Save File** and click **OK**.
6. In the **Browse** dialog box, navigate to the local file system and directory where you want to save the exported file, and click **Save**.

### To edit an HTML or XML Error Object in the GUI

You edit the text of HTML and XML error objects in the GUI without exporting and then reimporting them.

1. Navigate to **Security > Application Firewall > Imports**, and then select the tab for the type of file that you want to modify.
2. Navigate to **Application Firewall > Imports**, and then select the tab for the type of file that you want to modify.
3. Select the file that you want to modify, and then click **Edit**.

The text of the HTML or XML error object is displayed in a browser text area. You can modify the text by using the standard browser-based editing tools and methods for your browser.

Note: The edit window is designed to allow you to make minor changes to your HTML or XML error object. To make extensive changes, you may prefer to export the error object to your local computer and use standard HTML or XML web page editing tools.

4. Click **OK**, and then click **Close**.

---

**Global configuration**

September 18, 2018

The App Firewall global configuration affects all profiles and policies. The Global Configuration items are:

- **Engine Settings.** A collection of global settings—session cookie name, session time-out, maximum session lifetime, logging header name, undefined profile, default profile, and import size limit—that pertain to all connections that the App Firewall processes, rather than to a specific subset of connections.

- **Confidential Fields.** A set of form fields in web forms that contain sensitive information that should not be logged to the App Firewall logs. Form fields such as password fields on a logon page or credit card information on a shopping cart checkout form are normally designated as confidential fields.

- **Field Types.** The list of web form field types used by the Field Formats security check. Each of these field types is defined by a PCRE-compliant regular expression that defines the type of data and the minimum/maximum length of data that should be allowed in that type of form field.

- **XML Content Types.** The list of content types recognized as XML and subjected to XML-specific security checks. Each of these content types is defined by a PCRE-compliant regular expression that defines the exact MIME type assigned to that content.

- **JSON Content Types.** The list of content types recognized as JSON and subjected to JSON-specific security checks. Each of these content types is defined by a PCRE-compliant regular expression that defines the exact MIME type assigned to that content.

---

**Engine settings**

September 20, 2018

The engine settings affect all requests and responses that the App Firewall processes. They include the following items:
• **Cookie name**—The name of the cookie that stores the NetScaler session ID.

• **Session timeout**—The maximum inactive period allowed. If a user session shows no activity for this length of time, the session is terminated and the user is required to reestablish it by visiting a designated start page.

• **Cookie post-encrypt prefix**—The string that precedes the encrypted portion of any encrypted cookies.

• **Maximum session lifetime**—The maximum amount of time, in seconds, that a session is allowed to remain live. After this period is reached, the session is terminated and the user is required to reestablish it by visiting a designated start page. This setting cannot be less than the session timeout. To disable this setting, so that there is no maximum session lifetime, set the value to zero (0).

• **Logging header name**—The name of the HTTP header that holds the Client IP, for logging.

• **Undefined profile**—The profile applied when the corresponding policy action evaluates as undefined.

• **Default profile**—The profile applied to connections that do not match a policy.

• **Import size limit**—The maximum cumulative total byte count of all files imported to the appliance, including signatures, WSDLs, schemas, HTML and XML error pages. During an import, if the size of the imported object would cause the cumulative total sizes of all imported files to exceed the configured limit, the import operation fails and the appliance displays the following error message: ERROR: Import failed - exceeding the configured total size limit on the imported objects.

• **Learn message rate limit**—The maximum number of requests and responses per second that the learning engine is to process. Any additional requests or responses over this limit are not sent to the learning engine.

• **Entity decoding**—Decode HTML entities when running App Firewall checks.

• **Log malformed request**—Enable logging of malformed HTTP requests.

• **Use configurable secret key**—Use a configurable secret key for App Firewall operations.

• **Reset learned data**—Remove all learned data from the App Firewall. Restarts the learning process by collecting fresh data.

Two settings, **Reset Learned Data** and **Signatures Auto-Update**, are found in different places depending on whether you use the command line or the GUI to configure your App Firewall. When using the command line, you configure Reset Learned Data by using the `reset appfw learningdata` command, which takes no parameters and has no other functions. You configure Signatures Auto-Update in the `set appfw settings` command: the `-signatureAutoUpdate` parameter enables or disables auto-updating of the signatures, and `-signatureUrl` configures the URL which hosts the updated signatures file.

When using the GUI, you configure Reset Learned Data in **Security > App Firewall > Engine Settings**; the **Reset Learned Data** button is at the bottom of the dialog box. You configure Signatures Auto-Update for each set of signatures in **Security > App Firewall > Signatures**, by selecting the signatures file, clicking the right mouse button and selecting **Auto Update Settings**.
Normally, the default values for the App Firewall settings are correct. If the default settings cause a conflict with other servers or cause premature disconnection of your users, however, you might need to modify them.

The **App Firewall** session limit is configurable using the following command:

```
1 > set appfw settings -sessionLimit 500000
2 Done
3 Default value:100000  Max value:500000 per PE
```

**To configure engine settings by using the command line interface**

At the command prompt, type the following commands:

- `set appfw settings [-sessionCookieName <name>] [-sessionTimeout <positiveInteger>] [-sessionLifetime <positiveInteger>] [-clientIPLoggingHeader <headerName>] [-undefaction <profileName>] [-defaultProfile <profileName>] [-importSizeLimit <positiveInteger>] [-logMalformedReq ( ON | OFF )] [-signatureAutoUpdate ( ON | OFF )] [-signatureUrl <expression>] [-cookiePostEncryptPrefix <string>] [-entityDecoding ( ON | OFF )] [-useConfigurableSecretKey ( ON | OFF )] [-learnRateLimit <positiveInteger>]`

- `save ns config`

**Example**

```
1 set appfw settings -sessionCookieName citrix-appfw-id -sessionTimeout 3600
2 -sessionLifetime 14400 -clientIPLoggingHeader NS-AppFW-Client-IP -undefaction APPFW_RESET
3 -defaultProfile APPFW_RESET -importSizeLimit 4096
4 save ns config
```

**To configure engine settings by using the GUI**

1. Navigate to **Security > App Firewall**
2. In the details pane, click **Change Engine Settings**.
3. In the **App Firewall Engine Settings** dialog box, set the following parameters:
   - Cookie Name
   - Session Timeout
You can designate web-form fields as confidential to protect the information users type into them. Normally, any information a user types into a web form on one of your protected web servers is logged in the NetScaler logs. The information typed into a web-form field designated as confidential, however, is not logged. That information is saved only where the web site is configured to save such data, normally in a secure database.

Common types of information that you may want to protect with a confidential field designation include:

- Passwords
- Credit card numbers, validation codes, and expiration dates
- Social security numbers
- Tax ID numbers
- Home addresses
- Private telephone numbers

In addition to being good practice, proper use of confidential field designations may be necessary for PCI-DSS compliance on ecommerce servers, HIPAA compliance on servers that manage medical information in the United States, and compliance with other data protection standards.

**Important:**

In the following two cases, the Confidential Field designation does not function as expected:
NetScaler 12.0

- If a Web form has either a confidential field or an action URL longer than 256 characters, the field or action URL is truncated in the NetScaler logs.
- With certain SSL transactions, the logs are truncated if either the confidential field or the action URL is longer than 127 characters.

In either of these cases, the App Firewall masks a fifteen-character string with the letter “x,” instead of the normal eight character string. To ensure that any confidential information is removed, the user must use form field name and action URL expressions that match the first 256, or (in cases where SSL is used) the first 127 characters.

To configure your App Firewall to treat a web-form field on a protected web site as confidential, you add that field to the Confidential Fields list. You can enter the field name as a string, or you can enter a PCRE-compatible regular expression specifying one or more fields. You can enable the confidential-field designation when you add the field, or you can modify the designation later.

To add a confidential field by using the command line interface

At the command prompt, type the following commands:

- `add appfw confidField <fieldName> <url> [-isRegex ( REGEX | NOTREGEX ) ] [-comment "<string>" ] [-state ( ENABLED | DISABLED ) ]`
- `save ns config`

Example

The following example adds all web form fields whose names begin with Password to the confidential fields list.

```
1 add appfw confidField Password "https://www[.].example[.].com/[<^>*[^a-zA-Z]password[0-9a-zA-Z_-.]*[.](asp|cgi|htm|html|htp|js|php)" -isRegex REGEX -state ENABLED
2 save ns config
```

To modify a confidential field by using the command line interface

At the command prompt, type the following commands:

- `set appfw confidField <fieldName> <url> [-isRegex ( REGEX | NOTREGEX ) ] [-comment "<string>" ] [-state ( ENABLED | DISABLED ) ]`
- ‘save ns config’
Example

The following example modifies the confidential field designation to add a comment.

```
1 set appfw confidField Password "https://www[.]example[.]com/[^[<>]*[^a-z]password[0-9a-z_-]*[.]asp|cgi|htm|html|htp|js|php]" -comment "Protect password fields." -isRegex REGEX -state ENABLED
2 save ns config
```

To remove a confidential field by using the command line interface

At the command prompt, type the following commands:

- `rm appfw confidField <fieldName> <url>
- `save ns config`

To configure a confidential field by using the GUI

1. Navigate to Security > Application Firewall.
2. In the details pane, under Settings, click Manage Confidential Fields.
3. In the Manage Confidential Fields dialog box, do one of the following:
   - To add a new form field to the list, click Add.
   - To change an existing confidential field designation, select the field, and then click Edit.

   The App Firewall Confidential Fields dialog box appears.

   **Note:**
   If you select an existing confidential field designation and then click Add, the Create Confidential Form Field dialog box displays the information for that confidential field. You can modify that information to create your new confidential field.

4. In the dialog box, fill out the elements. They are:
   - **Enabled check box.** Select or clear to enable/disable this confidential field designation.
   - **Is form field name a regular expression check box.** Select or clear to enable PCRE-format regular expressions in the form field name.
   - **Field Name.** Enter a literal string or PCRE-format regular expression that either represents a specific field name or that matches multiple fields with names that follow a pattern.
   - **Action URL.** Enter a literal URL or a regular expression that defines one or more URLs of the web page(s) on which the web form(s) that contains the confidential field are located.
   - **Comments.** Enter a comment. Optional.
5. Click Create or OK.
6. To remove a confidential field designation from the confidential fields list, select the confidential field listing you want to remove, then click Remove to remove it, and then click OK to confirm.
your choice.
7. When you have finished adding, modifying, and removing confidential field designations, click Close.

Examples

Following are some regular expressions that define form field names that you might find useful:

- `^passwd_` (Applies confidential-field status to all field names that begin with the “passwd_” string.)

```
^([0-9a-zA-Z._-]*) \x[0-9A-Fa-f][0-9A-Fa-f]+- )?passwd_  (Applies confidential-field status to all field names that begin with the string passwd_, or that contain the string -passwd_ after another string that might contain non-ASCII special characters.)
```

Following are some regular expressions that define specific URL types that you might find useful. Substitute your own web host(s) and domain(s) for those in the examples.

- If the web form appears on multiple web pages on the web host www.example.com, but all of those web pages are named logon.pl?, you could use the following regular expression:

```
https?://www[.]example[.]com/([0-9A-Za-z][0-9A-Za-z._-]*[0-9A-Za-z._-]+)*logon[.]pl?
```

- If the web form appears on multiple web pages on the web host www.example-español.com, which contains the n-tilde (ñ) special character, you could use the following regular expression, which represents the n-tilde special character as an encoded UTF-8 string containing C3 B1, the hexadecimal code assigned to that character in the UTF-8 charset:

```
https?://www[.]example-espa\xc3\xb1ol[.]com/([0-9A-Za-z][0-9A-Za-z._-]*[0-9A-Za-z._-]+)*logon[.]pl?
```

- If the web form containing query.pl appears on multiple web pages on different hosts within the example.com domain, you could use the following regular expression:
If the web form containing query.pl appears on multiple web pages on different hosts in different domains, you could use the following regular expression:

```
https://([^A-Za-z][A-Za-z-]*[^A-Za-z]+[.])*example[.]com/([^A-Za-z][A-Za-z-]*[^A-Za-z]+[.])*logon[.]pl?
```

If the web form appears on multiple web pages on the web host www.example.com, but all of those web pages are named logon.pl?, you could use the following regular expression:

```
https://www[.]example[.]com/([^A-Za-z][A-Za-z-]*[^A-Za-z]+[.])*logon[.]pl?
```

**Field types**

September 20, 2018

A field type is a PCRE-format regular expression that defines a particular data format and minimum/maximum data lengths for a form field in a web form. Field types are used in the Field Formats check.

The App Firewall comes with several default field types, which are:

- **integer.** A string of any length consisting of numbers only, without a decimal point, and with an optional preceding minus sign (-).
- **alpha.** A string of any length consisting of letters only.
- **alphanum.** A string of any length consisting of letters and/or numbers.
- **nohtml.** A string of any length consisting of characters, including punctuation and spaces, that does not contain HTML symbols or queries.
- **any.** Anything at all.

---

**Important:**

Assigning the any field type as the default field type, or to a field, allows active scripts, SQL commands, and other possibly dangerous content to be sent to your protected web sites and applications in that form field. You should use the any type sparingly, if you use it at all.
You can also add your own field types to the Field Types list. For example, you might want to add a field type for a social security number, postal code, or phone number in your country. You might also want to add a field type for a customer identification number or store credit card number.

To add a field type to the Field Types list, you enter the field name as a literal string or PCRE-format regular expression.

**To add a field type by using the command line interface**

At the command prompt, type the following commands:

- `add appfw fieldType <name> <regex> <priority> [-comment "<string>"]`
- `save ns config`

**Example**

The following example adds a field type named SSN that matches US Social Security numbers to the Field Types list, and sets its priority to 1.

```plaintext
1  add appfw fieldType SSN "^[1-9][0-9]{2,2}[-][0-9]{4,4}$" 1
2  save ns config
```

**To modify a field type by using the command line interface**

At the command prompt, type the following commands:

- `set appfw fieldType <name> <regex> <priority> [-comment "<string>"]`
- `save ns config`

**Example**

The following example modifies the field type to add a comment.
To remove a field type by using the command line interface

At the command prompt, type the following commands:

- `> rm appfw fieldType <name>`
- `save ns config`

To configure a field type by using the GUI

1. Navigate to Security > Application Firewall.
2. In the details pane, under Settings, click Manage Field Types.
3. In the Manage Field Types dialog box, do one of the following:
   - To add a new field type to the list, click Add.
   - To change an existing field type, select the field type, and then click Edit.
     The Configure Field Type dialog box appears.
     Note:
     If you select an existing field type designation and then click Add, the dialog box displays the information for that field type. You can modify that information to create your new field type.
4. In the dialog box, fill out the elements. They are:
   - Name
   - Regular Expression
   - Priority
   - Comment
5. Click Create or OK.
6. To remove a field type from the Field Types list, select the field type listing you want to remove, then click Remove to remove it, and then click OK to confirm your choice.
7. When you have finished adding, modifying, and removing field types, click Close.
Examples

Following are some regular expressions for field types that you might find useful:

^\[1-9\][0-9]{ 2,2 } -[0-9 } { 2,2 } -[0-9]{ 4,4 } $ U.S. Social Security numbers

^\[A-C\]\[0-9\]{ 7,7 } $ California driver’s license numbers

^+[0-9]{ 1,3 } [0-9()-){ 1,40 } $ International phone numbers with country codes

^[0-9]{ 5,5 } -[0-9]{ 4,4 } $ U.S. ZIP code numbers.

^[0-9A-Za-z][0-9A-Za-z.+-] [0,25] @(^[0-9A-Za-z][0-9A-Za-z.+-]*[.]){ 1,4 } [A-Za-z]{ 2,6 } $ Email addresses.

XML content types

September 18, 2018

By default, the App Firewall treats files that follow certain naming conventions as XML. You can configure the App Firewall to examine web content for additional strings or patterns that indicate that those files are XML files. This can ensure that the App Firewall recognizes all XML content on your site, even if certain XML content does not follow normal XML naming conventions, ensuring that XML content is subjected to XML security checks.

To configure the XML content types, you add the appropriate patterns to the XML Content Types list. You can enter a content type as a string, or you can enter a PCRE-compatible regular expression specifying one or more strings. You can also modify the existing XML content types patterns.

To add an XML content type pattern by using the command line interface

At the command prompt, type the following commands:

- add appfw XMLContentType <XMLContentTypevalue> [-isRegex ( REGEX | NOTREGEX )]

- save ns config

Example

The following example adds the pattern .*/xml to the XML Content Types list and designates it as a regular expression.
To remove an XML content type pattern by using the command line interface

At the command prompt, type the following commands:

- `rm appfw XMLContentType <XMLContentTypevalue>`
- `save ns config`

To configure the XML content type list by using the GUI

1. Navigate to Security > App Firewall.
2. In the details pane, under Settings, click Manage XML Content Types.
3. In the Manage XML Content Types dialog box, do one of the following:
   - To add a new XML content type, click Add.
   - To modify an existing XML content type, select that type and then click Edit.
     The Configure App Firewall XML Content Type dialog appears. Note: If you select an existing XML content type pattern and then click Add, the dialog box displays the information for that XML content type pattern. You can modify that information to create your new XML content type pattern.
4. In the dialog box, fill out the elements. They are:
   - `IsRegex`. Select or clear to enable PCRE-format regular expressions in the form field name.
   - `XML ContentType` Enter a literal string or PCRE-format regular expression that matches the XML content type pattern that you want to add.
5. Click Create.
6. To remove an XML content type pattern from the list, select it, then click Remove to remove it, and then click OK to confirm your choice.
7. When you have finished adding and removing XML content type patterns, click Close.

JSON content types

September 18, 2018

By default, the App Firewall treats files with the content type “application/json” as JSON files. The default setting enables the App Firewall to recognize JSON content in requests and responses, and to handle that content appropriately.

You can configure the App Firewall to examine web content for additional strings or patterns that indicate that those files are JSON files. This can ensure that the App Firewall recognizes all JSON content.
on your site, even if certain JSON content does not follow normal JSON naming conventions, ensuring that JSON content is subjected to JSON security checks.

To configure the JSON content types, you add the appropriate patterns to the JSON Content Types list. You can enter a content type as a string, or you can enter a PCRE-compatible regular expression specifying one or more strings. You can also modify the existing JSON content types patterns.

**To add a JSON content type pattern by using the command line interface**

At the command prompt, type the following commands:

- `add appfw JSONContentType <JSONContentTypevalue> [-isRegex ( REGEX | NOTREGEX )]
- `save ns config`

**Example**

The following example adds the pattern `*/json` to the JSON Content Types list and designates it as a regular expression.

```
1 add appfw JSONContentType "*/json" -isRegex REGEX
```

**To configure the JSON content type list by using the GUI**

1. Navigate to Security > Application Firewall.
2. In the details pane, under Settings, click Manage JSON Content Types.
3. In the Manage JSON Content Types dialog box, do one of the following:
   - To add a new JSON content type, click Add.
   - To modify an existing JSON content type, select that type and then click Edit.
   The Configure App Firewall JSON Content Type dialog appears.
   Note: If you select an existing JSON content type pattern and then click Add, the dialog box displays the information for that JSON content type pattern. You can modify that information to create your new JSON content type pattern.
4. In the dialog box, fill out the elements. They are:
   - **IsRegex**. Select or clear to enable PCRE-format regular expressions in the form field name.
   - **JSON Content Type** Enter a literal string or PCRE-format regular expression that matches the JSON content type pattern that you want to add.
5. Click Create or OK.
6. To remove a JSON content type pattern from the list, select it, then click Remove to remove it, and then click OK to confirm your choice.
When you have finished adding and removing XML content type patterns, click **Close**.

### Statistics and reports

**September 20, 2018**

The information maintained in the logs and statistics, and displayed in the reports, provides important guidance for configuring and maintaining the App Firewall.

#### The App Firewall statistics

When you enable the statistics action for App Firewall signatures or security checks, the App Firewall maintains information about connections that match that signature or security check. You can view the accumulated statistics information on the Monitoring tab of the main logon page of your App Firewall appliance by selecting one of the following choices in the Select Group list box:

- **App Firewall**. A summary of all statistics information gathered by your App Firewall appliance for all profiles.
- **App Firewall (per profile)**. The same information, but displayed per-profile rather than summarized.

You can use this information to monitor how your App Firewall is operating and determine whether there is any abnormal activity or abnormal amounts of hits on a signature or security check. If you see such a pattern of abnormal activity, you can check the logs for that signature or security check, to diagnose the issue, and then take corrective action.

#### The App Firewall reports

The App Firewall reports provide information about your App Firewall configuration and how it is handling traffic for your protected web sites.

#### The PCI DSS report

The Payment Card Industry (PCI) Data Security Standard (DSS), version 1.2, consists of twelve security criteria that most credit card companies require businesses who accept online payments via credit and debit cards to meet. These criteria are designed to prevent identity theft, hacking, and other types of fraud. If an internet service provider or online merchant does not meet the PCI DSS criteria, that ISP or merchant risks losing authorization to accept credit card payments through its web site.
ISPs and online merchants prove that they are in compliance with PCI DSS by having an audit conducted by a PCI DSS Qualified Security Assessor (QSA) Company. The PCI DSS report is designed to assist them both before and during the audit. Before the audit, it shows which App Firewall settings are relevant to PCI DSS, how they should be configured, and (most important) whether your current App Firewall configuration meets the standard. During the audit, the report can be used to demonstrate compliance with relevant PCI DSS criteria.

The PCI DSS report consists of a list of those criteria that are relevant to your App Firewall configuration. Under each criterion, it lists your current configuration options, indicates whether your current configuration complies with the PCI DSS criterion, and explains how to configure the App Firewall so that your protected web site(s) will be in compliance with that criterion.

The PCI DSS report is located under **System > Reports**. To generate the report as an Adobe PDF file, click **Generate PCI DSS Report**. Depending on your browser settings, the report is displayed in the pop-up window or you are prompted to save it to your hard disk.

**Note:**
To view this and other reports, you must have the Adobe Reader program installed on your computer.

The PCI DSS report consists of the following sections:

- **Description.** A description of the PCI DSS Compliance Summary report.
- **Firewall License and Feature Status.** Tells you whether the App Firewall is licensed and enabled on your NetScaler appliance.
- **Executive Summary.** A table that lists the PCI DSS criteria and tells you which of those criteria are relevant to the App Firewall.
- **Detailed PCI DSS Criteria Information.** For each PCI DSS criterion that is relevant to your App Firewall configuration, the PCI DSS report provides a section that contains information about whether your configuration is currently in compliance and, if it is not, how to bring it into compliance.
- **Configuration.** Data for individual profiles, which you access either by clicking App Firewall Configuration at the top of the report, or directly from the Reports pane. The App Firewall Configuration report is the same as the PCI DSS report, with the PCI DSS-specific summary omitted, and is described below.

**The App Firewall configuration report**

The App Firewall Configuration report is located under **System > Reports**. To display it, click Generate App Firewall Configuration Report. Depending on your browser settings, the report is displayed in the pop-up window or you are prompted to save it to your hard disk.
The App Firewall Configuration report starts with a Summary page, which consists of the following sections:

- **App Firewall Policies.** A table that lists your current App Firewall policies, showing the policy name, the content of the policy, the action (or profile) it is associated with, and global binding information.
- **App Firewall Profiles.** A table that lists your current App Firewall profiles and indicates which policy each profile is associated with. If a profile is not associated with a policy, the table displays INACTIVE in that location.

To download all report pages for all policies, at the top of the Profiles Summary page click Download All Profiles. You display the report page for each individual profile by selecting that profile in the table at the bottom of the screen. The Profile page for an individual profile shows whether each check action is enabled or disabled for each check, and the other configuration settings for the check.

To download a PDF file containing the PCI DSS report page for the current profile, click **Download Current Profile** at the top of the page. To return to the Profiles Summary page, click **App Firewall Profiles.** To go back to the main page, click **Home.** You can refresh the PCI DSS report at any time by clicking **Refresh** in the upper right corner of the browser. You should refresh the report if you make changes to your configuration.

**App Firewall logs**

January 6, 2019

The App Firewall generated log messages can be quite useful for keeping track of the configurational changes, App Firewall policy invocations, and security check violations.

When the log action is enabled for security checks or signatures, the resulting log messages provide information about the requests and responses that the App Firewall has observed while protecting your web sites and applications. The most important information is the action taken by the App Firewall when a signature or a security check violation was observed. For some security checks, the log message can provide additional useful information, such as the location and the detected pattern that triggered the violation. You can deploy security checks in non-block mode and monitor the logs to determine whether the transactions that are triggering security violations are valid transactions (false positives). If they are, you can either remove, or reconfigure the signature or security checks, deploy relaxations, or take other appropriate measures to mitigate the false positives before you enable blocking for that signature or security check. An excessive increase in the number of violation messages in logs can indicate a surge in malicious requests. This can alert you that your application might be under attack to exploit a specific vulnerability that is detected and thwarted by App Firewall protections.
NetScaler 12.0

**NetScaler (Native) format logs**

The App Firewall uses the NetScaler format logs (also called native format logs) by default. These logs have the same format as those generated by other NetScaler features. Each log contains the following fields:

- **Timestamp.** Date and time when the connection occurred.
- **Severity.** Severity level of the log.
- **Module.** NetScaler module that generated the log entry.
- **Event Type.** Type of event, such as signature violation or security check violation.
- **Event ID.** ID assigned to the event.
- **Client IP.** IP address of the user whose connection was logged.
- **Transaction ID.** ID assigned to the transaction that caused the log.
- **Session ID.** ID assigned to the user session that caused the log.
- **Message.** The log message. Contains information identifying the signature or security check that triggered the log entry.

You can search for any of these fields, or any combination of information from different fields. Your selection is limited only by the capabilities of the tools you use to view the logs. You can observe the App Firewall log messages in the GUI by accessing the NetScaler syslog viewer, or you can manually connect to the NetScaler appliance and access logs from the command line interface, or you can drop into shell and tail the logs directly from the /var/log/ folder.

**Example of a Native Format Log message**

```
Jun 22 19:14:37 <local0.info> 10.217.31.98 06/22/2015:19:14:37 GMT ns 0-PPE-1 :

field text_area="Bad tag: script" <blocked>
```

**Common Event Format (CEF) Logs**

The App Firewall also supports CEF logs. CEF is an open log management standard that improves the interoperability of security-related information from different security and network devices and...
NetScaler 12.0

applications. CEF enables customers to use a common event log format so that data can easily be collected and aggregated for analysis by an enterprise management system. The log message is broken into different fields so that you can easily parse the message and write scripts to identify important information.

Analyzing the CEF Log Message

In addition to date, timestamp, client IP, log format, appliance, company, build version, module, and security check information, App Firewall CEF Log messages include the following details:

- src – source IP address
- spt – source port number
- request – request URL
- act – action (e.g. blocked, transformed)
- msg – message (Message regarding the observed security check violation)
- cn1 – event ID
- cn2 – HTTP Transaction ID
- cs1 – profile name
- cs2 – PPE ID (e.g. PPE1)
- cs3 – Session ID
- cs4 – Severity (e.g. INFO, ALERT)
- cs5 – event year
- cs6 – Signature violation category
- method – Method (e.g. GET/POST)

For example, consider the following CEF format log message, which was generated when a Start URL violation was triggered:

```
1 Jun 12 23:37:17 <local0.info> 10.217.31.98 CEF:0|Citrix|NetScaler|NS11.0
2 |APPFW|APPFW_STARTURL|6|src=10.217.253.62 spt=47606 method=GET
3 request=http://aaron.stratum8.net/FFC/login.html msg=Disallow Illegal URL. cn1=1340
4 cn2=653 cs1=pr_ffc cs2=PPE1 cs3=EsdGd3VD00aaURLcZnj05Y6D0mE0002 cs4=ALERT cs5=2015
5 act=blocked
```

The above message can be broken down into different components. Refer to the CEP log components table.

Example of a request check violation in CEF log format: request is not blocked

```
1 Jun 13 00:21:28 <local0.info> 10.217.31.98 CEF:0|Citrix|NetScaler|NS11.0
|APPFW|

```

Logging geolocation in the App Firewall violation messages

Geolocation, which identifies the geographic location from which requests originate, can help you configure the App Firewall for the optimal level of security. To bypass security implementations such as rate limiting, which rely on the IP addresses of the clients, malware or rogue computers can keep changing the source IP address in requests. Identifying the specific region from where requests are coming can help determine whether the requests are from a valid user or a device attempting to launch
cyberattacks. For example, if an excessively large number of requests are received from a specific area, it is easy to determine whether they are being sent by users or a rogue machine. Geolocation analysis of the received traffic can be very useful in deflecting attacks such as denial of service (DoS) attacks.

The App Firewall offers you the convenience of using the built-in NetScaler database for identifying the locations corresponding to the IP addresses from which malicious requests are originating. You can then enforce a higher level of security for requests from those locations. Citrix default syntax (PI) expressions give you the flexibility to configure location based policies that can be used in conjunction with the built-in location database to customize firewall protection, bolstering your defense against coordinated attacks launched from rogue clients in a specific region.

You can use the NetScaler built-in database, or you can use any other database. If the database does not have any location information for the particular client IP address, the CEF log shows geolocation as an Unknown geolocation.

Note: Geolocation logging uses the Common Event Format (CEF). By default, CEF logging and GeoLocationLogging are OFF. You must explicitly enable both parameters.

Example of a CEF log message showing geolocation information

Example of a log message showing geolocation= Unknown

Using the command line to configure the log action and other log parameters

To configure the log action for a security checks of a profile by using the command line
At the command prompt, type one of the following commands:
• set appfw profile <name> SecurityCheckAction ([log] | [none])
• unset appfw profile <name> SecurityCheckAction

Examples

set appfw profile pr_ffc StartURLAction log
unset appfw profile pr_ffc StartURLAction

To configure CEF logging by using the command line

The CEF logging is disabled by default. At the command prompt, type one of the following commands to change or display the current setting:

• set appfw settings CEFLogging on
• unset appfw settings CEFLogging
• sh appfw settings | grep CEFLogging

To configure the logging of the credit card numbers by using the command line

At the command prompt, type one of the following commands:

• set appfw profile <name> -doSecureCreditCardLogging ([ON] | [OFF])
• unset appfw profile <name> -doSecureCreditCardLogging

To configure Geolocation logging by using the command line

1. Use the set command to enable GeoLocationLogging. You can enable the CEF logging at the same time. Use the unset command to disable geolocation logging. The show command shows the current settings of all the App Firewall parameters, unless you include the grep command to show the setting for a specific parameter.

   • set appfw settings GeoLocationLogging ON [CEFLogging ON]
   • unset appfw settings GeoLocationLogging
   • sh appfw settings | grep GeoLocationLogging

2. Specify the database

   add locationfile /var/netscaler/inbuilt_db/Citrix_netscaler_InBuilt_GeoIP_DB.csv

   or

   add locationfile <path to database file>

Customizing App Firewall Logs

Default format (PI) expressions give you the flexibility to customize the information included in the logs. You have the option to include the specific data that you want to capture in the App Firewall generated log messages. For example, if you are using AAA-TM authentication along with the App
Firewall security checks, and would like to know the accessed URL that triggered the security check violation, the name of the user who requested the URL, the source IP address, and the source port from which the user sent the request, you can use the following commands to specify customized log messages that include all the data:

Default format (PI) expressions give you the flexibility to customize the information included in the logs. You have the option to include the specific data that you want to capture in the App Firewall generated log messages. For example, if you are using AAA-TM authentication along with the App Firewall security checks, and would like to know the accessed URL that triggered the security check violation, the name of the user who requested the URL, the source IP address, and the source port from which the user sent the request, you can use the following commands to specify customized log messages that include all the data:

```
1 > sh version
2 NetScaler NS12.1: Build 50.0013.nc, Date: Aug 28 2018, 10:51:08 (64-bit)
3 Done
```

```
1 > add audit messageaction custom1 ALERT 'HTTP.REQ.URL + " " + HTTP.REQ.USER.NAME + " " + CLIENT.IP.SRC + ":" + CLIENT.TCP.SRCPORT'
2 Warning: HTTP.REQ.USER has been deprecated. Use AAA.USER instead.
3 Done
```

```
1 > add appfw profile test_profile
2 Done
```

```
1 > add appfw policy appfw_pol true test_profile -logAction custom1
2 Done
```

### Configuring Syslog policy to segregate App Firewall logs

The App Firewall offers you an option to isolate and redirect the App Firewall security log messages to a different log file. This might be desirable if the App Firewall is generating a large number of logs, making it difficult to view other NetScaler log messages. You can also use this option when you are interested only in viewing the App Firewall log messages and do not want to see the other log messages.

To redirect the App Firewall logs to a different log file, configure a syslog action to send the App Firewall logs to a different log facility. You can use this action when configuring the syslog policy, and bind it globally for use by App Firewall.

**Example:**
1. Switch to the shell and use an editor such as vi to edit the /etc/syslog.conf file. Add a new entry to use local2.* to send logs to a separate file as shown in the following example:

   `local2.* /var/log/ns.log.appfw`

2. Restart the syslog process. You can use the grep command to identify the syslog process ID (PID), as shown in the following example:

   `root@ns## ps -A | grep syslog
   1063 ?? Ss 0:03.00 /usr/sbin/syslogd -b 127.0.0.1 -n -v -v -8 -C
   root@ns## kill -HUP 1063`

3. From the command line interface, configure the syslog action and policy. Bind it as a global App Firewall policy.

   ```
   > add audit syslogAction sysact 1.1.1.1 -logLevel ALL -logFacility LOCAL2
   > add audit syslogPolicy syspol1 ns_true sysact1
   > bind appfw global syspol1 100
   ```

   1. All App Firewall security check violations will now be redirected to the /var/log/ns.log.appfw file. You can tail this file to view the App Firewall violations that are getting triggered during the processing of the ongoing traffic.

   `root@ns## tail -f ns.log.appfw`

Warning: If you have configured the syslog policy to redirect the logs to a different log facility, the App Firewall log messages no longer appear in the /var/log/ns.log file.

**Viewing the App Firewall logs**

You can view the logs by using the syslog viewer, or by logging onto the NetScaler appliance, opening a UNIX shell, and using the UNIX text editor of your choice.

To access the log messages by using the command line

Switch to the shell and tail the nslogs in the /var/log/ folder to access the log messages pertaining to the App Firewall security check violations:

- Shell
  - `tail -f /var/log/ns.log`

You can use the vi editor, or any Unix text editor or text search tool, to view and filter the logs for specific entries. For example, you can use grep command to access the log messages pertaining to the Credit Card violations:

- `tail -f /var/log/ns.log | grep SAFECOMMERCE`
To access the log messages by using the GUI

The NetScaler GUI includes a very useful tool (Syslog Viewer) for analyzing the log messages. You have multiple options for accessing the Syslog Viewer:

- To view log messages for a specific security check of a profile, navigate to **App Firewall > Profiles**, select the target profile, and click Security Checks. Highlight the row for the target security check and click Logs. When you access the logs directly from the selected security check of the profile, it filters out the log messages and displays only the logs pertaining to the violations for the selected security check. Syslog viewer can display App Firewall logs in the Native format as well as the CEF format. However, in order for the syslog viewer to filter out the target profile specific log messages, the logs must be in the CEF log format when accessed from the profile.
- You can also access the Syslog Viewer by navigating to **NetScaler > System > Auditing**. In the Audit Messages section, click Syslog messages link to display the Syslog Viewer, which displays all log messages, including all App Firewall security check violation logs for all profiles. This is useful for debugging when multiple security check violations might be triggered during request processing.
- Navigate to **App Firewall > policies > Auditing**. In the Audit Messages section, click Syslog messages link to display the Syslog Viewer, which displays all log messages, including all security check violation logs for all profiles.

The HTML based Syslog Viewer provides the following filter options for selecting only the log messages that are of interest to you:

- **File**—The current `/var/log/ns.log` file is selected by default, and the corresponding messages appear in the Syslog Viewer. A list of other log files in the `/var/log` directory are available in a compressed `.gz` format. To download and un-compress an archived log file, just select the log file from the dropdown option. The log messages pertaining to the selected file are then displayed in the syslog viewer. To refresh the display, click the Refresh icon (a circle of two arrows).
- **Module list box**—You can select the NetScaler module whose logs you want to view. You can set it to APPFW for App Firewall logs.
- **Event Type list box**—This box contains a set of check boxes for selecting the type of event you are interested in. For example, to view the log messages pertaining to the signature violations, you can select the `APPFW_SIGNATURE_MATCH` check box. Similarly, you can select a check box to enable the specific security check that is of interest to you. You can select multiple options.
- **Severity**—You can select a specific severity level to show just the logs for that severity level. Leave all the check boxes blank if you want to see all logs.

To access the App Firewall security check violation log messages for a specific security check, filter by selecting **APPFW** in the dropdown options for Module. The Event Type displays a rich set of options to further refine your selection. For example, if you select the `APPFW_FIELDFORMAT` check box and click the Apply button, only log messages pertaining to the Field Formats secu-
rity check violations appear in the Syslog Viewer. Similarly, if you select the APPFW_SQL and APPFW_STARTURL check boxes and click the Apply button, only log messages pertaining to these two security check violations will appear in the syslog viewer.

If you place the cursor in the row for a specific log message, multiple options, such as Module, EventType, EventID, ClientIP, TransactionID, and so on appear below the log message. You can select any of these options to highlight the corresponding information in the logs.

**Click to Deploy:** This functionality is available only in the GUI. You can use the Syslog Viewer to not only view the logs but also to deploy relaxation rules based on the log messages for the App Firewall security check violations. The log messages must be in CEF log format for this operation. If the relaxation rule can be deployed for a log message, a check box appears at the right edge of the Syslog Viewer box in the row. Select the check box, and then select an option from the Action list to deploy the relaxation rule.

**Edit & Deploy, Deploy, and Deploy All** are available as Action options. For example, you can select an individual log message to edit and deploy. You can also select the check boxes for multiple log messages from one or more security checks and use the Deploy or Deploy All option. Click to Deploy functionality is currently supported for the following security checks:

- StartURL
- URL Buffer overflow
- SQL Injection
- XSS
- Field consistency
- Cookie consistency

To use Click to Deploy functionality in the GUI

1. In the Syslog Viewer, select APPFW in the Module options.
2. Select the security check for which to filter corresponding log messages.
3. Enable the check box to select the rule.
4. Use the Action drop-down list of options to deploy the relaxation rule.
5. Verify that the rule appears in the corresponding relaxation rule section.

**Note:**
SQL Injection and XSS rules that are deployed by using Click Deploy option do not include the fine grain relaxation recommendations.
Highlights

- **CEF Log Format support**—The CEF log format option provides a convenient option to monitor, parse, and analyze the App Firewall log messages to identify attacks, fine tune configured settings to decrease false positives, and gather statistics.
- **Click to Deploy**—The Syslog viewer provides an option to filter, evaluate, and deploy relaxation rules for single or multiple security check violations from one convenient location.
- **Option to customize log message**—You can use advanced PI expressions to customize log messages and include the data you want to see in the logs.
- **Segregate App Firewall specific logs**—You have an option to filter and redirect application-firewall specific logs to a separate log file.
- **Remote Logging**—You can redirect the log messages to a remote syslog server.
- **Geolocation Logging**—You can configure the App Firewall to include the geolocation of the area from where the request is received. A built-in geolocation database is available, but you have the option to use an external geolocation database. The NetScaler appliance supports both IPv4 and IPv6 static geolocation databases.
- **Information rich log message**—Following are some examples of the type of information that can be included in the logs, depending on the configuration:
  - An App Firewall policy was triggered.
  - A security check violation was triggered.
  - A request was considered to be malformed.
  - A request or the response was blocked or not blocked.
  - Request data (such as SQL or XSS special characters) or response data (such as Credit card numbers or safe object strings) was transformed.
  - The number of credit cards in the response exceeded the configured limit.
  - The credit card number and type.
  - The log strings configured in the signature rules, and the signature ID.
  - Geolocation information about the source of the request.
  - Masked (X’d out) user input for protected confidential fields.

Appendices

September 18, 2018

The following supplemental material provides additional detail about complex or peripheral App Firewall tasks.
PCRE character encoding format

September 18, 2018

The NetScaler operating system supports direct entry of characters in the printable ASCII character set only—characters with hexadecimal codes between HEX 20 (ASCII 32) and HEX 7E (ASCII 127). To include a character with a code outside that range in your App Firewall configuration, you must enter its UTF-8 hexadecimal code as a PCRE regular expression.

A number of character types require encoding using a PCRE regular expression if you include them in your App Firewall configuration as a URL, form field name, or Safe Object expression. They include:

- **Upper-ASCII characters.** Characters with encodings from HEX 7F (ASCII 128) to HEX FF (ASCII 255). Depending on the character map used, these encodings can refer to control codes, ASCII characters with accents or other modifications, non-Latin alphabet characters, and symbols not included in the basic ASCII set. These characters can appear in URLs, form field names, and safe object expressions.

- **Double-Byte characters.** Characters with encodings that use two 8-byte words. Double-byte characters are used primarily for representing Chinese, Japanese, and Korean text in electronic format. These characters can appear in URLs, form field names, and safe object expressions.

- **ASCII control characters.** Non-printable characters used to send commands to a printer. All ASCII characters with hexadecimal codes less than HEX 20 (ASCII 32) fall into this category. These characters should never appear in a URL or form field name, however, and would rarely if ever appear in a safe object expression.

The NetScaler appliance does not support the entire UTF-8 character set, but only the characters found in the following eight charsets:

- **English US (ISO-8859-1).** Although the label reads, “English US,” the App Firewall supports all characters in the ISO-8859-1 character set, also called the Latin-1 character set. This character set fully represents most modern western European languages and represents all but a few uncommon characters in the rest.

- **Chinese Traditional (Big5).** The App Firewall supports all characters in the BIG5 character set, which includes all of the Traditional Chinese characters (ideographs) commonly used in modern Chinese as spoken and written in Hong Kong, Macau, Taiwan, and by many people of Chinese ethnic heritage who live outside of mainland China.

- **Chinese Simplified (GB2312).** The App Firewall supports all characters in the GB2312 character set, which includes all of the Simplified Chinese characters (ideographs) commonly used in modern Chinese as spoken and written in mainland China.

- **Japanese (SJIS).** The App Firewall supports all characters in the Shift-JIS (SJIS) character set, which includes most characters (ideographs) commonly used in modern Japanese.

• **Korean (EUC-KR).** The App Firewall supports all characters in the EUC-KR character set, which includes all characters (ideographs) commonly used in modern Korean.

• **Turkish (ISO-8859-9).** The App Firewall supports all characters in the ISO-8859-9 character set, which includes all letters used in modern Turkish.

• **Unicode (UTF-8).** The App Firewall supports certain additional characters in the UTF-8 character set, including those used in modern Russian.

When configuring the App Firewall, you enter all non-ASCII characters as PCRE-format regular expressions using the hexadecimal code assigned to that character in the UTF-8 specification. Symbols and characters within the normal ASCII character set, which are assigned single, two-digit codes in that character set, are assigned the same codes in the UTF-8 character set. For example, the exclamation point (!), which is assigned hex code 21 in the ASCII character set, is also hex 21 in the UTF-8 character set. Symbols and characters from another supported character set have a paired set of hexadecimal codes assigned to them in the UTF-8 character set. For example, the letter a with an acute accent (á) is assigned UTF-8 code C3 A1.

The syntax you use to represent these UTF-8 codes in the App Firewall configuration is “xNN” for ASCII characters; “xNNxNN” for non-ASCII characters used in English, Russian, and Turkish; and “xNNxN-NxNN” for characters used in Chinese, Japanese, and Korean. For example, if you want to represent a ! in an App Firewall regular expression as a UTF-8 character, you would type x21. If you want to include an á, you would type xC3xA1.

**Note:**

Normally you do not need to represent ASCII characters in UTF-8 format, but when those characters might confuse a web browser or an underlying operating system, you can use the character’s UTF-8 representation to avoid this confusion. For example, if a URL contains a space, you might want to encode the space as \x20 to avoid confusing certain browsers and web server software.

Below are examples of URLs, form field names, and safe object expressions that contain non-ASCII characters that must be entered as PCRE-format regular expressions to be included in the App Firewall configuration. Each example shows the actual URL, field name, or expression string first, followed by a PCRE-format regular expression for it.

• A URL containing extended ASCII characters. Actual URL: [http://www.josenuñez.com](http://www.josenuñez.com)
  Encoded URL: ^http://www[.]jos\xC3\xA9nu\xC3\xB1ez[.]com$

• Another URL containing extended ASCII characters. Actual URL: [http://www.example.de/trömsö.html](http://www.example.de/trömsö.html)
  Encoded URL: ^http://www[.]example[.]de/tr\xC3\xB6msö[.]html$
A form field name containing extended ASCII characters. Actual Name: nome_do_usuário  Encoded Name: ^nome_do_usu\xC3\xA1rio$

A safe object expression containing extended ASCII characters. Unencoded Expression \[A-Z]{ 3,6 } \[1-9\][0-9]{ 6,6 }  Encoded Expression: \[A-Z]{ 3,6 } \xC2\xA5[1-9][0-9]{ 6,6 }

You can find a number of tables that include the entire Unicode character set and matching UTF-8 encodings on the Internet. A useful web site that contains this information is located at the following URL:

```
http://www.utf8-chartable.de/unicode-utf8-table.pl
```

For the characters in the table on this web site to display correctly, you must have an appropriate Unicode font installed on your computer. If you do not, the visual display of the character may be in error. Even if you do not have an appropriate font installed to display a character, however, the description and the UTF-8 and UTF-16 codes on this set of web pages will be correct.

**Whitehat WASC signature types for WAF use**

September 18, 2018

The NetScaler App Firewall accepts and generates blocking rules for all vulnerability types that the Whitehat scanners generate. However, certain vulnerabilities are most applicable to a web App Firewall. Following are lists of those vulnerabilities, categorized by whether they are addressed by WASC 1.0, WASC 2.0, or best practices signature types.

**WASC 1.0 signature types**

- HTTP Request Smuggling
- HTTP Response Splitting
- HTTP Response Smuggling
- Null Byte Injection
- Remote File Inclusion
- URL Redirector Abuse

**WASC 2.0 signature types**

- Abuse of Functionality
- Brute Force
- Content Spoofing
• Denial of Service  
• Directory Indexing  
• Information Leakage  
• Insufficient Anti-automation  
• Insufficient Authentication  
• Insufficient Authorization  
• Insufficient Session Expiration  
• LDAP Injection  
• Session Fixation

**Best Practices**

• Autocomplete Attribute  
• Insufficient Cookie Access Control  
• Insufficient Password Strength  
• Invalid HTTP Method Usage  
• Non-HttpOnly Session Cookie  
• Persistent Session Cookie  
• Personally Identifiable Information  
• Secured Cachable HTTP Messages  
• Unsecured Session Cookie

**Streaming support for request processing**

January 18, 2019

**Note:**

This feature is available in NetScaler release 10.5.e.

The NetScaler App Firewall now uses request side streaming, which results in a significant performance boost. Instead of buffering the entire request before processing it, the App Firewall now looks at the incoming data, field by field, to inspect the input of each field for any configured security check violation (SQL, XSS, Field Consistency, Field Formats, etc.). As soon as the processing of the data for a field is completed, it is forwarded to the backend while the evaluation continues for the remaining fields. This significantly improves the processing time specially when handling large posts where the forms have large number of fields.

**Note:**

When Web App Firewall perform request side streaming, only additional 64 non-standard http
headers are parsed as part of web app firewall streaming process. The requests containing more than 64 non standard http headers are dropped.

Although the streaming process is transparent to the users, minor configuration adjustments are required due to the following changes:

**RegEx Pattern Match**: RegEx pattern match is now restricted to 4K for contiguous character string match.

**FieldNameMatch**: App Firewall learning engine can only distinguish the first 128 bytes of the name for learning. If a form has multiple fields with names that have identical string match for the first 128 bytes, the learning engine may not be able to distinguish between them. Similarly, the deployed relaxation rule might inadvertently relax all such fields.

Removing white spaces, percent decoding, unicode decoding, and charset conversion which is done during canonicalization is carried out prior to security check inspection. The 128 byte limit is applicable to the canonicalized representation of the field name in UTF-8 character format. The ASCII characters are 1 byte but the UTF-8 representation of the characters in some international languages may range from 1-4 bytes. If each character in the name takes 4 bytes when converted to UTF-8 format, only first 32 characters in the name may be distinguished by the learned rule for such a language.

**Field Consistency Check**: When the field Consistency check is enabled, all the forms in the session are now stored based on the “as_fid” tag inserted by the App Firewall without consideration for the “action_url.”

- **Mandatory Form tagging for Form Field consistency**: When the field consistency check is enabled, the form tag must be enabled also. The Field Consistency protection might not work if form tagging is turned off.

- **Sessionless Form Field Consistency**: The App Firewall no longer carries out the “GET” to “POST” conversion of forms when sessionless field consistency parameter is enabled. The form tag is required for sessionless field consistency also.

- **Tampering of as_fid**: If a form is submitted after tampering as_fid, it now triggers field consistency violation even if no other field was tampered. In non-streaming requests, this was allowed because the forms could be validated using the “action_url” stored in the session.

**Signatures**: The signatures now have the following specifications:

- **Location**: It is now a mandatory requirement that location must be specified for each pattern. All patterns in the rule **MUST** have a `<Location>` tag.

- **Fast Match**: All signature rules must have a fast match pattern. If there is no fast match pattern, an attempt will be made to select one if possible. Fast match must be a literal string but some PCRE’s can be used for fast match if they contain a usable literal string.

- **Deprecated Locations**: Following locations are no longer supported in signature rules.
  - HTTP_ANY
NetScaler 12.0

- HTTP_RAW_COOKIE
- HTTP_RAW_HEADER
- HTTP_RAW_RESP_HEADER
- HTTP_RAW_SET_COOKIE

**XSS/SQL Transform:** Raw data is used for transformation because the SQL special characters (single quote('), backslash (), and semicolon (;), and XSS tags (< and >)) are same in all languages and do not need canonicalization of data. All representations of these characters, such as HTML entity encoding, percent encoding, or ASCII are evaluated for transform operation.

The App Firewall no longer inspects both the attribute name and value for the XSS transform operation. Now only XSS attribute names are transformed when streaming is engaged.

**Processing XSS Tags:** As part of the streaming changes in 10.5.e build onwards, the App Firewall processing of the Cross-site Scripting tags has changed. In earlier releases, presence of either open bracket (<), or close bracket (>), or both open and close brackets (<>) was flagged as Cross-site Scripting Violation. The behavior has changed in 10.5.e build onwards. Presence of only the open bracket character (<), or only the close bracket character (>) is no longer considered as an attack. It is when an open bracket character (<) is followed by a close bracket character (>) that the Cross-site scripting attack gets flagged. Both characters must be present in the right order (< followed by >) to trigger Cross-site scripting violation.

**Note**

**Change in SQL violation log Message:** As part of the streaming changes in 10.5.e build onwards, we now process the input data in blocks. RegEx pattern matching is now restricted to 4K for contiguous character string matching. With this change, the SQL violation log messages might include different information compared to the earlier builds. The keyword and special character in the input could be separated by a large number of bytes. We now keep track of the SQL keywords and special strings when processing the data, instead of buffering the entire input value. In addition to the field name, the log message now includes the SQL keyword, or the SQL special character, or both the SQL keyword and the SQL special character, as determined by the configured setting. The rest of the input is no longer included in the log message, as shown in the following example:

**Example:**

In 10.5, when the App Firewall detects the SQL violation, the entire input string might be included in the log message, as shown below:

SQL Keyword check failed for field text="select a name from testbed1;\(\(;\)\)".*<blocked>

In 11.0, we log only the field name, keyword and special character (if applicable) in the log message, as shown below:

© 1999-2018 Citrix Systems, Inc. All rights reserved. 1696
SQL Keyword check failed for field text="select()"

This change is applicable to requests that contain application/x-www-form-urlencoded, or multipart/form-data, or text/x-gwt-rpc content-types. Log messages generated during processing of JSON or XML payloads are not affected by this change.

**RAW POST Body:** The security check inspections are always done on RAW POST body.

**Form ID:** The App Firewall inserted “as_fid” tag, which is a computed hash of the form, will no longer be unique for the user session. It will now have an identical value for a specific form irrespective of the user or the session.

**Charset:** If a request does not have a charset, the default charset specified in the application profile is used when processing the request.

**Counters:**

Counters with prefix “se_” and “appfwreq_” are added to track the streaming engine and the App Firewall streaming engine request counters respectively.

```
nsconsmg -d statswt0 -g se_err_
nsmmsg -d statswt0 -g se_tot_
nsmmsg -d statswt0 -g se_cur_
nsmmsg -d statswt0 -g appfwreq_err_
nsmmsg -d statswt0 -g appfwreq_tot_
nsmmsg -d statswt0 -g appfwreq_cur_
```

_err counters: indicate the rare event which should have succeeded but failed due to either memory allocation problem or some other resource crunch.

_tot counters: ever increasing counters.

_cur counters: counters indicating current values that keep changing based on usage from current transactions.

**Tips:**

- The App Firewall security checks should work exactly the same as before.
- There is no set ordering for the processing of the security checks.
- The response side processing is not affected and remains unchanged.
- Streaming is not engaged if CVPN is used.

**Important**

**Calculating the Cookie length:** In release 10.5.e (in a few interim enhancement builds prior to 59.13xx.e build) as well as in the 11.0 release (in builds prior to 65.x), App Firewall processing of the
Cookie header was changed. In those releases, every cookie is evaluated individually, and if the length of any one cookie received in the Cookie header exceeds the configured BufferOverflow-MaxCookieLength, the Buffer Overflow violation is triggered. As a result of this change, requests that were blocked in 10.5 and earlier release builds might be allowed, because the length of the entire cookie header is not calculated for determining the cookie length. In some situations, the total cookie size forwarded to the server might be larger than the accepted value, and the server might respond with “400 Bad Request”.

Note that this change has been reverted. The behavior in the 10.5.e -59.13xx.e and subsequent 10.5.e enhancement builds as well as in the 11.0 release 65.x and subsequent builds is now similar to that of the non-enhancement builds of release 10.5. The entire raw Cookie header is now considered when calculating the length of the cookie. Surrounding spaces and the semicolon (;) characters separating the name-value pairs are also included in determining the cookie length.

### Trace HTML requests with security logs

January 6, 2019

**Note:**

This feature is available in NetScaler release 10.5.e.

Troubleshooting a problem, which requires analysis of data received in the client request can be quite challenging specially when there is heavy traffic flowing through the box. Diagnosing issues which may affect the functionality or security of the application require a quick response.

The NetScaler now offers the option to isolate traffic for a specific App Firewall profile and collect nstrace for the HTML requests that trigger a log or block action or malformed requests that might be causing reset or aborts. The nstrace collected in –appfw mode will include details of the entire request including the App Firewall generated log messages. You can use “Follow TCP stream” in the trace to view the details of the individual transaction including headers, payload, as well as the corresponding log message, together in the same screen.

This gives you a comprehensive overview regarding your traffic. Having a detailed view of the request, payload, and associated log records can be very useful to analyze security check violation. You can easily identify the pattern that is triggering the violation. If the pattern should be allowed, you can take a decision to modify the configuration and/or add a relaxation rule.

This enhancement helps in troubleshooting the NetScaler and offers the following benefits:

1. **Isolate traffic for specific profile:** This enhancement can be quite useful when you need to isolate traffic for only one profile or specific transactions of a profile for troubleshooting. You no longer have to skim through the entire data collected in the trace or need special filters to
isolate requests that are of interest to you which can be tedious especially with heavy traffic. You now have the option to view only the data that you are interested in.

2. **Collect data for specific requests:** The trace can be collected for a specified duration. You can collect trace for only a couple of requests to isolate, analyze, and debug specific transactions if needed.

3. **Identify resets or aborts:** Unexpected closing of connections are not easily visible. The trace collected in –appfw mode captures a reset or an abort, triggered by the App Firewall. This allows a quicker isolation of issue when you do not see a security check violation message. Malformed requests or other non-RFC compliant requests terminated by App Firewall will now be easier to identify.

4. **View decrypted SSL traffic:** HTTPS traffic is captured in plain text to allow for easier troubleshooting.

5. **Provides comprehensive view:** Allows you to look at the entire request at the packet level, check the payload, look at the logs to check what security check violation is being triggered and identify the match pattern in the payload. If the payload consists of any unexpected data, junk strings, or non-printable characters (null character, \r or \n etc), they are easy to discover in the trace.

6. **Modify configuration:** The debugging can provide useful information to decide if the observed behavior is the correct behavior or the configuration should be modified.

7. ** Expedite response time:** Faster debugging on target traffic can improve the response time to provide explanations and/or root cause analysis by Citrix engineering and support team.

Please see any task topic in eDocs for documenting tasks. Manual Configuration by using the command line interface

To configure debug tracing for a profile by using the command line interface

Step 1. Enable tracing for the profile. You can use the show command to verify the configured setting.

• `set appfw profile <profile> -trace ON`

Step 2. Start collecting trace. You can continue to use all the options which are applicable for the nstrace command.

• `start nstrace -mode APPFW`

Stop collecting the trace

• `stop nstrace`

**Location of the trace:** The nstrace is stored in a time-stamped folder which is created in the /var/nstrace directory and can be viewed using wireshark. You can tail the /var/log/ns.log to see the log messages providing details regarding the location of the new trace.

**Tips:**
• When –appfw mode option is used, the nstrace will only collect the data for the profile(s) for which “trace” was enabled.

• Enabling trace on the profile will not automatically start collecting the traces till you explicitly execute the “start nstrace” command to collect the trace.

• Although, enabling trace on a profile may not have any adverse effect on the performance of the App Firewall but you may want to enable this feature only for the duration for which you want to collect the data. It is recommended that you turn the –trace flag off after you have collected the trace. This will prevent the risk of inadvertently getting data from profiles for which you had enabled this flag in the past.

• The Block or Log action must be enabled for the security check for the transaction record to be included in the nstrace.

• Resets and aborts will be logged independently of security checks actions when trace is “On” for the profile(s).

• This feature is only applicable for troubleshooting the requests received from the client. The traces in –appfw mode do not include the responses received from the server.

• You can continue to use all the options which are applicable for the nstrace command. For example,

  
  start nstrace -tcpdump enabled -size 0 -mode appFW

• If a request triggers multiple violations, the nstrace for that record will include all the corresponding log messages.

• CEF log message format is supported for this functionality.

• Signature violations triggering block and/or log action for request side checks will also be included in the trace.

• Only HTML (non-XML) requests are collected in the trace.

Example of a Log record in the trace:

**App Firewall support for cluster configurations**

September 18, 2018

**Note:**

App Firewall support for Striped and partially striped configurations was introduced in NetScaler release 11.0.
A cluster is a group of NetScaler appliances that are configured and managed as a single system. Each appliance in the cluster is called a node. Depending on the number of nodes the configurations are active on, cluster configurations are referred to as striped, partially striped, or spotted configurations. The App Firewall is fully supported in all configurations.

The two main advantages of striped and partially striped virtual server support in cluster configurations are the following:

1. Session failover support—Striped and partially striped virtual server configurations support session failover. The advanced App Firewall security features, such as Start URL Closure and the Form Field Consistency check, maintain and use sessions during transaction processing. In ordinary high availability configurations, or in spotted cluster configurations, when the node that is processing the App Firewall traffic fails, all the session information is lost and the user has to reestablish the session. In striped virtual server configurations, user sessions are replicated across multiple nodes. If a node goes down, a node running the replica becomes the owner. Session information is maintained without any visible impact to the user.

2. Scalability—Any node in the cluster can process the traffic. Multiple nodes of the cluster can process the incoming requests served by the striped virtual server. This improves the App Firewall’s ability to handle multiple simultaneous requests, thereby improving the overall performance.

Security checks and signature protections can be deployed without the need for any additional cluster-specific App Firewall configuration. You just do the usual App Firewall configuration on the configuration coordinator (CCO) node for propagation to all the nodes.

**Note:**

The session information is replicated across multiple nodes, but not across all the nodes in the striped configuration. Therefore, failover support accommodates a limited number of simultaneous failures. If multiple nodes fail simultaneously, the App Firewall might lose the session information if a failure occurs before the session is replicated on another node.

**Highlights**

- App Firewall offers scalability, high throughput, and session failover support in cluster deployments.
- All App Firewall security checks and signature protections are supported in all cluster configurations.
- Character-Maps are not yet supported for a cluster. The learning engine recommends Field-Types in learned rules for the Field Format security check.
- Stats and learned rules are aggregated from all the nodes in a cluster.
- Distributed Hash Table (DHT) provides the caching of the session and offers the ability to replicate session information across multiple nodes. When a request comes to the virtual server, the
NetScaler appliance creates App Firewall sessions in the DHT, and can also retrieve the session information from the DHT.

- Clustering is licensed with the Enterprise and Platinum licenses. This feature is not available with the Standard license.

### Debugging and troubleshooting

**September 18, 2018**

Refer to the following troubleshooting and debugging information related to each of the App Firewall functionality:

- Application Firewall - High CPU
- Memory
- Large File Upload Failure
- Learning
- Signatures
- Trace log
- Miscellaneous

### High CPU

**December 18, 2018**

Following are some of the functionality and high CPU related debugging issues encountered and the best practices to follow when working with App Firewall:

- **Check Policy hits, Bindings, Network configuration, App Firewall configuration**
  - Identify misconfiguration
  - Identify vserver that is serving the affected traffic

- **Inspect logs in the following log files for security violations and recent configuration changes**
  - `/var/log/ns.log`
  - `/var/nslog/import.log`
  - `/var/nslog/aslearn.log`

  ```
tail -f /var/log/ns.log  grep APPFW_SIGNATURE_MATCH
  ```
Example:

```
Jun 13 01:11:09 <local0.info> 10.217.31.98 CEF:0|Citrix|NetScaler|NS11.0|APPFW| APPFW_SIGNATURE_MATCH|6|src=10.217.253.62 spt=61141 method =GET request= http://aaron.stratum8.net/FFC/wwwboard/passwd.txt msg=Signature violation rule ID 807: web-cgi/wwwboard/passwd.txt access cn1=140 cn2=841 cs1=pr_fcc cs2=PPE0 cs3=OyTgjbXBqcBFeENKD1de30kMQ00001 cs4=ALERT cs5=2015 cs6=web-cgi act=not blocked
```

- Isolate the traffic that is affected
  - Isolate the profile
  - Isolate the security check
  - Isolate the URL, vserver and traffic parameters

- Conditional profile level trace helps identify the traffic and violation records
  - `set appfw profile <profile> -trace ON`
  - `start nstrace -mode APPFW -size 0`
  - `stop nstrace`

Note: Ensure that the trace is collected with `-size 0` option.

- Check appfw, dht, IP reputation activity counters
  - `nsconmsg -g cc_cpu_use -g appfwreq -g iprep -d current`

- Monitor window size for resets in connection
  - Appfw sets the window size to 9845 when NetScaler resets the connection due to an invalid http message.

Examples:

- Malformed request received - connection reset
- High CPU related issues
- Check data sheets for system limits
- Inspect for cpu usage, appfw, DHT and memory related activity. Monitor appfw sessions
  - `nsconmsg -g cc_cpu_use -g appfwreq -g as -g dht -g mem_AS_OBJ -g mem_AS_COMPONENT -d current`

- Monitor memory allocated and freed from App Firewall components and objects during the target time period. It helps in isolating the protection leading to high CPU usage.
  - Profiler output
- Observe logs

- **Isolate appfw check leading to high CPU**
  - startURLClosure
  - Formfiledconsistency
  - CSRF
  - Cookie protections
  - Referer header check

**Ascertain that autoupdate of signatures is not leading to high CPU (Disable to confirm).**

**Memory**

September 18, 2018

Following are some of the best practices to follow when encountered with App Firewall usage memory related issues:

**nsconmsg command usage:**

- Look for global memory statistics to ascertain that there is enough memory in the system and there are no memory allocation failures by executing the following command:

  ```
  * * nsconmsg -d memstats
  ```

- Observe current allocated and maximum memory limits for appsecure, IP reputation, cache and compression by executing the following command:

  ```
  - nsconmsg -d memstats | egrep -i APPSECURE|IPREP|CACHE|CMP
  ```

- Check appfw, DHT, IP reputation activity counters by executing the following command:

  ```
  - nsconmsg -g as -g appfwreq_ -g iprep -d current
  ```

- Check all App Firewall error counters by executing the following command:

  ```
  - nsconmsg -g as_ -g appfwreq_ -g iprep_ -d stats | grep err
  ```

- Check all system error counters by executing the following command:

  ```
  - nsconmsg -g err -d current
  ```

- Inspect for CPU, APPFWREQ, AS and DHT counters by executing the following command:

  ```
  - nsconmsg -g cc_cpu_use -g appfwreq -g as -g dht -d current
  ```

- Check the configured Cache memory by executing the following command:
• show cacheparameter

• Check the configured memory by executing the following command:
  
  • nsconmsg -d memstats | egrep -i CACHE

• Identify distribution of memory in App Firewall components and objects:

  Display AS_OBJ_memory:
  
  • nsconmsg -K newnslog -d stats | grep AS_OBJ | egrep -v AppFW_cpu0 | total
  | sort -k3

  Display AS_COMPONENT_memory:
  
  • nsconmsg -K newnslog -d stats | grep AS_COMPONENT | egrep -v AppFW_cpu0
  | total | sort -k3

• Check for number of alive sessions by executing the following command:

  Monitor/plot active session counts:
  
  • nsconmsg -g as_alive_sessions -d current

  Monitor/plot total allocated, free, updated sessions:
  
  • nsconmsg -g as_tot_alloc_sessions -g as_tot_free_sessions -d current
  • nsconmsg -g as_tot_update_sessions -d current

  If required, reduce session timeout to ensure that session limits are not used by executing the following command:
  
  -set appfwsettings -sessionTimeout <300>

  If required, set maximum lifetime of session by executing the following command:
  
  -set appfwsettings -sessionLifetime <7200>

### Checking allocated and used memory

To check the total allocated memory and used memory:

• Use the nsconmsg –d memstats command. Observe the MEM_APPSECURE field.
• Use the stat appfw command to obtain memory consumption information.

App Firewall does not automatically delete the logs after certain period of time or size.

• All AppFw logs are archived in the */var/log/ns.* file. The ns.log file performs the rollover task.
For more information, refer to the following link: <http://support.citrix.com/article/CTX121898>

**Increasing App Firewall memory:**

- There is no CLI option to increase App Firewall memory. App Firewall memory is platform-specific.
- You may use the `nsapimg` option to increase memory but it is not recommended.

The max allowed memory for App Firewall is determined by the platform and disabling IC does not impact memory allocation.

**Large file upload failure**

September 18, 2018

When you encounter large file upload failures, ensure that you check the following:

- Misconfigured appfw postbody limit
- Enabled file upload scanning leading to increased processing time
- Hitting system limits

- Since release 11.0, the streaming flag can be enabled on per profile basis to avoid buffering by executing the following command:

  ```
  - set appfw profile <profile name> -streaming on
  ```

- Ensure that the backend server supports chunked requests.

**Learning**

September 18, 2018

Following are some of the best practices recommended when encountered with Learning functionality issues:

**Aslearn process:**

- Verify that the process `aslearn` is running.
- Check top command output
- Check output of `ps` command by executing the following command:

  ```
  - ps -ax | grep aslearn | grep -v "grep"
  ```

**Example:**
Identify recent configuration commands executed prior to the observed problem by verifying the `ns.log` file:

- `/var/log/ns.log`

Inspect aslearn logs to check for aslearn messages:

- `/var/log/aslearn.log`

Isolate the profile and security check that is effected

Identify the GUI and CLI command which is failing by executing the following command:

```
show appfw learningdata <profileName> <securityCheck>
```

Examples:

- show learningdata test_profile starturl
- show learningdata test_profile crosssiteScripting
- show learningdata test_profile sqLInjection
- show learningdata test_profile csRFtag
- show learningdata test_profile fieldformat
- show learningdata test_profile fieldconsistency

Perform integrity check of sqlite from ns prompt:

```
nsshell ## sqlite3 /var/nslog/asl/<profile_name_in_lowercase>.db pragma integrity_check;
```

Examples:

```
1 - root@ns# sqlite3 /var/nslog/asl/tsk0247284.db pragma integrity_check;
2
3 - Error: file is encrypted or is not a database
4
5 - root@ns# sqlite3 /var/nslog/asl/tsk0247284.db pragma integrity_check;
```

Ok

Deploy or remove rules to start learning again:
• If 2000 learn items (per protection) are reached, you cannot start learning any more for that protection
• If 20 MB size is reached for the database, stop learning for all protections
• Restart aslearn process

*/netscaler/aslearn -start -f/netscaler/aslearn.conf*

• Check the space in the /var folder by executing the following:
  • du -h /var

• Check the learning threshold limits by executing the following command:
  • show appfwlearningsettings <profile_name> <securityCheck>

• Collect learned data by executing the following command:
  • export appfwlearningdata <profile_name> <securityCheck>

• Ascertain that learned data is uploaded in the collector.

**Signatures**

September 18, 2018

**Getting started with signatures**

To add signature:

1. Select the Default-signature and click **add** to make a copy.
2. Give a meaningful name. The new sig object is added as a User-Defined object.
3. Enable the target rules that are pertinent to your specific need.

– The rules are disabled by default.
– more rules require more processing

4; Configure the actions:

– Block and Log actions are enabled by default. Stats is another option

5; Set the signature to be used by your profile.
**Tips for using signatures**

- Optimize the processing overhead by enabling only those signatures that are applicable for protecting your application.
- Every pattern in the rule must match to trigger a signature match.
- You can add your own customized rules to inspect incoming requests to detect various types of attacks, such as SQL injection or cross-site scripting attacks.
- You can also add rules to inspect the responses to detect and block leakage of sensitive information such as credit card numbers.
- Add multiple security check conditions to create your own customized check.

**Best practices for using signatures**

Following are some of the best practices you can follow when encountered with issues related to Signatures:

- Verify that the import command has succeeded on primary as well as secondary.
- Verify that CLI and GUI outputs are consistent.
- Check ns.log to identify any errors during signature import and auto update.
- Check if the DNS name server is configured properly.
- Check schema version incompatibility.
- Check if the device is unable to access the Signature Update URL hosted on AWS for auto-update.
- Check for the version mismatch between Default signature and user-added ones.
- Check for version mismatch between signature objects on the primary and secondary nodes.
- Monitor for High CPU Utilization (disable auto-update to rule out issue with signature update).

**Trace Log**

September 18, 2018

To record trace logs:

1. Enable tracing for the profile. You can use the show command to verify the configured setting.
   ```bash
   set appfw profile <profile> -trace ON
   ```
2. Start collecting trace. You can continue to use all the options which are applicable for the nstrace command.
start nstrace -mode APPFW

3. Stop collecting the trace
   stop nstrace

Location of the trace: The nstrace is stored in a time-stamped folder which is created in the /var/nstrace directory and can be viewed using wireshark. You can tail the /var/log/ns.log file to see the log messages providing details regarding the location of the new trace.

Advantages of trace logs:
- Isolate traffic for specific profile
- Collect data for specific requests
- Identify resets or aborts
  - View decrypted SSL traffic: HTTPS traffic is captured in plain text to allow for easier troubleshooting.
- Provides comprehensive view: Allows you to look at the entire request at the packet level, check the payload, view logs to check what security check violation is being triggered and identify the match pattern in the payload. If the payload consists of any unexpected data, junk strings, or non-printable characters (null character, \r or \n etc), they are easy to discover in the trace.
- Expedite response time: Faster debugging on target traffic to do root cause analysis.

Miscellaneous

September 18, 2018

Following are the resolutions for some of the issues that you might encounter when using App Firewall.

- App Firewall sets window size to 9845 when resetting connection for invalid http messages.
- Malformed request received - connection reset [Client/Server sending invalid content-length header]
- Unknown content-type in request headers
- System Limit: the application appears frozen
- Occurs when maximum session limit is reached. (100K)
- Less system memory for operation.
- IP Reputation feature not working
The iprep process takes about five minutes to start after you enable the reputation feature. The IP reputation feature might not work for that duration.

• Unexpected App Firewall violations being triggered

  – Session timeout has a default value of 900 seconds. If session timeout is set to a low value, browser may trigger false positives for checks which rely on sessionization (e.g., CSRF, FFC). Check for session timeout and look at the session ID (cs3 in CEF logs). If the session ID is different, the session timeout could be the reason.

  – If form is dynamically generated by javascript, it may trigger false FFC violations.

• Empty field name in FFC violation logs (prior to 11.0 release)

This may be seen in scenarios where we come across a form field which is not in the forms in our session.

Scenarios where this may occur:

  – The session has timed out from when the form was sent to the client and when it was received.
  – The form was generated on the client side using a java script.

Cache Redirection

September 28, 2018

In a typical deployment, different clients ask web servers for the same content repeatedly. To relieve the origin web server of processing each request, a NetScaler appliance with cache redirection enabled can serve this content from a cache server instead of from the origin server.

The NetScaler appliance analyzes incoming requests, sends requests for cacheable data to cache servers, and sends non-cacheable requests and dynamic HTTP requests to origin servers.

Cache redirection is a policy-based feature. By default, requests that match a policy are sent to the origin server, and all other requests are sent to a cache server. For testing or maintenance, you might want to skip policy evaluation and direct all requests to the cache or to the origin server.

You can combine content switching with cache redirection to cache selective content and serve content from specific cache servers for specific types of requested content.

A NetScaler appliance configured for cache redirection can be deployed at the edge of a network, in front of the origin server, or anywhere along the network backbone. In an edge deployment, commonly used by Internet Service Providers (ISPs), cable companies, content delivery distribution networks, and enterprise networks, the NetScaler appliance resides directly in front of the clients. In a server-side deployment, the NetScaler appliance is closer to the origin servers.

Cache redirection is used most commonly with the HTTP service type, but it also supports the secure HTTPS protocol.

Cache redirection policies

September 19, 2018

A cache redirection virtual server applies cache redirection policies to each incoming request. By default, if a request matches one of the configured policies, it is considered non-cacheable, and the
NetScaler appliance sends it to the origin server. Other requests are sent to a cache server. This behavior can be reversed, so that requests that match configured cache redirection policies are sent to cache servers.

The appliance provides a set of policies for cache redirection. If these built-in policies are not adequate for your deployment, you can configure user-defined cache redirection policies.

**Note**

Once you have determined which built-in cache redirection policies to use, or have created user-defined policies, proceed with configuring cache redirection. To use this feature, you must configure at least one cache redirection virtual server, and, for normal operation, you must bind at least one cache redirection policy to that virtual server.

## Built-in cache redirection policies

September 19, 2018

The NetScaler appliance provides built-in cache redirection policies that handle typical cache requests. These policies are based on HTTP methods, the URL or URL tokens of the incoming request, the HTTP version, or the HTTP headers and their values in the request.

Built-in cache redirection policies can be directly bound to a virtual server and do not need further configuration.

Cache redirection policies use two types of appliance expressions languages, classic and default syntax. For more information about these languages, see Policies and expressions.

### Built-in classic cache redirection policies

Built-in cache redirection policies based on classic expressions are called classic cache redirection policies. For a complete description of classic expressions and how to configure them, see Policies and Expressions.

The classic cache redirection policies evaluate basic characteristics of traffic and other data. For example, classic cache redirection policies can determine whether an HTTP request or response contains a particular type of header or URL.

The NetScaler appliance provides the following built-in classic cache redirection policies:
<table>
<thead>
<tr>
<th>Built-In Policy Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bypass-non-get</td>
<td>Bypass the cache if the request uses an HTTP method other than GET.</td>
</tr>
<tr>
<td>bypass-cache-control</td>
<td>Bypass the cache if the request header contains a Cache-Control: no-cache or Cache-Control: no-store header, or if the HTTP request contains a pragma header.</td>
</tr>
<tr>
<td>bypass-dynamic-url</td>
<td>Bypass the cache if the URL suggests that the content is dynamic, as indicated by the presence of any of the following extensions: cgi, asp, exe, cfm, ex, shtml, or htx. Also bypass the cache if the URL starts with any of the following: /cgi-bin/, /bin/, or /exec/.</td>
</tr>
<tr>
<td>bypass-urltokens</td>
<td>Bypass the cache because the request is dynamic, as indicated by one of the following tokens in the URL: ?, !, or =.</td>
</tr>
<tr>
<td>bypass-cookie</td>
<td>Bypass the cache for any URL that has a cookie header and an extension other than .gif or .jpg.</td>
</tr>
</tbody>
</table>

**Built-in default syntax cache redirection policies**

Built-in cache redirection policies based on default syntax expressions are called *default syntax cache redirection policies*. For a complete description of default syntax expressions and how to configure them, see *Policies and Expressions*.

In addition to the same types of evaluations done by classic cache redirection policies, default syntax cache redirection policies enable you to analyze more data (for example, the body of an HTTP request) and to configure more operations in the policy rule (for example, directing the request to either cache or origin server).

NetScaler appliances provide the following two built-in actions for the default syntax cache redirection policies:

- CACHE
- ORIGIN

As implied by their names, they direct the request to the cache server or the origin server, respectively.
NetScaler 12.0

Note
If you are using the built-in default syntax cache redirection policy, you cannot modify the action.

The NetScaler appliance provides the following built-in default syntax cache redirection policies:

<table>
<thead>
<tr>
<th>Built-In Policy Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bypass-non-get_adv</td>
<td>Bypass the cache if the request uses an HTTP method other than GET.</td>
</tr>
<tr>
<td>bypass-cache-control_adv</td>
<td>Bypass the cache if the request header contains a Cache-Control: no-cache or</td>
</tr>
<tr>
<td></td>
<td>Cache-Control: no-store header, or if the HTTP request contains a pragma</td>
</tr>
<tr>
<td></td>
<td>header.</td>
</tr>
<tr>
<td>bypass-dynamic-url_adv</td>
<td>Bypass the cache if the URL suggests that the content is dynamic, as</td>
</tr>
<tr>
<td></td>
<td>indicated by the presence of any of the following extensions: cgi, asp,</td>
</tr>
<tr>
<td></td>
<td>exe, cfm, ex, shtml, or htx. Also bypass the cache if the URL starts with</td>
</tr>
<tr>
<td></td>
<td>any of the following: /cgi-bin/, /bin/, or /exec/.</td>
</tr>
<tr>
<td>bypass-urltokens_adv</td>
<td>Bypass the cache because the request is dynamic, as indicated by one of</td>
</tr>
<tr>
<td></td>
<td>the following tokens in the URL: ?, !, or =.</td>
</tr>
<tr>
<td>bypass-cookie_adv</td>
<td>Bypass the cache for any URL that has a cookie header and an extension</td>
</tr>
<tr>
<td></td>
<td>other than .gif or .jpg.</td>
</tr>
</tbody>
</table>

Display the built-in cache redirection policies

You can display the available cache redirection policies by using the command line interface or the configuration utility.

Display the built-in cache redirection policies by using the CLI

At the command prompt, type:

```
show cr policy [policyName]
```

Example:

```
> show cr policy
1) Cache-By-Pass RULE: NS_NON_GET Policy:bypass-non-get
```
### Display the built-in cache redirection policies by using the GUI

2. Select one of the configured policies to view details.

### Configure a cache redirection policy

September 19, 2018

A cache redirection policy includes one or more expressions (also called rules). Each expression represents a condition that is evaluated when the client request is compared to the policy.

You do not explicitly configure actions for cache redirection policies. By default, the NetScaler appliance considers any request that matches a policy to be non-cacheable and directs the request to the origin server instead of the cache.

Cache redirection policies based on the classic policy format are called **classic cache redirection policies**. Each such policy has a name and includes a classic expression or a set of classic expressions that are combined by using logical operators.

For classic cache redirection policies, you do not explicitly configure actions for the policies. By default, the NetScaler appliance considers any request that matches a policy to be non-cacheable and directs the request to the origin server instead of the cache.

Cache redirection policies based on the newer policy format are called **Advanced redirection policies**. Such policy has a name and includes a default syntax expression, or a set of default syntax expressions that are combined by using logical operators, and the following built-in actions:

<table>
<thead>
<tr>
<th>Policy Number</th>
<th>Cache-By-Pass RULE</th>
<th>Policy: bypass-cache-control</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>(NS_CACHECONTROL_NOSTORE</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>(NS_EXT_CGI</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>NS_URL_TOKENS Policy: bypass-urltokens</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>(NS_HEADER_COOKIE &amp;&amp; NS_EXT_NOT_GIF &amp;&amp; NS_EXT_NOT_JPEG) Policy: bypass-cookie</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>Done</td>
<td></td>
</tr>
</tbody>
</table>
NetScaler 12.0

• CACHE
• ORIGIN

For more information about classic expressions and default syntax expressions, see Policies and Expressions.

Add a cache redirection policy by using the CLI

At the command prompt, type the following commands to add a cache redirection policy and verify the configuration:

1 - add cr policy <policyName> -rule** <expression>
2 - show cr policy [ <policyName> ]

Examples:

Policy with a simple expression:

1 > add cr policy Policy-CRD-1 -rule "REQ.HTTP.URL != /*.jpeg"
2 Done
3 > show cr policy Policy-CRD-1
4 Cache-By-Pass RULE: REQ.HTTP.URL != '/*.jpeg' Policy:Policy-CRD-1
5 Done

Policy with a compound expression:

1 > add cr policy Policy-CRD-2 -rule "REQ.HTTP.METHOD == POST && (REQ.HTTP.URL == /*.cgi || REQ.HTTP.URL != /*.gif)"
2 Done
3 > show cr policy Policy-CRD-2
4 Cache-By-Pass RULE: REQ.HTTP.METHOD == POST && (REQ.HTTP.URL == '/*.cgi' || REQ.HTTP.URL != '/*.gif') Policy:Policy-CRD-2
5 Done

Policy that evaluates a header:

1 > add cr policy Policy-CRD-3 -rule "REQ.HTTP.HEADER If-Modified-Since EXISTS"
2 Done
3 > show cr policy Policy-CRD-3
4 Cache-By-Pass RULE: REQ.HTTP.HEADER If-Modified-Since EXISTS
   Policy:Policy-CRD-3
5 Done
Add a default syntax cache redirection policy by using the CLI

At the command prompt, type the following commands to add a cache redirection policy and verify the configuration:

```
1 - add cr policy <policyName> **-rule** <expression> [-action<string>] [-logAction<string>]
2 - show cr policy [<policyName>]
```

Examples:

Policy with a simple expression:

```
1 > add cr policy crpol1 -rule !(HTTP.REQ.URL.ENDSWITH(".jpeg")) -action origin
2   Done
3 > show cr policy crpol1
4   Policy: crpol1 Rule: !(HTTP.REQ.URL.ENDSWITH(".jpeg")) Action: ORIGIN
5   Done
```

Policy with a compound expression:

```
1 > add cr policy crpol11 -rule "http.req.method.eq(post) && (HTTP.REQ.URL.ENDSWITH(".gif") || HTTP.REQ.URL.ENDSWITH(".cgi"))" -action cache
2   Done
3 > show cr policy crpol11
4   Policy: crpol11 Rule: http.req.method.eq(post) && (HTTP.REQ.URL.ENDSWITH(".gif") || HTTP.REQ.URL.ENDSWITH(".cgi"))
5   Action: CACHE
```

Policy that evaluates a header:

```
1 > add cr policy crpol12 -rule http.req.header("If-Modified-Since").exists -action origin
2   Done
3 > show cr policy crpol12
4   Policy: crpol12 Rule: http.req.header("If-Modified-Since").exists
5   Action: ORIGIN
```

© 1999-2018 Citrix Systems, Inc. All rights reserved.
Modify or remove a cache redirection policy by using the CLI

- To modify a cache redirection policy, use the set cr policy command, which is just like add cr policy command, except that you enter the name of an existing policy.
- To remove a policy, use the `rm cr policy` command, which accepts only the `<name>` argument. If the policy is bound to a virtual server, you have to unbind the policy, before you can remove it.

For the details of unbinding a cache redirection policy, see “Unbind a policy from a cache redirection virtual server.”

Configure a cache redirection policy with a simple expression by using the GUI

2. In the details pane, click Add.
3. In the Create Cache Redirection Policy dialog box, in the Name* text box, type the name of the policy, and then in the Expression area, click Add.
4. To configure a simple expression, enter the expression. Following is an example of an expression that checks for a .jpeg extension in a URL:
   - Expression Type-General
   - Flow Type -REQ
   - Protocol -HTTP
   - Qualifier -URL
   - Operator - !=
   - Value* - /*.jpeg

The simple expression in the following example checks for an If-Modified-Since header in a request:
   - Expression Type -General
   - Flow Type -REQ
   - Protocol -HTTP
   - Qualifier -HEADER
   - Operator - EXISTS
   - Header Name - If-Modified-Since

5. When you are finished entering the expression, click OK or Create, and then click Close.

Configure a cache redirection policy with a compound expression by using the GUI

2. In the details pane, click Add.

3. In the Name text box, enter a name for the policy.

   The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 127 letters, numbers, and the hyphen (-), period (.), pound (#), space ( ), at (@), equals (=), and underscore (_) symbols. You should choose a name that will make it easy for others to tell what type of content this policy was created to detect.

4. Choose the type of compound expression that you want to create. Your choices are:

   • **Match Any Expression**. The policy matches the traffic if one or more individual expressions match the traffic.

   • **Match All Expressions**. The policy matches the traffic only if every individual expression matches the traffic.

   • **Tabular Expressions**. Switches the Expressions list to a tabular format with three columns. In the rightmost column, you place one of the following operators:

     - The AND [ && ] operator, to require that, to match the policy, a request must match both the current expression and the following expression.

     - The OR [ ] operator, to require that, to match the policy, a request must match either the current expression or the following expression, or both. Only if the request does not match either expression does it not match the policy.

   - You can also group expressions in nested subgroups by selecting an existing expression and clicking one of the following operators:

     - The BEGIN SUBGROUP [ + ( ] operator, which tells the NetScaler appliance to begin a nested subgroup with the selected expression. (To remove this operator from the expression, click -( .)

     - The END SUBGROUP [ + ) ] operator, which tells the NetScaler appliance to end the current nested subgroup with the selected expression. (To remove this operator from the expression, click -) .)

   • **Advanced Free-Form**. Switches off the Expressions Editor entirely and turns the Expressions list into a text area in which you can type a compound expression. This is both the
most powerful and the most difficult method of creating a policy expression, and is recommended only for those thoroughly familiar with the NetScaler appliance classic expressions language.

For more information about creating classic expressions in the Advanced Free-Form text area, see “Configuring Classic Policies and Expressions”.

**Caution:** If you switch to Advanced Free Form expression editing mode, you cannot switch back to any of the other modes. Do not choose this expression editing mode unless you are sure that you want to use it.

5. If you chose Match Any Expression, Match All Expressions, or Tabular Expressions, click **Add** to display the Add Expression dialog box.

   You should leave the expression type set to General for cache redirection policies.

6. In the Flow Type drop-down list, choose a flow type for your expression.

   The flow type determines whether the policy examines incoming or outgoing connections. You have two choices:
   
   - **REQ.** Configures the NetScaler appliance to examine incoming connections, or requests.
   - **RES.** Configures the appliance to examine outgoing connections, or responses.

7. In the Protocol drop-down list, choose a protocol for your expression.

   The protocol determines the type of information that the policy examines in the request or response. Depending upon whether you chose REQ or RES in the previous drop-down list, either all four or only three of the following choices are available:
   
   - **HTTP.** Configures the appliance to examine the HTTP header.
   - **SSL.** Configures the appliance to examine the SSL client certificate. Available only if you chose REQ (requests) in the previous drop-down list.
   - **TCP.** Configures the appliance to examine the TCP header.
   - **IP.** Configures the appliance to examine the source or destination IP address.

8. Choose a qualifier for your expression from the Qualifier drop-down list.

   The contents of the Qualifier drop-down list depend on which protocol you chose. The following table describes the choices available for each protocol.

   **Table 1. Cache Redirection Policy Qualifiers Available for Each Protocol**

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Qualifier</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>HTTP</td>
<td>METHOD</td>
<td>HTTP method used in the request.</td>
</tr>
<tr>
<td></td>
<td>URL</td>
<td>Contents of the URL header.</td>
</tr>

9. Choose the operator for your expression from the Operator drop-down list.
   Your choices depend on the qualifier you chose in the previous step. The complete list of operators that can appear in this drop-down list is:
   - == . Matches the following text string exactly.
   - != . Does not match the following text string.
     - > . Is greater than the following integer.
   - CONTAINS . Contains the following text string.
   - CONTENTS . The contents of the designated header, URL, or URL query.
   - EXISTS . The specified header or query exists.
   - NOTCONTAINS . Does not contain the following text string.
   - NOTEXISTS . The specified header or query does not exist.

   If you want this policy to operate on requests sent to a specific Host, you can leave the default, the equals (==) sign.

10. If the Value text box is visible, type the appropriate string or number into the text box.
   For example, if you want this policy to select requests sent to the host shopping.example.com, you would type that string in the Value text box.

11. If you chose HEADER as the qualifier, type the header you want in the Header Name text box.

12. Click OK to add your expression to the Expression list.

13. Repeat steps 4 through 11 to create additional expressions.
14. Click Close to close the Add Expression dialog box and return to the Create Cache Redirection Policy dialog box.

**Cache redirection configurations**

September 19, 2018

Depending on your deployment and network topology, you can configure one of the following types of cache redirection:

- **Transparent.** A transparent cache can reside on a variety of points along a network backbone to alleviate traffic along the delivery route. In transparent mode, the cache redirection virtual server intercepts all traffic flowing to the NetScaler appliance and applies cache redirection policies to determine whether content should be served from the cache or from the origin server.

- **Forward proxy.** A forward proxy cache server resides on the edge of an enterprise LAN and faces the WAN. In the forward proxy mode, the cache redirection virtual server resolves the hostname of the incoming request by using a DNS server and forwards requests for non-cacheable content to the resolved origin servers. Cacheable requests are sent to the configured cache servers.

- **Reverse proxy.** Reverse proxy caches are configured for specific origin servers. Incoming traffic directed to the reverse proxy, can either be served from a cache server or be sent to the origin server with or without modification to the URL.

**Configure transparent redirection**

September 19, 2018

When you configure transparent cache redirection, the NetScaler appliance evaluates all traffic it receives, to determine whether it is cacheable. This mode alleviates traffic along the delivery route and is often used when the cache server resides on the backbone of an ISP or carrier.

By default, cacheable requests are sent to a cache server, and non-cacheable requests to the origin server. For example, when the NetScaler appliance receives a request that is directed to a web server, it compares the HTTP headers in the request with a set of policy expressions. If the request does not match the policy, the appliance forwards the request to a cache server. If the request does match a policy, the appliance forwards the request, unchanged, to the web server.

For details on how to modify this default behavior, see “Direct policy hits to the cache instead of the origin.”

To configure transparent redirection, first enable cache redirection and load balancing, and configure edge mode. Then, create a cache redirection virtual server with a wildcard IP address (*), so that this virtual server can receive traffic coming to the appliance on any IP address the appliance owns. To this
virtual server, bind cache redirection policies that describe the types of requests that should not be
cached. Then, create a load balancing virtual server that will receive traffic from the cache redirection
virtual server for cacheable requests. Finally, create a service that represents a physical cache server
and bind it to the load balancing virtual server.

Enable cache redirection and load balancing

September 19, 2018

The appliance cache redirection and load balancing features are not enabled by default. They must
be enabled before any cache redirection configuration can take effect.

Enable cache redirection and load balancing by using the CLI

At the command prompt, type the following command to enable cache redirection and load balancing
and verify the settings:

1 - enable ns feature cr lb
2 - show ns feature

Example:

1 > enable ns feature cr lb
Done
2 > show ns feature

<table>

Enable cache redirection and load balancing by using the GUI

1. In the navigation pane, expand System, and then click Settings.
2. To enable cache redirection, in the details pane, under Modes and Features, click Configure advanced features.
   a) In Configure Advanced Features dialog box, select the check box next to the Cache Redirection, and then click OK.
   b) In Enable/Disable Feature(s)? dialog box, click Yes.
3. To enable load balancing, in the details pane, under Modes and Features, click Configure basic features.
   a) In Configure Basic Features dialog box, select the check box next to the Load Balancing, and then click OK.
   b) In Enable/Disable Feature(s)? dialog box, click Yes.

Configure edge mode

September 19, 2018

When deployed at the edge of a network, the NetScaler appliance dynamically learns about the servers on that network. Edge mode enables the appliance to dynamically learn about up to 40,000 HTTP servers and proxy TCP connections for these servers.

This mode turns on the collection of statistics for the dynamically learned services and is typically used in transparent deployments for cache redirection.

Enable edge mode by using the CLI

At the command prompt, type the following commands to enable edge mode and verify the setting:

<table>
<thead>
<tr>
<th></th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>enable ns mode Edge</td>
</tr>
<tr>
<td>2</td>
<td>show ns mode</td>
</tr>
</tbody>
</table>

Example:

<table>
<thead>
<tr>
<th></th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>&gt; enable ns mode edge</td>
</tr>
<tr>
<td>2</td>
<td>Done</td>
</tr>
<tr>
<td>3</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>&gt; show ns mode</td>
</tr>
<tr>
<td>5</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>Mode</td>
</tr>
<tr>
<td>7</td>
<td>---------</td>
</tr>
<tr>
<td>8</td>
<td>...</td>
</tr>
</tbody>
</table>
## Enable edge mode by using the GUI

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Configure modes.
3. In Configure Modes dialog box, select the check box next to the Edge Configuration, and then click OK.
4. In Enable/Disable Feature(s)? dialog box, click Yes.

## Configure a cache redirection virtual server

September 19, 2018

By default, a cache redirection virtual server forwards cacheable requests to the load balancing virtual server for the cache, and forwards non-cacheable requests to the origin server (except in a reverse proxy configuration, in which non-cacheable requests are sent to a load balancing virtual server). There are three types of cache redirection virtual servers: transparent, forward proxy, and reverse proxy.

A transparent cache redirection virtual server uses an IP address of * and a port number, usually 80, that can accept HTTP traffic sent to any IP address that the appliance represents. As a result, you can configure only one transparent cache redirection virtual server. Any additional cache redirection virtual servers that you configure must be forward proxy or reverse proxy redirection servers.

### add a cache redirection virtual server in transparent mode by using the cli

At the command prompt, type the following commands to add a cache redirection virtual server and verify the configuration:

```
$ add cr vserver <name> <serviceType> [IPAddress <port> ] [-cacheType <cacheType>] [-redirect <redirect>]
```
Modify or remove a cache redirection virtual server by using the CLI

- To modify a virtual server, use the set cr vserver command, which is just like using the add cr vserver command, except that you enter the name of an existing virtual server.
- To remove a virtual server, use the `rm cr vserver` command, which accepts only the `<name>` argument.

Add a cache redirection virtual server in transparent mode by using the GUI

2. In the details pane, click Add.
3. In the Create Virtual Server (Cache Redirection) dialog box, specify values for the following parameters as shown:
   - Name*—name
   - Port*—port
   *A required parameter
4. In the Protocol drop-down list, select a supported protocol (for example, HTTP). If the virtual server is to receive traffic on a port other than the standard port for the selected protocol, enter a new value in the Port field.
5. Click the Advanced tab.
6. Verify that Cache Type is set to TRANSPARENT and Redirect is set to POLICY.

7. Click Create, and then click Close. The Cache Redirection Virtual Servers pane displays the new virtual server.

8. Select the new cache redirection virtual server to display the details of its configuration.

**Bind policies to the cache redirection virtual server**

September 19, 2018

Cache redirection policies are not automatically bound to the cache redirection virtual server. A policy based cache redirection virtual server cannot function unless you bind at least one policy to it.

**Bind policies to a cache redirection virtual server by using the CLI**

At the command prompt, type:

```
1 - bind cr vserver <name> -policyName <string>
2 - show cr vserver [ <name> ]
```

**Example:**

```
1 > bind cr vserver Vserver-CRD-1 -policyName bypass-cache-control
Done
2 > bind cr vserver Vserver-CRD-1 -policyName bypass-dynamic-url
Done
3 > bind cr vserver Vserver-CRD-1 -policyName bypass-urltokens
Done
4 > bind cr vserver Vserver-CRD-1 -policyName bypass-cookie
Done
5 > show cr vserver Vserver-CRD-1
Vserver-CRD-1 (*:80) - HTTP   Type: CONTENT
   State: UP   ARP:DISABLED
   Client Idle Timeout: 180 sec
   Down state flush: ENABLED
   Disable Primary Vserver On Down : DISABLED
   Default:   Content Precedence: RULE   Cache:
               TRANSPARENT
   On Policy Match: ORIGIN L2Conn: OFF   OriginUSIP: OFF
   Redirect: POLICY   Reuse: ON   Via: ON ARP: OFF
1) Cache bypass   Policy: bypass-cache-control
```
Bind a user-defined policy to a cache redirection virtual server by using the GUI

2. Click the virtual server that you want to configure, and click Open.
3. On the Policies tab, select type of the policy and then click Insert Policy.
4. Under Policy Name column, select the policy that you want to bind.
5. Click OK.

Unbind a policy from a cache redirection virtual server

September 19, 2018

When you unbind a policy from the cache redirection virtual server, the NetScaler appliance no longer applies the policy when evaluating client requests.

Unbind a policy from a cache redirection virtual server by using the command CLI

At the command prompt, type:

1 - unbind cr vserver <name> -policyName <string>
2 - show cr vserver [/<name>]

Example:

1  unbind cr vserver Vserver-CR-1 -policyName bypass-non-get
2 > show cr vserver Vserver-CR-1
3  Vserver-CR-1 (*:80) - HTTP       Type: CONTENT
4  State: UP   ARP:DISABLED
5  Client Idle Timeout: 180 sec
6  Down state flush: ENABLED
7  Disable Primary Vserver On Down : DISABLED
8  Default:       Content Precedence: RULE       Cache: 
                    TRANSPARENT
9  On Policy Match: ORIGIN L2Conn: OFF   OriginUSIP: OFF
10 Redirect: POLICY       Reuse: ON   Via: ON ARP: OFF
**Unbind a user-defined policy from a cache redirection virtual server by using the GUI**

2. Click the virtual server that you want to configure, and then click Open.
3. On the Policies tab, under Policy Name, select the policy that you want to unbind.
4. Click Unbind Policy, and then click OK.

**Create a load balancing virtual server**

September 19, 2018

The cache redirection virtual server on the NetScaler appliance can send requests to either a cache server farm, if the request is cacheable, or to the origin server farm if the request is not cacheable.

Each cache server is represented on the appliance by a service, which is bound to a load balancing virtual server that receives requests from the cache redirection virtual server and forwards those requests to the servers.

For details on configuring load balancing virtual servers and other configuration options, see “Load Balancing.”

**Create a load balancing virtual server by using the CLI**

At the command prompt, type the following commands to create a load balancing virtual server and verify the configuration:

```
1 - add lb vserver <name> <serviceType> [IPAddress] [port]
2 - show lb vserver [<name>]
```

**Example:**

```
1 > add lb vserver Vserver-LB-CR HTTP 10.102.20.30 80
2 Done
3 > show lb vserver Vserver-LB-CR
   Vserver-LB-CR (10.102.20.30:80) - HTTP Type: ADDRESS
   State: DOWN
   Last state change was at Fri Jul 2 08:47:52 2010
   Time since last state change: 0 days, 00:00:08.470
```
### Create a load balancing virtual server by using the GUI

2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters as shown:
   - Name*-name
   - IP Address*- IPAddress
   - Port*-port
   *A required parameter
4. In the Protocol list, select a supported protocol (for example, HTTP). If the virtual server is to receive traffic on a port other than the well-known port for the selected protocol, enter a new value in the Port field.
5. Click Create, and then click Close. The Load Balancing Virtual Servers pane displays the new virtual server.

### Configure an HTTP service

September 19, 2018

On the NetScaler appliance, a service represents a physical server on the network. In the transparent cache redirection configuration, the service represents the cache server. Cacheable requests are sent
by the cache redirection virtual server to the load balancing virtual server, which in turn forwards each request to the correct service, which passes it on to the cache server.

**Configure an HTTP service by using the CLI**

At the command prompt, type the following commands to create an HTTP service and verify the configuration:

```
1 - add service <name> <IP> <serviceType> <port> -cacheType <cacheType>
2 - show service [<name>]
```

**Example:**

```
1 > add service Service-HTTP-1 10.102.29.40 HTTP 80 -cacheType TRANSPARENT
   Done
2 > show service Service-HTTP-1
   Service-HTTP-1 (10.102.40.29:80) - HTTP
   State: DOWN
   Last state change was at Fri Jul 2 09:14:17 2010
   Time since last state change: 0 days, 00:00:13.820
   Server Name: 10.102.29.40
   Server ID: 0 Monitor Threshold: 0
   Max Conn: 0 Max Req: 0 Max Bandwidth: 0 kbits
   Use Source IP: NO
   Client Keepalive (CKA): NO
   Access Down Service: NO
   TCP Buffering (TCPB): NO
   HTTP Compression (CMP): YES
   Idle timeout: Client: 180 sec Server: 360 sec
   Client IP: DISABLED
   Cache Type: TRANSPARENT Redirect Mode:
   Cacheable: NO
   SC: OFF
   SP: ON
   Down state flush: ENABLED
   1)   Monitor Name: tcp-default
   State: DOWN Weight: 1
   Probes: 3 Failed [Total: 3 Current: 3]
   Last response: Failure - Time out during TCP connection establishment stage
   Response Time: N/A
   Done
```
Modify or remove a service by using the CLI

- To modify a service, use the set service command, which is just like using the add service command, except that you enter the name of an existing service.
- To remove a service, use the `rm service` command, which accepts only the `<name>` argument.

Add an HTTP service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters as shown:
   - Service Name*—name
   - Server*—IP
   - Port*—port
   *A required parameter
4. In the Protocol* drop-down list, select a supported protocol (for example, HTTP).
5. Click Create, and then click Close.

Bind/unbind a service to/from a load balancing virtual server

September 19, 2018
You must bind a service to the load balancing virtual server. This enables the load balancer to forward the request to the server that the service represents. If your configuration changes, you can unbind a service from the load balancing virtual server.

Bind a service to a load balancing virtual server by using the CLI

At the command prompt, type:

```
1  bind lb vserver <name> <serviceName>
2  show lb vserver [<name>]
```

Example:

```
1  > bind lb vserver vserver-LB-CR service-HTTP-1
2    Done
3  > show lb vserver Vserver-LB-CR
```
### Unbind a service from a load balancing virtual server by using the CLI

To unbind a service, use the `unbind lb vserver` command instead of `bind lb vserver`.

### Bind/unbind a service from a load balancing virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers
2. In the details pane, select the virtual server from which you want to bind/unbind the service, and then click Open.
3. On the Services tab, in the Active column, select/clear the check box next to the Service Name.
4. Click OK.

### Disable the use the proxy port setting for transparent caching

September 19, 2018

If the use source IP (USIP) option is disabled on a cache service configured on the NetScaler appliance, the appliance forwards client requests to the cache service by using a appliance-owned subnet IP (SNIP) address or mapped IP (MIP) address as the source IP address and a random port as the source port. The randomly selected port is called the proxy port.
However, if you want to configure a fully transparent cache (a cache configuration in which the cache service receives the client’s IP address and port number), you must not only enable the USIP option, either globally or on the cache service, but also disable the Use Proxy Port setting, either globally or on the cache service. Disabling the Use Proxy Port setting enables the appliance to use the client’s source port as the source port when it connects to the cache service, and ensures a fully transparent cache configuration.

For more information about configuring the Use Proxy Port option globally or on a service, see Configuring the Source Port for Server-Side Connections.

**Assign a port range to the NetScaler appliance**

September 19, 2018

Sharing of the client IP address may create a conflict that makes network devices, such as routers, cache servers, origin servers, and other NetScaler appliances, unable to determine the appliance, and therefore the client, to which the response should be sent.

A method to solve this problem is to assign a source port range to the NetScaler appliance. This allotment enables network devices to unambiguously identify the NetScaler appliance that sent the request.

**Assign a source port range to a NetScaler appliance by using the CLI**

At the command prompt, type:

```
set ns param -crPortRange <startPortNumber-endPortNumber>
```

**Assign a source port range to a NetScaler appliance by using the appliance GUI**

1. In the navigation pane, click System, and then click Settings.
2. In the Settings group, click the Change global system settings link.
3. In the Cache Redirection Port Range group, specify the port range for the appliance by typing a port number for Start Port and a port number for End Port.
4. Click OK.

**Enable load balancing virtual servers to redirect requests to cache**

September 19, 2018
If a load balancing virtual server is configured to listen on a particular IP address and port combination, it takes precedence over the cache redirection virtual server for any requests destined for that address-port combination. Therefore, the cache redirection virtual server does not process those requests.

If you want to override this functionality and let the cache redirection virtual server decide whether the request should be served from the cache or not, configure the particular load balancing virtual server to be cacheable.

Such a configuration is typically used when an ISP uses a NetScaler appliance at the edge of its network and all traffic flows through the appliance.

**Enable load balancing virtual servers to redirect requests to the cache by using the CLI**

At the command prompt, type:

```
1 - set lb vserver <name> [-cacheable ( YES | NO)]
2 - show lb vserver [<name>]
```

**Example:**

```
1 set lb vserver Vserver-LB-CR - cacheable YES
2 > show lb vserver vserver-LB-CR
   Vserver-LB-CR (10.102.20.30:80) - HTTP Type: ADDRESS
   State: DOWN
   Last state change was at Fri Jul 2 08:47:52 2010
   Time since last state change: 0 days, 01:05:51.510
   Effective State: DOWN
   Client Idle Timeout: 180 sec
   Down state flush: ENABLED
   Disable Primary Vserver On Down : DISABLED
   Port Rewrite : DISABLED
   No. of Bound Services : 1 (Total)   0 (Active)
   Configured Method: LEASTCONNECTION
   Mode: IP
   Persistence: NONE
   Cacheable: YES   PQ: OFF  SC: OFF
   Vserver IP and Port insertion: OFF
   Push: DISABLED   Push VServer:
   Push Multi Clients: NO
   Push Label Rule: none
1) Service-HTTP-1 (10.102.29.40: 80) - HTTP State: DOWN Weight: 1
23 Done
```
For transparent cache redirection, the appliance intercepts all traffic and evaluates every request to determine whether it is cacheable. Non-cacheable requests are sent unchanged to the origin server. When using transparent cache redirection, you may want to turn off cache redirection for load balancing virtual servers that always direct traffic to origin servers.

**Turn off caching for a load balancing virtual server by using the CLI**

To turn off caching for a load balancing virtual, use the `unset lb vserver` command instead of `set lb vserver`. Specify a value of NO value for the **cacheable** parameter.

**Enable or disable load balancing virtual servers to redirect requests to the cache by using the GUI**

2. In the details pane, select the virtual server from which you want to enable/disable the caching, and then click Open.
3. On the Advanced tab, select/clear Cache Redirection check box.
4. Click OK.

**Configure forward proxy redirection**

September 19, 2018

A forward proxy is a single point of contact for a client or group of clients. In this configuration, the NetScaler appliance redirects non-cacheable requests to an origin server and redirects cacheable requests to either a forward proxy cache or a transparent cache.

When the appliance is configured as a forward proxy, users must modify their browsers so that the browser sends requests to the forward proxy instead of the destination servers.

A forward proxy cache redirection virtual server on the appliance compares the request with a policy for caching. If the request is not cacheable, the appliance queries a DNS load balancing virtual server for resolution of the destination, and then sends the request to the origin server. If the request is cacheable, the appliance forwards the request to a load balancing virtual server for the cache.

The appliance relies on a host domain name or IP address in the request’s HOST header to determine the requested destination. If there is no HOST header in the request, the appliance inserts a HOST header based on the destination IP address in the request.

Typically, the NetScaler appliance acts as a forward proxy in an enterprise LAN. In such a configuration, the appliance resides at the edge of an enterprise LAN and intercepts client requests before they are
fanned out to the WAN. Configuring the appliance in the forward proxy mode reduces traffic on the WAN.

To configure forward proxy cache redirection, first enable load balancing and cache redirection on the appliance. Then, configure a DNS load balancing virtual server and associated services. Also configure a load balancing virtual server and bind to it appropriate services for the cache. Configure a forward proxy cache redirection virtual server and bind the DNS and load balancing virtual servers to it. You must also configure caching policies and bind them to the cache redirection virtual server. To complete the setup, configure the client browsers to use the forward proxy.

For details on how to enable cache redirection and load balancing on the appliance, see “Enable cache redirection and load balancing.”

For details on how to create a load balancing virtual server, see “Create a load balancing virtual server.”

For details on how to configure services that represent the cache server, see “Configure an HTTP service.”

For details on how to bind the service to a virtual server, see “Bind/unbind a service to/from a load balancing virtual server.”

For details on how to create a forward proxy cache redirection server, see “Configure a cache redirection virtual server”, and create a virtual server of type TRANSPARENT or FORWARD.

For details on binding cache redirection policies to the cache redirection virtual server, see “Configure a cache redirection policy.”

Create a DNS service

September 19, 2018

A DNS service is a representation, on the NetScaler appliance, of a physical DNS server in the network. A DNS load balancing virtual server sends DNS requests to the DNS server in the network through such a service.

Create a DNS service by using the CLI

At the command line, type the following commands to create a DNS service and verify the configuration:

```
1 - add service <name> <IP> <serviceType> <port>
2 - show service [<name>]
```

Example:
Add a DNS service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters as shown:
   - Service Name*—name
   - Server*—IP
   - Port*—port

* A required parameter

1. In the Protocol* drop down list, select a supported protocol (for example, DNS).
2. Click Create, and then click Close.
Create a DNS load balancing virtual server

September 19, 2018

The DNS virtual server enables the forward proxy to perform DNS resolution before forwarding a client request to an origin server. The DNS load balancing virtual server is associated with the DNS service that represents the physical DNS server on the network.

Create a DNS load balancing virtual server by using the CLI

At the command line, type the following commands to create a DNS load balancing virtual server and verify the configuration:

1. `add lb vserver <name> <serviceType>`
2. `show lb vserver [<name>]`

Example:

```
1 > add lb vserver Vserver-DNS-1 DNS
2   Done
3 > show lb vserver Vserver-DNS-1
4   Vserver-DNS-1 (0.0.0.0:0) - DNS Type: ADDRESS
5   State: DOWN
6   Last state change was at Fri Jul 2 10:32:28 2010
7   Time since last state change: 0 days, 00:00:08.10
8   Effective State: DOWN ARP:DISABLED
9   Client Idle Timeout: 120 sec
10  Down state flush: ENABLED
11  Disable Primary Vserver On Down : DISABLED
12  No. of Bound Services : 0 (Total) 0 (Active)
13  Configured Method: LEASTCONNECTION

15  Persistence: NONE
16   Done
```

Create a DNS load balancing virtual server by using the GUI

2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, in the Name box, type a name for the virtual server.
4. In the Protocol* drop down list, select a supported protocol (for example, DNS).
5. Click Create, and then click Close. The DNS Virtual Servers pane displays the new virtual server.

**Bind the DNS service to the virtual server**

September 19, 2018

For the DNS server to respond to DNS requests, the service representing the DNS server must be bound to the DNS virtual server.

**Bind the DNS service to the load balancing virtual server by using the CLI**

At the command prompt, type the following commands to bind the DNS service to the load balancing virtual server and verify the configuration:

```
1. bind lb vserver <name> <serviceName>
2. show lb vserver <name>
```

**Example:**

```
1) > bind lb vserver Vserver-DNS-1 Service-DNS-1
2)  Done
3) > show lb vserver Vserver-DNS-1
  Vserver-DNS-1 (0.0.0.0:0) - DNS Type: ADDRESS
  State: DOWN
  Last state change was at Fri Jul 2 10:32:28 2010
  Time since last state change: 0 days, 00:12:16.80
  Effective State: DOWN ARP:DISABLED
  Client Idle Timeout: 120 sec
  Down state flush: ENABLED
  Disable Primary Vserver On Down : DISABLED
  No. of Bound Services : 1 (Total) 0 (Active)
  Configured Method: LEASTCONNECTION
  Mode: IP
  Persistence: NONE
1) Service-DNS-1 (10.102.29.41: 53) - DNS State: DOWN Weight: 1
2)  Done
3) >
```

**Unbind a DNS service from the load balancing virtual server by using the CLI**

Use the `unbind lb vserver` command instead of `bind lb vserver`. 
Bind/Unbind a DNS service to/from a load balancing virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers
2. In the details pane, select the virtual server to/from which you want to bind/unbind the DNS service, and then click Open.
3. On the Services tab, in the Active column, select/clear the check box next to the Service Name.
4. Click OK.

Configure a client web browser to use a forward proxy

September 19, 2018

When you configure the NetScaler appliance as forward proxy cache redirection virtual server in the network, you must configure the client Web browser to send requests to the forward proxy. Typically, when you use a forward proxy, the only route to the servers in the network is through the forward proxy.

Refer the documentation for your browser to configure the browser to use a forward proxy. Specify the IP address and port number of the forward proxy cache redirection virtual server for this configuration.

Configure reverse proxy redirection

September 19, 2018

A reverse proxy resides in front of one or more Web servers and shields the origin server from client requests. Often, a reverse proxy cache is a front-end for all client requests to a server. An administrator assigns a reverse proxy cache to a specific origin server. This is unlike transparent and forward proxy caches, which cache frequently requested content for all requests to any origin server, and the choice of a server is based on the request.

Unlike a transparent proxy cache, the reverse proxy cache has its own IP address and can replace destination domains and URLs in a non-cacheable request with new destination domains and URLs.

You can deploy reverse proxy cache redirection at the origin-server side or at the edge of a network. When deployed at the origin server, the reverse proxy cache redirection virtual server is a front-end for all requests to the origin server.

In the reverse proxy mode, when the appliance receives a request, a cache redirection virtual server evaluates the request and forwards it to either a load balancing virtual server for the cache or a load balancing virtual server for the origin. The incoming request can be transformed by changing the host header or the host URL before they it is sent to the backend server.
To configure reverse proxy cache redirection, first enable cache redirection and load balancing. Then, configure a load balancing virtual server and services to send cacheable requests to the cache servers. Also configure a load balancing virtual server and associated services for the origin servers. Then, configure a reverse proxy cache redirection virtual server and bind relevant cache redirection policies to it. Finally, configure mapping policies and bind them to the reverse proxy cache redirection virtual server.

The mapping policies have an associated action that enables the cache redirection virtual server to forward any non-cacheable request to the load balancing virtual server for the origin.

Be sure to create the default cache server destination.

For details on how to enable cache redirection and load balancing on the appliance, see Enable cache redirection and load balancing.

For details on how to create a load balancing virtual server, see Create a load balancing virtual server.

For details on how to configure services that represent the cache server, see Configure an HTTP service.

For details on how to bind the service to a virtual server, see Bind/unbind a service to/from a load balancing virtual server.

For details on how to create a reverse proxy cache redirection server, see Configure a cache redirection virtual server, and create a virtual server of type REVERSE.

For details on binding built-in cache redirection policies to the cache redirection virtual server, see Bind policies to the cache redirection virtual server.

**Configure mapping policies**

If an incoming request is non-cacheable, the reverse-proxy cache redirection virtual server replaces the domain and URL in the request with the domain and URL of a target origin server and forwards the request to the load balancing virtual server for the origin.

A mapping policy enables the reverse proxy cache redirection virtual server to replace the destination domain and URL and forward the request to the load balancing virtual server for the origin.

A mapping policy must first translate the domain and the URL, and then pass the request on to the origin load balancing virtual server.

A mapping policy can map a domain, a URL prefix, and a URL suffix, as follows:

- Domain mapping: You can map a domain without a prefix or suffix. The domain mapping is the default mapping for the virtual server (for example, mapping www.mycompany.com to www.myrealcompany.com).
Prefix mapping: You can replace a specified pattern prefixed as part of the URL (for example, mapping www.mycompany.com/sports/index.html to www.mycompany.com/news/index.html).

Suffix mapping: You can replace the file suffix in the URL (for example, mapping www.mycompany.com/sports/index.html to www.mycompany.com/sports/index.asp).

The source and the destination strings being mapped must be similar. If you specify a source domain, you must specify a destination domain, and if you specify a source suffix, you must specify a destination suffix. Similarly, if you specify an exact URL from the source, the target URL must also be an exact URL.

Once you configure mapping policies for the reverse proxy mode, you must bind them to the cache redirection virtual server.

You can use combinations of the source URL, target URL, and source and target domains to configure all three types of domain mapping.

**Configure a mapping policy for reverse proxy mode by using the CLI**

At the command prompt, type the following command to add a policy map and verify the configuration:

```
1 - add policy map <mapPolicyName> -sd <string> [ -su <string> ] [ -td <string> ] [ -tu <string> ]
2 - show policy map [ <mapPolicyName> ]
```

**Example:**

The following command maps a domain in a client request to a target domain:

```
1 > add policy map myMappingPolicy -sd www.mycompany.com -td www.myrealcompany.com
2   Done
3 > show policy map myMappingPolicy
4 1)   Name: myMappingPolicy
5    Source Domain: www.mycompany.com   Source Url: 
6    Target Domain: www.myrealcompany.com   Target Url: 
7   Done
```

Following is an example of mapping a URL suffix to a different URL suffix:

```
2   Done
3 > show policy map myOtherMappingPolicy
4 1)   Name: myOtherMappingPolicy
```
Configure a mapping policy for reverse proxy mode by using the GUI

2. In the details pane, click Add.
3. In the Create Map Policy dialog box, specify values for the following parameters as shown:
   - Name*- mapPolicyName
   - Source Domain*-sd
   - Target Domain*-td
   - Source URL-su
   - Target URL-tu
   *A required parameter
4. Click Create, and then click Close. The Map pane displays the new mapping policy.

Bind the mapping policy to the cache redirection virtual server by using the CLI

At the command prompt, type the following commands to bind the mapping policy to the cache redirection virtual server and verify the configuration:

```bash
1 - bind cr vserver <name> -policyName <string> [<targetVserver>]
2 - show cr vserver <name>
```

Example:

```
1 > bind cr vserver Vserver-CRD-3 -policyName myMappingPolicy Vserver-LB-CR
2  Done
3 > show cr vserver Vserver-CRD-3
4     Vserver-CRD-3 (10.102.29.50:88) - HTTP Type: CONTENT
5     State: UP
6     Client Idle Timeout: 180 sec
7     Down state flush: ENABLED
8     Disable Primary Vserver On Down : DISABLED
9     Default: Vserver-LB-CR Content Precedence: RULE Cache: REVERSE
```
Bind the mapping policy to the cache redirection virtual server by using the GUI

2. In the details pane, select the virtual server from which you want to bind the mapping policy, and then click Open.
3. In the Configure Virtual Server(Cache Redirection), on the Policies tab, select Map, and then click Insert Policy.
4. In the Policy Name column, select the policy from drop down list.
5. In the Target column, click the down arrow, and then select the vserver from drop down list.
6. Click OK.

Selective cache redirection

September 19, 2018

Selective cache redirection sends requests for particular types of content, for example, images, to one cache server or group of cache servers and sends other types of content to a different cache server or group of cache servers. You can configure advanced cache redirection in transparent, reverse proxy, or forward proxy modes.

In selective cache redirection, the NetScaler appliance intercepts a client request and forwards non-cacheable requests to the original destination in the client request. For cacheable requests, the appliance sends the requests to the destination cache server that can serve content of a specific content type.

Selective cache redirection involves configuring content switching policies in addition to cache redirection policies. The appliance first evaluates the cache redirection policies that are bound to the cache redirection virtual server. If a request matches a cache redirection policy, the cache redirection virtual server sends the request to the origin server or a load balancing virtual server for the origin. If no cache redirection policies match the request, the appliance evaluates the content switching policies bound to the cache redirection virtual server. If a content switching policy matches the request, the cache redirection virtual server redirects the request to a load balancing virtual server for the cache.
To configure selective cache redirection, first enable cache redirection, load balancing, and content switching on the NetScaler appliance. Then, configure a load balancing virtual server for the cache and an associated HTTP service. After this, configure a cache redirection virtual server and bind both the cache redirection and content switching policies to it. Once you have bound the policies, you can configure the virtual server to give precedence to either rule based or URL based content-switching policies.

When configured for transparent mode cache redirection in an edge deployment topology, the appliance sends all cacheable HTTP traffic to a transparent cache farm. Clients access the Internet through the appliance, which is configured as a Layer 4 switch that receives traffic on port 80.

The appliance can direct requests for images (for example, .gif and .jpg files) to one server in the transparent cache farm, and all other requests for static content to other servers in the farm. For this configuration, you configure content switching policies to send images to the image cache and send all other cacheable content to a default cache.

**Note**
The configuration described here is for transparent selective cache redirection. Therefore, it does not require a load balancing virtual server for the origin, as would a reverse proxy configuration.

To configure this type of selective cache redirection, first enable cache redirection, load balancing, and content switching. Then, configure a load balancing virtual server for the cache and configure an associated HTTP service. Then, configure a cache redirection virtual server and create and bind both cache redirection and content switching policies to this virtual server.

For details on how to enable cache redirection and load balancing on the appliance, see Enable cache redirection and load balancing.

**Enable content switching**

September 19, 2018

To configure selective cache redirection, after you enable both the load balancing and cache redirection features on the appliance, you must enable content switching.

**Enable content switching by using the CLI**

At the command prompt, type:

```
1 - enable ns feature CS
2
3 - show ns feature
```
**Example:**

```
1  > enable ns feature cs
2    Done
3  > show ns feature

<table>
<thead>
<tr>
<th>Feature</th>
<th>Acronym</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>1) Web Logging</td>
<td>WL</td>
<td>ON</td>
</tr>
<tr>
<td>2) Surge Protection</td>
<td>SP</td>
<td>ON</td>
</tr>
<tr>
<td>3) Load Balancing</td>
<td>LB</td>
<td>ON</td>
</tr>
<tr>
<td>4) Content Switching</td>

<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**Enable cache redirection and load balancing by using the GUI**

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Configure basic features.
3. In Configure Basic Features dialog box, select the check box next to the Content Switching, and then click OK.
4. In Enable/Disable Feature(s)? dialog box, click Yes.

**Configure a load balancing virtual server for the cache**

September 19, 2018

Create a load balancing virtual server and an HTTP service for each type of cache server that will be used. For example, if you want to serve JPEG files from one cache server and GIF files from another cache server, and use a third cache server for the rest of the content, create an HTTP service and virtual server for each of the three types of cache servers. Then bind each service to its respective virtual server.

For details on how to create a load balancing virtual server, see [Create a load balancing virtual server.](#)

For details on how to configure services that represent the cache server, see [Configure an HTTP service.](#)
For details on how to bind the service to a virtual server, see Bind/unbind a service to/from a load balancing virtual server.

For details on how to create a transparent proxy cache redirection server, see Configure a cache redirection virtual server, and create a virtual server of type TRANSPARENT.

For details on binding built-in cache redirection policies to the cache redirection virtual server, see Bind policies to the cache redirection virtual server.

**Configure a cache redirection policy for a specific type of content**

To identify requests that contain a .gif or .jpeg extension as cacheable, you configure a cache redirection policy and bind it to the cache redirection virtual server.

**Note**

If a request matches a policy, the NetScaler appliance forwards it to the origin server. As a result, in the following procedure, you configure policies to match requests that do not have “.gif” or “.jpeg” extensions.

To configure cache redirection for a specific type of content, configure a policy that uses a simple expression, as described in Configure a cache redirection policy.

**Configure policies for content switching**

September 19, 2018

You must create a content switching policy to identify specific types of content to be cached in one cache server or farm and identify other types of content to serve from another cache server or farm. For example, you can configure a policy to determine the location for image files with .gif and .jpeg extensions.

After defining the content switching policy, you bind it to a cache redirection virtual server and specify a load balancing virtual server. Requests that match the policy are forwarded to the named load balancing virtual server. Requests that do not match the content switching policy are forwarded to the default load balancing virtual server for the cache.

For more details about the content switching feature and configuring content switching policies, see Content switching.

You must first create the content switching policy and then bind it to the cache redirection virtual server.
Create a content switching policy by using the command CLI

At the command line, type:

```
1 - add cs policy <policyName> [-url <string> | -rule <expression>]
2 - show cs policy [<policyName>]
```

Examples:

```
1 > add cs policy Policy-CS-JPEG -rule "REQ.HTTP.URL == '/*.jpeg'"
2  Done
3 > show cs policy Policy-CS-JPEG
  Rule: REQ.HTTP.URL == '/*.jpeg'  Policy: Policy-CS-JPEG
  Hits: 0
4  Done
5 >
6
7 > add cs policy Policy-CS-GIF -rule "REQ.HTTP.URL == '/ *.gif'"
8  Done
9 > show cs policy Policy-CS-GIF
  Rule: REQ.HTTP.URL == '/ *.gif'  Policy: Policy-CS-GIF
  Hits: 0
10  Done
11 >
12
13
14
15
16
17 > add cs policy Policy-CS-JPEG-URL -url /*.jpg
18  Done
19 > show cs policy Policy-CS-JPEG-URL
  URL: /*.jpg  Policy: Policy-CS-JPEG-URL
  Hits: 0
20  Done
21 >
22
23
24
25 > add cs policy Policy-CS-GIF-URL -url /*.gif
26  Done
27 > show cs policy Policy-CS-GIF-URL
  URL: /*.gif  Policy: Policy-CS-GIF-URL
  Hits: 0
28  Done
29
30
```

Create a URL-based content switching policy by using the GUI

1. Navigate to Traffic Management > Content Switching > Policies.
2. In the details pane, click Add.
3. In the Create Content Switching Policy dialog box, in the Name text box, type a name for the policy.
4. Select the URL radio button.
5. In the Value text box, type the string value (for example, /sports).
6. Click Create and click Close. The policy you created appears in the Content Switching Policies page.

Create a rule-based content switching policy by using the GUI

1. Navigate to Traffic Management > Content Switching > Policies.
2. In the details pane, click Add.
3. In the Create Content Switching Policy dialog box, in the Name text box, type a name for the policy.
4. Select the Expression radio button, and then click Configure.
5. In the Create Expression dialog box, choose the expression syntax that you want to use.
   - If you want to use default syntax, accept the default and proceed to the next step.
   - If you want to use classic syntax, click Switch to Classic Syntax.
   The Expression portion of the dialog box changes to match your choice. The default syntax Expression view has fewer elements than does the classic syntax Expression view. In the default syntax Expression view, instead of a preview window, a button provides access to an expression evaluator. The evaluator evaluates the expression you entered, to verify that it is valid, and displays an analysis of the expression's effect.
6. Enter your policy expressions.
   For information about using the advanced syntax, see Configure advanced policy expression: Get started.
7. Click Create and click Close. The policy you created appears in the Content Switching Policies pane.

Bind the content switching policy to a cache redirection virtual server by using the CLI

At the command prompt, type the following commands to bind the content switching policy to a cache redirection virtual server and verify the configuration:

```
1 - bind cs vserver <name> <targetVserver> [-policyName <string>]
2 - show cs vserver [<name>]
```

Example:
Bind the content switching policy to a cache redirection virtual server by using the GUI

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, select the virtual server for which you want to bind the policy (for example, Vserver-CS-1), and then click Open.
3. In the Configure Virtual Server (Content Switching) dialog box, on the Policies tab, click CSW, and then click Insert Policy.
4. In the Policy Name column, select the policy that you want to configure for the content switching virtual server.
5. In the Target column, click the green arrow, and select the target load balancing virtual server from the list.
6. Click OK.
Configure precedence for policy evaluation

September 19, 2018

You can configure a content switching policy based on either a rule, which is a generic configuration to accommodate various content types, or a URL, which is more specific and defines exactly the type of content that has to be sent to a particular cache server. Essentially, the same content can be defined by either a rule based policy or a URL based policy.

Once you bind content switching policies of either type to a cache redirection virtual server, you can configure the virtual server to give precedence to either rule based or URL based policies. This will, in turn, decide which servers the particular requests are directed to.

To configure precedence for policy evaluation, use the precedence parameter, which specifies the type of policy (URL or RULE) that takes precedence on the content redirection virtual server.

Possible values: RULE, URL

Default value: RULE

Configure precedence for policy evaluation by using the CLI

At the command prompt, type the following commands to configure precedence for policy evaluation and verify the configuration:

```
1  -  set cr vserver <name> [-precedence (RULE | URL)]
2  -  show cr vserver <name>
```

Example:

```
1 > set cr vserver Vserver-CRD-1 -precedence URL
2   Done
3 > show cr vserver Vserver-CRD-1
4   Vserver-CRD-1 (*:80) - HTTP     Type: CONTENT
5   State: UP   ARP:DISABLED
6   Client Idle Timeout: 180 sec
7   Down state flush: ENABLED
8   Disable Primary Vserver On Down : DISABLED
9   Default:          Content Precedence: URL Cache: TRANSPARENT
10  On Policy Match: ORIGIN L2Conn: OFF   OriginUSIP: OFF
11  Redirect: POLICY   Reuse: ON   Via: ON ARP: OFF
12  1) Cache bypass   Policy: bypass-cache-control
13  2) Cache bypass   Policy: Policy-CRD
14   Done
```
Configure precedence for policy evaluation by using the GUI

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure precedence, (for example, Vserver-CS-1), and then click Open.
3. In the Configure Virtual Server (Content Switching) dialog box, on the Advanced tab, next to Precedence, click Rule or URL, and then click OK.

Administer a cache redirection virtual server

September 19, 2018

To administer a cache redirection virtual server, you need to view cache redirection statistics. You might need to enable or disable cache redirection servers, or direct policy hits to the cache instead of the origin. Administrative tasks also include backing up a cache redirection virtual server and managing client connections.

View cache redirection virtual server statistics

September 19, 2018

You can view properties of a cache redirection virtual server and statistics on the traffic that has passed through a cache redirection virtual server. You can also view the cache redirection virtual servers and policies that you have bound to load balancing virtual servers.

To view statistics for a specific cache redirection virtual servers, use the name parameter to specify the name of the virtual server for which statistics will be displayed. Otherwise, statistics for all cache redirection virtual servers are displayed. Maximum Length: 127

View statistics for a cache redirection virtual server by using the CLI

At the command prompt, type:

```
stat cr vserver [<name>]
```

Example:
NetScaler 12.0

> stat cr vserver Vserver-CRD-1

Vserver Summary

<table>

**View statistics for a cache redirection virtual server by using the GUI**

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers
2. In the details pane, select the virtual server for which you want to view statistics, (for example, Vserver-CRD-1), and then click Statistics.

Omit the server name to display basic statistics for all cache redirection virtual servers. Include the server name to display detailed statistics for that virtual server, including number and size of requests and responses that pass through the virtual server.

**View the statistics of a cache redirection virtual server by using the monitoring and dashboard utilities**

1. To view the statistics by using the monitoring utilities, click the Monitoring tab.
2. In the Select Group drop-down menu, choose CR Virtual Servers. A list of cache redirection virtual servers appears.
3. To view the statistics by using the dashboard utilities, click the Dashboard tab.
4. Click Applet Client or Web Start Client next to Statistical Utility.
6. To see a chart of virtual server activity, click Chart. A graphical representation of the virtual server statistics appears.

**Enable or disable a cache redirection virtual server**

September 19, 2018

When you create a cache redirection virtual server, it is enabled by default. If you disable a cache redirection virtual server, its state changes to OUT OF SERVICE and it stops redirecting cacheable client requests. However, the NetScaler appliance continues to respond to ARP and ping requests for the IP address of this virtual server.

**Enable or disable a cache redirection virtual server by using the CLI**

At the command line, type one of the following commands:

```
1 - enable cr vserver <name>
2 - show cr vserver <name>
3 - disable cr vserver <name>
4 - show cr vserver <name>
```

**Examples:**

```
1 > enable cr vserver Vserver-CRD-1
   Done
3 > show cr vserver Vserver-CRD-1
   Vserver-CRD-1 (*:80) - HTTP    Type: CONTENT
   State: UP    ARP:DISABLED
   Client Idle Timeout: 180 sec
   Down state flush: ENABLED
   Disable Primary Vserver On Down: DISABLED
   Default:     Content Precedence: URL Cache: TRANSPARENT
   On Policy Match: ORIGIN L2Conn: OFF    OriginUSIP: OFF
   Redirect: POLICY    Reuse: ON    Via: ON ARP: OFF
   1) Cache bypass Policy: bypass-cache-control
   2) Cache bypass Policy: Policy-CRD
   Done

5 >

18 > disable cr vserver Vserver-CRD-1
19   Done
20 > show cr vserver Vserver-CRD-1
```
Enable or disable a cache redirection virtual server by using the GUI

2. In the navigation pane, expand Cache Redirection, and then click Virtual Servers.
3. In the details pane, select the virtual server that you want to enable or disable, (for example, Vserver-CRD-1), and then click Statistics.
4. In the Proceed dialog box, click Yes.

Direct policy hits to the cache instead of the origin

September 19, 2018

By default, when a request matches a policy, the NetScaler appliance forwards the request either to the origin server directly, or to a load balancing virtual server for the origin, depending on how you have configured cache redirection.

You can change the default behavior so that when a request matches a policy, the request is forwarded to a load balancing virtual server for the cache.

To change the destination for a policy hit to the origin or the cache, use the onPolicyMatch parameter, which specifies where to send requests that match the cache redirection policy.

The valid options are:

1. CACHE - Directs all matching requests to the cache.
2. ORIGIN - Directs all matching requests to the origin server.
For this option to work, you must select the cache redirection type as POLICY.

Possible values: CACHE, ORIGIN

Default value: ORIGIN

Change the destination for a policy hit to the origin or the cache by using the CLI

At the command prompt, type the following commands to change the destination for a policy hit and verify the configuration:

1. `set cr vserver <name> [-onPolicyMatch (ORIGIN | CACHE)]`
2. `show cr vserver <name>`

Example:

```
1 > set cr vserver Vserver-CRD-1 -onPolicyMatch CACHE
2   Done
3 > show cr vserver Vserver-CRD-1
   Vserver-CRD-1 (*:80) - HTTP       Type: CONTENT
   State: UP     ARP:DISABLED
   Client Idle Timeout: 180 sec
   Down state flush: ENABLED
   Disable Primary Vserver On Down: DISABLED
   Default:       Content Precedence: URL Cache: TRANSPARENT
   On Policy Match: CACHE    L2Conn: OFF    OriginUSIP: OFF
   Redirect: POLICY         Reuse: ON      Via: ON ARP: OFF
13 1) Cache bypass Policy: bypass-cache-control
14 2) Cache bypass Policy: Policy-CRD
15   Done
```

Change the destination for a policy hit to the origin or the cache by using the GUI

2. In the details pane, select the virtual server for which you want to change the destination for a policy hit, (for example, Vserver-CRD-1), and then click Open.
3. In Configure Virtual Server (Cache Redirection) dialog box, click Advanced tab.
4. Select CACHE or ORIGIN from the Redirect To drop-down list.
5. Click OK.
NetScaler 12.0

Back up a cache redirection virtual server

September 19, 2018

Cache redirection can fail if the primary virtual server fails, or if it is unable to handle excessive traffic. You can specify a backup virtual server to take over the processing of traffic when the primary virtual server fails.

To specify a backup cache redirection virtual server, use the backupVServer parameter, which specifies Backup Virtual Server. Maximum Length: 127

Specify a backup cache redirection virtual server by using the CLI

At the command prompt, type the following commands to specify a backup cache redirection virtual server and verify the configuration:

1. `set cr vserver <name> [-backupVServer <string>]`
2. `show cr vserver <name>`

Example:

```
1 > set cr vserver Vserver-CRD-1 -backupVServer Vserver-CRD-2
2    Done
3 > show cr vserver Vserver-CRD-1
4      Vserver-CRD-1 (*:80) - HTTP Type: CONTENT
5          State: UP ARP:DISABLED
6          Client Idle Timeout: 180 sec
7          Down state flush: ENABLED
8          Disable Primary Vserver On Down : DISABLED
9          Default: Content Precedence: URL Cache: TRANSPARENT
10         On Policy Match: CACHE L2Conn: OFF OriginUSIP: OFF
11         Redirect: POLICY Reuse: ON Via: ON ARP: OFF
12         Backup: Vserver-CRD-2
13
14 1) Cache bypass Policy: bypass-cache-control
15 2) Cache bypass Policy: Policy-CRD
16    Done
```

Specify a backup cache redirection virtual server by using the GUI

2. In the details pane, select the virtual server for which you want to change the destination for a policy hit, (for example, Vserver-CRD-1), and then click Open.
3. In Configure Virtual Server (Cache Redirection) dialog box, select the Advanced tab.
4. In the Backup Virtual Server drop-down list, select the virtual server.
5. Click OK.

Manage client connections for a virtual server

September 19, 2018

You can configure timeouts on a cache redirection virtual server so that client connections are not kept open indefinitely. You can also insert Via headers in requests. To possibly reduce network congestion, you can reuse open TCP connections. You can enable or disable delayed cleanup of cache redirection virtual server connections.

You can configure the appliance to send ICMP responses to PING requests according to your settings. On the IP address corresponding to the virtual server, set the ICMP RESPONSE to VSVR_CNTRLD, and on the virtual server, set the ICMP VSERVER RESPONSE.

The following settings can be made on a virtual server:

- When you set ICMP VSERVER RESPONSE to PASSIVE on all virtual servers, appliance always responds.
- When you set ICMP VSERVER RESPONSE to ACTIVE on all virtual servers, appliance responds even if one virtual server is UP.
- When you set ICMP VSERVER RESPONSE to ACTIVE on some and PASSIVE on others, appliance responds even if one virtual server set to ACTIVE is UP.

This document includes the following information:

- Configure client timeout
- Insert Via headers in the requests
- Reuse TCP connections
- Configure delayed connection cleanup

Configure client timeout

You can specify expiration of client requests by setting a timeout value for the cache redirection virtual server. The timeout value is the number of seconds for which the cache redirection virtual server waits to receive a response for the client request.

To configure a time-out value, use the cltTimeout parameter, which specifies the time, in seconds, after which the NetScaler appliance closes any idle client connections. The default value is 180sec for HTTP/SSL-based services and 9000sec for TCP-based services.
Configure client timeout by using the CLI

At the command prompt, type the following commands to configure client timeout and verify the configuration:

```
1 - set cr vserver <name> [-cltTimeout <secs>]
2 - show cr vserver <name>
```

Example:

```
1 > set cr vserver Vserver-CRD-1 -cltTimeout 6000
2   Done
3 > show cr vserver Vserver-CRD-1
4     Vserver-CRD-1 (*:80) - HTTP      Type: CONTENT
5     State: UP     ARP:DISABLED
6     Client Idle Timeout: 6000 sec
7     Down state flush: ENABLED
8     Disable Primary Vserver On Down : DISABLED
9     Default:     Content Precedence: URL Cache: TRANSPARENT
10    On Policy Match: CACHE     L2Conn: OFF     OriginUSIP: OFF
11    Redirect: POLICY     Reuse: ON     Via: ON ARP: OFF
12    Backup: Vserver-CRD-2
13
14 1) Cache bypass Policy: bypass-cache-control
15 2) Cache bypass Policy: Policy-CRD
16 Done
```

Configure client timeout by using the GUI

2. In the details pane, select the virtual server for which you want to configure client timeout, (for example, Vserver-CRD-1), and then click Open.
3. In Configure Virtual Server (Cache Redirection) dialog box, select the Advanced tab.
4. In the Client Time-out(secs) text box, enter the time-out value in seconds.
5. Click OK.

Insert Via headers in the requests

A Via header lists the protocols and recipients between the start and end points for a request or a response and informs the server of proxies through which the request was sent. You can configure the cache redirection virtual server to insert a Via header in each HTTP request. The via parameter is enabled by default when you create a cache redirection virtual server.
To enable or disable Via-header insertion in client requests, use the via parameter, which specifies the state of the system in inserting a Via header in the HTTP requests.

Possible values: ON, OFF

Default value: ON

Enable or disable Via-header insertion in client requests by using the CLI

At the command prompt, type:

```
1  - set cr vserver <name> [-via (ON|OFF)]
2  - show cr vserver <name>
```

Example:

```
1 > set cr vserver Vserver-CRD-1 -via ON
2 Done
3 > show cr vserver Vserver-CRD-1
4   Vserver-CRD-1 (*:80) - HTTP       Type: CONTENT
5     State: UP    ARP:DISABLED
6   Client Idle Timeout: 6000 sec
7   Down state flush: ENABLED
8   Disable Primary Vserver On Down : DISABLED
9     Default:      Content Precedence: URL Cache: TRANSPARENT
10    On Policy Match: CACHE   L2Conn: OFF OriginUSIP: OFF
11   Redirect: POLICY       Reuse: ON       Via: ON ARP: OFF
12 Backup: Vserver-CRD-2
13
14 1) Cache bypass Policy: bypass-cache-control
15 2) Cache bypass Policy: Policy-CRD
16 Done
17 >
```

Enable or disable Via-header insertion in client requests by using the GUI

2. In the details pane, select the virtual server for which you want to configure client timeout, (for example, **Vserver-CRD-1**), and then click Open.
3. In Configure Virtual Server (Cache Redirection) dialog box, select the Advanced tab.
4. Select the Via check box.
5. Click OK.
NetScaler 12.0

Reuse TCP connections

You can configure the NetScaler appliance to reuse TCP connections to the cache and origin servers across client connections. This can improve performance by saving the time required to establish a session between the server and the appliance. The reuse option is enabled by default when you create a cache redirection virtual server.

To enable or disable the reuse of TCP connections, use the reuse parameter, which specifies the state of reuse of TCP connections to the cache or origin servers across client connections.

Possible values: ON, OFF

Default value: ON

Enable or disable the reuse of TCP connections by using the CLI

At the command prompt, type:

```
1 - set cr vserver <name> [-reuse (ON|OFF)]
2 - show cr vserver <name>
```

Example:

```
1 > set cr vserver Vserver-CRD-1 -reuse ON
2   Done
3 > show cr vserver Vserver-CRD-1
   Vserver-CRD-1 (*:80) - HTTP       Type: CONTENT
   State: UP   ARP:DISABLED
   Client Idle Timeout: 6000 sec
   Down state flush: ENABLED
   Disable Primary Vserver On Down : DISABLED
   Default:    Content Precedence: URL Cache: TRANSPARENT
   On Policy Match: CACHE   L2Conn: OFF   OriginUSIP: OFF
   Redirect: POLICY         Reuse: ON     Via: ON ARP: OFF
   Backup: Vserver-CRD-2

14 1) Cache bypass Policy: bypass-cache-control
15 2) Cache bypass Policy: Policy-CRD
16   Done
```

Enable or disable the reuse of TCP connections by using the GUI

2. In the details pane, select the virtual server for which you want to configure client timeout, (for example, Vserver-CRD-1), and then click Open.
3. In Configure Virtual Server (Cache Redirection) dialog box, select the Advanced tab.
4. Select the Reuse check box.
5. Click OK.

**Configure delayed connection cleanup**

The down state flush option performs delayed cleanup of connections on a cache redirection virtual server. The down state flush option is enabled by default when you create a cache redirection virtual server.

To enable or disable the down state flush option, set the downStateFlush parameter.

Possible values: ENABLED, DISABLED

Default value: ENABLED

**Enable of disable the down state flush option by using the CLI**

At the command prompt, type the following commands to configure delayed connection clean up and verify the configuration:

```
1  -  set cr vserver <name> [-downStateFlush (ENABLED | DISABLED)]
2  -  show cr vserver <name>
```

**Example:**

```
> set cr vserver Vserver-CRD-1 -downStateFlush ENABLED
Done
> show cr vserver Vserver-CRD-1
Vserver-CRD-1 (*:80) - HTTP Type: CONTENT
State: UP ARP:DISABLED
Client Idle Timeout: 6000 sec
Down state flush: ENABLED
Disable Primary Vserver On Down : DISABLED
Default: Content Precedence: URL Cache: TRANSPARENT
On Policy Match: CACHE L2Conn: OFF OriginUSIP: OFF
Redirect: POLICY Reuse: ON Via: ON ARP: OFF
Backup: Vserver-CRD-2

1) Cache bypass Policy: bypass-cache-control
2) Cache bypass Policy: Policy-CRD
Done
```
Enable or disable the reuse of TCP connections by using the GUI

2. In the details pane, select the virtual server for which you want to configure client timeout, (for example, Vserver-CRD-1), and then click Open.
3. In Configure Virtual Server (Cache Redirection) dialog box, click Advanced tab.
4. Select the Down state flush check box.
5. Click OK.

N-Tier cache redirection

January 6, 2019

To efficiently handle large amounts of cached data, typically several gigabytes per second, an Internet Service Provider (ISP) deploys several dedicated cache servers. The cache redirection feature of the NetScaler appliance can help load balance the cache servers, but a single appliance or a couple of appliances might not efficiently handle the large volume of traffic.

You can solve the problem by deploying the NetScaler appliances in two tiers (layers), where the appliances in the upper tier load balance those in the lower tier and the appliances in the lower tier load balance the cache servers. This arrangement is called n-tier cache redirection.

For purposes such as auditing and security, an ISP has to track client details such as the IP address, information provided, and the time of the interaction. Therefore, client connections through a NetScaler appliance have to be fully transparent. However, if you configure transparent cache redirection, with the NetScaler appliances deployed in parallel, the IP address of the client has to be shared among all the appliances. Sharing of the client IP address creates a conflict that makes network devices, such as routers, cache servers, origin servers, and other NetScaler appliances, unable to determine the appliance, and therefore the client, to which the response should be sent.

How N-tier cache redirection Is implemented

To solve the problem, appliance n-tier cache redirection splits the source port range among the appliances in the lower tier and includes the client IP address in the request sent to the cache servers. The upper-tier NetScaler appliances are configured to do sessionless load balancing in order to avoid unnecessary load on the appliances.

When the lower-tier NetScaler appliance communicates with a cache server, it uses a mapped IP address (MIP) to represent the source IP address. Therefore, the cache server can identify the appliance from which it received the request and send the response to the same appliance.
The lower-tier NetScaler appliance inserts the client IP address into the header of the request sent to the cache server. The client IP in the header helps the appliance to determine the client to which the packet should be forwarded when it receives the response from a cache server, or the origin server in case of a cache miss. The origin server determines the response to be sent according to the client IP inserted in the request header.

The origin server sends the response to an upper-tier appliance, including the source port number from which the origin server received the request. The entire source port range, 1024 to 65535, is distributed among the lower-tier NetScaler appliances. Each lower-tier appliance is exclusively assigned a group of addresses within the range. This allotment enables the upper-tier appliance to unambiguously identify the lower-tier NetScaler appliance that sent the request to the origin server. The upper-tier appliance can therefore forward the response to the correct lower-tier appliance.

The upper-tier NetScaler appliances are configured to do policy-based routing, and the routing policies are defined to determine the IP address of the destination appliance from the source port range.

**Setup necessary for configuring N-Tier CRD**

The following setup is necessary for the functioning of n-tier cache redirection:

For each upper-tier NetScaler appliance:

- Enable Layer 3 mode.
- Define policies for policy-based routes (PBRs) so that traffic is forwarded according to the range of the destination port.
- Configure a load balancing virtual server.
- Configure the virtual server to listen to all the traffic coming from the client. Set the Service Type/Protocol to be ANY and IP Address as asterisk (*).
- Enable sessionless load balancing with MAC-based redirection mode to avoid unnecessary load on the upper-tier NetScaler appliances.
- Make sure that the Use Proxy Port option is enabled.
- Create a service for each lower-tier appliance and bind all the services to the virtual server.

For each lower-tier NetScaler appliance,

- Configure the cache redirection port range on the appliance. Assign an exclusive range to each lower-tier appliance.
- Configure a load balancing virtual server and enable MAC-based redirection.
- Create a service for each cache server that is to be load balanced by this appliance. When creating the service, enable insertion of client IP in the header. Then, bind all the services to the load balancing virtual server.
- Configure a transparent mode cache redirection virtual server with the following settings:
  - Enable the Origin USIP option.
Add a source IP expression to include the client IP in the header.
- Enable the Use Port Range option.

How N-tier cache redirection works during a cache hit

The following figure shows how cache redirection works when a client request is cacheable and the response is sent from a cache server.

Figure 1. Cache Redirection in Case of a Cache Hit

Two NetScaler appliances, L1NS1 and L1NS2, are deployed in the upper tier, and four NetScaler appliances, L2NS1, L2NS2, L2NS3, and L2NS4, are deployed in the lower tier. Client A sends a request, which is forwarded by the router. Cache servers CRS1, CRS2, and CRS3 service the cache requests. Origin Server O services the uncached requests.

Traffic flow

1. Client sends a request, and the router forwards it to L1NS1.
2. L1NS1 load balances the request to L2NS2.
3. L2NS2 load balances the request to the cache server CRS1, and the request is cacheable. L2NS2 includes the client IP in the request header.
4. CRS1 sends the response to L2NS2 because L2NS2 used its MIP as the source IP address when connecting to CRS1.
5. With the help of the client IP address in the request header, L2NS2 identifies the client from which the request came. L2NS2 directly sends the response to the router, avoiding unnecessary load on the appliance in the upper tier.
6. The router forwards the response to Client A.

How N-tier cache redirection works during a cache bypass

The following figure shows how cache redirection works when a client request is sent to an origin server for a response.

Figure 2. Cache Redirection in Case of a Cache Bypass

Two NetScaler appliances, L1NS1 and L1NS2, are deployed in the upper tier, and four NetScaler appliances, L2NS1, L2NS2, L2NS3, and L2NS4, are deployed in the lower tier. Client A sends a request, which is forwarded by the router. Cache servers CRS1, CRS2, and CRS3 service the cache requests. Origin Server O services the uncached requests.
Traffic flow

1. Client sends a request, and the router forwards it to L1NS1.
2. L1NS1 load balances the request to L2NS2.
3. The request is uncachable (cache bypass). Therefore, L2NS2 sends the request to the origin server through the router.
4. The origin server sends the response to an upper-tier appliance, L1NS2.
5. According to the PBR policies, L1NS2 forwards the traffic to the appropriate appliance in the lower tier, L2NS2.
6. L2NS2 uses the client IP address in the request header to identify the client from which the request came and sends the response directly to the router, avoiding unnecessary load on the appliance in the upper tier.
7. The router forwards the response to Client A.

How N-tier cache redirection works during a cache miss

The following figure shows how cache redirection works when a client request is not cached.

Figure 3. Cache Redirection in Case of a Cache Miss

Two NetScaler appliances, L1NS1 and L1NS2, are deployed in the upper tier, and four NetScaler appliances, L2NS1, L2NS2, L2NS3, and L2NS4, are deployed in the lower tier. Client A sends a request, which is forwarded by the router. Cache servers CRS1, CRS2, and CRS3 service the cache requests. Origin Server O services the uncached requests.

Traffic flow

1. Client sends a request, and the router forwards it to L1NS1.
2. L1NS1 load balances the request to L2NS2.
3. L2NS2 load balances the request to the cache server CRS1 because the request is cacheable.
4. CRS1 does not have the response (cache miss). CRS1 forwards the request to the origin server through the appliance in the lower tier. L2NS3 intercepts the traffic.
5. L2NS3 takes the client IP from the header and forwards the request to the origin server. The source port included in the packet is the L2NS3 port from which the request is sent to the origin server.
6. The origin server sends the response to an upper-tier appliance, L1NS2.
7. According to the PBR policies, L1NS2 forwards the traffic to the appropriate appliance in the lower tier, L2NS3.
8. L2NS3 forwards the response to the router.
9. The router forwards the response to Client A.
Configure the upper-tier NetScaler appliances

September 19, 2018

Configure each of the upper-tier NetScaler appliances as follows.

Configure an upper-tier appliance for n-tier cache redirection by using the command CLI

At the command prompt, type the following commands:

```
1 - add service \<name\>@ \<serviceIP\> \<serviceType\> \<port\>
2   Run this command for each service to be added.
4
5 - add lb vserver \<name\>@ ANY \* \<port\> -persistenceType \<persistenceMethod\> -lbMethod \<lbMethod\> -m MAC -sessionless
9   ENABLED -cltTimeout \<client\>_Timeout\_Value\>
6
7
8 - bind lb vserver \<name\>@ \<serviceName\>
9   Run this command for each service to be bound.
10
12 - enable ns mode l3
14 - add ns pbr \<name\> \<action\> -srcPort \<sourcePortNumber\> -destPort \<startPortNumber-endPortNumber\> -nexthop \<serviceIpAddress\> -protocol TCP
16 - apply ns pbrs
18   Run this command after adding all the necessary PBRs.
```

Configure an upper-tier appliance for n-tier cache redirection by using the GUI

1. Enable L3 mode:
   a) In the navigation pane, click System, and then click Settings.
   b) In the Settings group, click the Configure modes link.
   c) Select the Layer 3 Mode (IP Forwarding) check box.
   d) Click OK.
2. Configure policy-based routing (PBR):
a) Navigate to System > Network > PBRs.
b) In the Policy-Based Routing (PBRs) pane, click Add.
c) Type a name for the PBR.
d) Select the action as Allow.
e) In the Next Hop box, type the IP address of the service, which represents a lower-tier appliance.
f) Select TCP from the Protocol drop-down list.
g) Type the source port and the range of the destination port corresponding to the lower-tier appliance being added.
h) Click Create.
i) In the details pane, select the PBR and click Apply.
j) Repeat Step (i) to Step (vii) for each lower-tier appliance.

3. Create a service for each lower-tier appliance:
a) Navigate to Traffic Management > Load Balancing > Services.
b) In the details pane, click Add.
c) Specify the name, protocol, IP address, and port. The protocol should be ANY.
d) Click Create.

4. Configure a load balancing virtual server:
a) Navigate to Traffic Management > Load Balancing > Virtual Servers.
b) In the details pane, click Add.
c) Specify the name, protocol, IP address, and port. The protocol should be ANY and the IP address should be *.
d) In the Services tab, select the services that represent the lower-tier NetScaler appliances.
e) In the Advanced tab, select the Redirection Mode as MAC Based and select the Sessionless check box.
f) Click Create.

Configure the lower-tier NetScaler appliances

September 19, 2018

Configure each of the lower-tier NetScaler appliances as follows.

Configure a lower-tier appliance for n-tier cache redirection by using the CLI

At the command prompt, type the following commands:

```
1 - add service <name>@<cacheServiceIP> <serviceType> <port> -cip
   ENABLED "ClientIP" - cachetype transparent
```
Configure a lower-tier appliance for n-tier cache redirection by using the GUI

1. Create a service for each cache server. To create a service:
   a) Navigate to Traffic Management > Load Balancing > Services.
   b) In the details pane, click Add, and specify the name and protocol. Clear the Directly Addressable check box.
   c) In the Advanced tab, select the Override Global check box and the Client IP check box, and then in the Header box, type ClientIP.
   d) In the Cache Type box, select Transparent Cache.
   e) Click Create.
2. Configure a load balancing virtual server:
   a) Navigate to Traffic Management > Load Balancing > Virtual Services.
   b) In the details pane, click Add and specify the name, protocol, IP address, and port. The IP address should be an asterisk (*).
   c) In the Services tab, select the services that represent the cache servers.
   d) In the Advanced tab, for Redirection Mode, select MAC Based.
   e) Click Create.
3. Configure a cache redirection virtual server:
   a) Navigate to Traffic Management > Load Balancing > Virtual Services.
   b) In the details pane, click Add and specify the name, protocol, IP address, and port. The IP address should be *.
   c) For Cache Type, select Transparent.
   d) On the Advanced tab, in the Cache Server box, select the new load balancing virtual server and check the Origin USIP and Use Port Range check boxes. In the Source IP Expression box, type HTTP.REQ.HEADER("ClientIP").
   e) Click Create.
4. Assign a source port range for the appliance:
a) In the navigation pane, click System, and then click Settings.
b) In the Settings group, click the Change global system settings link.
c) In the Cache Redirection Port Range group, specify the port range for the appliance by typing a port number for Start Port and a port number for End Port.
d) Click OK.

Clustering

September 17, 2018

Note

This feature is available with a NetScaler enterprise or platinum edition license.

A NetScaler cluster is a group of nCore appliances working together as a single system image. Each appliance of the cluster is called a node. The cluster can have one appliance or as many as 32 NetScaler nCore hardware or virtual appliances as nodes.

The client traffic is distributed between the nodes to provide high availability, high throughput, and scalability.

To create a cluster, you must add the appliances as cluster nodes, set up communication between the nodes, set up links to the client and server networks, configure the appliances, and configure the distribution of client and server traffic.

NetScaler appliance configuration support in a cluster

November 6, 2018

Clustering of NetScaler appliances is supported from NetScaler 10 onwards.

The following table lists the NetScaler appliance configurations that are not supported in NetScaler 10 and also gives the status of the features in subsequent releases.

Important

- Unless specified otherwise in this table, all NetScaler appliance features are supported in a cluster.
- The “Node-level” entry in the table indicates that the feature is supported only on individual cluster nodes.

**NetScaler appliance configurations supported from NetScaler 10 onwards**

Load balancing, load balancing persistency, DNS load balancing, SIP, maxClient, Spillover (connection and dynamic), Spillover based on bandwidth, DataStream, Compression control, Content filtering, TCP buffering, Cache redirection, Distributed Denial-of-Service (DDoS), Client Keep-alive, Basic networking (IPv4 and IPv6), OSPF (IPv4 and IPv6), RIP (IPv4 and IPv6), RIP (IPv4 and IPv6), VLAN, ICMP, Fragmentation, MBF, ACL, Simple ACL, MSR, Path MTU discovery, IP-IP, SNMP, Policies (classic and advanced), Rewrite, Responder, HTTP callout, Web server logging, Audit logging (nslog and syslog), USIP, Location commands, HTML injection, NITRO API, AppExpert, KRPC.

**Prerequisites for cluster nodes**

October 9, 2018

NetScaler appliances that are to be added to a cluster must satisfy the following criteria:

- All appliances must have the same software version and build.
All appliances must be of the same platform type. This means that a cluster must have either all hardware appliances (MPX) or virtual appliances (VPX) or SDX NetScaler appliance instances.

Note

- For a cluster of hardware appliances (MPX), the appliances must be of the same model type.
- For the formation of the heterogeneous cluster, all appliances must be of MPX platform type.
- For a cluster of virtual appliances (VPX), the appliances must be deployed on the following hypervisors: XenServer, Hyper-V, VMware ESX, and KVM.
- Clusters of SDX NetScaler appliance instances are supported in NetScaler 10.1 and later releases. To create a cluster of SDX NetScaler appliance instances, see “Set up a cluster of Citrix NetScaler instances”.
- Jumbo frames are supported on a NetScaler cluster that is made up of NetScaler appliance SDX instances.
- You can create L3 clusters of SDX instances.

(For releases prior to NetScaler 11.0) All appliances must be on the same network. In NetScaler 11.0 and later releases, appliances can belong to different networks.

All appliances must have the same licenses. Also, depending on the NetScaler appliance version, there are some additional aspects to address:

- For releases prior to NetScaler 10.5 Build 52.x:
  * A separate cluster license file is required. This file must be copied to the /nsconfig/license/ directory of the configuration coordinator.
  * Because of the separate cluster license file, the cluster feature is available irrespective of the NetScaler appliance license.
- For releases after NetScaler 10.5 Build 52.x:
  * No separate cluster license is required.
  * Cluster is licensed with the Enterprise and Platinum licenses. Cluster is not available for Standard license.

Be initially configured and connected to a common client-side and server-side network.

Note

For a cluster of virtual appliances, that has large configurations, it is recommended to use 6 GB RAM for each node of the cluster.
Cluster overview

A NetScaler cluster is formed by grouping NetScaler appliances together. Based on the network location of the NetScaler appliances that you intend adding to the cluster, you must be aware of the following cluster setups:

**Note**

Unless specified otherwise, cluster features and configurations are the same for L2 and L3 clusters.

- **L2 cluster**: In this cluster deployment, all cluster nodes belong to the same network.

- **L3 cluster (also referred to as ‘cluster in INC mode’)**: In this cluster deployment, cluster nodes can belong to different networks. The cluster nodes from a specific network must be grouped into nodegroups that include only nodes from that network. From the following figure, we see that nodes n1, n2, n3 are in the same network and are grouped into Nodegroup1.

  Similarly, the case for nodes n4 and n5, that are grouped in Nodegroup2. In the third network, there are two nodegroups. Nodegroup3 includes n6 and n7 and Nodegroup4 includes n8 and n9.

  **Note**

  Supported from NetScaler 11.0 onwards.

Synchronization across cluster nodes

All configurations on a NetScaler cluster are performed on the cluster IP address, which is the management address of the cluster. This cluster IP address is owned by a cluster node that is referred to as the cluster configuration coordinator as shown in the following figure:

The configurations that are available on the configuration coordinator are automatically propagated to the other cluster nodes and therefore all cluster nodes have the same configurations.

- NetScaler appliance allows only a few configurations to be performed on individual cluster nodes through their NSIP address. In these cases, you must ensure configuration consistency manually across all nodes in the cluster. These configurations are not propagated across the other cluster nodes. For more information on operations supported on each cluster nodes, see “Operations Supported on Individual Cluster Nodes”.

- The following commands when executed on the cluster IP address are not propagated to other cluster nodes:
NetScaler 12.0

- **shutdown.** Shuts down only the configuration coordinator.
- **reboot.** Reboots only the configuration coordinator.
- **rm cluster instance.** Removes the cluster instance from the node that you are executing the command on.

  - For a command to propagate to other cluster nodes:
    1. The quorum must be configured on cluster instance.
    2. The majority of the cluster quorum with \((n/2 + 1)\) of the cluster nodes must be active for the cluster to be operational.
    3. A cluster can run with a minimum number of nodes when majority rule \((n/2 + 1)\) is relaxed.

When a node is added to a cluster, the configurations and the files (SSL certificates, licenses, DNS, and so on) that are available on the cluster configuration coordinator are synchronized to the newly added cluster node. When an existing cluster node, that was intentionally disabled or that had failed, is once again added, the cluster compares the configurations available on the node with the configurations available on the configuration coordinator. If there is a mismatch in configurations, the node is synchronized by using one of the following:

  - **Full synchronization.** If the difference between configurations exceeds 255 commands, all the configurations of the configuration coordinator are applied to the node that is rejoining the cluster. The node remains operationally unavailable for the duration of the synchronization.
  - **Incremental Synchronization.** If the difference between configurations is less than or equal to 255 commands, only the configurations that are not available are applied to the node that is rejoining the cluster. The operational state of the node remains unaffected.

**Note**

You can also manually synchronize the configurations and files. For more information, see “Synchronizing Cluster Configurations” and “Synchronizing Cluster Files”.

**Striped, partially striped, and spotted configurations**

January 6, 2019

By virtue of command propagation, all nodes in a cluster have the same configurations. However, you may want some configurations to be available only on certain cluster nodes. While you cannot restrict the nodes on which the configurations are available, you can specify the nodes on which the configurations are active.

For example, you can define a SNIP address to be active on only one node, or define a SNIP address to be active on all nodes, or define a VIP address to be active on only one node, or define a VIP address to be active on all nodes, or define a VIP address to be active only on two nodes of a 3-node cluster.
Depending on the number of nodes the configurations are active on, cluster configurations are referred to as striped, partially striped, or spotted configurations.

Figure 1. Three-node cluster with striped, partially striped, and spotted configurations

The following table provides more details on the types of configurations:

<table>
<thead>
<tr>
<th>Configuration Type</th>
<th>Active on</th>
<th>Applicable to</th>
<th>Configurations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Striped configuration</td>
<td>All the cluster nodes</td>
<td>All entries</td>
<td>No specific configuration required to make an entity striped. By default, all entities defined on a cluster IP address are striped on all the cluster nodes.</td>
</tr>
<tr>
<td>Partially striped configuration</td>
<td>A subset of cluster nodes</td>
<td>Refer Cluster Nodegroups.</td>
<td>Bind the entities that you want to be partially striped, to a node group. The configuration is active only on the cluster nodes that belong to the node group.</td>
</tr>
<tr>
<td>Spotted configuration</td>
<td>Single cluster node</td>
<td>SNIP address; SNMP Engine ID; Hostname of cluster nodes; Entities that can be bound to a node group</td>
<td>A spotted configuration can be defined using one of two approaches. <strong>SNIP address</strong> When creating the SNIP address, specify the node on which you want the SNIP address to be active, as the owner node. <strong>Example</strong>, add ns ip 10.102.29.106 255.255.255.0 -type SNIP -ownerNode 2 (assuming node NS2 ID is 2). <strong>Note</strong>: You cannot change the ownership of a spotted SNIP address at run time. To change the ownership, you must first delete the SNIP address and add it again by specifying the new owner. <strong>Entities that can be bound to a node group.</strong> By binding the entity to a single-member node group.</td>
</tr>
</tbody>
</table>

**Note**

When USIP is disabled, Citrix recommends you to use spotted SNIP addresses. You can use striped SNIP addresses only if there is a shortage of IP addresses. The use of striped IP addresses can result in ARP flux issues. When USIP is enabled, Citrix recommends you to use striped SNIP addresses as a gateway for server initiated traffic.

**Communication in a cluster setup**

January 6, 2019

The interfaces of NetScaler appliances that are added to a cluster, are prefixed with a node ID. This helps identify the cluster node to which the interface belongs. Therefore, the interface identifier c/u, where c is the controller number and u is the unit number, now becomes n/c/u, where n is the node ID. For example, in the following figure, interface 1/2 of node n1 is represented as 0/1/2, interface 1/1 of node n2 is represented as 1/1/1, and interface 1/4 of node n3 is represented as 2/1/4.

Figure 1. Interface naming convention in a cluster

- **Server communication**-
The cluster communicates with the server through the physical connections between the cluster node and the server-side connecting device. The logical grouping of these physical connections is called the server data plane.

- **Client communication** - The cluster communicates with the client through the physical connections between the cluster node and the client-side connecting device. The logical grouping of these physical connections is called the client data plane.

- **Inter-node communication** - The cluster nodes can also communicate with each other. The manner in which they communicate depends on whether the node exists on the same network or across networks.
  - Cluster nodes within the same network communicate with each other by using the cluster backplane. The backplane is a set of interfaces in which one interface of each node is connected to a common switch, which is called the cluster backplane switch. The different types of traffic that goes through backplane, which is used by internode communication are:
    * Node to Node Messaging (NNM)
    * Steered traffic
    * Configuration propagation and synchronization
  - Each node of the cluster uses a special MAC cluster backplane switch address to communicate with other nodes through the backplane. The cluster special MAC is of the form: (**0x02 0x00 0x6F **), where is the cluster instance ID, is the node number of the NetScaler appliance that are added to a cluster.

The following figures shows the communication interfaces in L2 clusters and L3 clusters.

**Figure 2. Cluster communication interfaces - L2 cluster**

**Figure 3. Cluster communication interfaces - L3 cluster**

**Traffic distribution in a cluster setup**

January 6, 2019

In a cluster setup, external networks view the collection of NetScaler appliances as a single entity. So, the cluster must select a single node that must receive the traffic. The cluster does this selection by using Equal Cost Multiple Path (ECMP) or cluster link aggregation traffic distribution mechanism. The selected node is called the flow receiver.

**Note**

For an L3 cluster (nodes across different networks), only ECMP traffic distribution can be used.

The flow receiver gets the traffic and then, using internal cluster logic determines the node that must process the traffic. This node is called the flow processor. The flow receiver steers the traffic to the flow...
processor over the backplane (if the flow receiver and the flow processor are on the same network) or through the tunnel (if the flow receiver and the flow processor are on different networks).

Note

- The flow receiver and flow processor must be nodes capable of serving traffic.
- From NetScaler 11 onwards, you can disable steering on the cluster backplane. For more information, see “Disabling Steering on the Cluster Backplane”.

Figure 1. Traffic distribution in a cluster

The above figure shows a client request flowing through the cluster. The client sends a request to a virtual IP (VIP) address. A traffic distribution mechanism configured on the client data plane selects one of the cluster nodes as the flow receiver. The flow receiver receives the traffic, determines the node that must process the traffic, and steers the request to that node (unless the flow receiver selects itself as the flow processor).

The flow processor establishes a connection with the server. The server processes the request and sends the response to the subnet IP (SNIP) address that sent the request to the server.

- If the SNIP address is a striped or partially striped IP address, the traffic distribution mechanism configured on the server data plane selects one of the cluster nodes as the flow receiver. The flow receiver receives the traffic, determines the flow processor, and steers the request to the flow processor through the cluster backplane.
- If the SNIP address is a spotted IP address, the node that owns the SNIP address receives the response from the server.

In an asymmetric cluster topology (all cluster nodes are not connected to the external switch), you must use linksets either exclusively or combined with ECMP or cluster link aggregation. For more information, see “Using Linksets”.

Cluster nodegroups

January 6, 2019

Note

Nodegroups are supported from NetScaler 10.1 onwards.

As the name indicates, a cluster nodegroup is a group of cluster nodes.

Figure 1. NetScaler cluster with nodegroups

The above figure shows a cluster which has nodegroups NG1 and NG2 that include 3 cluster nodes each. The cluster also has 3 nodes that are not part of any nodegroup.

A nodegroup can be configured for the following:
• To define spotted and partially striped configurations. For more information, see “Nodegroups for Spotted and Partially-Striped Configurations”.

• To configure redundancy of nodegroups. For more information, see “Configuring Redundancy for Nodegroups”.

  Note: Supported from NetScaler 10.5 Build 52.1115.e onwards.

• To define an L3 cluster (also called a cluster in INC mode). In an L3 cluster, cluster nodes can be from different networks. You must group nodes that belong to a network in a single nodegroup. For example, if n1, n2, n3 are in network1 and n4, n5, n6 are in network2, then NG1 must include nodes of network1 and NG2 must include nodes of network2. For setting up an L3 cluster, see “Creating a NetScaler cluster”.

  Note
  • Supported from NetScaler 11 onwards.
  • The above functions of a nodegroup are mutually exclusive. This means that a nodegroup can provide only one of the above mentioned functionality.

**Cluster and node states**

January 6, 2019

For a cluster to be functional, a majority of the nodes \((n/2 + 1)\) must be operationally active (operational state is ACTIVE). Check table below.

**Important**

From NetScaler release 10.5, you can configure the cluster to be functional even when the majority criteria is not satisfied. This configuration must be performed when creating a cluster.

For more information on states of a cluster node, refer to States of a cluster node.

**Routing in a cluster**

September 18, 2018

Routing in a cluster works in much the same way as routing in a standalone system. A few points to note:

• All routing configurations must be performed from the cluster IP address and the configurations are propagated to the other cluster nodes.

• Routing runs only on spotted SNIP addresses and NSIP addresses.
• Routes are limited to the maximum number of ECMP routes supported by the upstream router.

• Node-specific routing configurations must be performed by using the owner-node argument as follows:

```plaintext
  1  !
  2  interface vlan97
  3  !
  4  router ospf
  5  owner-node 0
  6  ospf router-id 97.131.0.1
  7  exit-owner-node
  8  owner-node 1
  9  ospf router-id 97.131.0.2
 10  exit-owner-node
 11  owner-node 2
 12  ospf router-id 97.131.0.3
 13  exit-owner-node
 14  redistribute kernel
 15  network 97.0.0.0/8 area 0
 16  !
```

• Retrieve node-specific routing configurations by specifying the node(s) in the owner-node argument as follows:

```plaintext
  1  > vtysh
  2  ns# owner-node 0 1
  3  ns(node-0 1)# show cluster state
  4  ns(node-0 1)# exit-owner-node
```

• Clear node-specific routing configurations by specifying the node(s) in the owner-node argument as follows:

```plaintext
  1  > vtysh
  2  ns# owner-node 0 1
  3  ns(node-0 1)# clear config
  4  ns(node-0 1)# exit-owner-node
```

• Routing protocol daemons can run and adjacencies can be formed on active and inactive nodes of a cluster.

• Only active nodes advertise host routes to striped VIP addresses. Spotted VIP addresses are advertised by active owner node.

• Active and inactive nodes can learn dynamic routes and install them into the routing table.
• Routes learnt on a node are propagated to other nodes in the cluster only if route propagation is configured. This is mostly needed in asymmetric topologies where the unconnected nodes may not be able to form adjacencies.

```
1 ns(config)# ns route-install propagate
```

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Make sure that route propagation is not configured in a symmetric cluster topology as it can result in making the node unavailable to the cluster.</td>
</tr>
</tbody>
</table>

**IP addressing for a cluster**

September 18, 2018

In addition to the standard types of NetScaler appliance-owned IP addresses—NetScaler appliance NSIP, Virtual IP (VIP), and Subnet IP (SNIP)—a clustered NetScaler appliance can have a cluster management IP (CLIP) address. It can also have striped and spotted IP addresses.

**CLIP address.** An IP address owned by the cluster coordinator node (CCO). The CLIP address can float between different nodes in a cluster setup. If the CLIP is moved to a different node of the cluster, that node becomes the CCO. The CCO is the NetScaler appliance that is responsible for management tasks in the cluster. A network administrator uses the CLIP address to connect to the cluster to perform configuration and management tasks, such as accessing unified GUI, reporting, tracing packet flow, and collecting logs. The CCO node does not have an NSIP address. Only configurations performed on the CCO through the cluster IP address are propagated to other nodes in the cluster.

**Striped IP address.** A logical IP address available on all nodes of the cluster, it can be either a VIP or SNIP address.

**Spotted IP address.** A logical IP (preferably SNIP address) is available only on one node. A spotted IP address has visibility on only that node. To minimize traffic-steering overhead, Citrix recommends that you use spotted SNIP address for backend communication with the server.

For example, in a four-node cluster group, you must configure each node with a spotted SNIP address. For more information on how to configure a spotted IP configuration, see [Striped, Partially Striped, and Spotted Configurations](#). You can define a SNIP address to be active on only one node, or active on all nodes. If a virtual IP address and Subnet IP address is available only on a specific node, it is of spotted configuration or if the Subnet IP address and Virtual server IP address are available on all nodes, it is defined as striped configuration.
NetScaler 12.0

Note

In a four-node cluster setup, you must configure a spotted SNIP address on each node. For more information about configuring a spotted IP configuration, see Striped, Partially Striped, and Spotted Configurations.

In an L3 cluster setup, only spotted SNIP configuration is supported, as shown in the following table.

<table>
<thead>
<tr>
<th>IP Address</th>
<th>NSIP</th>
<th>VIP</th>
<th>SNIP</th>
</tr>
</thead>
<tbody>
<tr>
<td>Spotted</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>

</tr>
</tbody>
</table>

Configuring layer 3 clustering

January 6, 2019

Understanding L3 Cluster

The demand to expand the high availability deployment and increase the scalability of the client traffic across different networks guided to establish L3 cluster. The L3 cluster lets you to group NetScaler appliances across individual subnets (L2 cluster).

L3 cluster is also referred to as “cluster in Independent Network Configuration (INC) mode”. In L3 cluster deployment, the cluster nodes in the same network are grouped together to form a Nodegroup. L3 cluster uses GRE tunneling to steer the packets across networks. The heartbeat messages across L3 clusters will be routed.

This document includes the following details:

- Architecture
- Example

Architecture

The L3 cluster architecture comprises of the following components:

- Nodegroup. The cluster nodes from each network (n1, n2) and (n3, n4), as depicted in below figure, are grouped together to form a Nodegroup. These Nodegroups are terminated to the layer 3 switch on either side of the network.
- The cluster communicates with the client through the physical connections between the cluster node and the client-side connecting device. The logical grouping of these physical connections is called the client data plane.
- The cluster communicates with the server through the physical connections between the cluster node and the server side connecting device. The logical grouping of these physical connections is called the server data plane.

• **Backplane Switch.** Cluster nodes within the same network communicate with each other by using the cluster backplane. The backplane is a set of interfaces in which one interface of each node is connected to a common switch, which is called the cluster backplane switch.

• **GRE Tunnel.** The packets between nodes in a L3 cluster are exchanged over an unencrypted GRE tunnel that uses the NSIP addresses of the source and destination nodes for routing. The steering mechanism will change for nodes belonging to different network. The packets are steered through a GRE tunnel to the node on the other subnet, instead of rewriting the MAC.

### Example

Consider an example of an L3 cluster deployment consisting of the following:

- Three NetScaler appliances (n1, n2, and n3) nodes are grouped together into Nodegroup1.
- Similarly, the nodes n4 and n5 are grouped in Nodegroup2. In the third network, there are two nodegroups. Nodegroup3 includes n6 and n7 and Nodegroup4 includes n8 and n9.
- The NetScaler appliances that belong to the same network are combined together to form a Nodegroup.

### Points to Consider before Configuring L3 Cluster

Consider the following points before configuring L3 cluster on a NetScaler appliance:

- The backplane is not mandatory while configuring L3 subnets. If the backplane is not specified, the node will not go to backplane fail state.

  **Note**

  If you have some cluster nodes in the L2 network, it is mandatory to enable steering on the cluster backplane, else the nodes will go to backplane fail state.

- The external traffic distribution in L3 cluster supports only Equal Cost Multiple Path (ECMP).

- The following parameters are processed when steering is disabled in an L3 cluster deployment:
  - ICMP errors
  - Fragmentation
  - Striped SNIPs or MIPs
• The entities (route, route6, pbr, and pbr6) can be bound to configuration nodegroup.
• VLAN, RNAT, and IP tunnel cannot be bound to a config nodegroup.
• Config nodegroup should always have property STRICT “YES.
• The cluster nodes should not be added to a config nodegroup via “add cluster node” command.
• The “clear config extended+” command will not clear the entities (route, route6, pbr, pbr6, rnat, IP tunnel, ip6tunnel). These entities should be cleared when an “add cluster instance –INC enabled” command is configured.

Configuring L3 Cluster

In an L3 cluster configuration, the cluster command has different attributes to configure that is based on nodes, and nodegroups. The L3 cluster configuration also includes an IPv6 profile apart from IPv4 profiles.

Configuring L3 cluster on a NetScaler appliance consists of the following tasks:
  • Create a cluster instance
  • Create a nodegroup in L3 cluster
  • Add a NetScaler appliance to the cluster and group with nodegroup
  • Add cluster IP address to the node
  • Enable the cluster instance
  • Save the configuration
  • Add a new node to an existing nodegroup
  • Create a new nodegroup in L3 cluster
  • Group new nodes to the newly created nodegroup
  • Join the node to the cluster

Configuring the following by Using the Command Line

• To create a cluster instance by using the NetScaler CLI

<table>
<thead>
<tr>
<th>add cluster instance &lt;clid&gt;</th>
<th>DISABLED&gt; -processLocal</th>
<th>DISABLED&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>-inc &lt;ENABLED&gt;</td>
<td>&lt;ENABLED&gt;</td>
<td></td>
</tr>
</tbody>
</table>

• To create a nodegroup in L3 cluster

  add cluster nodegroup <ng>

• To add a NetScaler appliance to the cluster and to associate with nodegroup
add cluster node <nodeid> <nodeip> -nodegroup <ng>

• To add the cluster IP address on this node
  add ns ip <IPAddress> <netmask> -type clip

• Enable the cluster instance
  enable cluster instance <clId>

• Save the configuration
  save ns config

• Warm reboot the appliance
  reboot -warm

  • To add a new node to an existing nodegroup
    add cluster node <nodeid> <nodeip> -nodegroup <ng>

  • To create a new nodegroup in L3 cluster
    add cluster nodegroup <ng>

  • To group new nodes to the newly created nodegroup
    add cluster node <nodeid> <nodeip> -nodegroup <ng>

  • To join the node to the cluster

    1. **join cluster - clip** \<ip\_addr> -password \<password\>**
    2. add cluster instance 1 - inc ENABLED - processLocal ENABLED
    3. Done

  **Note**
  The “inc” parameter should be ENABLED for an L3 cluster.

    1. add cluster nodegroup ng1
    2. Done
    3. > add cluster node 0 1.1.1.1 - state ACTIVE - nodegroup ng1
    4. Done
    5. > add ns ip 1.1.1.100 255.255.255.255 - type clip
Advertising Cluster IP address of a Layer 3 Cluster

You must configure the cluster IP address to be advertised to the upstream router to make the cluster configuration accessible from any subnet. The cluster IP address is advertised as a kernel route by the dynamic routing protocols configured on a node.

Advertising the cluster IP address consists of the following tasks:

- **Enable the host route option of the cluster IP address.** The host route option pushes the cluster IP address to ZebOS routing table for kernel route redistribution through dynamic routing protocols.

- **Configuring a dynamic routing protocol on a node.** A dynamic routing protocol advertises the cluster IP address to the upstream router. For more information on configuring a dynamic routing protocol, see Configuring Dynamic Routes.
To enable the host route option of the cluster IP Address by using the NetScaler CLI

At the command prompt, type:

1 - **add nsip** \<IPAddress\> \<netmask\> -**hostRoute ENABLED**
2 - **show nsip** \<IPAddress\>
3
4  > add ns ip 10.102.29.60 255.255.255.255 -hostRoute ENABLED
5
6  Done

Spotted, partially striped configurations on L3 cluster

The spotted and partially striped configurations on L3 cluster slightly differs from L2 cluster. The configuration might differ from node to node as the nodes reside on different subnets. The network configurations can be node specific in L3 cluster, hence you have to configure the spotted or partially striped configurations based on the below-mentioned parameters.

To configure spotted, partially striped configurations on a NetScaler appliance over L3 cluster perform the following tasks:

1 - Add a cluster ownergroup to an IPv4 static routing table
2 - Add a cluster ownergroup to an IPv6 static routing table
3 - Add a cluster ownergroup to an IPv4 policy based routing (PBR)
4 - Add a cluster ownergroup to an IPv6 PBR
5 - Add a VLAN
6 - Bind a VLAN to a specific ownergroup of cluster nodegroup

Configuring the following by Using the Command Line

- To add a cluster ownergroup to an IPv4 static route table of the NetScaler appliance
  add route <network> <netmask> <gateway> -ownergroup <ng>
- To add a cluster ownergroup to an IPv6 static route table of the NetScaler appliance
  add route6 <network> -ownergroup <ng>
- To add a cluster ownergroup to an IPv4 PBR
  add pbr <name> <action> -ownergroup <ng>
- To add a cluster ownergroup to an IPv6 PBR
  add pbr6 <name> <action> -ownergroup <ng>
To add a VLAN

```
add vlan <id>
```

To bind a VLAN to a specific ownergroup of cluster nodegroup

```
bind vlan <id> -ifnum - IPv6_addr > [-ownergroup <ng>]
[IPAddress <ip_addr]
```

The following commands are sample examples of spotted and partially striped configurations which can be configured by using the NetScaler CLI.

```
> add route 10.102.29.0 255.255.255.0 10.102.29.2 - ownergroup ng2
Done

> add route6 fe80::9404:60ff:fedd:a464/64 - ownergroup ng1
Done

> add pbr pbr1 allow - ownergroup ng1
Done

> add pbr6 pbr2 allow - ownergroup ng2
Done

> add vlan 2
Done

> bind vlan 2 - ifnum 1/2 - [IPAddress 10.102.29.80 | fe80::9404:60ff:fedd:a464/64- ownergroup ng1
Done
```

**Configure nodegroup**

In an L3 cluster, to replicate the same set of configurations on more than one nodegroup, the following commands are used:
NetScaler 12.0

Configuring the following by Using the Command Line

- To add an IPv4 static route to the routing table of the NetScaler appliance
  
  `add route <network> <netmask> <gateway> -ownerGroup <ng>`

Sample Configuration

```
1  add route 0 0 10.102.53.1 - ownerGroup ng1
2
3  add route 0 0 10.102.53.1 - ownerGroup ng2
```

To support the above configuration, a new nodegroup ‘all’ has to be defined and you have to configure the following commands:

Configuring the following by Using the Command Line

- To add a new nodegroup to cluster with strict parameter

  `add cluster nodegroup** <name> -strict <YES NO>`

- To bind a cluster node or an entity to the given nodegroup
  
  `bind cluster nodegroup <name> -node <nodeid>`

- To add IPv4 static route to all ownergroup
  
  `add route <network> <netmask> <gateway> -ownerGroup <ng>`

Sample configuration:

```
1  add cluster nodegroup all - strict YES
2
3  bind cluster nodegroup all - node 1
4
5  bind cluster nodegroup all - node 2
6
7  add route 0 0 10.102.53.1 - ownerGroup all
```

Setting up a NetScaler cluster

September 18, 2018
NetScaler appliances that you want to add to the cluster must satisfy the criteria specified in “Prerequisites for Cluster Nodes”. Before actually setting up a cluster, you must be aware of cluster basics. For information, see “Cluster Overview”.

Forming a cluster requires you to set up inter-node communication, create the cluster (by adding the first NetScaler appliance), and then add the other cluster nodes. Each of these steps is explained with relevant details in subsequent topics.

**Note**

While there are some differences in setting up an L2 and L3 cluster, there are many similarities too. The subsequent topics explain the setup for both cluster types while highlighting the configurations that are specific to L3 clusters.

### Setting up inter-node communication

September 18, 2018

The nodes in a cluster setup communicate with one another using the following inter-node communication mechanisms:

- Nodes that are within the network (same subnet) communicate with each other through the cluster backplane. The backplane must be explicitly set up. See the detailed steps listed below.
- Across networks, steering of packets is done through a GRE tunnel and other node-to-node communication is routed across nodes as required.

**Note:**

- A cluster can include nodes from different networks from NetScaler 11.0 onwards.
- In an L3 cluster deployment, packets between NetScaler appliance nodes are exchanged over an unencrypted GRE tunnel that uses the NSIP addresses of the source and destination nodes for routing. When this exchange occurs over the internet, in the absence of an IPSec tunnel, the NSIPs will be exposed on the internet and this could result in security issues. Citrix advises customers to establish their own IPSec solution when using a L3 cluster.

### To set up the cluster backplane, do the following for every node

1. Identify the network interface that you want to use for the backplane.
2. Connect an Ethernet or optical cable from the selected network interface to the cluster backplane switch.

For example, to use interface 1/2 as the backplane interface for node 4, connect a cable from the 1/2 interface of node 4 to the backplane switch.
Important points to note when setting up the cluster backplane

- Do not use the appliance’s management interface (0/x) as the backplane interface. In a cluster, the interface 0/1/x is read as:
  
  0 -> node ID 0  
  1/x -> NetScaler appliance interface

- Backplane interfaces must not be used for the client or server data planes.

- Configure a link aggregate (LA) channel to optimize the throughput of the cluster backplane.

- Citrix recommends that you dedicate a separate switch for the backplane, so that large amounts of traffic can be handled seamlessly.

- Backplane interfaces of all nodes of a cluster must be connected to the same switch and bound to the same L2 VLAN.

- If you have multiple clusters with the same cluster instance ID, make sure that the backplane interfaces of each cluster are bound to a different VLAN.

- The backplane interface is always monitored, regardless of the HA monitoring settings of that interface.

- The state of MAC spoofing on the different virtualization platforms can affect the steering mechanism on the cluster backplane. Therefore, make sure the appropriate state is configured:
  
  - XenServer - Disable MAC spoofing
  - Hyper-V - Enable MAC spoofing
  - VMware ESX - Enable MAC spoofing (also make sure “Forged Transmits” is enabled)

- The MTU for the cluster backplane is automatically updated. However, if jumbo frames are configured on the cluster, the MTU of the cluster backplane must be explicitly configured. The value must be set to 78 + X, where X is the maximum MTU of the client and server data planes. For example, if MTU of server data plane is 7500 and of the client data plane is 8922, then the MTU of cluster backplane must be set to 78 + 8922 = 9000. To set this MTU, use the following command:

  ```
  1 > set interface <backplane_interface> -mtu <value>
  ```

- The MTU for interfaces of the backplane switch must be specified to be greater than or equal to 1578 bytes, if the cluster has features like MBF, L2 policies, ACLs, routing in CLAG deployments, and vPath.

Creating a NetScaler cluster

September 18, 2018
To create a cluster, start by taking one of the NetScaler appliances that you want to add to the cluster. On this node, you must create the cluster instance and define the cluster IP address. This node is the first cluster node and is called the cluster configuration coordinator. All configurations that are performed on the cluster IP address are stored on this node and then propagated to the other cluster nodes.

The responsibility of configuration coordination in a cluster is not fixed to a specific node. It can change over time depending on the following factors:

- The priority of the node. The node with the highest priority (lowest priority number) is made the configuration coordinator. Therefore, if a node with a priority number lower than that of the existing configuration coordinator is added, the new node takes over as the configuration coordinator.

  **Note**

  Node priority can be configured from NetScaler 10.1 onwards.

- If the current configuration coordinator goes down. The node with the next lowest priority number takes over as the configuration coordinator. If the priority is not set or if there are multiple nodes with the lowest priority number, the configuration coordinator is selected from one of the available nodes.

  **Note**

  The configurations of the appliance (including SNIP addresses and VLANs) are cleared by implicitly executing the clear ns config extended command. However, the default VLAN and NSVLAN are not cleared from the appliance. Therefore, if you want the NSVLAN on the cluster, make sure it is created before the appliance is added to the cluster.

  For an L3 cluster (cluster nodes on different networks), networking configurations are not cleared from the appliance.

  **Important**

  HA Monitor (HAMON) on a cluster setup is used to monitor the health of an interface on each node. The HAMON parameter should be enabled on each node to monitor the state of the interface. If the operational state of the HAMON enabled interface goes down due to any reason, the respective cluster node is marked as unhealthy (NOT UP) and that node cannot serve traffic.

**To create a cluster by using the command line interface**

1. Log on to an appliance (for example, appliance with NSIP address 10.102.29.60) that you want to add to the cluster.

2. Add a cluster instance.
NetScaler 12.0

add cluster instance <clId> -quorumType <NONE | MAJORITY> -inc <ENABLED | DISABLED>

Note
• The cluster instance ID must be unique within a LAN.
• For an L3 cluster, make sure the inc parameter is set to ENABLED. The “inc” parameter must be disabled for an L2 cluster.

3. [Only for an L3 cluster] Create a nodegroup. In the next step, the newly added cluster node must be associated with this nodegroup.

Note
This nodegroup will include all or a subset of the NetScaler appliances that belong to the same network.

add cluster nodegroup <name>

4. Add the NetScaler appliance to the cluster.

add cluster node <nodeId> <IPAddress> -state <state> -backplane <interface_name> -nodegroup <name>

Note For an L3 cluster:
• The nodegroup parameter must be set to the name of the nodegroup created above.
• The backplane parameter is mandatory for nodes that are associated with a nodegroup that has more than one node, so that the nodes within the network can communicate with each other.

Example

Adding a node for an L2 cluster (all cluster nodes are in the same network).

```
> add cluster node 0 10.102.29.60 -state PASSIVE -backplane 0/1/1
```

Adding a node for an L3 cluster which includes a single node from each network. Here, you do not have to set the backplane.

```
> add cluster node 0 10.102.29.60 -state PASSIVE -nodegroup ng1
```

Adding a node for an L3 cluster which includes multiple nodes from each network. Here, you have to set the backplane so that nodes within a network can communicate with each other.

```
> add cluster node 0 10.102.29.60 -state PASSIVE -backplane 0/1/1 -nodegroup ng1
```
1. Add the cluster IP address (for example, 10.102.29.61) on this node.

   ```shell
   add ns ip <IPAddress> <netmask> -type clip
   ```

   **Example**

   ```shell
   1 > add ns ip 10.102.29.61 255.255.255.255 -type clip
   ```

2. Enable the cluster instance.

   ```shell
   enable cluster instance <clId>
   ```

3. Save the configuration.

   ```shell
   save ns config
   ```

4. Warm reboot the appliance.

   ```shell
   reboot -warm
   ```

Verify the cluster configurations by using the show cluster instance command. Verify that the output of the command displays the NSIP address of the appliance as a node of the cluster.

**To create a cluster by using the configuration utility**

1. Log on to an appliance (for example, an appliance with NSIP address 10.102.29.60) that you intend to add to the cluster.
2. Navigate to **System > Cluster**.
3. In the details pane, click the **Manage Cluster** link.
4. In the Cluster Configuration dialog box, set the parameters required to create a cluster. For a description of a parameter, hover the mouse cursor over the corresponding text box.
5. Click **Create**.
6. In the Configure cluster instance dialog box, make sure that the Enable cluster instance check box is selected.
7. In the Cluster Nodes pane, select the node and click **Open**.
8. In the Configure Cluster Node dialog box, set the State.
9. Click **OK**, and then click **Save**.
10. Warm reboot the appliance.

**Adding a node to the cluster**

September 18, 2018
You can seamlessly scale the size of a cluster to include a maximum of 32 nodes. When a NetScaler appliance is added to the cluster, the configurations from that appliance are cleared (by internally executing the clear ns config -extended command). The SNIP addresses, MTU settings of the backplane interface, and all VLAN configurations (except the default VLAN and NSVLAN) are also cleared from the appliance.

The cluster configurations are then synchronized on this node. There can be an intermittent drop in traffic while the synchronization is in progress.

Important
Before you add a NetScaler appliance to a cluster:

- Set up the backplane interface for the node. Check preceding topic.
- Check if the licenses that are available on the appliance match those available on the configuration coordinator. The appliance is added only if the licenses match.
- If you want the NSVLAN on the cluster, make sure that the NSVLAN is created on the appliance before it is added to the cluster.
- <Citrix recommends that you add the node as a passive node. Then, after joining the node to the cluster, complete the node specific configuration from the cluster IP address. Run the force cluster sync command if the cluster has only spotted IP addresses, has L3 VLAN binding, or has static routes.
- When an appliance with a preconfigured link aggregate (LA) channel is added to a cluster, the LA channel continues to exist in the cluster environment. The LA channel is renamed from LA/x to nodeId/LA/x, where LA/x is the LA channel identifier.

To add a node to the cluster by using the command line interface

1. Log on to the cluster IP address and, at the command prompt, do the following:
   - Add the appliance (for example, 10.102.29.70) to the cluster.
   
   ```
   add cluster node <nodeId> <IPAddress> -state <state> -backplane <interface_name> -nodegroup <name>
   ```

   Note For an L3 cluster:
   - The nodegroup parameter must be set to a nodegroup that has nodes of the same network.
If this node belongs to the same network as the first node that was added, then configure the nodegroup that was used for that node.

If this node belongs to a different network, then create a nodegroup and bind this node to the nodegroup.

The backplane parameter is mandatory for nodes that are associated with a nodegroup that has more than one node, so that the nodes within the network can communicate with each other.

Example

```
> add cluster node 1 10.102.29.70 -state PASSIVE -backplane 1/1/1
```

Save the configuration.

```
save ns config
```

1. Log on to the newly added node (for example, 10.102.29.70) and do the following:

   - Join the node to the cluster.

   ```
   > join cluster -clip <ip_addr> -password <password>
   ```

   **Example**

   ```
   > join cluster -clip 10.102.29.61 -password nsroot
   ```

1. Perform the following configurations:

   - If the node is added to a cluster that has only spotted IPs, the configurations are synchronized before the spotted IP addresses are assigned to that node. In such cases, L3 VLAN bindings can be lost. To avoid this loss, either add a striped IP or add the L3 VLAN bindings.
   - Define the required spotted configurations.
   - Set the MTU for the backplane interface.

2. Save the configuration.

```
save ns config
```

3. Warm reboot the appliance.

```
reboot -warm
```
To add a node to the cluster by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to System > Cluster > Nodes.
3. In the details pane, click Add to add the new node (for example, 10.102.29.70).
4. In the Create Cluster Node dialog box, configure the new node. For a description of a parameter, hover the mouse cursor over the corresponding text box.
5. Click Create. When prompted to perform a warm reboot, click Yes.

To join a previously added node to the cluster by using the configuration utility

If you have used the command line to add a node to the cluster, but have not joined the node to the cluster, you can use the following procedure.

Note
When a node joins the cluster, it takes over its share of traffic from the cluster and hence an existing connection can get terminated.

1. Log on to the node that you want to join to the cluster (for example, 10.102.29.70).
2. Navigate to System > Cluster.
3. In the details pane, under Get Started, click the Join Cluster link.
4. In the Join to existing cluster dialog box, set the cluster IP address and the nsroot password of the configuration coordinator. For a description of a parameter, hover the mouse cursor over the corresponding text box.
5. Click OK.

Viewing the details of a cluster

September 18, 2018

You can view the details of the cluster instance and the cluster nodes by logging on to the cluster IP address.

To view details of a cluster instance by using the command line interface

Log on to the cluster IP address and, at the command prompt, type:

```
1 show cluster instance <clId>
```
When executed from the NSIP address of a cluster node that is not the configuration coordinator, this command displays the status of the cluster on this node.

**To view details of a cluster node by using the command line interface**

Log on to the cluster IP address and, at the command prompt, type:

```
show cluster node <nodeId>
```

**To view details of a cluster instance by using the configuration utility**

1. Log on to the cluster IP address.
2. Navigate to System > Cluster.
3. In the details pane, under Get Started, click the Manage Cluster link to view the details of the cluster.

**To view details of a cluster node by using the configuration utility**

1. Log on to the cluster IP address.
2. Navigate to System > Cluster > Nodes.
3. In the details pane, click the node for which you want to view the details.

**Distributing traffic across cluster nodes**

September 18, 2018

After you have created the NetScaler cluster and performed the required configurations, you must deploy Equal Cost Multiple Path (ECMP) or cluster Link Aggregation (LA) on the client data plane (for client traffic) or server data plane (for server traffic). These mechanisms distribute external traffic across the cluster nodes.

**Using Equal Cost Multiple Path (ECMP)**

January 6, 2019

By using the Equal Cost Multiple Path (ECMP) mechanism on a cluster deployment, active cluster nodes advertise the virtual server IP addresses. The cluster node which receives the advertised traffic
steers the traffic to the node that must process the traffic. There can be redundant steering in spotted and partially striped virtual servers. Therefore, from NetScaler 11 onwards, spotted and partially striped virtual server IP addresses advertise the owner nodes, which reduce the redundant steering.

You must have detailed knowledge of routing protocols to use ECMP. For more information, see “Configuring Dynamic Routes”. For more information on routing in a cluster, see “Routing in a Cluster”.

To use ECMP, you must first perform the following:

- Enable the required routing protocol (OSPF, RIP, BGP, or ISIS) on the cluster IP address.
- Bind the interfaces and the spotted IP address (with dynamic routing enabled) to a VLAN.
- Configure the selected routing protocol and redistribute the kernel routes on the ZebOS by using the vtysh shell.

You must perform similar configurations on the cluster IP address and on the external connecting device.

**Note**

- Make sure that the licenses on the cluster support dynamic routing, otherwise ECMP does not work.
- ECMP is not supported for wildcard virtual servers since RHI needs a VIP address to advertise to a router and wildcard virtual servers do not have associated VIP addresses.

As seen in the above figure, the ECMP router can reach the VIP address via SNIP0, SNIP1, or SNIP2.

**To configure ECMP on the cluster by using the command line interface**

1. Log on to the cluster IP address.
2. Enable the routing protocol.
   
   `enable ns feature <feature>`

   **Example:** To enable the OSPF routing protocol.
   ```
   1 > enable ns feature ospf
   ```
3. Add a VLAN.
   
   `add vlan <id>`

   **Example**
   ```
   1 > add vlan 97
   ```
4. Bind the interfaces of the cluster nodes to the VLAN.

   `bind vlan <id> -ifnum <interface_name>`

   **Example**

   ```
   1 > bind vlan 97 -ifnum 0/1/2 1/1/2 2/1/2
   ```

5. Add a spotted SNIP address for each node and enable dynamic routing on it.

   `add ns ip <SNIP> <netmask> -ownerNode <positive_integer> -dynamicRouting ENABLED`

   **Example**

   ```
   1 > add ns ip 97.131.0.1 255.0.0.0 -ownerNode 0 -dynamicRouting ENABLED -type SNIP
   2
   3 > add ns ip 97.131.0.2 255.0.0.0 -ownerNode 1 -dynamicRouting ENABLED -type SNIP
   4
   5 > add ns ip 97.131.0.3 255.0.0.0 -ownerNode 2 -dynamicRouting ENABLED -type SNIP
   ```

6. Bind one of the spotted SNIP addresses to the VLAN. When you bind one spotted SNIP address to a VLAN, all other spotted SNIP addresses defined on the cluster in that subnet are automatically bound to the VLAN.

   `bind vlan <id> -IPAddress <SNIP> <netmask>`

   **Example**

   ```
   1 > bind vlan 97 -IPAddress 97.131.0.1 255.0.0.0
   ```

   **Note**

   You can use NSIP addresses of the cluster nodes instead of adding SNIP addresses. If so, you do not have to perform steps 3-6.

7. Configure the routing protocol on ZebOS using vtysh shell.

   **Example:** To configure OSPF routing protocol on node IDs 0, 1, and 2.

   ```
   1 > vtysh  ! interface vlan97  ! router ospf  owner-node 0
   ospf router-id 97.131.0.1  exit-owner-node  owner-node 1
   ospf router-id 97.131.0.2  exit-owner-node  owner-node 2
   ospf router-id 97.131.0.3  exit-owner-node  redistribute
   kernel  network 97.0.0.0/8 area 0  !
   ```
NetScaler 12.0

Note

For VIP addresses to be advertised, RHI setting must done by using the vserverRHIlevel parameter as follows:

`add ns ip <IPAddress> <netmask> -type VIP -vserverRHIlevel <vserverRHIlevel>`

For OSPF specific RHI settings, there are additional settings that can be done as follows:

`add ns ip <IPAddress> <netmask> -type VIP -ospfLSAType (TYPE1 | TYPES) -ospfArea <positive_integer>`

Use the add ns ip6 command to perform the above commands on IPv6 addresses.

8. Configure ECMP on the external switch. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1) switch. Similar configurations must be performed on other switches.

| 1 | //For OSPF (IPv4 addresses) Global config: Configure terminal feature ospf Interface config: Configure terminal interface Vlan10 no shutdown ip address 97.131.0.5/8 Configure terminal router ospf 1 network 97.0.0.0/8 area 0.0.0.0 ----------------------------- //For OSPFv3 (IPv6 addresses) Global config: Configure terminal feature ospfv3 Configure terminal interface Vlan10 no shutdown ipv6 address use-link-local-only ipv6 router ospfv3 1 area 0.0.0.0 Configure terminal router ospfv3 1 |

**Router monitoring cluster nodes in ECMP deployment**

In a cluster setup, on an owner node that has a spotted SNIP address configuration, you can now disable the ownerDownResponse option. By default, the option is enabled, allowing the node to respond to an ICMP/ARP/ICMP6/ND6 request coming from the upstream router. You can now disable this option to allow the router to monitor if a cluster node is active or inactive. When the router sends a request, if the option is disabled, it identifies the owner node to be inactive and unavailable for traffic distribution.

**To configure ECMP for static routes traffic distribution by using the command line interface**

`add ns ip <ipaddress> <netmask> -ownernode <node-id> -ownerDownResponse disable`
To configure ECMP with BGP routing protocol, perform the following steps:

1. Log on to the cluster IP address.

```bash
1 > enable ns feature bgp
```

2. Enable BGP routing protocol.

3. Add VLAN and bind the required interfaces.

```bash
1 > add vlan 985
2 > bind vlan 985 -ifnum 0/0/1 1/0/1
```

4. Add the spotted IP address and bind them to the VLAN.

```bash
1 > add ns ip 10.100.26.14 255.255.255.0 -ownerNode 1 -dynamicRouting ENABLED
2 > add ns ip 10.100.26.15 255.255.255.0 -ownerNode 2 -dynamicRouting ENABLED
3 > bind vlan 985 -ipAddress 10.100.26.10 255.255.255.0
```

5. Configure BGP routing protocol on ZebOS using vtysh shell.

```bash
1 > vtysh
2 conf t
3 router bgp 65535
4 neighbor 10.100.26.1 remote-as 65535
```

6. Configure BGP on the external switch. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(I) switch. Similar configurations must be performed on other switches.

```bash
1 router bgp 65535
2 no synchronization
3 bgp log-neighbor-changes
4 neighbor 10.100.26.14 remote-as 65535
5 neighbor 10.100.26.15 remote-as 65535
6 no auto-summary
7 dont-capability-negotiate
dont-capability-negotiate
9 no dynamic-capability
```
Using cluster link aggregation

January 6, 2019

Cluster link aggregation, as the name suggests, is a group of interfaces of cluster nodes. It is an extension of NetScaler appliance link aggregation. The only difference is that, while link aggregation requires the interfaces to be from the same device, in cluster link aggregation, the interfaces are from different nodes of the cluster. For more information about link aggregation, see “Configuring Link Aggregation”.

Important

• Cluster link aggregation is supported for a cluster of hardware (MPX) appliances.

• Cluster link aggregation is supported for a cluster of virtual (VPX) appliances that are deployed on ESX and KVM hypervisors, with the following restrictions:

• Dedicated interfaces need to be used. This means that the interfaces must not be shared with other virtual machines.

• If the cluster link aggregation member interfaces are manually disabled or if cluster link aggregation itself is manually disabled, then interface power down capability is achieved only by LACP timeout mechanism.

• Jumbo MTU is not supported on LACP cluster link aggregation.

Note: Cluster link aggregation is not supported on VPX appliances that are deployed on XenServer, AWS, and Hyper-V.

• Starting from 12.0 release, cluster link aggregation is supported on NetScaler appliance SDX appliances.

• The number of interfaces that can be bound to cluster LA is 16 (from each node), and the maximum number of interfaces in cluster LA can be (16 * n), where n is the number of nodes in a cluster. The total number of interfaces in cluster LA depends on the number of interfaces for every port channel on upstream switch.

For example, consider a three-node cluster where all three nodes are connected to the upstream switch. A cluster LA channel (CLA/1) is formed by binding interfaces 0/1/2, 1/1/2, and 2/1/2.

Figure 1. Cluster Link Aggregation topology

A cluster LA channel has the following attributes:

• Each channel has a unique MAC agreed upon by cluster nodes.

• The channel can bind both local and remote nodes’ interfaces.

• A maximum of four cluster LA channels are supported in a cluster.

• Backplane interfaces cannot be part of a cluster LA channel.
- When an interface is bound to a cluster LA channel, the channel parameters have precedence over the network interface parameters. A network interface can be bound to one channel only.
- Management access to a cluster node, must not be configured on a cluster LA channel (for example, CLA/1) or its member interfaces. This is because when the node is INACTIVE, the corresponding cluster LA interface is marked as power down and therefore loses management access.

Figure 2. Traffic distribution flow using cluster LA

**Static cluster link aggregation**

September 18, 2018

You must configure a static cluster LA channel on the cluster IP address and on the external connecting device. If possible, configure the upstream switch to distribute traffic based on IP address or port instead of MAC address.

**To configure a static cluster LA channel by using the command line interface**

1. Log on to the cluster IP address.

   **Note**
   Make sure that you configure the cluster LA channel on the cluster IP address before configuring link aggregation on the external switch. Otherwise, the switch will forward traffic to the cluster even though the cluster LA channel is not configured. This can lead to loss of traffic.

2. Create a cluster LA channel.

   ```
   add channel <id> -speed <speed>
   ```

   **Example**

   ```
   1 > add channel CLA/1 -speed 1000
   ```

   **Note**
   You must not specify the speed as AUTO. Rather, you must explicitly specify the speed as 10, 100, 1000, or 10000. Only interfaces that have the speed matching the <speed> attribute in the cluster LA channel are added to the active distribution list.

3. Bind the required interfaces to the cluster LA channel. Make sure that the interfaces are not used for the cluster backplane.
bind channel <id> <ifnum>

Example

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>&gt; bind channel CLA/1 0/1/2 1/1/2 2/1/2</td>
</tr>
</tbody>
</table>

4. Verify the configurations.

show channel <id>

Example

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>&gt; show channel CLA/1</td>
</tr>
</tbody>
</table>

Note
You can bind the cluster LA channel to a VLAN by using the bind vlan command. The interfaces of the channel are automatically bound to the VLAN.

5. Configure static LA on the external switch. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(l). Similar configurations must be performed on other switches.

```
1
2 Global config:
3 Configure terminal
4
5 Interface level config:
6
7 interface Ethernet2/47
8   switchport
9   switchport access vlan 10
10  channel-group 7 mode on
11  no shutdown
12
13 interface Ethernet2/48
14   switchport
15   switchport access vlan 10
16  channel-group 7 mode on
17  no shutdown
```

**Dynamic cluster link aggregation**

September 18, 2018
Dynamic cluster LA channel uses Link Aggregation Control Protocol (LACP).

You must perform similar configurations on the cluster IP address and on the external connecting device. If possible, configure the upstream switch to distribute traffic based on IP address or port instead of MAC address.

**Points to remember:**

- Enable LACP (by specifying the LACP mode as either ACTIVE or PASSIVE).
  
  **Note**
  
  Make sure the LACP mode is not set as PASSIVE on both the NetScaler cluster and the external connecting device.

- Specify the same LACP key on each interface that you want to be the part of the channel. For creating a cluster LA channel, the LACP key can have a value from 5 through 8. For example, if you set the LACP key on interfaces 0/1/2, 1/1/2, and 2/1/2 to 5, CLA/1 is created. The interfaces 0/1/2, 1/1/2, and 2/1/2 are automatically bound to CLA/1. Similarly, if you set the LACP key to 6, CLA/2 channel is created.

- Specify the LAG type as Cluster.

**To configure a dynamic cluster LA channel by using the command line interface**

On the cluster IP address, for each interface that you want to add to the cluster LA channel, type:

```
set interface <id> -lacpMode <lacpMode> -lacpKey <positive_integer> -lagType CLUSTER
```

**Example:** To configure a cluster LA channel CLA/1 of 3 interfaces.

```
1 > set interface 0/1/2 -lacpMode active -lacpKey 5 -lagType Cluster
2 > set interface 1/1/2 -lacpMode active -lacpKey 5 -lagType Cluster
3 > set interface 2/1/2 -lacpMode active -lacpKey 5 -lagType Cluster
```

**Note**

Optionally, you can enable

**Link Redundancy in a Cluster with LACP.**

Similarly, configure dynamic LA on the external switch. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1). Similar configurations must be performed on other switches.

```
1
2 Global config:
3 Configure terminal
```
Link redundancy in a cluster with LACP

January 6, 2019

A NetScaler cluster provides link redundancy for LACP to ensure that all nodes have the same partner key.

To understand the need for link redundancy, let us consider the example of the following cluster setup along with the accompanying cases (with attention to case 3):

In this setup, interfaces I1, I2, I3 and I4 are bound to LACP channel with KEY 5. On the partner side, I1 and I2 are connected to Switch 1 to form a single LA channel with KEY 1. Similarly, I3 and I4 are connected to Switch 2 to form a single LA channel with KEY 2.

Now let us consider the following cases to understand the need for link redundancy:

- **Case 1: Switch 1 is up and Switch 2 is down**
  In this case, cluster LA on both the nodes would stop receiving LACPDUs from Key2 and would start receiving LACPDUs from Key1. On both the nodes, cluster LA is connected to KEY 1 and I1 and I2 will be UP and channel on both the nodes would be UP.

- **Case 2: Switch1 goes down and Switch2 becomes UP**
  In this case, cluster LA on both the nodes would stop receiving LACPDUs from Key1 and would start receiving LACPDUs from Key2. On both the nodes, cluster LA is connected to Key2 and I3 and I4 will be UP and channel on both the nodes would be UP.

- **Case 3: Both Switch1 and Switch2 are UP**
In this case, it is possible that cluster LA on node1 chooses Key1 as its partner and cluster LA on node2 chooses Key2 as its partner. This means that I1 on node1 and I4 on node2 are receiving traffic which is undesirable. This can happen because the LACP state machine is node-level and chooses its partners on first-come first-serve basis.

To solve these concerns, link redundancy of dynamic cluster LA is supported. To configure link redundancy on a channel or interface, you must enable it and optionally specify the threshold throughput as follows:

```
set channel CLA/1 -linkRedundancy ON -lrMinThroughput <positive_integer>
```

The throughput of the partner channels is checked against the configured threshold throughput. The partner channel that satisfies the threshold throughput is selected in first-in-first-out (FIFO) manner. If none of the partner channel meets the threshold, or if threshold throughput is not configured, the partner channel with the maximum number of links is selected.

**Note**
The threshold throughput can be configured from NetScaler 11 onwards.

**Managing the NetScaler cluster**

September 18, 2018

After you have created a cluster and configured the required traffic distribution mechanism, the cluster is able to serve traffic. During the lifetime of the cluster, you can perform cluster tasks such as configuring nodegroups, disabling nodes of a cluster, discovering NetScaler appliances, viewing statistics, synchronizing cluster configurations, cluster files, and the time across the nodes, and upgrading or downgrading the software of cluster nodes.

**Configuring linksets**

January 6, 2019

Linksets must be used when some cluster nodes are not physically connected to the external network. In such a cluster topology, the unconnected cluster nodes use the interfaces specified in the linkset to communicate with the external network through the cluster backplane. Linksets are typically used in scenarios when the connecting devices have insufficient ports to connect the cluster nodes.

**Note**

Linksets are a mandatory configuration in the following scenarios:

- For deployments that require MAC-Based Forwarding (MBF).
• To improve manageability of ACL and L2 policies involving interfaces. You must define a linkset of the interfaces and add ACL and L2 policies based on linksets.

Linksets must be configured only through the cluster IP address.

For example, consider a three node cluster where the upstream switch has only two ports available. Using linksets, you can connect two nodes to the switch and leave the third node unconnected. In the following figure, a linkset (LS/1) is formed by binding the interfaces 0/1/2 and 1/1/2. NS2 is the unconnected node of the cluster.

Figure 1. Linksets topology

The linkset informs NS2 that it can use interfaces 0/1/2 and 1/1/2 to communicate with the network devices. All traffic to and from NS2 is now routed through interfaces 0/1/2 or 1/1/2.

Figure 2. Traffic distribution flow using linksets

**To configure a linkset by using the command line interface**

1. Log on to the cluster IP address.

2. Create a linkset.

   ```
   add linkset <id>
   ```

   **Example**

   ```
   1 add linkset LS/1
   ```

3. Bind the required interfaces to the linkset. Make sure the interfaces are not used for the cluster backplane.

   ```
   bind linkset <id> -ifnum <interface_name> ...
   ```

   **Example**

   ```
   1 > bind linkset LS/1 -ifnum 0/1/2 1/1/2
   ```

4. Verify the linkset configurations.

   ```
   show linkset <id>
   ```

   **Example**

   ```
   1 > show linkset LS/1
   ```

   **Note**

   You can bind the linkset to a VLAN by using the `bind vlan` command. The interfaces of the
To configure a linkset by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to System > Network > Linksets.
3. In the details pane, click Add.
4. In the Create Linkset dialog box:
   • Specify the name of the linkset by setting the Linkset parameter.
   • Specify the Interfaces to be added to the linkset and click Add. Repeat this step for each interface you want to add to the linkset.
5. Click Create, and then click Close.

Nodegroups for spotted and partially-stripped configurations

January 6, 2019

By virtue of the default cluster behavior, all configurations performed on the cluster IP address are available on all nodes of the cluster. However, there might be cases where you need some configurations to be available only on specific cluster nodes.

You can achieve this requirement by defining a nodegroup that includes the specific cluster nodes, and then binding the configuration to that nodegroup. This ensures that the configuration is active only on those cluster nodes. These configurations are called partially-stripped or spotted (if active only one a single node). For more information, see Striped, Partially Striped, and Spotted Configurations.

For example, consider a cluster with three nodes. You create a nodegroup NG0 that includes node n1 and another nodegroup NG1 that includes n2 and n3. Bind load balancing virtual servers .77 to NG0 and load balancing virtual server .69 to NG1.

This means that virtual server .77 will be active only on n1 and consequently only n1 will receive traffic that is directed to .77. Similarly, virtual server .69 will be active only on nodes n2 and n3 and consequently only n2 and n3 will receive traffic that is directed to .69.

Figure 1. NetScaler cluster with nodegroups configured for spotted and partial-stripped configurations

The entities or configurations that you can bind to a nodegroup are:

- Load balancing, content switching, cache redirection, authentication, authorization, and auditing virtual servers

© 1999-2018 Citrix Systems, Inc. All rights reserved.
FTP load balancing virtual servers cannot be bound to nodegroups.

- VPN virtual server (Supported from NetScaler 10.5 Build 50.10 onwards)
- Global Server Load Balancing (GSLB) sites and other GSLB entities (Supported from NetScaler 10.5 Build 52.11 onwards)
- Limit identifiers and stream identifiers

Behavior of nodegroups

September 18, 2018

Due to the interoperability of nodegroups with different NetScaler features and entities, there are some behavioral aspects to be noted. Nodes in a nodegroup can also be backed up. Read on for more information.

General behavior of a cluster nodegroup

- A nodegroup that has entities bound to it cannot be removed.
- A cluster node that belongs to a nodegroup with entities bound to it, cannot be removed.
- A cluster instance that has nodegroups with entities bound to it, cannot be removed.
- You cannot add an entity that has a dependency on another entity that is not part of the nodegroup. If you need to do so, first remove the dependency. Then, add both the entities to the nodegroup and reassociate the entities.

Examples:

- Assume you have a virtual server, VS1, whose backup is virtual server VS2. To add VS1 to a nodegroup, first make sure that VS2 is removed as the backup server of VS1. Then, bind each server individually to the nodegroup, and then configure VS2 as the backup for VS1.
- Assume you have a content switching virtual server, CSV1, whose target load balancing virtual server is LBVS1. To add CSV1 to a nodegroup, first remove LBVS1 as the target. Then, bind each server individually to the nodegroup, and then configure LBVS1 as the target.
- Assume you have a load balancing virtual server, LBVS1, that has a policy which invokes another load balancing virtual server, LBVS2. To add either one of the virtual servers, first remove the association. Then, bind each server individually to the nodegroup, and then reassociate the virtual servers.
• You cannot bind an entity to a nodegroup that has no nodes and that has the strict option enabled. Consequently, you cannot unbind the last node of a nodegroup that has entities bound to it and that has the strict option enabled.

• The strict option cannot be modified for a nodegroup that has no nodes but has entities bound to it.

**Backing up nodes in a nodegroup**

By default, a nodegroup is designed to provide back up nodes for members of a nodegroup. If a nodegroup member goes down, a cluster node that is not a member of the nodegroup dynamically replaces the failed node. This node is called the replacement node.

Note: For a single-member nodegroup, a backup node is automatically preselected when an entity is bound to the nodegroup.

When the original member of the nodegroup comes up, the replacement node, by default, is replaced by the original member node.

From NetScaler 10.5 Build 50.10 onwards, however, the NetScaler appliance allows you to change this replacement behavior. When you enable the sticky option, the replacement node is retained even after the original member node comes up. The original node takes over only when the replacement node goes down.

You can also disable the backup functionality. To do this, you must enable the strict option. In this scenario, when a nodegroup member goes down, no other cluster node is picked up as a backup node. The original node continues being part of the nodegroup when it comes up. This option ensures that entities bound to a nodegroup are active only on nodegroup members.

---

**Note**

The strict and sticky option can be set only when creating a nodegroup.

---

**Configuring nodegroups for spotted and partially-striped configurations**

September 18, 2018

To configure a nodegroup for spotted and partially-striped configurations you must first create a nodegroup and then bind the required nodes to the nodegroup. You must then associate the required entities to that nodegroup. The entities that are bound to the nodegroup will be:

- **Spotted** - If bound to a nodegroup that has a single node.
- **Partially Striped** - If bound to a nodegroup that has more than one node.

**Some points to remember:**
NetScaler 12.0

- GSLB is supported on a cluster only when GSLB sites are bound to nodegroups that have a single cluster node. For more information, see Setting Up GSLB in a Cluster.
- NetScaler Gateway is supported on a cluster only when the VPN virtual servers are bound to nodegroups that have a single cluster node. The sticky option must be enabled on the nodegroup.
- For versions prior to NetScaler 11, application firewall is supported only on individual cluster nodes (spotted configuration). Application firewall profiles can be associated only with virtual servers that are bound to nodegroups that have a single cluster node. This means that application You are not allowed to do the following:
  - Bind application firewall profiles to striped or partially striped virtual servers.
  - Bind the policy to a global bind point or to user-defined policy labels.
  - Unbind, from a nodegroup, a virtual server that has application firewall profiles.
- NetScaler 11 introduced application firewall support for striped and partially-striped configurations. For more information, see Application Firewall Support for Cluster Configurations.

Check NetScaler appliance Features Supported in a Cluster to see the NetScaler versions from which GSLB, Citrix Gateway, and application firewall are supported in a cluster.

To configure a nodegroup by using the command line interface

1. Log on to the cluster IP address.
2. Create a nodegroup. Type:

   `add cluster nodegroup <name> -strict (**YES** | **NO**)`

   **Example**

   ```
   1 add cluster nodegroup NG0 -strict YES
   ```

3. Bind the required nodes to the nodegroup. Type the following command for each member of the nodegroup:

   `bind cluster nodegroup <name> -node <nodeId>`

   **Example**

   To bind nodes with IDs 1, 5, and 6.

   ```
   1 > bind cluster nodegroup NG0 -node 1
   2 > bind cluster nodegroup NG0 -node 5
   3 > bind cluster nodegroup NG0 -node 6
   ```

4. Bind the entity to the nodegroup. Type the following command once for every entity that you want to bind:
bind cluster nodegroup <name> (-vServer <string> | -identifierName <string> | -gslbSite <string> -service <string>)

Note
The gslbSite and service parameters are available from NetScaler 10.5 onwards.

Example
To bind virtual servers VS1 and VS2 and rate limit identifier named identifier1.

```bash
1 > bind cluster nodegroup NG0 -vServer VS1
2 > bind cluster nodegroup NG0 -vServer VS2
3 > bind cluster nodegroup NG0 -identifierName identifier1
```

5. Verify the configurations by viewing the details of the nodegroup. Type:

```
show cluster nodegroup <name>
```

Example
```
1 > show cluster nodegroup NG0
```

To configure a nodegroup by using the configuration utility

1. Log on to the cluster IP address.
3. In the details pane, click Add.
4. In the Create Node Group dialog box, configure the nodegroup:
   a) Under Cluster Nodes, click the Add button.
      - The Available list displays the nodes that you can bind to the nodegroup and the Configured list displays the nodes that are bound to the nodegroup.
      - Click the + sign in the Available list to bind the node. Similarly, click the - sign in the Configured list to unbind the node.
   b) Under Virtual Servers, select the tab corresponding to the type of virtual server that you want to bind to the nodegroup. Click the Add button.
      - The Available list displays the virtual servers that you can bind to the nodegroup and the Configured list displays the virtual servers that are bound to the nodegroup.
      - Click the + sign in the Available list to bind the virtual server. Similarly, click the - sign in the Configured list to unbind the virtual server.
**Configuring redundancy for nodegroups**

January 6, 2019

**Note**

Supported from NetScaler 10.5 Build 52.1115.e onwards.

Nodegroups can be configured such that when one nodegroup goes down, another nodegroup can take over and process traffic. For example, when a nodegroup NG1 goes down, NG2 takes over.

**Note**

This functionality can be used to configure datacenter redundancy where each nodegroup is configured as a datacenter.

To achieve this use case, cluster nodes must be logically grouped into nodegroups, where some nodegroups must be configured as ACTIVE and others as SPARE. The active nodegroup with the highest priority (that is, the lowest priority number) is made operationally active and therefore serves traffic. When a node from this operationally active nodegroup goes down, the node count of this nodegroup is compared with the node count of the other active nodegroups in order of their priority. If a nodegroup has a higher or equal node count, that nodegroup is made operationally active. Else, the spare nodegroups are checked.

**Note**

- Only one state-specific nodegroup can be active at a given point in time.
- A cluster node inherits the state of the nodegroup. So, if a node with “SPARE” state is added to nodegroup with state as “ACTIVE”, the node automatically behaves as an active node.
- The preemption parameter that is defined for the cluster instance decides whether the initial active nodegroup will take control when the it comes up again.
- A spare node group can take up a node group and host active traffic when an active node group goes down.

The following figure shows a nodegroup setup that has nodegroup redundancy defined. NG1 is initially the active nodegroup. When it loses one of the nodes, the spare nodegroup (NG3) with the highest priority starts serving traffic.

**Figure 1. NetScaler cluster with nodegroup redundancy configured**

**Configuring redundancy for nodegroups**

1. Log on to the cluster IP address.
2. Create the active nodegroup and bind the required cluster nodes.
1. Create the spare nodegroup and bind the requisite nodes.

1. Create another spare nodegroup and bind the requisite nodes.

Disabling steering on the cluster backplane

September 18, 2018

Note
Supported from NetScaler 11 onwards.

The default behavior of a NetScaler cluster is to direct the traffic that it receives (flow receiver) to another node (flow processor) that must then process the traffic. This process of directing the traffic from flow receiver to flow processor occurs over the cluster backplane and is called steering.

If required, you can disable steering so that the process becomes local to the flow receiver and therefore makes the flow receiver as the flow processor. Such a configuration setup can come handy when you have a high latency link.

Note
This configuration is applicable only for striped virtual servers.

- For partially striped virtual servers, if the flow receiver is a non-owner node, the traffic is steered to a owner node. If however, the flow receiver is a owner node, then steering is disabled.
- For spotted virtual servers, flow receiver is the flow processor, and hence there is no need for steering.

Some points to remember when disabling the steering mechanism:
• Striped SNIPs are not supported as steering is disabled.
• MPTCP and FTP does not work.
• L2 mode must be disabled.
• If USIP is enabled, traffic may not reach back to the same node as the steering is disabled.
• Traffic that is directed to the cluster IP address is steered to the configuration coordinator.
• When a node joins or leaves a cluster, it is possible that more than 1/N connections will be affected. This is due to the fact that a change in the nodes available, may cause the routes to be rehashed. As a result, the traffic will be routed to another node and due to the non-availability of steering, the traffic will not be processed.

Steering can be disabled at the individual virtual server level or at the global level. The global configuration takes precedence over the virtual server setting.

• Disabling backplane steering for all striped virtual servers
  Configured at cluster instance level. Traffic meant for any striped virtual server will not be steered on cluster backplane.
  
  add cluster instance \<clId\> -processLocal ENABLED

• Disabling backplane steering for a specific striped virtual server
  Configured on a striped virtual server. Traffic meant for the virtual server will not be steered on cluster backplane.
  
  add lb vserver <name> <serviceType> -processLocal ENABLED

Synchronizing cluster configurations

September 18, 2018

NetScaler appliance configurations that are available on the configuration coordinator are synchronized to the other nodes of the cluster when:

• A node joins the cluster
• A node rejoins the cluster
• A new command is executed through the cluster IP address.

Additionally, you can forcefully synchronize the configurations that are available on the configuration coordinator (full synchronization) to a specific cluster node. Make sure you synchronize one cluster node at a time, otherwise the cluster can get affected.

To synchronize cluster configurations by using the command line interface

At the command prompt of the appliance on which you want to synchronize the configurations, type:
To synchronize cluster configurations by using the configuration utility

1. Log on to the appliance on which you want to synchronize the configurations.
2. Navigate to System > Cluster.
3. In the details pane, under Utilities, click Force cluster sync.
4. Click OK.

Synchronizing time across cluster nodes

September 18, 2018

The cluster uses Precision Time Protocol (PTP) to synchronize the time across cluster nodes. PTP uses multicast packets to synchronize the time. If there are some issues in time synchronization, you must disable PTP and configure Network Time Protocol (NTP) on the cluster.

To enable/disable PTP by using the command line interface

At the command prompt of the cluster IP address, type:

```
set ptp -state disable
```

To enable/disable PTP by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to System > Cluster.
3. In the details pane, under Utilities, click Configure PTP Settings.
4. In the Enable/Disable PTP dialog box, select whether you want to enable or disable PTP.
5. Click OK.

Synchronizing cluster files

September 18, 2018

The files available on the configuration coordinator are called cluster files. These files are automatically synchronized on the other cluster nodes when the node is added to the cluster and periodically, during the lifetime of the cluster. Additionally, you can manually synchronize the cluster files.
The directories and files from the configuration coordinator that are synchronized are:

- /nsconfig/ssl/
- /var/netscaler/ssl/
- /var/vpn/bookmark/
- /nsconfig/dns/
- /nsconfig/htmlinjection/
- /netscaler/htmlinjection/ens/
- /nsconfig-monitors/
- /nsconfig/nstemplates/
- /nsconfig/ssh/
- /nsconfig/rc.netScaler
- /nsconfig/resolv.conf
- /nsconfig/inetd.conf
- /nsconfig/syslog.conf
- /nsconfig/snmpd.conf
- /nsconfig/ntp.conf
- /nsconfig/httpd.conf
- /nsconfig/sshd_config
- /nsconfig/host.config
- /nsconfig/enckey
- /var/nslw.bin/etc/krb5.conf
- /var/nslw.bin/etc/krb5.keytab
- /var/lib/likewise/db/
- /var/download/
- /var/wi/tomcat/webapps/
- /var/wi/tomcat/conf/Catalina/localhost/
- /var/wi/java_home/lib/security/cacerts
- /var/wi/java_home/jre/lib/security/cacerts
- /nsconfig/license/
- /nsconfig/rc.conf

Tip

Files (certificates and key files) that are copied to the cluster configuration coordinator manually (or through the shell) are not automatically available on the other cluster nodes. You must execute the “sync cluster files” command from the cluster IP address before executing a command that depends on these file(s).
To synchronize cluster files by using the command line interface

At the command prompt of the cluster IP address, type:

```
sync cluster files <mode>
```

To synchronize cluster files by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to **System > Cluster**.
3. In the details pane, under **Utilities**, click Synchronize cluster files.
4. In the **Synchronize cluster files** dialog box, select the files to be synchronized in the Mode dropdown box.
5. Click **OK**.

Viewing the statistics of a cluster

September 18, 2018

You can view the statistics of a cluster instance and cluster nodes to evaluate the performance or to troubleshoot the operation of the cluster.

To view the statistics of a cluster instance by using the command line interface

At the command prompt of the cluster IP address, type:

```
stat cluster instance <clId>
```

To view the statistics of a cluster node by using the command line interface

At the command prompt of the cluster IP address, type:

```
stat cluster node <nodeId>
```

**Note**

When executed from the cluster IP address, this command displays the cluster level statistics. However, when executed from the NSIP address of a cluster node, the command displays node level statistics.
To view the statistics of a cluster instance by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to System > Cluster.
3. In the details pane, in the center of the page, click Statistics.

To view the statistics of a cluster node by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to System > Cluster > Nodes.
3. In the details pane, select a node and click Statistics to view the statistics of the node. To view the statistics of all the nodes, click Statistics without selecting a specific node.

Discovering NetScaler appliances

September 18, 2018

You can discover the appliances present in the same subnet as the current node. The required discovered appliances can then be selectively added to the cluster. This operation can be performed to either create a new cluster or to add nodes to an existing cluster.

Note

- The discover operation can be performed only through the configuration utility.
- This operation cannot discover NetScaler appliances from different networks.
- When performing this operation to add nodes to an existing cluster, the L3 VLAN configurations will be cleared from the node. You must make sure to define these configurations once the appliance is added to the cluster.

To discover appliances by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to System > Cluster > Nodes.
3. In the details pane, at the bottom of the page, click Discover NetScalers.
4. In the Discover NetScalers dialog box, set the following parameters:
   - IP address range - Specify the range of IP addresses within which you want to discover appliances. For example, you can search for all NSIP addresses between 10.102.29.4 to 10.102.29.15 by specifying this option as 10.102.29.4 - 15.
• **Backplane interface** - Specify the interfaces to be used as the backplane interface. This is an optional parameter. If you do not specify this parameter, you must update it after the node is added to the cluster.

5. Click **OK**.

6. Select the appliances that you want to add to the cluster.

7. Click **OK**.

### Disabling a cluster node

**September 18, 2018**

You can temporarily remove a node from a cluster by disabling the cluster instance on that node. A disabled node is not synchronized with the cluster configurations. When the node is enabled again, the cluster configurations are automatically synchronized on it. For more information, see *Synchronization across cluster nodes*.

A disabled node cannot serve traffic and all existing connections on this node are terminated.

**Note**

If the configurations of a disabled non-configuration coordinator node are modified (through the NSIP address of the node), the configurations are not automatically synchronized on that node. You must manually synchronize the configurations as described in *Synchronizing Cluster Configurations*.

### To disable a cluster node by using the command line interface

At the command prompt of the node that you want to disable, type:

```plaintext
disable cluster instance <clId>
```

**Note**

To disable the cluster, run the disable cluster instance command on the cluster IP address.

### To disable a cluster node by using the configuration utility

1. On the node that you want to disable, navigate to **System > Cluster**, and click **Manage Cluster**.

2. In the **Configure** cluster instance dialog box, unselect the **Enable** cluster instance check box.
Note
To disable the cluster instance on all the nodes, perform the above procedure on the cluster IP address.

Removing a cluster node

September 18, 2018

When a node is removed from the cluster, the cluster configurations are cleared from the node (by internally executing the clear ns config -extended command). The SNIP addresses, MTU settings of the backplane interface, and all VLAN configurations (except the default VLAN and NSVLAN) are also cleared from the appliance.

Note
• If the deleted node was the cluster configuration coordinator, another node is automatically selected as the cluster configuration coordinator, and the cluster IP address is assigned to that node. All the current cluster IP address sessions will be invalid and you will have to start a new session.
• To delete the whole cluster, you must remove each node individually. When you remove the last node, the cluster IP address(es) are deleted.
• When an active node is removed, the traffic serving capability of the cluster is reduced by one node. Existing connections on this node are terminated.

To remove a cluster node by using the command line interface

For NetScaler 10.1 and later versions

Logon to the cluster IP address and at the command prompt, type:

```bash
rm cluster node <nodeId>
```

Note
If the cluster IP address is unreachable from the node, execute the `rm cluster instance` command on the NSIP address of that node itself.

For NetScaler 10

1. Log on to the node that you want to remove from the cluster and remove the reference to the cluster instance.
To remove a cluster instance

1. \texttt{rm cluster instance <clId>}
2. \texttt{save ns config}

2. Log on to the cluster IP address and remove the node from which you removed the cluster instance.

1. \texttt{rm cluster node <nodeId>}
2. \texttt{save ns config}

Make sure you do not run the \texttt{rm cluster node} command from the local node as this results in inconsistent configurations between the configuration coordinator and the node.

**To remove a cluster node by using the configuration utility**

On the cluster IP address, navigate to System > Cluster > Nodes, select the node you want to remove and click Remove.

---

**Removing a node from a cluster deployed using cluster link aggregation**

September 18, 2018

To remove a node from a cluster that uses cluster link aggregation as the traffic distribution mechanism, you must make sure that the node is made passive so that it does not receive any traffic and then, on the upstream switch, remove the corresponding interface from the channel.

For detailed information on cluster link aggregation, see Using Cluster Link Aggregation.

**To remove a node from a cluster that uses cluster link aggregation as the traffic distribution mechanism**

1. Log on to the cluster IP address.
2. Set the state of the cluster node that you want to remove to PASSIVE.
   
   \texttt{set cluster node <nodeId> -state PASSIVE}
3. On the upstream switch, remove the corresponding interface from the channel by using switch-specific commands.
Note
You do not have to manually remove the nodes interface on the cluster link aggregation channel. It is automatically removed when the node is deleted in the next step.

4. Remove the node from the cluster.
   
   \texttt{rm cluster node <nodeId>}

Detecting jumbo probe on a cluster

September 18, 2018

If a Jumbo frame is enabled on a Cluster interface, the backplane interface should be large enough to support the all packets in the Jumbo frame. This is achieved by setting the Maximum Transmission Unit (MTU) of the backplane as:

\texttt{Backplane\_MTU = maximum (all cluster interface MTU's) + 78}

To verify the above configuration, you must send a jumbo probe (of the above computational size) to all peer nodes of a Cluster setup. If the probe does not succeed, the appliance displays a warning message in the output of the “show cluster instance” command.

In the command interface mode, type the following command:

<table>
<thead>
<tr>
<th>Sl. no</th>
<th>Member Nodes</th>
<th>Health</th>
<th>Admin State</th>
<th>Operation State</th>
</tr>
</thead>
<tbody>
<tr>
<td>---</td>
<td>---</td>
<td>---</td>
<td>---</td>
<td>---</td>
</tr>
</tbody>
</table>

Warning

The MTU for a backplane interface must be large enough to handle all packets in the frame. It must be equal to \texttt{<MTU\_VAL>}. If the recommended value is not user configurable, you must review the MTU value of jumbo interfaces.
Monitoring cluster setup using SNMP MIB with SNMP link

September 18, 2018

SNMP mib is device specific information that has been configured on the SNMP agent for the purpose of identifying a NetScaler appliance, such as appliance name, administrator, location. In a cluster setup, you can now configure the SNMP MIB in any node by including the “ownerNode” parameter in the set snmp mib command. Without this parameter, the set snmp mib command applies only to the Cluster Coordinator (CCO) node.

To display the MIB configuration for a cluster node other than the CCO, include the “ownerNode” parameter in the show snmp mib command

Configuring SNMP MIB on CLIP

To configure and view MIB configuration on CLIP by using the command line interface.

```
1 set snmp mib [-contact <string>] [-name <string>] [-location <string>] [-customID <string>] [-ownerNode <positive_integer>]
2 Done
4 show snmp mib [-ownerNode <positive_integer>]

> set mib -contact John -name NS59 -location San Jose -customID 123 -ownerNode 3
7 Done
8 > sh mib -ownerNode 3

-----------------------------
Cluster Node ID: 3
-----------------------------
NetScaler system MIB:
sysDescr: NetScaler NS11.1: Build 46.4.a.nc, Date: Jun 7 2016, 10:27:29
sysUpTime: 124300
sysObjectID: .1.3.6.1.4.1.5951.1.1
sysContact: John
sysName: NS59
sysLocation: San Jose
sysServices: 72
Custom ID: 123
Done
```
IPv6 ready logo support for clusters

September 18, 2018

You can test clustered appliances for IPv6 Ready Logo certification. Modified commands for testing IPv6 core protocols, such as for ND test cases, Router Solicitation processing, and sending route advertisement and router redirection messages are available in a clustered setup. Following are the IPv6 functionalities available for testing the IPv6 core protocols.

Following are the modified functionalities available to pass IPv6 core protocols, such as ND test cases, Router Solicitation processing and sending Route advertisement and router redirection messaging in IPv6readylogo phase2 test suite.

- Link Local SNIPs
- Address Resolution and Neighbor Unreachability
- Router and Prefix Discovery
- Router Redirection
- DoDAD

With these modified commands, the following configurations are supported in a clustered appliance.
Supportable configurations for testing IPv6 core protocols

For a clustered setup to pass IPv6 Ready Logo test cases, you can execute the following configurations on the Cluster Management IP address (CLIP).

- global IP6 configuration
- basic IPv6 configuration
- additional IPv6 configurations

Global configuration

A global IPv6 configuration enables you to set the global IPv6 parameters (such as relearning, routeRedirection, ndBasereachTime, nRetransmissionTime, natprefix, td, and doodad) to run the basic IPv6 configuration.

At the command prompt, type the following:

```
set ipv6 [-ralearning ( ENABLED | DISABLED )] [-routerRedirection ( ENABLED | DISABLED )] [-ndBasereachTime<positive_integer>] [-ndRetransmissionTime<positive_integer>] [-natprefix <ipv6_addr|*>][-td<positive_integer>] [-doDAD ( ENABLED | DISABLED )]
```

Basic IPv6 configuration

The basic IPv6 configuration enables you to create an IPv6 address and bind to a VLAN interface. You must perform the following configurations to test the IPv6 core protocols.

To add a VLAN to the clustered setup by using the NetScaler command line

At the command prompt, type:

```
add vlan <id>
```

To add another VLAN to the clustered set up by using the NetScaler command line

At the command prompt, type:

```
add vlan <id>
```

To bind an interface to a VLAN by using the NetScaler command line

At the command prompt, type:

```
bind vlan <id> -ifnum <interface_name>
```
NetScaler 12.0

To bind an interface to a VLAN by using the NetScaler command line

This command adds the global prefix as on-link prefix into RA information for subsequent Router Ad-
vertisements. At the command prompt, type:

```
bind vlan <id> -ifnum <interface_name>
```

To add IPv6 SNIP address on a VLAN by using the NetScaler command line

At the command prompt, type the following:

```
add ns ip6 <IPv6Address>@ [-scope ( global | link-local )][-type <type>
```

To add IPv6 address on VLAN by using the NetScaler command line

At the command prompt, type the following:

```
add ns ip6 <IPv6Address>@ [-scope ( global | link-local )][-type <type>
```

To bind IPv6 address to VLAN by using the NetScaler command line

At the command prompt, type the following:

```
bind vlan <id> [-ifnum <interface_name> [-tagged]][-IPAddress <ip_addr|
ipv6_addr]
```

To bind IPv6 address to VLAN by using the NetScaler command line

At the command prompt, type the following:

```
bind vlan <id> [-ifnum <interface_name> [-tagged]][-IPAddress <ip_addr|
ipv6_addr]
```

To display link local IPv6 address attached to VLAN by using the NetScaler command line

At the command prompt, type the following:

```
sh VLAN
```

**Example 1**

```
add vlan 2
add vlan 3
bind vlan 2 -ifnum 1/2
bind vlan 3 -ifnum 1/3
```
**Example 2**

```
sh vlan
1) VLAN ID: 2   VLAN Alias Name:
   Interfaces : 1/6
   IPs :
   3ffe:501:ffff:100:2e0:edff:fe15:ea2a/64
3) VLAN ID: 3   VLAN Alias Name:
   Link-local IPv6 addr: fe80::9404:60ff:fedd:a464/64
   Interfaces : 1/5
   IPs :
   3ffe:501:ffff:101:2e0:edff:fe15:ea2b/64
Done
```

**Additional IPv6 cluster configuration**

To test IPv6 core protocols, you can use the following new or modified IPv6 configurations.

To set VLAN specific Router Advertisement parameters by using the NetScaler command line

At the command prompt, type:

```
set nd6RAvariables -vlan <positive_integer> [-ceaseRouterAdv ( YES | NO )] [-sendRouterAdv ( YES | NO )] [-srcLinkLayerAddrOption ( YES | NO )][-onlyUnicastRtAdvResponse ( YES | NO )] [-managedAddrConfig ( YES | NO )][-otherAddrConfig ( YES | NO )] [-currHopLimit < positive_integer>] [-maxRtAdvInterval < positive_integer>] [-minRtAdvInterval<positive_integer>] [-linkMTU <positive_integer>] [-reachableTime<positive_integer>] [-retransTime <positive_integer>] [-defaultLifeTime<integer>]
```

To set an on-link global prefix’s configurable parameters by using the NetScaler command line

At the command prompt, type:
To add configurable parameters to an on-link global prefix by using the NetScaler command line
At the command prompt, type:

```
set onLinkIPv6Prefix <ipv6Prefix> [-onLinkPrefix (YES | NO)][-autonomousPrefix (YES | NO)][-depricatePrefix (YES | NO)][-decrementPrefixLifeTimes (YES | NO)][-prefixValideLifeTime <positive_integer>][-prefixPreferredLifeTime <positive_integer>]
```

To set on-link link IPv6 prefix’s configurable parameters by using the NetScaler command line
At the command prompt, type the following:

```
help set onLinkIPv6Prefix
```

To bind an on-link link IPv6 prefix’s configurable parameters by using the NetScaler command line
At the command prompt, type:

```
help bind nd6RAvariables
```

To show nd6RAvariables by using the NetScaler command line
At the command prompt, type:

```
help sh nd6RAvariables
```

**Example**

```
> sh nd6RAvariables
1) Vlan : 1
SendAdvert : NO CeaseAdv : NO SourceLLAddress:
YES
UnicastOnly : NO ManagedFlag : NO OtherConfigFlag:
NO
CurHopLimit : 64 MaxRtrAdvInterv: 600 MinRtrAdvInterv:
198
LinkMTU : 0 ReachableTime : 0 RetransTimer : 0
```
Managing cluster heartbeat messages

September 18, 2018

Managing heartbeat messages in a cluster is similar to managing them in a high availability (HA) configuration. Nodes can send and receive heartbeat messages to and from each other on all interfaces that are enabled. To avoid increased traffic resulting from heartbeat messages, you can now disable the heartbeat option on node interfaces. However, the heartbeat option on the backplane interface cannot be disabled, because it is required for maintaining connectivity among the cluster nodes.

For more information about managing heart messages, see Managing High Availability Heartbeat Mes-
To manage heartbeat messages on a node interface by using the NetScaler CLI

At the command prompt, type:

```
1  set interface <ID> [-HAHeartBeat (ON | OFF)]
2  Show interface <ID>
```

Configuring owner node response status

September 18, 2018

In a cluster setup, on a node has a spotted SNIP address, you can configure the ownerDownResponse option. By default, the option is enabled, allowing the spotted IP address to respond to PING or ARP requests (coming from the upstream router) when the node is inactive. If you disable the option, the IP address cannot respond to the router requests when the owner node is inactive.

To know how this feature is used for monitoring static routes in ECMP deployment, see Using Equal Cost Multiple Path (ECMP) topic.

To set owner node response status by using the NetScaler CLI

At the command prompt, type:

```
1  add ns ip <IPAddress> [-ownerNode <positive_integer>] [-ownerDownResponse (YES | NO)] [-td <positive_integer>]
```

Example

```
1  add ns ip 2.2.2.2 255.255.255.0 -ownerNode 6 -ownerdownResponse YES
```

To set owner node response status by using the NetScaler GUI

1. Navigate to System > Network > IPs and click Add to create a spotted SNIP address.
2. On the Create IP Address page, select or clear the ownerDownResponse check box.
To edit owner node response status by using the NetScaler GUI

Navigate to System > Network > IPS, select an IP address, and click Edit to select or clear the ownerDownResponse check box.

Monitor static route (MSR) support for inactive nodes in a spotted cluster configuration

September 18, 2018

In a cluster set up with MSR option enabled on the route, only active nodes can probe to a static route and reach a network while inactive and spare nodes have no link to the route and cannot probe to it. You can now configure an inactive or spare node to send PING and ARP probe to IPv4 route and send ping6 and nd6 probe to IPv6 route. You can perform this only in a Spotted Cluster configuration in which the SNIP address is active and owned exclusively only by one node.

VRRP interface binding in a single node active cluster

September 18, 2018

When you migrate a high availability (HA) setup to a cluster setup, all configurations must be compatible and must be supportable in the cluster. To achieve this, you can now configure virtual router IDs (VRIDs and VRID6s) on a node interface.

Important: Currently, only a single-node active cluster system supports VRIDs and VRID6s.

For instructions for configuring VRIDs and VRID6s, see Configuring Virtual MAC Addresses.

To configure a virtual router ID on a single-node active cluster, add the VRID or VRID6 and bind it to the cluster-node interface.

To add a VRID by using the NetScaler CLI

At the command prompt, type:

```
add vrID <ID>
```

To bind a VRID to the cluster-node interface by using the NetScaler CLI

At the command prompt, type:

```
Bind vrid <ID> -ifnum <interface_name> | -trackifNum <interface_name>
```

```
Add vrID 100
```
To add a VRID6 by using the NetScaler CLI

At the command prompt, type:

```
add vrid <ID>
```

To bind a VRID6 to cluster node interface by using the NetScaler CLI

At the command prompt, type:

```
bind vrid6 <ID> -ifnum <interface_name> | -trackifNum <interface_name>
```

### Cluster setup and usage scenarios

September 18, 2018

This section aims at explaining some scenarios in which the NetScaler cluster can be setup and also how it can be configured for different features and network topologies. These are just some scenarios that we have documented. Provide feedback if you want some other scenarios to be included.

- Creating a Two-Node Cluster
- Migrating an HA Setup to a Cluster Setup
- Transitioning between a L2 and L3 Cluster [From NetScaler 11 onwards]
- Setting Up GSLB in a Cluster [From NetScaler 10.5 onwards]
- Using Cache Redirection in a Cluster
- Using L2 Mode in a Cluster Setup
- Using Cluster LA Channel with Linksets
- Backplane on LA Channel
- Common Interface for Client and Server and Dedicated Interfaces for Backplane
- Common Switch for Client, Server, and Backplane
- Common Switch for Client and Server and Dedicated Switch for Backplane
- Different Switch for Every Node
- Sample Cluster Configurations
Creating a two-node cluster

September 18, 2018

A two-node cluster is an exception to the rule that a cluster is functional only when a minimum of \( \frac{n}{2} + 1 \) nodes, where \( n \) is the number of cluster nodes, are able to serve traffic. If that formula were applied to a two-node cluster, the cluster would fail if one node went down \( \frac{n}{2} + 1 = 2 \).

A two-node cluster is functional even if only one node is able to serve traffic.

Creating a two node cluster is the same as creating any other cluster. You must add one node as the configuration coordinator and the other node as the other cluster node.

**Note**

Incremental configuration synchronization is not supported in a two-node cluster. Only full synchronization is supported.

Migrating an HA setup to a cluster setup

September 18, 2018

Migrating an existing high availability (HA) setup to a cluster setup requires you to first remove the NetScaler appliances from the HA setup and create a backup of the HA configuration file. You must then use the two appliances to create a cluster and upload the backed-up configuration file to the cluster.

**Note**

- Before uploading the backed-up HA configuration file to the cluster, you must modify it to make it cluster compatible. Refer to the relevant step of the procedure below.
- Use the `batch -f <backup_filename>` command to upload the backed-up configuration file.

The above approach is a very basic migration solution which results in downtime for the deployed application. As such, it must be used only in deployments where there is no consideration to application availability.

However, in most deployments, the availability of the application is of paramount importance. For such cases, you must use the approach where an HA setup can be migrated to a cluster setup without any resulting downtime. In this approach, an existing HA setup is migrated to a cluster setup by first removing the secondary appliance and using that appliance to create a single-node cluster. After the cluster becomes operational and serves traffic, the primary appliance of the HA setup is added to the cluster.
To convert a HA setup to cluster setup (without any downtime) by using the command line interface

Let us consider the example of a HA setup with primary appliance (NS1) - 10.102.97.131 and secondary appliance (NS2) - 10.102.97.132.

1. Make sure the configurations of the HA pair are stable.
2. Log on to any one of the HA appliances, go to the shell, and create a copy of the ns.conf file (for example, ns_backup.conf).
3. Log on to the secondary appliance, NS2, and clear the configurations. This operation removes NS2 from the HA setup and makes it a standalone appliance.

```plaintext
> clear ns config full
```

**Note**

- This step is required to make sure that NS2 does not start owning VIP addresses, now that it is a standalone appliance.
- At this stage, the primary appliance, NS1, is still active and continues to serve traffic.

4. Create a cluster on NS2 (now no longer a secondary appliance) and configure it as a PASSIVE node.

```plaintext
> add cluster instance 1
> add cluster node 0 10.102.97.132 -state PASSIVE -backplane 0/1/1
> add ns ip 10.102.97.133 255.255.255.255 -type CLIP
> enable cluster instance 1
> save ns config
> reboot -warm
```

5. Modify the backed-up configuration file as follows:

- Remove the features that are not supported on a cluster. For the list of unsupported features, see NetScaler appliance Features Supported by a Cluster. This is an optional step. If you do not perform this step, the execution of unsupported commands will fail.

- Remove the configurations that have interfaces, or update the interface names from the c/u convention to the n/c/u convention.

**Example**
• The backup configuration file can have SNIP addresses or MIP addresses. These addresses are striped on all the cluster nodes. It is recommended that you add spotted IP addresses for each node.

**Example**

```bash
> add vlan 10 -ifnum 0/1
> add vlan 10 -ifnum 0/0/1 1/0/1
```

• Update the hostname to specify the owner node.

**Example**

```bash
> set ns hostname ns0 -ownerNode 0
> set ns hostname ns1 -ownerNode 1
```

• Change all other relevant networking configuration that depend on spotted IPs. For example, L3 VLAN, RNAT configuration which uses SNIPs as NATIP, INAT rules that refers to SNIPs/MIPs).

6. On the cluster, do the following:

• Make the topological changes to the cluster by connecting the cluster backplane, the cluster link aggregation channel, and so on.

• Apply configurations from the backed-up and modified configuration file to the configuration coordinator through the cluster IP address.

```bash
> batch -f ns_backup.conf
```

• Configure external traffic distribution mechanisms like ECMP or cluster link aggregation.

7. Switch the traffic from the HA setup to the cluster.

• Log on to the primary appliance, NS1, and disable all the interfaces on it.

```bash
> disable interface <interface_id>
```

• Log on to the cluster IP address and configure NS2 as an ACTIVE node.
8. Log on to the primary appliance, NS1, and remove it from the HA setup.
   - Clear all the configurations. This operation removes NS1 from the HA setup and makes it a standalone appliance.
     
     ```sh
clear ns config full
```
   - Enable all the interfaces.
     
     ```sh
enable interface <interface_id>
```

9. Add NS1 to the cluster.
   - Log on to the cluster IP address and add NS1 to the cluster.
     
     ```sh
add cluster node 1 10.102.97.131 -state PASSIVE -backplane 1/1/1
```
   - Log on to NS1 and join it to the cluster by sequentially executing the following commands:
     
     ```sh
join cluster -clip 10.102.97.133 -password nsroot
save ns config
reboot -warm
```

10. Log on to NS1 and perform the required topological and configuration changes.
11. Log on to the cluster IP address and set NS1 as an ACTIVE node.

```sh
set cluster node 1 -state ACTIVE
```

**Transitioning between a L2 and L3 Cluster**

October 9, 2018
An L2 cluster is one where all the nodes are from the same network and an L3 cluster is one that can include nodes from different networks. You can seamlessly transition from one type of cluster to the other without any downtime for the applications that are deployed on the NetScaler appliance.

**Transitioning a cluster from L2 to L3**

You can transition to an L3 cluster when you want the cluster to include nodes from other networks.

On the cluster IP address, do the following:

1. Create a nodegroup.

   **Example**
   
   ```
   1 > add cluster nodegroup NG0
   ```

   This nodegroup is used in the next step to group all the nodes from the existing L2 cluster.

2. Transition the L2 cluster to an L3 cluster.

   **Example**
   
   ```
   1 > set cluster instance 1 -inc ENABLED -nodegroup NG0
   ```

   This command achieves the dual purpose of transitioning to L3 cluster and also adding all the nodes of the L2 cluster to the nodegroup.

3. Now, you can add more nodes to the cluster as explained in “Adding a Node to the Cluster”.

**Transitioning a cluster from L3 to L2**

You can transition to an L2 cluster when you want to retain nodes that belong to a single network.

On the cluster IP address, do the following:

1. Remove the cluster nodes from the networks that you do not want to retain.

   **Example**
   
   ```
   1 > rm cluster node <nodeId>
   ```

2. Transition the L3 cluster to a L2 cluster.

   **Example**
The cluster now includes nodes only of a single network.

### Setting up GSLB in a cluster

September 18, 2018

**Note**

Supported from NetScaler 10.5 Build 52.11 onwards.

To set up GSLB in a cluster you must bind the different GSLB entities to a node group. The node group must have a single member node.

**Note**

- The parent-child topology of GSLB is not supported in a cluster.
- If you have configured the static proximity GSLB method, make sure that the static proximity database is present on all the cluster nodes. This happens by default if the database file is available at the default location. However, if the database file is maintained in a directory other than `/var/netscaler/locdb/`, you must manually synch the file to all the cluster nodes.

**To set up GSLB in a cluster by using the command line interface:**

Log on to the cluster IP address and perform the following operations at the command prompt:

1. Configure the different GSLB entities. For information, see [GSLB Configuration Entities](#).

   **Note**

   When creating the GSLB site, make sure that you specify the cluster IP address and public cluster IP address (needed only when the cluster is deployed behind a NAT device). These parameters are required to ensure the availability of the GSLB auto-sync functionality.

   ```
   add gslb site <siteName> <siteType> <siteIPAddress> -publicIP <ip_addr> -clip <ip_addr> <publicCLIP>
   ```

2. Create a cluster node group.

   ```
   add cluster nodegroup <name> [-sticky ( YES | NO )]
   ```

   **Note**

   Enable the sticky option if you want to set up GSLB based on VPN users.

3. Bind a single cluster node to the node group.

   ```
   bind cluster nodegroup <name> -node <nodeId>
   ```
4. Bind the local GSLB site to the nodegroup.

```bash
bind cluster nodegroup <name> -gslbSite <string>
```

**Note**

Make sure that the IP address of the local GSLB site IP address is striped (available across all cluster nodes).

5. Bind the ADNS (or ADNS-TCP) service or the DNS (or DNS-TCP) load balancing virtual server to the node group.

**To bind the ADNS service:**

```bash
bind cluster nodegroup <name> -service <string>
```

**To bind the DNS load balancing virtual server:**

```bash
bind cluster nodegroup <name> -vServer <string>
```

6. Bind the GSLB virtual server to the node group.

```bash
bind cluster nodegroup <name> -vServer <string>
```

7. [Optional] To setup GSLB based on VPN users, bind the VPN virtual server to the GSLB node group.

```bash
bind cluster nodegroup <name> -vServer <string>
```

8. Verify the configurations.

```bash
show gslb runningConfig
```

**To set up GSLB in a cluster by using the graphical user interface:**

Log on to the cluster IP address and perform the following operations in the Configuration tab:

1. Configure the GSLB entities.

   Navigate to **Traffic Management > GSLB** to perform the required configurations.

2. Create a node group and perform other node group related configurations.

   Navigate to **System > Cluster > Node Groups** to perform the required configurations.

For the detailed configurations to be performed, see the description provided in the CLI procedure mentioned above.

**Using cache redirection in a cluster**

September 18, 2018
Cache redirection in a cluster works in the same way as it does on a standalone NetScaler appliance. The only difference is that the configurations are done on the cluster IP address. For more information on cache redirection, see “Cache Redirection.”

Points to remember when using cache redirection in transparent mode on a cluster:

- Before configuring cache redirection, make sure that you have connected all nodes to the external switch and that you have linksets configured. Otherwise, client requests will be dropped.
- When MAC mode is enabled on a load balancing virtual server, make sure MBF mode is enabled on the cluster by using the enable ns mode MBF command. Otherwise, the requests are sent to origin server directly instead of being sent to the cache server.

Using L2 mode in a cluster setup

September 18, 2018

Note
Supported from NetScaler 10.5 and later releases.

To use L2 mode in a cluster setup, you must make sure of the following:

- Spotted IP addresses must be available on all the nodes as required.
- Linksets must be used to communicate with the external network.
- Asymmetric topologies or asymmetric cluster LA groups are not supported.
- Cluster LA group is recommended.
- Traffic is distributed between the cluster nodes only for deployments where services exist.

Using cluster LA channel with linksets

January 6, 2019

In an asymmetric cluster topology, some cluster nodes are not connected to the upstream network. In such a case, you must use linksets. To optimize the performance, you can bind the interfaces that are connected to the switch as a cluster LA channel and then bind the channel to a linkset.

To understand how a combination of cluster LA channel and linksets can be used, consider a three-node cluster for which the upstream switch has only two ports available. You can connect two of the cluster nodes to the switch and leave the other node unconnected.

Note
Similarly, you can also use a combination of ECMP and linksets in an asymmetric topology.

Figure 1. Linksets and cluster LA channel topology
To configure cluster LA channel and linksets by using the NetScaler appliance command line

1. Log on to the cluster IP address.
2. Bind the connected interfaces to a cluster LA channel.
   ```
   add channel CLA/1 -ifnum 0/1/2 1/1/2
   ```
3. Bind the cluster LA channel to the linkset.
   ```
   add linkset LS/1 -ifnum CLA/1
   ```

Backplane on LA channel

January 6, 2019

In this deployment, LA channels are used for the cluster backplane.

- NS0 - nodeId: 0, NSIP: 10.102.29.60
- NS1 - nodeId: 1, NSIP: 10.102.29.70
- NS2 - nodeId: 2, NSIP: 10.102.29.80

To deploy a cluster with the backplane interfaces as LA channels

1. Create a cluster of nodes NS0, NS1, and NS2.
   a) Log on to the first node that you want to add to the cluster and do the following:
   ```
   create cluster instance 1
   add cluster node 0 10.102.29.60 -state ACTIVE
   enable cluster instance 1
   add ns ip 10.102.29.61 255.255.255.255 -type CLIP
   save ns config
   reboot -warm
   ```
   b) Log on to the cluster IP address and do the following:
   ```
   add cluster node 1 10.102.29.70 -state ACTIVE
   add cluster node 2 10.102.29.80 -state ACTIVE
   ```
   c) Log on to the nodes 10.102.29.70 and 10.102.29.80 to join the nodes to the cluster.
As seen in the above commands the interfaces 0/1/1, 1/1/1, and 2/1/1 are configured as the back-plane interfaces of the three cluster nodes.

2. Log on to the cluster IP address and do the following:
   a) Create the LA channels for nodes NS0 and NS1.

```
1 add channel 0/LA/1 -ifnum 0/1/1 0/1/2
2 add channel 1/LA/2 -ifnum 1/1/1 1/1/2
```

b) Configure the backplane for the cluster nodes.

```
1 set cluster node 0 -backplane 0/LA/1
2 set cluster node 1 -backplane 1/LA/2
3 set cluster node 2 -backplane 2/1/1
```

Common interfaces for client and server and dedicated interfaces for backplane

January 6, 2019

This is a one-arm deployment of the NetScaler cluster. In this deployment, the client and server networks use the same interfaces to communicate with the cluster. The cluster backplane uses dedicated interfaces for inter-node communication.

- NS0 - nodeId: 0, NSIP: 10.102.29.60
- NS1 - nodeId: 1, NSIP: 10.102.29.70
- NS2 - nodeId: 2, NSIP: 10.102.29.80

To deploy a cluster with a common interface for the client and server and a different interface for the cluster backplane

1. Create a cluster of nodes NS0, NS1, and NS2.

2. Log on to the first node that you want to add to the cluster and do the following:

```
1 create cluster instance 1
2 add cluster node 0 10.102.29.60 -state ACTIVE -backplane 0/1/1
3 enable cluster instance 1
```
3. Log on to the cluster IP address and do the following:

```
1 add ns ip 10.102.29.61 255.255.255.255 -type CLIP
2 save ns config
3 reboot -warm
```

4. Log on to the nodes 10.102.29.70 and 10.102.29.80 to join the nodes to the cluster.

```
1 join cluster -clip 10.102.29.61 -password nsroot
2 save ns config
3 reboot -warm
```

As seen in the above commands the interfaces 0/1/1, 1/1/1, and 2/1/1 are configured as the backplane interfaces of the three cluster nodes.

1. On the cluster IP address, create VLANs for the backplane interfaces and for the client and server interfaces.

```
1 //For the backplane interfaces
2 add vlan 10
3 bind vlan 10 0/1/1 1/1/1 2/1/1
4
5 //For the interfaces that are connected to the client and server networks.
6 add vlan 20
7 bind vlan 20 0/1/2 1/1/2 2/1/2
```

2. On the switch, create VLANs for the interfaces corresponding to the backplane interfaces and the client and server interfaces. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1) switch. Similar configurations must be performed on other switches.

```
1 //For the backplane interfaces. Repeat for each interface...
2 interface Ethernet2/47
3 switchport access vlan 100
4 switchport mode access
5 end
6
7 //For the interfaces connected to the client and server networks. Repeat for each interface...
8 interface Ethernet2/47
9 switchport access vlan 200
```
Common switch for client, server, and backplane

January 6, 2019

In this deployment, the client, server, and backplane use dedicated interfaces on the same switch to communicate with the NetScaler cluster.

- NS0 - nodeId: 0, NSIP: 10.102.29.60
- NS1 - nodeId: 1, NSIP: 10.102.29.70
- NS2 - nodeId: 2, NSIP: 10.102.29.80

**To deploy a cluster with a common switch for the client, server, and backplane**

1. Create a cluster of nodes NS0, NS1, and NS2.

2. Log on to the first node that you want to add to the cluster and do the following:

   ```console
   1  create cluster instance 1
   2  add cluster node 0 10.102.29.60 -state ACTIVE -backplane 0/1/1
   3  enable cluster instance 1
   4  add ns ip 10.102.29.61 255.255.255.255 -type CLIP
   5  save ns config
   6  reboot -warm
   ```

3. Log on to the cluster IP address and do the following:

   ```console
   1  add cluster node 1 10.102.29.70 -state ACTIVE -backplane 1/1/1
   2  add cluster node 2 10.102.29.80 -state ACTIVE -backplane 2/1/1
   ```

4. Log on to the nodes 10.102.29.70 and 10.102.29.80 to join the nodes to the cluster.

   ```console
   1  join cluster -clip 10.102.29.61 -password nsroot
   2  save ns config
   3  reboot -warm
   ```

As seen in the above commands the interfaces 0/1/1, 1/1/1, and 2/1/1 are configured as the backplane interfaces of the three cluster nodes.

1. On the cluster IP address, create VLANs for the backplane, client, and server interfaces.

   ```console
   1  //For the backplane interfaces
   ```
2. On the switch, create VLANs for the interfaces corresponding to the backplane interfaces and the client and server interfaces. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1) switch. Similar configurations must be performed on other switches.

```bash
//For the backplane interfaces. Repeat for each interface...
interface Ethernet2/47
switchport access vlan 100
switchport mode access
end

//For the client interfaces. Repeat for each interface...
interface Ethernet2/48
switchport access vlan 200
switchport mode access
end

//For the server interfaces. Repeat for each interface...
interface Ethernet2/49
switchport access vlan 300
switchport mode access
end
```

**Common switch for client and server and dedicated switch for backplane**

January 6, 2019

In this deployment, the clients and servers use different interfaces on the same switch to communicate with the NetScaler cluster. The cluster backplane uses a dedicated switch for inter-node communication.
To deploy a cluster with the same switch for the clients and servers and a different switch for the cluster backplane

1. Create a cluster of nodes NS0, NS1, and NS2.

   a. Log on to the first node that you want to add to the cluster and do the following:

```
create cluster instance 1
add cluster node 0 10.102.29.60 -state ACTIVE -backplane 0/1/1
enable cluster instance 1
add ns ip 10.102.29.61 255.255.255.255 -type CLIP
save ns config
reboot -warm
```

   b. Log on to the cluster IP address and do the following:

```
add cluster node 1 10.102.29.70 -state ACTIVE -backplane 1/1/1
add cluster node 2 10.102.29.80 -state ACTIVE -backplane 2/1/1
```

   c. Log on to the nodes 10.102.29.70 and 10.102.29.80 to join the nodes to the cluster.

```
join cluster -clip 10.102.29.61 -password nsroot
save ns config
reboot -warm
```

As seen in the above commands the interfaces 0/1/1, 1/1/1, and 2/1/1 are configured as the backplane interfaces of the three cluster nodes.

2. On the cluster IP address, create VLANs for the backplane, client, and server interfaces.

```
//For the backplane interfaces
add vlan 10
bind vlan 10 0/1/1 1/1/1 2/1/1

//For the client-side interfaces
add vlan 20
bind vlan 20 0/1/2 1/1/2 2/1/2

//For the server-side interfaces
```
3. On the switch, create VLANs for the interfaces corresponding to the backplane interfaces and the client and server interfaces. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1) switch. Similar configurations must be performed on other switches.

```
10  add vlan 30
11  bind vlan 30 0/1/3 1/1/3 2/1/3
```

```
// For the backplane interfaces. Repeat for each interface...
2  interface Ethernet2/47
3  switchport access vlan 100
4  switchport mode access
5  end
6

// For the client interfaces. Repeat for each interface...
7  interface Ethernet2/48
8  switchport access vlan 200
9  switchport mode access
10  end
11

// For the server interfaces. Repeat for each interface...
12  interface Ethernet2/49
13  switchport access vlan 300
14  switchport mode access
15  end
16
```

**Different switch for every node**

January 6, 2019

In this deployment, each cluster node is connected to a different switch and trunk links are configured between the switches.

The cluster configurations will be the same as the other deployments scenarios. Most of the client-side configurations will be done on the client-side switches.

**Sample cluster configurations**

September 18, 2018

The following example can be used to configure a four-node cluster with ECMP, cluster LA, or Linksets.
1. Create the cluster.
   • Log on to first node.
   • Add the cluster instance.
     ```
     add cluster instance 1
     ```
   • Add the first node to the cluster.
     ```
     add cluster node 0 10.102.33.184 -backplane 0/1/1
     ```
   • Enable the cluster instance.
     ```
     enable cluster instance 1
     ```
   • Add the cluster IP address.
     ```
     add ns ip 10.102.33.185 255.255.255.255 -type CLIP
     ```
   • Save the configurations.
     ```
     save ns config
     ```
   • Warm reboot the appliance.
     ```
     reboot -warm
     ```

2. Add the other three nodes to the cluster.
   • Log on to cluster IP address.
   • Add the second node to the cluster.
     ```
     add cluster node 1 10.102.33.187 -backplane 1/1/1
     ```
   • Add the third node to the cluster.
     ```
     add cluster node 2 10.102.33.188 -backplane 2/1/1
     ```
   • Add the fourth node to the cluster.
     ```
     add cluster node 3 10.102.33.189 -backplane 3/1/1
     ```

3. Join the added nodes to the cluster. This step is not applicable for the first node.
   • Log on to each newly added node.
• Join the node to the cluster.

```bash
join cluster -clip 10.102.33.185 -password nsroot
```

• Save the configuration.

```bash
save ns config
```

• Warm reboot the appliance.

```bash
reboot -warm
```

4. Configure the NetScaler cluster through the cluster IP address.

```bash
// Enable load balancing feature
enable ns feature lb
// Add a load balancing virtual server
add lb vserver first_lbvserver http
```

5. Configure any one of the following (ECMP, cluster LA, or Linkset) traffic distribution mechanisms for the cluster.

**ECMP**

• Log on to the cluster IP address.

• Enable the OSPF routing protocol.

```bash
enable ns feature ospf
```

• Add a VLAN.

```bash
add vlan 97
```

• Bind the interfaces of the cluster nodes to the VLAN.

```bash
bind vlan 97 -ifnum 0/1/4 1/1/4 2/1/4 3/1/4
```

• Add a spotted SNIP on each node and enable dynamic routing on it.

```bash
add ns ip 1.1.1.10 255.255.255.0 -ownerNode 0 -dynamicRouting ENABLED
add ns ip 1.1.1.11 255.255.255.0 -ownerNode 1 -dynamicRouting ENABLED
```
• Bind one of the SNIP addresses to the VLAN.

```plaintext
1 bind vlan 97 -ipAddress 1.1.1.10 255.255.255.0
```

• Configure the routing protocol on ZebOS by using vtysh shell.

**Static cluster LA**
- Log on to the cluster IP address.
- Add a cluster LA channel.

```plaintext
1 add channel CLA/1 -speed 1000
```
- Bind the interfaces to the cluster LA channel.

```plaintext
1 bind channel CLA/1 0/1/5 1/1/5 2/1/5 3/1/5
```
- Perform equivalent configuration on the switch.

**Dynamic cluster LA**
* Log on to the cluster IP address.
* Add the interfaces to the cluster LA channel.

```plaintext
1 set interface 0/1/5 -lacpmode active -lacpkey 5 -lagtype cluster
2 set interface 1/1/5 -lacpmode active -lacpkey 5 -lagtype cluster
3 set interface 2/1/5 -lacpmode active -lacpkey 5 -lagtype cluster
4 set interface 3/1/5 -lacpmode active -lacpkey 5 -lagtype cluster
```
* Perform equivalent configuration on the switch.

**Linksets.** Assume that the node with nodeId 3 is not connected to the switch. You must configure a linkset so that the unconnected node can use the other node interfaces to communicate with the switch.

a) Log on to the cluster IP address.

b) Add a linkset.
Using VRRP in a cluster setup

September 18, 2018

Virtual Router Redundancy Protocol (VRRP) is supported in a cluster setup for both IPv4 and IPv6. The two VRRP features supported in a cluster setup are Interface based VRRP and IP based VRRP.

Interface based VRRP

The Interface based VRRP feature is applicable only to a two-node cluster with one node active state and the other serving as a spare.

In this feature, the same VMAC address is configured on both the nodes of the cluster. This VMAC address is used in GARP advertisements and ARP responses for the IP addresses configured on a node. This feature is useful in an active-spare two-node cluster setup that has external devices/routers that do not accept GARP advertisements.

With the same VMAC address on both cluster nodes, when the active node goes down and the spare node takes over as active, the MAC address for the IP addresses on the new active node remain unchanged and the ARP tables on the external devices/routers do not need to be updated.

Configuring Interface based VRRP for IPv4

Perform the following tasks on a cluster setup to configure interface based VRRP for IPv4:

- **Add a VRID.** A VRID is an integer used by the Cluster setup to form a VMAC address.
• **Bind the VRID to node interfaces.** Bind the interfaces to the created VRID. The bound interfaces (in the current active node) use the VMAC address in GARP advertisements and ARP responses for its IPv4 addresses. You must associate the VRID to the interfaces of both nodes of the active-spare cluster setup. This is because unlike in a high availability setup, interface IDs differ in a cluster setup.

**To add a VRID by using NetScaler appliance Command line**

1. `add vrid <ID>
2. `show vrid <ID>

**To bind the VRID to an interface by using the NetScaler appliance Command line**

At the command prompt, type:

1. `bind vrid <ID> -ifnum <interface_name>
2. `show vrid <ID>

**To add a VRID and bind it to interfaces by using the NetScaler GUI**

1. Navigate to **System > Network > VMAC** and, on the **VMAC** tab, click **Add**.
2. On the **Create VMAC** page, specify a value in the **Virtual Router ID** field, bind interfaces in the **Associate Interfaces** section, and then click **Create**.

```
add vrid 300
Done
bind vrid 300 -ifnum 1/1/2 2/1/3
Done
```

**Configuring interface based VRRP for IPv6**

Perform the following tasks on a cluster setup to configure interface based VRRP for IPv6:

- **Add a VRID6.** A VRID6 is an integer used by the Cluster setup to form a VMAC6 address. The generic VMAC6 address is in the form of 00:00:5e:00:01:<VRID6>.
- **Bind the VRID6 to node interfaces.** Bind the interfaces to the created VRID6. The bound interfaces (in the current active node) use the VMAC6 address in GARP advertisements and ARP responses for its IPv6 addresses. You must associate the VRID6 to the interfaces of both nodes.
of the active-spare cluster setup. This is because unlike in a high availability setup, interface IDs differ in a cluster setup.

**To add a VRID6 by using NetScaler appliance Command line**

```
1 - add vrid6 <ID>
2 - show vrid6 <ID>
```

**To bind the VRID6 to an interface by using the NetScaler appliance Command line**

At the command prompt, type:

- `bind vrid6 <ID> -ifnum <interface_name>`
- `show vrid6 <ID>`

**To add a VRID6 and bind it to interfaces by using the NetScaler GUI**

1. Navigate System > Network > VMAC and, on the VMAC6 tab, click Add.
2. On the Create VMAC6 page, specify a value in the Virtual Router ID* field, bind interfaces in the Associate Interfaces section, and then click Create.

```
1 > add vrid 100
2 Done
3 > bind vrid 100 -ifnum 0/1/1 1/1/2 2/1/3
4 Done
```

**IP based VRRP**

In IP based VRRP, striped VIP addresses bound to the same VRID are configured on all nodes of a cluster setup. These VIP addresses are active on all the nodes.

One of the cluster nodes acts as the VRID owner and sends out the VRRP advertisement to other nodes. In case of failure of the VRID owner node, another node in the cluster assumes the ownership of the VRID and starts sending VRRP advertisements. You can also assign a specific cluster node as the owner of the VRID.

**Configuring IP based VRRP for IPv4**

Perform the following tasks on a cluster setup for configuring IP based VRRP for IPv4:
NetScaler 12.0

- **Add a VRID.** A VRID is an integer used by the Cluster setup to form a VMAC address. The generic VMAC address is in the form of 00:00:5e:00:02:<VRID>.

- **(Optional) Assign a node as the owner of the VMAC address.** You can set the owner node parameter (while adding or modifying VRID6) to the ID of the cluster node to assign it as the owner of the VMAC address. If the assigned owner node fails, one of the UP cluster nodes is dynamically elected as the owner of the VMAC address.

- **Bind the VRID to the VIP address of the nodes.** Bind the created VRID to the striped VIP address.

To add a VRID by using the NetScaler appliance Command line

```
1 - add vrid <ID> [-ownerNode <positive_integer>]
2 - show vrid <ID>
```

To bind the VRID to VIP address by using the NetScaler appliance Command line

```
set ns ip <IPv4Address> -vrid <ID>
show vrid <ID>
```

To add a VRID by using the NetScaler GUI

1. Navigate to System > Network > VMAC and, on the VMAC tab, click Add.
2. On the Create VMAC page, specify a value in the Virtual Router ID field and then click Create.

To bind the VRID to a VIP address by using the NetScaler GUI

1. Navigate to System > Network > IPs, on the IPV4s tab, select a VIP address and click Edit.
2. Set the Virtual Router ID parameter while editing the VIP configuration.

```
1 > add vrid 90
2  Done
3 > set ns ip 192.0.2.90 -vrid 90
4  Done
```

**Configuring IP based VRRP for IPv6**

Perform the following tasks on a cluster setup for configuring IP based VRRP for IPv6:

- **Add a VRID6.** A VRID6 is an integer used by the Cluster setup to form a VMAC6 address. The generic VMAC6 address is in the form of 00:00:5e:00:02:<VRID6>.

- **(Optional) Assign a node as the owner of the VMAC6 address.** You can set the owner node parameter (while adding or modifying VRID6) to the ID of the cluster node to assign it as the owner of the VMAC6 address. If the assigned owner node fails, one of the UP cluster nodes is dynamically elected as the owner of the VMAC6 address.
**Bind the VRID6 to the VIP6 address of the nodes.** Bind the created VRID6 to the striped VIP6 address.

To add a VRID6 by using the NetScaler appliance Command line

- `add vrid6 <ID> [-ownerNode <positive_integer>]`
- `show vrid6 <ID>`

To bind the VRID6 to VIP6 address by using the NetScaler appliance Command line

- `set ns ip6 <IPv6Address> -vrid6 <ID>`
- `show vrid6 <ID>`

To add a VRID6 by using the NetScaler GUI

1. Navigate to **System > Network > VMAC** and, on the **VMAC6** tab, click **Add**.
2. On the **Create VMAC6** page, specify a value in the **Virtual Router ID** field and then click **Create**.

To bind the VRID6 to a VIP6 address by using the NetScaler GUI

1. Navigate to **System > Network > IPs**, on the **IPV6s** tab, select a VIP address and click **Edit**.
2. Set the **Virtual Router ID** parameter while editing the VIP6 configuration.

```
1 > add vrid6 90
2       Done
3 > set ns ip6 2001::db8::5001 - vrid6 90
4       Done
```

## Upgrading or downgrading the NetScaler cluster

**September 18, 2018**

All the nodes of a NetScaler cluster must be running the same software version. Therefore, to upgrade or downgrade the cluster, you must upgrade or downgrade each NetScaler appliance of the cluster, one node at a time.

A node that is being upgraded or downgraded is not removed from the cluster. The node continues to be a part of the cluster and serves traffic uninterrupted, except for the down-time when the node reboots after it is upgraded or downgraded.

However, due to software version mismatch among the cluster nodes, configuration propagation is disabled on the cluster and is enabled only after all the cluster nodes are of the same version. Since configuration propagation is disabled during upgrading on downgrading a cluster, you cannot perform any configurations through the cluster IP address during this time.
Important

- Configurations can be lost on downgrading the cluster.
- When you are upgrading a cluster to NetScaler 11.0 build 64.x from an earlier NetScaler 11.0 build, cluster configuration propagation is disabled. This exception arises because the cluster version in build 64.x is different from the one in previous NetScaler 11.0 builds.

Traditionally, this issue occurred only during an upgrade of a cluster to a different NetScaler version (for example, from 10.5 to 11.0). It must be noted that normally the cluster version matches the NetScaler version.

Note
Configuration propagation remains disabled until all the cluster nodes are upgraded to Build 64.x.

Points to note before upgrading or downgrading the cluster

- You cannot add cluster nodes while upgrading or downgrading the cluster software version.
- You can perform node-level configurations through the NSIP address of individual nodes, but make sure to perform the same configurations on all the nodes to maintain them in synch.
- You cannot execute the “start nstrace” command from the cluster IP address when the cluster is being upgraded. However, you can get the trace of individual nodes by performing this operation on individual cluster nodes through their NSIP address.
- Owing to changes in cluster licensing that were made in NetScaler 10.5 Build 52.11 see Prerequisites for cluster nodes, look into the following:
  - If the cluster is setup in a build prior to NetScaler 10.5 Build 52.11, the cluster will work with the separate cluster license file. No changes are required.
  - If the cluster is setup in NetScaler 10.5 Build 52.11 or later releases and then downgraded to a build prior to NetScaler 10.5 Build 52.11, the downgraded cluster will not work as it now expects a separate cluster license file.
- While upgrading from any NetScaler 10.1 build to a later release, syncookie must be disabled on all TCP profiles (using the “set ns tcpProfile <name> -synCookie DISABLED” command) and after that a striped SNIP must be added on the CLIP subnet. Once upgraded, syncookie can be enabled again.
- While upgrading the NetScaler appliance from a NetScaler 10.1 build to a NetScaler 10.5 build, do not execute the “show audit messages” command as this can cause the NetScaler appliance to become unresponsive.
• NetScaler 10.5 54.x and 55.x builds are not suitable for cluster deployment. This is because, for services that need probing, SYN packets are processed locally (on the flow receiver) even though syncookie is disabled.

• When a cluster is being upgraded, it is possible that the upgraded nodes have some additional features activated that are not available on the nodes that are not upgraded. This results in a license mismatch warning while the cluster is being upgraded. This warning will be automatically resolved when all the cluster nodes are upgraded.

**Important**

• Citrix recommends that you wait for the previous node to become active before upgrading or downgrading the next node.

• Citrix recommends that the cluster configuration node must be upgraded/downgraded last to avoid multiple disconnect of cluster IP sessions.

**To upgrade or downgrade the software of the cluster nodes**

1. Make sure the cluster is stable and the configurations are synchronized on all the nodes.

2. Access each node through its NSIP address and perform the following:
   • Upgrade or downgrade the cluster node. For detailed information about upgrading and downgrading the software of an appliance, see [Upgrade and downgrade a NetScaler appliance](#).
   • Save the configurations.
   • Reboot the appliance.

3. Repeat step 2 for each of the other cluster nodes.

**Operations supported on individual cluster nodes**

September 18, 2018

As a rule, NetScaler appliances that are a part of a cluster cannot be individually configured from their NSIP address. However, there are some operations that are an exception to this rule. These operations, when executed from the NSIP address, are not propagated to other cluster nodes.

The operations are:

| cluster instance (set, rm, enable, disable) |
cluster node (set \(\text{rm}\))

nstrace (start \show\ stop)

interface (set \enable\ \disable)

route (add \rm\ \set\ \unset)

arp (add \rm\ \send -all)

- force cluster sync
- sync cluster files
- disable ntp sync
- save ns config
- reboot
- shutdown

For example, when you execute the command disable interface 1/1/1 from the NSIP address of a cluster node, the interface is disabled only on that node. Since the command is not propagated, the interface 1/1/1 remains enabled on all the other cluster nodes.

**Support for heterogeneous cluster**

September 21, 2018

© 1999-2018 Citrix Systems, Inc. All rights reserved.
NetScaler appliance now supports heterogeneous cluster in a cluster deployment. A heterogeneous cluster spans nodes of different NetScaler hardware and you can have a combination of different platforms in the same cluster.

**Important**

The formation or supportability of a heterogeneous cluster is possible and limited only to MPX hardware platforms.

The supportability and formation of the heterogeneous cluster depend on certain NetScaler models. The following table lists the platforms that are supported in the formation of a heterogeneous cluster.

<table>
<thead>
<tr>
<th>Number of Packet Engines</th>
<th>MPX Hardware Platforms</th>
<th>Supported MPX Hardware Platforms to form Heterogeneous Cluster</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>MPX 11500</td>
<td>MPX 14020</td>
</tr>
<tr>
<td>7</td>
<td>MPX 11515</td>
<td>MPX 14040</td>
</tr>
<tr>
<td>9</td>
<td>MPX 11530</td>
<td>MPX 14060</td>
</tr>
</tbody>
</table>

**Note**

If you run the “join cluster” command from the node that has an unequal number of packet engines, the following error message appears: “Mismatch in the number of active PPEs between CCO and local node”.

**Limitations of using heterogeneous cluster**

1. The number of packet engines present on all of the MPX hardware appliances should be same in the cluster deployment.
2. The extra management CPU setting should be same on all the cluster nodes.
3. The newly added node should have the same capacity on the data planes and backplane, as that of existing cluster nodes.
4. If there are mixed platform devices supporting different ciphers, then the cluster would agree upon a common cipher list.

**FAQs**

November 6, 2018

A list of the frequently asked questions about clustering (NetScaler 11.0, 10.5, 10.1). Click a question to view its answer.
How many NetScaler appliances can be included in a single NetScaler cluster?

A NetScaler cluster can include one appliance or as many as 32 NetScaler appliance nCore hardware or virtual appliances. Each of these nodes must satisfy the criteria specified in Prerequisites for Cluster Nodes.

Can a NetScaler appliance be a part of multiple clusters?

No. A NetScaler appliance can belong to can belong to one cluster only.

What is a cluster IP address? What is its subnet mask?

The cluster IP address is the management address of a NetScaler cluster. All cluster configurations must be performed by accessing the cluster through this address. The subnet mask of the cluster IP address is fixed at 255.255.255.255.

How can I make a specific cluster node as the cluster configuration coordinator?

To manually set a specific node as the cluster configuration coordinator, you must set the priority of that node to the lowest numeric value (highest priority). To understand, let us consider a cluster with three nodes that have the following priorities:

n1 - 29, n2 - 30, n3 - 31

Here, n1 is the configuration coordinator. If you want to make n2 the configuration coordinator, you must set its priority to a value that is lower than n1, for example, 28. On saving the configuration, n2 becomes the configuration coordinator.

Note

n2 with its original priority value of 30 will also become the configuration coordinator when n1 goes down, as the node with the next lowest priority value is selected in the event that the configuration coordinator goes down.

Why are the network interfaces of a cluster represented in 3-tuple (n/u/c) notation instead of the regular 2-tuple (u/c) notation?

When a NetScaler appliance is part of a cluster, you must be able to identify the node to which the interface belongs. Therefore, the network interface naming convention for cluster nodes is modified from u/c to n/u/c, where n denotes the node Id.

How can I set the hostname for a cluster node?

The hostname of a cluster node must be specified by executing the set ns hostname command through the cluster IP address. For example, to set the hostname of the cluster node with ID 2, the command is:

set ns hostname hostName1 -ownerNode 2

Can I automatically detect NetScaler appliances so that I can add them to a cluster?
Yes. The configuration utility allows you to discover appliances that are present in the same subnet as the NSIP address of the configuration coordinator. For more information, see Discovering NetScaler Appliances.

Is the traffic serving capability of a cluster affected if a node is removed or disabled or reboot or shutdown or made inactive?

Yes. When any of these operations are performed on an active node of the cluster, the cluster will have one less node to serve traffic. Also, existing connections on this node are terminated.

I have multiple standalone appliances, each of which has different configurations. Can I add them to a single cluster?

Yes. You can add appliances that have different configurations to a single cluster. However, when the appliance is added to the cluster, the existing configurations are cleared. To use the configurations that are available on each of the individual appliances, you must:

1. Create a single *.conf file for all the configurations.
2. Edit the configuration file to remove features that are not supported in a cluster environment.
3. Update the naming convention of interfaces from 2-tuple (u/c) format to 3-tuple (n/u/c) format.
4. Apply the configurations to the configuration coordinator node of the cluster by using the batch command.

Can I migrate the configurations of a standalone NetScaler appliance or an HA setup to the clustered setup?

No. When a node is added to a clustered setup, its configurations are implicitly cleared by using the clear ns config command (with the extended option). In addition, the SNIP addresses and all VLAN configurations (except default VLAN and NSVLAN) are cleared. Therefore, it is recommended that you back up the configurations before adding the appliance to a cluster. Before using the backed-up configuration file for the cluster, you must:

1. Edit the configuration file to remove features that are not supported in a cluster environment.
2. Update the naming convention of interfaces from two-tuple (x/y) format to three-tuple (x/y/z) format.
3. Apply the configurations to the configuration coordinator node of the cluster by using the batch command.

Are backplane interfaces part of the L3 VLANs?

Yes, by default, backplane interfaces have presence on all the L3 VLANs that are configured on the cluster.

How can I configure a cluster that includes nodes from different networks?
A cluster that includes nodes from different networks is called a L3 cluster (sometimes referred to as a cluster in INC mode). In an L3 cluster, all nodes that belong to a single network must be grouped together in a single nodegroup. Therefore, if a cluster includes two nodes each from three different networks, you will have to create 3 nodegroups (one for each network) and associate each of these nodegroups with the nodes that belong to that network. For configuration information, see the steps to setup a cluster.

**How can I configure/un-configure the NSVLAN on a cluster?**

Do either one of the following:

- To make the NSVLAN available in a cluster, make sure that each appliance has the same NSVLAN configured before it is added to cluster.
- To remove the NSVLAN from a cluster node, first remove the node from the cluster and then delete the NSVLAN from the appliance.

**I have a cluster setup where some NetScaler appliance nodes are not connected to the external network. Can the cluster still function normally?**

Yes. The cluster supports a mechanism called linksets, which allows unconnected nodes to serve traffic by using the interfaces of connected nodes. The unconnected nodes communicate with the connected nodes through the cluster backplane. For more information, see [Using Linksets](#).

**How can deployments that require MAC-Based Forwarding (MBF) be supported in a clustered setup?**

Deployments that use MBF must use linksets. For more information, see [Using Linksets](#).

**Can I execute commands from the NSIP address of a cluster node?**

No. Access to individual cluster nodes through the NSIP addresses is read-only. Therefore, when you log on to the NSIP address of a cluster node you can only view the configurations and the statistics. You cannot configure anything. However, there are some operations you can execute from the NSIP address of a cluster node. For more information, see [Operations Supported on Individual Nodes](#).

**Can I disable configuration propagation among cluster nodes?**

No, you cannot explicitly disable the propagation of cluster configurations among cluster nodes. However, during a software upgrade or downgrade, a version mismatch error can automatically disable configuration propagation.

**Can I change the NSIP address or change the NSVLAN of a NetScaler appliance when it is a part of the cluster?**

```
No. To make such changes you must first remove the appliance from the cluster, perform the changes, and then add the appliance to the cluster.

**Does the NetScaler cluster support L2 and L3 VLANs?**

Yes. A cluster supports VLANs between cluster nodes. The VLANs must be configured on the cluster IP address.

- **L2 VLAN.** You can create a layer2 VLAN by binding interfaces that belong to different nodes of the cluster.

- **L3 VLAN.** You can create a layer3 VLAN by binding IP addresses that belong to different nodes of the cluster. The IP addresses must belong to the same subnet. Make sure that one of the following criteria is satisfied. Otherwise, the L3 VLAN bindings can fail.
  - All nodes have an IP address on the same subnet as the one bound to the VLAN.
  - The cluster has a striped IP address and the subnet of that IP address is bound to the VLAN.

When you add a new node to a cluster that has only spotted IPs, the sync happens before spotted IP addresses are assigned to that node. In such cases, L3 VLAN bindings can be lost. To avoid this loss, either add a striped IP or add the L3 VLAN bindings on the NSIP of the newly added node.

**How can I configure SNMP on a NetScaler cluster?**

SNMP monitors the cluster, and all the nodes of the cluster, in the same way that it monitors a standalone appliance. The only difference is that SNMP on a cluster must be configured through the cluster IP address. When generating hardware specific traps, two additional varbinds are included to identify the node of the cluster: node ID and NSIP address of the node.

**What details must I have available when I contact technical support for cluster-related issues?**

The NetScaler appliance provides a `show techsupport -scope cluster` command that extracts configuration data, statistical information, and logs of all the cluster nodes. You must run this command on the cluster IP address.

The output of this command is saved in a file named `collector_cluster_<nsip_CCO>_P_<date-timestamp>.tar.gz` which is available in the `/var/tmp/support/cluster/` directory of the configuration coordinator.

Send this archive to the technical support team to debug the issue.

**Can I use striped IP addresses as the default gateway of servers?**

In case of cluster deployments, make sure the default gateway of the server points to a striped IP address (if you are using a NetScaler appliance-owned IP address). For example, in case of LB deployments with USIP enabled, the default gateway must be a striped SNIP address.

**Can I view routing configurations of a specific cluster node from the cluster IP address?**
Yes. You can view and clear the configurations specific to a node by specifying the owner node while entering the vtysh shell.

For example, to view the output of a command on nodes 0 and 1, the command is as follows:

```
1 \> vtysh
2
3 ns# owner-node 0 1
4 ns(node-0 1)# show cluster state
5 ns(node-0 1)# exit-cluster-node
6 ns#
```

**How can I specify the node for which I want to set the LACP system priority?**

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Supported from NetScaler 10.1 onwards.</td>
</tr>
</tbody>
</table>

In a cluster, you must set that node as the owner node by using the `set lacp` command.

**For example:** To set the LACP system priority for node with ID 2:

```
set lacp -sysPriority 5 -ownerNode 2
```

**How are IP tunnels configured in a cluster setup?**

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Supported from NetScaler 10.1 onwards.</td>
</tr>
</tbody>
</table>

Configuring IP tunnels in a cluster is the same as on a standalone appliance. The only difference is that in a cluster setup, the local IP address must be a striped SNIP or MIP address.

**How can I add a failover interface set (FIS) on the nodes of a NetScaler cluster?**

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Supported from NetScaler 10.5 onwards.</td>
</tr>
</tbody>
</table>

On the cluster IP address, specify the ID of the cluster node on which the FIS must be added, using the command as follows:

```
add fis <name> -ownerNode <nodeId>
```

<table>
<thead>
<tr>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>• The FIS name for each cluster node must be unique.</td>
</tr>
<tr>
<td>• A cluster LA channel can be added to a FIS. You must make sure that the cluster LA channel has a local interface as a member interface.</td>
</tr>
</tbody>
</table>

For more information on FIS, see Configuring failover interface set.

**How are net profiles configured in a cluster setup?**
You can bind spotted IP addresses to a net profile. This net profile can then be bound to spotted load balancing virtual server or service (that is defined using a nodegroup). The following recommendations must be followed, failing which, the net profile configurations are not honored and the USIP/USNIP settings will be used:

- If the strict parameter of the nodegroup is set to Yes, the net profile must contain a minimum of one IP address from each nodegroup member.
- If the strict parameter of the nodegroup is set to No, the net profile must include at least one IP address from each of the cluster nodes.

How can I configure Wl on NS in a cluster setup?

To use Wl on NS on a cluster, you must do the following:

1. Make sure that the Java package and the Wl package are present in the same directory on all the cluster nodes.
2. Create a load balancing virtual server that has persistency configured.
3. Create services with IP addresses as the NSIP address of each of the cluster nodes that you want to serve Wl traffic. This step can only be configured using the NetScaler CLI.
4. Bind the services to the load balancing virtual server.

If you are using Wl on NS over a VPN connection, make sure that the load balancing virtual server is set as WlHOME.

Can the cluster LA channel be used for management access?

No. Management access to a cluster node, must not be configured on a cluster LA channel (for example, CLA/1) or its member interfaces. This is because when the node is INACTIVE, the corresponding cluster LA interface is marked as power down and therefore loses management access.

How cluster nodes communicate to each other and what are the different types of traffic that goes through backplane?

A backplane is a set of interfaces in which one interface of each node is connected to a common switch, which is called the cluster backplane switch. The different types of traffic that goes through backplane, which is used by internode communication are:

- Node to Node Messaging (NNM)
• Steered traffic
• Configuration propagation and synchronization

Each node of the cluster uses a special MAC cluster backplane switch address to communicate with other nodes through the backplane. The cluster special MAC is of the form: \texttt{0x02 0x00 0x6F <cluster\_id> <node\_id> <reserved>}, where <cluster\_id> is the cluster instance ID, <node\_id> is the node number of the NetScaler appliance that are added to a cluster.

\textbf{Note}

The amount of traffic that is handled by a backplane will have negligible CPU overhead.

\textbf{What gets routed over GRE tunnel for Layer 3 cluster?}

Only steered data traffic goes over the GRE tunnel. The packets are steered through the GRE tunnel to the node on the other subnet.

\textbf{How Node to Node Messaging (NNM) and heartbeat messages are exchanged, and how are they routed?}

The NNM, heartbeat messages, and cluster protocol are non-steering traffic. These messages are not sent through the tunnel, but they are routed directly.

\textbf{What are the MTU recommendations when Jumbo frames are enabled for layer 3 cluster tunneled traffic?}

The following are the layer 3 cluster recommendations of Jumbo MTU over GRE tunnel:

• The Jumbo MTU can be configured among cluster nodes across the L3 path to accommodate GRE tunnel overhead.
• The fragmentation does not happen for full sized packets which need to be steered.
• Steering of traffic continues to work even if Jumbo frames are not allowed, but with more overhead due to fragmentation.

\textbf{How the global hash key is generated and shared across all nodes?}

The rsskey for a standalone appliance is generated at the boot time. In a cluster setup, the first node holds the rsskey of the cluster. Every new node joining to the cluster will synchronize the rsskey.

\textbf{What is the need of “set rsskeytype -rsskey symmetric” command for *:*\_USIP\_on, useproxyport off, topologies?}

This is not specific to cluster, applies to a standalone appliance as well. With USIP ON, and use proxy port disabled, symmetric rsskey reduces both Core to Core (C2C) steering and node to node steering.

\section*{Troubleshooting the NetScaler cluster}

September 18, 2018
If a failure occurs in a NetScaler cluster, the first step in troubleshooting is to get information on the cluster instance and the cluster nodes by running the show cluster instance <clId> and show cluster node <nodeId> commands respectively.

If you are not able to find the issue by using the above two approaches, you can use one of the following:

- **Isolate the source of the failure.** Try bypassing the cluster to reach the server. If the attempt is successful, the problem is probably with the cluster setup.

- **Check the commands recently executed.** Run the history command to check the recent configurations performed on the cluster. You can also review the ns.conf file to verify the configurations that have been implemented.

- **Check the ns.log files.** Use the log files, available in the /var/log/ directory of each node, to identify the commands executed, status of commands, and the state changes.

- **Check the newnslog files.** Use the newnslog files, available in the /var/nslog/ directory of each node, to identify the events that have occurred on the cluster nodes. You can view multiple newnslog files as a single file, by copying the files to a single directory, and then running the following command:

```
1 nscommsg -K newnslog-node<id> -K newnslog.node<id> -d current
```

If you still cannot resolve the issue, you can try tracing the packets on the cluster or use the show techsupport -scope cluster command to send the report to the technical support team.

**Tracing the packets of a NetScaler cluster**

January 6, 2019

The NetScaler appliance operating system provides a utility called nstrace to get a dump of the packets that are received and sent out by an appliance. The utility stores the packets in trace files. You can use these files to debug problems in the flow of packets to the cluster nodes. The trace files must be viewed with the Wireshark application.

Some salient aspects of the nstrace utility are:

- Can be configured to trace packets selectively by using classic expressions and default expressions.
- Can capture the trace in multiple formats: nstrace format (.cap) and TCP dump format (.pcap).
- Can aggregate the trace files of all cluster nodes on the configuration coordinator.
- Can merge multiple trace files into a single trace file (only for .cap files).

You can use the nstrace utility from the NetScaler appliance command line or the NetScaler appliance shell.
To trace packets of a standalone appliance

Run the start nstrace command on the appliance. The command creates trace files in the /var/nstrace/<date-timestamp> directory. The trace file names are of the form ntrace<id>.cap.

You can view the status by executing the show nstrace command. You can stop tracing the packets by executing the stop nstrace command.

Note
You can also run the nstrace utility from the NetScaler appliance shell by executing the nstrace.sh file. However, it is recommended that you use the nstrace utility through the NetScaler appliance command line interface.

To trace packets of a cluster

You can trace the packets on all the cluster nodes and obtain all the trace files on the configuration coordinator.

Run the start nstrace command on the cluster IP address. The command is propagated and executed on all the cluster nodes. The trace files are stored in individual cluster nodes in the /var/nstrace/<date-timestamp> directory. The trace file names are of the form ntrace<id>_node<id>.cap.

You can use the trace files of each node to debug the nodes operations. But if you want the trace files of all cluster nodes in one location, you must run the stop nstrace command on the cluster IP address. The trace files of all the nodes are downloaded on the cluster configuration coordinator in the /var/nstrace/<date-timestamp> directory as follows:

Merge multiple trace files

You can prepare a single file from the trace files (supported only for .cap files) obtained from the cluster nodes. The single trace files gives you a cumulative view of the trace of the cluster packets. The trace entries in the single trace file are sorted based on the time the packets were received on the cluster.

To merge the trace files, at the NetScaler appliance shell, type:

```
nstracemerge.sh -srcdir <DIR> -dstdir <DIR> -filename <name> -filesize <num>
```

where,

- srcdir is the directory from which the trace files are merged. All trace files within this directory are merged into a single file.
- dstdir is the directory where the merged trace file are created.
- filename is the name of the trace file that is created.
- filesize is the size of the trace file.
Examples

Following are some examples of using the nstrace utility to filter packets.

- To trace the packets on the backplane interfaces of three nodes:
  
  **Using classic expressions:**
  
  ```
  start nstrace -filter "INTF == 0/1/1 && INTF == 1/1/1 && INTF == 2/1/1"
  ```

  **Using default expressions:**
  
  ```
  start nstrace -filter "CONNECTION.INTF.EQ("0/1/1") && CONNECTION.INTF.EQ("1/1/1") && CONNECTION.INTF.EQ("2/1/1")"
  ```

- To trace the packets from a source IP address 10.102.34.201 or from a system whose source port is greater than 80 and the service name is not “s1”:
  
  **Using classic expressions**
  
  ```
  start nstrace -filter "SOURCEIP == 10.102.34.201 || (SVCNAME != s1 && SOURCEPORT > 80)"
  ```

  **Using default expressions**
  
  ```
  start nstrace -filter "CONNECTION.SRCIP.EQ(10.102.34.201) || (CONNECTION.SVCNAME.NE("s1") && CONNECTION.SRCPORT.GT(80))"
  ```

**Note**

For more information about filters used in nstrace, see `nstrace`.

Capturing SSL Session Keys During a Trace

When you run the “start nstrace” command, you can set the new “capsslkeys” parameter to capture the SSL master keys for all SSL sessions. If you include this parameter, a file named nstrace.sslkeys is generated along with the packet trace. This file can be imported into Wireshark to decrypt the SSL traffic in the corresponding trace file.

This functionality is similar to web browsers exporting session keys that can later be imported into Wireshark for decrypting SSL traffic.

Advantages of using SSL session keys

Following are the advantages of using SSL session keys:
NetScaler 12.0

1. Generates smaller trace files that do not include the extra packets created by the SSLPLAIN mode of capturing.
2. Provides the ability to view plaintext [SP(1)] from the trace and choose whether to share the master keys file or protect sensitive data by not sharing it.

Limitations of using SSL session keys

Following are the limitations of using SSL session keys:

1. SSL sessions cannot be decrypted if initial packets of the session are not captured.
2. SSL sessions cannot be captured if the Federal Information Processing Standard (FIPS) mode is enabled.

To capture SSL session keys by using the command line interface (CLI)

At the command prompt, type the following commands to enable or disable SSL session keys in a trace file and verify trace operation.

```bash
1 > start nstrace -capsslkeys ENABLED
2 > show nstrace
3 Example
4 > start nstrace -capsslkeys ENABLED
5 > show nstrace
6   State: RUNNING   Scope: LOCAL   TraceLocation: "/var/nstrace/04May2016_17_51_54/..."
7     Nf: 24   Time: 3600   Size: 164
     Mode: TXB NEW_RX
8   Traceformat: NSCAP   PerNIC: DISABLED   FileName: 04May2016_17_51_54
9     Link: DISABLED
10   Merge: ONSTOP   Doruntimecleanup: ENABLED   TraceBuffers: 5000
11     SkipRPC: DISABLED
12     SkipLocalSSH: DISABLED   Capsslkeys: ENABLED   InMemoryTrace: DISABLED
13   Done
```

To configure SSL session keys by using the NetScaler GUI

1. Navigate to Configuration > System > Diagnostics > Technical Support Tools and click Start new Trace to start tracing encrypted packets on an appliance.
2. On the Start Trace page, select the Capture SSL Master Keys check box.
3. Click OK and Done.
To import the SSL Master Keys into Wireshark

On the Wireshark GUI, navigate to Edit > Preferences > Protocols > SSL > (Pre)-Master-Secret log filename and specify the master key files obtained from the appliance.

Troubleshooting common issues

September 18, 2018

While joining a node to the cluster, I get the following message, “ERROR: Invalid interface name/number.” What must I do to resolve this error?

This error occurs if you provided an invalid or incorrect backplane interface while using the add cluster node command to add the node. To resolve this error, verify the interface you provided while adding the node. Make sure that you have not specified the appliance's management interface as the backplane interface, and that the <nodeId> bit of the interface is the same as the node's Id. For example, if the nodeId is 3, the backplane interface must be 3/<c>/<u>.

While joining a node to the cluster, I get the following message, “ERROR: Clustering cannot be enabled, because the local node is not a member of the cluster.” What must I do to resolve this error?

This error occurs when you try to join a node without adding the node's NSIP to the cluster. To resolve this error, you must first add the node's NSIP address to the cluster by using the add cluster node command and then execute the join cluster command.

While joining a node to the cluster, I get the following message, “ERROR: Connection refused.” What must I do to resolve this error?

This error can occur due to the following reasons:

- **Connectivity problems.** The node cannot connect to the cluster IP address. Try pinging the cluster IP address from the node that you are trying to join.

- **Duplicate cluster IP address.** Check to see if the cluster IP address exists on some non-cluster node. If it does, create a new cluster IP address and try re-joining the cluster.

While joining a node to the cluster, I get the following message, “ERROR: License mismatch between the configuration coordinator and the local node.” What must I do to resolve this error?

The appliance that you are joining to the cluster must have the same licenses as the configuration coordinator. This error occurs when the licenses on the node you are joining do not match the licenses on the configuration coordinator. To resolve this error, run the following commands on both the nodes and compare the outputs.

From the command line:
- show ns hardware
- show ns license

**From the shell:**

- nsconmsg -g feature -d stats
- ls /nsconfig/license
- View the contents of the /var/log/license.log file

**What must I do when the configurations of a cluster node are not in synch with the cluster configurations?**

In most cases, the configurations are automatically synchronized between all the cluster nodes. However, if you feel that the configurations are not synchronized on a specific node, you must force the synchronization by executing the force cluster sync command from the node that you want to synchronize. For more information, see [Synchronizing Cluster Configurations](#).

When configuring a cluster node, I get the following message, “ERROR: Session is read-only; connect to the cluster IP address to modify the configuration.”

All configurations on a cluster must be done through the cluster IP address and the configurations are propagated to the other cluster nodes. All sessions established through the NSIP address of individual nodes are read-only.

**Why does the node state show “INACTIVE” when the node health shows “UP”?**

A healthy node can be in the INACTIVE state for a number of reasons. A scan of ns.log or error counters can help you determine the exact reason.

**How can I resolve the health of a node when its health shows “NOT UP”?**

Node health “Not UP” indicates that there are some issues with the node. To know the root cause, you must run the `show cluster node` command. This command displays the node properties and the reason for the node failure.

**What must I do when the health of a node shows as “NOT UP” and the reason indicates that configuration commands have failed on a node?**

This issue arises when some commands are not executed on the cluster nodes. In such cases, you must make sure that the configurations are synchronized using one of the following options:

- If some of the cluster nodes are in this state, you must perform the force cluster synchronization operation on those nodes. For more information, see [Synchronizing Cluster Configurations](#).
- If all cluster nodes are in this state, you must disable and then enable the cluster instance on all the cluster nodes.
When I run the set vserver command, I get the following message, “No such resource.” What must I do to resolve this issue?

The `set vserver` command is not supported in clustering. The `unset vserver`, `enable vserver`, `disable vserver`, and `rm vserver` commands are also not supported. However, the `show vserver` command is supported.

I cannot configure the cluster over a Telnet session. What must I do?

Over a telnet session, the cluster IP address can be accessed only in read-only mode. Therefore, you cannot configure a cluster over a telnet session.

I notice a significant time difference across the cluster nodes. What must I do to resolve this issue?

When PTP packets are dropped due to backplane switch or if the physical resources are over-committed in a virtual environment, the time will not get synchronized. To synchronize the times, you must do the following on the cluster IP address:

1. Disable PTP.
   
   `set ptp-state disable`

2. Configure Network Time Protocol (NTP) for the cluster. For more information, see *Setting up Clock Synchronization*.

What must I do, if there is no connectivity to the cluster IP address and the NSIP address of a cluster node?

If you cannot access the cluster IP address or the NSIP of a cluster node, you must access the appliance through the serial console. If the NSIP address is reachable, you can SSH to the cluster IP address from the shell by executing the following command at the shell prompt:

```
## ssh nsroot@<cluster IP address>
```

What must I do to recover a cluster node that has connectivity issues?

To recover a node that has connectivity issues:

1. Disable the cluster instance on that node (since you cannot execute commands from the NSIP of a cluster node).

2. Execute the commands required to recover the node.

3. Enable the cluster instance on that node.

Some nodes of the cluster have two default routes. How can I remove the second default route from the cluster node?

To delete the additional default route, do the following on each node that has the extra route:
1. Disable the cluster instance.
   
   ```bash
disable cluster instance <clId>
   ```

2. Remove the route.
   
   ```bash
rm route <network> <netmask> <gateway>
   ```

3. Enable the cluster instance.
   
   ```bash
enable cluster instance <clId>
   ```

**The cluster functionality gets affected when an existing cluster node comes online. What must I do to resolve this issue?**

If RPC password of node is changed from the cluster IP address when that node is out of the cluster, then, when the node comes online, there is a mismatch in rpc credentials and this could affect cluster functionality. To solve this issue, use the set ns rpcNode command to update the password on the NSIP of the node which has come online.

---

**Content Switching**

January 6, 2019

In today’s complex Web sites, you may want to present different content to different users. For example, you may want to allow users from the IP range of a customer or partner to have access to a special Web portal. You may want to present content relevant to a specific geographical area to users from that area. You may want to present content in different languages to the speakers of those languages. You may want to present content tailored to specific devices, such as smartphones, to those who use the devices. The NetScaler content switching feature enables the appliance to distribute client requests across multiple servers on the basis of specific content that you wish to present to those users.

To configure content switching, first create a basic content switching setup, and then customize it to meet your needs. This entails enabling the content switching feature, setting up load balancing for the server or servers that host each version of the content that is being switched, creating a content switching virtual server, creating policies to choose which requests are directed to which load balancing virtual server, and binding the policies to the content switching virtual server. You can then customize the setup to meet your needs by setting precedence for your policies, protecting your setup by configuring a backup virtual server, and improving the performance of your setup by redirecting requests to a cache.

**How Content Switching Works**

Content Switching enables the NetScaler appliance to direct requests sent to the same Web host to different servers with different content. For example, you can configure the appliance to direct requests
for dynamic content (such as URLs with a suffix of .asp, .dll, or .exe) to one server and requests for static content to another server. You can configure the appliance to perform content switching based on TCP/IP headers and payload.

You can also use content switching to configure the appliance to redirect requests to different servers with different content on the basis of various client attributes. Some of those client attributes are:

- **Device Type.** The appliance examines the user agent or custom HTTP header in the client request for the type of device from which the request originated. Based on the device type, it directs the request to a specific Web server. For example, if the request came from a cell phone, the request is directed to a server that is capable of serving content that the user can view on his or her cell phone. A request from a computer is directed to a different server that is capable of serving content designed for a computer screen.

- **Language.** The appliance examines the Accept-Language HTTP header in the client request and determines the language used by the client’s browser. The appliance then sends the request to a server that serves content in that language. For example, using content switching based on language, the appliance can send someone whose browser is configured to request content in French to a server with the French version of a newspaper. It can send someone else whose browser is configured to request content in English to a server with the English version.

- **Cookie.** The appliance examines the HTTP request headers for a cookie that the server set previously. If it finds the cookie, it directs requests to the appropriate server, which hosts custom content. For example, if a cookie is found that indicates that the client is a member of a customer loyalty program, the request is directed to a faster server or one with special content. If it does not find a cookie, or if the cookie indicates that the user is not a member, the request is directed to a server for the general public.

- **HTTP Method.** The appliance examines the HTTP header for the method used, and sends the client request to the right server. For example, GET requests for images can be directed to an image server, while POST requests can be directed to a faster server that handles dynamic content.

- **Layer 3/4 Data.** The appliance examines requests for the source or destination IP, source or destination port, or any other information present in the TCP or UDP headers, and directs the client request to the right server. For example, requests from source IPs that belong to customers can be directed to a custom web portal on a faster server, or one with special content.

A typical content switching deployment consists of the entities described in the following diagram.

**Figure 1. Content Switching Architecture**

A content switching configuration consists of a content switching virtual server, a load balancing setup consisting of load balancing virtual servers and services, and content switching policies. To configure content switching, you must configure a content switching virtual server and associate it with policies and load balancing virtual servers. This process creates a content group—a group of all virtual servers and policies involved in a particular content switching configuration.
Content switching can be used with HTTP, HTTPS, TCP, and UDP connections. For HTTPS, you must enable SSL Offload.

When a request reaches the content switching virtual server, the virtual server applies the associated content switching policies to that request. The priority of the policy defines the order in which the policies bound to the content switching virtual server are evaluated. If you are using default syntax policies, when you bind a policy to the content switching virtual server, you must assign a priority to that policy. If you are using NetScaler classic policies, you can assign a priority to your policies, but are not required to do so. If you assign priorities, the policies are evaluated in the order that you set. If you do not, the NetScaler appliance evaluates your policies in the order in which they were created.

In addition to configuring policy priorities, you can manipulate the order of policy evaluation by using Goto expressions and policy bank invocations. For more details about default syntax policy configuration, see “Configuring Default Syntax Policies.”

After it evaluates the policies, the content switching virtual server routes the request to the appropriate load balancing virtual server, which sends it to the appropriate service.

Content switching virtual servers can only send requests to other virtual servers. If you are using an external load balancer, you must create a load balancing virtual server for it and bind its virtual server as a service to the content switching virtual server.

**Configuring basic content switching**

November 2, 2018

Before you configure content switching, you must understand how content switching is set up and how the services and virtual servers are connected.

To configure a basic, functional content switching setup, first enable the content switching feature. Then, create at least one content group. For each content group, create a content switching virtual server to accept requests to a group of web sites that use content switching. Also create a load balancing setup, which includes a group of load balancing virtual servers to which the content switching virtual server directs requests. To specify which requests to direct to which load balancing virtual server, create at least two content switching policies, one for each type of request that is to be redirected. When you have created the virtual servers and policies, bind the policies to the content switching virtual server. You can also bind a policy to multiple content switching virtual servers. When you bind a policy, you specify the load balancing virtual server to which requests that match the policy are to be directed.

In addition to binding individual policies to a content switching virtual server, you can bind policy labels. If you create additional content groups, you can bind a policy or policy label to more than one of the content switching virtual servers.
Enabling content switching

September 19, 2018

To use the content switching feature, you must enable content switching. You can configure content switching entities even though the content switching feature is disabled. However, the entities will not work.

To enable content switching by using the command line interface

At the command prompt, type the following commands to enable content switching and verify the configuration:

- `enable ns feature CS`
- `show ns feature`

Example

```
1 > enable feature ContentSwitch
2   Done
3 > show feature
```
<table>
<thead>
<tr>
<th>Feature</th>
<th>Acronym</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>1) Web Logging</td>
<td>WL</td>
<td>OFF</td>
</tr>
<tr>
<td>2) Surge Protection</td>
<td>SP</td>
<td>ON</td>
</tr>
<tr>
<td>3) Load Balancing</td>
<td>LB</td>
<td>ON</td>
</tr>
<tr>
<td>4) Content Switching</td>
<td>CS</td>
<td>ON</td>
</tr>
<tr>
<td>22) Responder</td>
<td>RESPONDER</td>
<td>ON</td>
</tr>
<tr>
<td>23) HTML Injection</td>
<td>HTMLInjection</td>
<td>ON</td>
</tr>
<tr>
<td>24) NetScaler Push</td>
<td>push</td>
<td>OFF</td>
</tr>
</tbody>
</table>

To enable content switching by using the configuration utility

Navigate to System > Settings and, in the Modes and Features group, select Configure Basic Features, and select Content Switching.

Creating content switching virtual servers

September 19, 2018

You can add, modify, and remove content switching virtual servers. The state of a virtual server is DOWN when you create it, because the load balancing virtual server is not yet bound to it.

To create a virtual server by using the command line interface

At the command prompt, type:

```
add cs vserver \<name\> \<protocol\> \<IPAddress\> \<port\>
```

Example

```
 1 add cs vserver Vserver-CS-1 HTTP 10.102.29.161 80
```

To add a content switching virtual server by using the configuration utility

Navigate to Traffic Management > Content Switching > Virtual Servers, and add a virtual server.
Configuring a load balancing setup for content switching

September 19, 2018

The content switching virtual server redirects all requests to a load balancing virtual server. You must create one load balancing virtual server for each version of the content that is being switched. This is true even when your setup has only one server for each version of the content, and you are therefore not doing any load balancing with those servers. You can also configure actual load balancing with multiple load-balanced servers that mirror each version of the content. In either scenario, the content switching virtual server needs to have a specific load balancing virtual server assigned to each version of the content that is being switched.

The load balancing virtual server then forwards the request to a service. If it has only one service bound to it, it selects that service. If it has multiple services bound to it, it uses its configured load balancing method to select a service for the request, and forwards that request to the service that it selected.

To configure a basic load balancing setup, you need to perform the following tasks:

- Create load balancing virtual servers
- Create services
- Bind services to the load balancing virtual server

For more information on load balancing, see Load Balancing. For detailed instructions on setting up a basic load balancing configuration, see Set up basic load balancing.

Configuring a content switching action

September 19, 2018

You specify the target load balancing virtual server for a content switching policy when binding the policy to the content switching virtual server. Consequently, you have to configure one policy for each load balancing virtual server to which to direct traffic.

However, if your content switching policy uses a default syntax rule, you can configure an action for the policy. In the action, you can specify the name of the target load balancing virtual server, or you can configure a request-based expression that, at run time, computes the name of the load balancing virtual server to which to send the request. The action expression must be specified in the default syntax.

The expression option can drastically reduce the size of your content switching configuration, because you need only one policy per content switching virtual server. Content switching policies that use an action can also be bound to multiple content switching virtual servers, because the target load balancing virtual server is no longer specified in the content switching policy. The ability to bind a single
policy to multiple content switching virtual servers helps to further reduce the size of your content switching configuration.

After you create an action, you create a content switching policy and specify the action in the policy, so that the action is performed when that policy matches a request.

Note
You can also, for a content switching policy that uses a default syntax rule, specify the target load balancing virtual server when binding the policy to a content switching virtual server, instead of using a separate action. For domain-based policies, URL-based policies, and rule based policies that use classic expressions, an action is not available. So, for these types of policies, you specify the name of the target load balancing virtual server when binding the policy to a content switching virtual server. For more information, see “Binding Policies to a Content Switching Virtual Server.”

Configuring an Action that Specifies the Name of the Target Load Balancing Virtual Server

If you choose to specify the name of the target load balancing virtual server in a content switching action, you need as many content switching policies as you have target load balancing virtual servers. Content switching decisions, in this case, are based on the rule in the content switching policy, and the action merely specifies the target load balancing virtual server. When a request matches the policy, the request is forwarded to the specified load balancing virtual server.

To create and verify a content switching action that specifies the name of the target load balancing virtual server, by using the command line interface

At the command prompt, type:

- `add cs action <name> -targetLBVserver <string> [-comment <string>]`
- `show cs action <name>`

Example

```
1 > add cs action mycsaction -targetLBVserver mylbvserver -comment "Forwards requests to mylbvserver."
Done
2 > show cs action mycsaction
3 Name: mycsaction
4 Target LB Vserver: mylbvserver
5 Hits: 0
```
To configure a content switching action that specifies the name of the target load balancing virtual server, by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Actions.
2. Configure a content switching action, and specify the name of the target load balancing virtual server.

Configuring an Action that Specifies an Expression for Selecting the Target at Run Time

If you choose to configure a request-based expression that can dynamically compute the name of the target load balancing virtual server, you need to configure only one content switching policy to select the appropriate virtual server. The rule for the policy can be a simple TRUE (the policy matches all requests) because, in this case, content switching decisions are based on the expression in the action. By configuring an expression in an action, you can drastically reduce the size of your content switching configuration.

If you choose to configure a request-based expression for computing the name of the target load balancing virtual server at run time, you must carefully consider how to name the load balancing virtual servers in the configuration. You must be able to derive their names by using the request-based policy expression in the action.

For example, if you are switching requests on the basis of the URL suffix (file extension of the requested resource), when naming the load balancing virtual servers, you can follow the convention of appending the URL suffix to a predetermined string, such as mylb_. For example, load balancing virtual servers for HTML pages and PDF files could be named mylb_html and mylb_pdf, respectively. In that case, the rule that you can use in the content switching action, to select the appropriate load balancing virtual server, is “mylb_“+HTTP.REQ.URL.SUFFIX. If the content switching virtual server receives a request for an HTML page, the expression returns mylb_html, and the request is switched to virtual server mylb_html.
To create a content switching action that specifies an expression, by using the command line interface

At the command line, type the following commands to create a content switching action that specifies an expression and verify the configuration:

```
1 - add cs action \<name\> -targetVserverExpr \<expression\> \[-comment \<string\>]\]
2 - show cs action \<name\>
```

Example

```
1 > add cs action mycsaction1 -targetvserverExpr ""mylb_" + HTTP.REQ.URL.SUFFIX"
2   Done
3 > show cs action mycsaction1
4   Name: mycsaction1
5   Target Vserver Expression: ""mylb_" + HTTP.REQ.URL.SUFFIX
6   Target LB Vserver: No_Target
7   ...
8   Done
9 >
```

To configure a content switching action that specifies an expression by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Actions.
2. Configure a content switching action, and specify an expression that will dynamically compute the name of the target load balancing virtual server.

Configuring content switching policies

November 2, 2018

A content switching policy defines a type of request that is to be directed to a load balancing virtual server. These policies are applied in the order of the priorities assigned to them or (if you are using NetScaler appliance classic policies and do not assign priorities when binding them) in the order in which the policies were created.

The policies can be:
**Domain-based policies.** The NetScaler appliance compares the domain of an incoming URL with the domains specified in the policies. The appliance then returns the most appropriate content. Domain-based policies must be classic policies; default syntax policies are not supported for this type of content switching policy.

**URL-based policies.** The appliance compares an incoming URL with the URLs specified in the policies. The appliance then returns the most appropriate URL-based content, which is usually the longest matching configured URL. URL-based policies must be classic policies; default syntax policies are not supported for this type of content switching policy.

**Rule-based policies.** The appliance compares incoming data to expressions specified in the policies. You create rule-based policies by using either a classic expression or a default syntax expression. Both classic and default syntax policies are supported for rule-based content switching policies.

**Note**

A rule based policy can be configured with an optional action. A policy with an action can be bound to multiple virtual servers or policy labels.

If you set a priority when binding your policies to the content switching virtual server, the policies are evaluated in order of priority. If you do not set specific priorities when binding your policies, the policies are evaluated in the order in which they were created.

For information about NetScaler appliance classic policies and expressions, see “Configuring Classic Policies and Expressions.” For information about Default Syntax policies, see “Configuring Default Syntax Expressions.”

**To create a content switching policy by using the command line interface**

At the command prompt, type one of the following commands:

- add cs policy <policyName> -domain <domain>
- add cs policy <policyName> -url <URLValue>
- add cs policy <policyName> -rule <RULEValue>
- add cs policy <policyName> -rule <RULEValue> -action <actionName>

**Example:**

```
1 add cs policy Policy-CS-1 -url "http://example.com"
2 add cs policy Policy-CS-1 -domain "example.com"
4
5 add cs policy Policy-CS-1 -rule "CLIENT.IPSRC.SUBNET(24).EQ (10.217.84.0)"
6
```
To rename a content switching policy by using the command line interface

At the command prompt, type:

```
rename cs policy <policyName> <newName>
```

**Example:**

```
rename cs policy myCSPolicy myCSPolicy1
```

To rename a content switching policy by using the configuration utility

Navigate to **Traffic Management > Content Switching > Policies**, select a policy and, in the Action list, select Rename.

To create a content switching policy by using the configuration utility

Navigate to **Traffic Management > Content Switching > Policies**, and configure a content switching policy.

Configuring content switching policy labels

September 19, 2018

A policy label is a user-defined bind point to which policies are bound. When a policy label is invoked, all the policies bound to it are evaluated in the order of the priority that you assigned to them. A policy label can include one or more policies, each of which can be assigned its own result. A match on one policy in the policy label can result in proceeding to the next policy, invoking a different policy label or appropriate resource, or an immediate end to policy evaluation and return of control to the policy that invoked the policy label. You can create policy labels for default syntax policies only.

For information about policy labels, see the “Creating Policy Labels.”

A content switching policy label consists of a name, a label type, and a list of policies bound to the policy label. The policy label type specifies the protocol that was assigned to the policies bound to the label. It must match the service type of the content switching virtual server to which the policy
that invokes the policy label is bound. For example, you can bind TCP Payload policies to a policy label of type TCP only. Binding TCP Payload policies to a policy label of type HTTP is not supported.

Each policy in a content switching policy label is associated with either a target (which is equivalent to the action that is associated with other types of policies, such as rewrite and responder policies) or a gotoPriorityExpression option and/or an invoke option. That is, for a given policy in a content switching policy label, you can specify a target, or you can set the gotoPriorityExpression option and/or the invoke option. Additionally, if multiple policies evaluate to true, only the target of the last policy that evaluates to true is considered.

You can use either the NetScaler appliance CLI or the configuration utility to configure content switching policy labels. In the NetScaler appliance CLI, you first create a policy label by using the add cs policylabel command. Then, you bind policies to the policy label, one policy at a time, by using the bind cs policylabel command. In the NetScaler appliance GUI, you perform both tasks in a single dialog box.

**To create a content switching policy label by using the command line interface**

At the command prompt, type:

`add cs policylabel <labelName> <cspolicylabelTypetype>`

**Example**

```
add cs policylabel testpollab http
```

**To rename a content switching policy label by using the command line interface**

At the command prompt, type:

`rename cs policylabel <labelName> <newName>`

**Example**

```
rename cs policylabel oldPolicyLabelName newPolicyLabelName
```

**To rename a content switching policy label by using the configuration utility**

Navigate to Traffic Management > Content Switching > Policy Labels, select a policy label and, in the Action list, select Rename.
To bind a policy to a content switching policy label by using the command line interface

At the command prompt, type the following commands to bind a policy to a policy label and verify the configuration:

```
bind cs policylabel <labelName> <policyName> <priority> [-targetVserver <string>] [-gotoPriorityExpression <expression>] [-invoke <labeltype> <labelName>] 
```

- show cs policylabel <labelName>

Example

```
1 bind cs policylabel testpollab test_Pol 100 -targetVserver LBVIP
2 show cs policylabel testpollab
3   Label Name: testpollab
4   Label Type: HTTP
5   Number of bound policies: 1
6   Number of times invoked: 0
7   Policy Name: test_Pol
8   Priority: 100
9   Target Virtual Server: LBVIP
```

Note: If a policy is configure with an action, the target virtual server (targetVserver), go to priority expression (gotoPriorityExpression), and invoke (invoke) parameters are not required. If a policy is not configure with an action, you need to configure at least one of the following parameters: targetVserver, gotoPriorityExpression, and invoke.

To unbind a policy from a policy label by using the command line interface

At the command prompt, type the following commands to unbind a policy from a policy label and verify the configuration:

- unbind cs policylabel <labelName> <policyName>
- show cs policylabel <labelName>
Example

```
1  unbind cs policylabel testpollab test_Pol
2  show cs policylabel testpollab
3     Label Name: testpollab
4     Label Type: HTTP
5     Number of bound policies: 0
6     Number of times invoked: 0
```

To remove a policy label by using the command line interface

At the command prompt, type:

```
rm cs policylabel <labelName>
```

To manage a content switching policy label by using the configuration utility

Navigate to Traffic Management > Content Switching > Policy Labels, configure a policy label, bind policies to the label, and optionally specify a priority, gotoPriority expression, and an invoke option.

Binding policies to a content switching virtual server

September 19, 2018

After you create your content switching virtual server and policies, you bind each policy to the content switching virtual server. When binding the policy to the content switching virtual server, you specify the target load balancing virtual server.

Note

If your content switching policy uses a default syntax rule, you can configure a content switching action for the policy. If you configure an action, you must specify the target load balancing virtual server when you are configuring the action, not when you are binding the policy to the content switching virtual server. For more information about configuring a content switching action, see Configuring a Content Switching Action.

To bind a policy to a content switching virtual server and select a target load balancing virtual server by using the command line interface

At the command prompt, type:
**NetScaler 12.0**

```bash
bind cs vserver <name> [-lbvserver <string> ] -targetLBVServer <string> ] -policyname <string> ] -priority <positive_integer> ] ] [-gotoPriorityExpression <expression>] ] [-type ( REQUEST | RESPONSE )]] [-invoke ( <labelType> <labelName> )]
```

**Example:**

```bash
1 bind cs vserver csw-vip2 -policyname csw-ape-policy2 -priority 14 -gotoPriorityExpression NEXT
2
3 bind cs vserver csw-vip3 -policyname rewrite-policy1 -priority 17 -gotoPriorityExpression
4 'q.header("a").count' -flowtype REQUEST -invoke policylabel label1
```

**Note**

The parameters, target load balancing virtual server (targetVSserver), go to priority expression (gotoPriorityExpression), and invoke method (invoke) cannot be used if a policy has an action.

**To bind a policy to a content switching virtual server and select a target load balancing virtual server by using the configuration utility**

Navigate to **Traffic Management > Content Switching > Virtual Servers**, open a virtual server and, in the **Content Switching Policy Binding section**, bind a policy to the virtual server, and specify a target load balancing virtual server.

**Configuring policy based logging for content switching**

September 19, 2018

You can configure policy based logging for a content switching policy. Policy based logging enables you to specify a format for log messages. The contents of the log message are defined by using a default syntax expression in the content switching policy. When the content switching action specified in the policy is performed, the NetScaler appliance constructs the log message from the expression and writes the message to the log file. Policy based logging is particularly useful if you want to test and troubleshoot a configuration in which content switching actions identify the target load balancing virtual server at run time.
NetScaler 12.0

Note

If multiple policies bound to a given virtual server evaluate to TRUE and are configured with an audit message action, the NetScaler appliance does not perform all the audit message actions. It performs only the audit message action that is configured for the policy whose content switching action is performed.

To configure policy based logging for a content switching policy, you must first configure an audit message action. For more information about configuring an audit message action, see Configuring the NetScaler appliance for Audit Logging. After you configure the audit message action, you specify the action in a content switching policy.

To configure policy based logging for a content switching policy by using the command line interface

At the command line, type the following commands to configure policy based logging for a content switching policy and verify the configuration:

- set cs policy <policyName> -logAction <string>
- show cs policy <policyName>

Example

```
> set cs policy cspoll -logAction csLogAction
Done
> show cs policy cspoll

Policy: cspoll  Rule: TRUE  Action: csact1
LogAction: csLogAction
Hits: 0
1) CS Vserver: csvs1
    Priority: 10
Done
> 
```

To configure policy based logging for a content switching policy by using the configuration utility

Navigate to Traffic Management > Content Switching > Policies, open a policy and, in the Log Action list, select a log action for the policy.
NetScaler 12.0

Verifying the configuration

November 2, 2018

To verify that your content switching configuration is correct, you need to view the content switching entities. To verify proper operation after your content switching configuration has been deployed, you can view the statistics that are generated as the servers are accessed.

Viewing the Properties of Content Switching Virtual Servers

You can view the properties of content switching virtual servers that you have configured on the NetScaler appliance. You can use the information to verify whether the virtual server is correctly configured and, if necessary, to troubleshoot. In addition to details such as name, IP address, and port, you can view the various policies bound to a virtual server, and its traffic-management settings.

The content switching policies are displayed in the order of their priority. If more than one policy has the same priority, they are shown in the order in which they are bound to the virtual server.

Note

If you have configured the content switching virtual server to forward traffic to a load balancing virtual server, you can also view the content switching policies by viewing the properties of the load balancing virtual server.

To view the properties of content switching virtual servers by using the command line interface

To list basic properties of all content switching virtual servers in your configuration, or detailed properties of a specific content switching virtual server, at the command prompt, type one of the following commands:

- `show cs vserver`
- `show cs vserver \<name\>`

Example

```
1  show cs vserver Vserver-CS-1
2  Vserver-CS-1 (10.102.29.161:80) - HTTP Type: CONTENT
3  State: UP
4  Last state change was at Thu Jun 30 10:48:59 2011
5  Time since last state change: 6 days, 00:03:00.760
6  Client Idle Timeout: 180 sec
7  Down state flush: ENABLED
```
NetScaler 12.0

Disable Primary Vserver On Down : DISABLED
Appflow logging : DISABLED
Port Rewrite : DISABLED
State Update : DISABLED
Default: Content Precedence: RULE
Vserver IP and Port insertion: OFF
Case Sensitivity: ON
Push: DISABLED Push VServer:
Push Label Rule: none

1) Policy : __ESNS_PREBODY_POLICY Priority:0
2) Policy : __ESNS_POSTBODY_POLICY Priority:0

1) Compression Policy Name: __ESNS_CMP_POLICY Priority: 2147483647
GotoPriority Expression: END
Flowtype: REQUEST

2) Rewrite Policy Name: __ESNS_REWRITE_POLICY Priority: 2147483647
GotoPriority Expression: END
Flowtype: REQUEST

3) Cache Policy Name: dfbx Priority: 10
GotoPriority Expression: END
Flowtype: REQUEST

4) Responder Policy Name: __ESNS RESPONDER_POLICY Priority: 2147483647
GotoPriority Expression: END

2) Policy: plain Target: LBVIP1 Priority: 90 Hits: 0
3) Policy: DispOrderTest2 Target: KerbAuthLBVS Priority: 91 Hits: 0
4) Policy: test_Pol Target: LBVIP1 Priority: 92 Hits: 0
5) Policy: PolicyNameTesting Target: LBVIP1 Priority: 100 Hits: 0
Done

show cs vserver

1) Vserver-CS-1 (10.102.29.161:80) - HTTP Type: CONTENT
State: UP
...
Viewing Content Switching Policies

You can view the properties of the content switching policies that you defined, such as the name, domain, and URL or expression, and use the information to find any mistakes in the configuration, or to troubleshoot if something is not working as it should.

To view the properties of content switching policies by using the command line interface

To list either basic properties of all content switching policies in your configuration or detailed properties of a specific content switching policy, at the command prompt, type one of the following commands:

- `show cs policy`
- `show cs policy <PolicyName>`

Example

```
1  show cs policy
2
3  show cs policy Policy-CS-1
```

To view the properties of content switching policies by using the configuration utility

Navigate to Traffic Management > Content Switching > Policies, select a policy and, in the Action list, select Show Bindings.
Viewing a Content Switching Virtual Server Configuration by Using the Visualizer

The Content Switching Visualizer is a tool that you can use to view a content switching configuration in graphical format. You can use the visualizer to view the following configuration items:

- A summary of the load balancing virtual servers to which the content switching virtual server is bound.
- All services and service groups that are bound to the load balancing virtual server and all monitors that are bound to the services.
- The configuration details of any displayed element.
- Any policies bound to the content switching virtual server. These policies need not be content switching policies. Many types of policies, such as Rewrite policies, can be bound to a content switching virtual server.

After you configure the various elements in a content switching and load balancing setup, you can export the entire configuration to an application template file.

**Note**

The Visualizer requires a graphical interface, so it is available only through the configuration utility.

To view a content switching configuration by using the Visualizer in the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, select the virtual server that you want to view, and then click Visualizer.
3. In the Content Switching Visualizer window, you can adjust the viewable area as follows:
   - Click the Zoom In and Zoom Out icons to increase or decrease the viewable area.
   - Click the Save Image icon to save the graph as an image file.
   - In the Search in text field, begin typing the name of the item you are looking for. When you have typed enough characters to identify the item, its location is highlighted. To restrict the search, click the drop-down menu and select the type of element that you want to search for.
4. To view configuration details for entities that are bound to this virtual server, you can do the following:
   - To view policies that are bound to the virtual server, in the tool bar at the top of the dialog box select one or more feature-specific policy icons. If policy labels are configured, they appear in the main view area.
   - To view the configuration details for a bound service or service group, click the icon for the service, click the Related Tasks tab, and then click Show Member Services.
   - To view the configuration details for a monitor, click the icon for the monitor, click the Related Tasks tab, and then click View Monitor.
5. To view detailed statistics for any virtual server in the content switching configuration, click the virtual server for which you want to view statistics, then click the Related Tasks tab, and then click Statistics.

6. To view a comparative list of the parameters whose values either differ or are not defined across service containers for a load balancing virtual server, click the icon for a container, click the Related Tasks tab, and then click Service Attributes Diff.

7. To view monitor binding details for the services in a container, in the Service Attributes Diff dialog box, in the Group column for the container, click Details. This comparative list helps you determine which service container has the configuration you want to apply to all the service containers.

8. To view the number of requests received per second at a given point in time by the virtual servers in the configuration, and the number of hits per second at a given point in time for rewrite, responder, and cache policies, click Show Stats. The statistical information is displayed on the respective nodes in the Visualizer. This information is not updated in real time. It has to be refreshed manually. To refresh the information, click Refresh Stats.

   **Note:** This option is available only on NetScaler appliance nCore builds.

9. To copy configuration details for an element to a document or spreadsheet, click the icon for that element, click Related Tasks, click Copy Properties, and then paste the information into a document.

10. To export the entire configuration that is displayed in the Visualizer to an application template file, click the icon for the content switching virtual server, click Related Tasks, and then click Create Template. When creating the application template, you can configure variables in some policy expressions and actions. For more information about creating the application template file and configuring variables for a template, see [AppExpert](#).

### Customizing the basic content switching configuration

**December 5, 2018**

After you configure a basic content switching setup, you might need to customize it to meet your requirements. If your web servers are UNIX-based and rely on case sensitive pathnames, you can configure case sensitivity for policy evaluation. You can also set precedence for evaluation of the content switching policies that you configured. You can configure HTTP and SSL content switching virtual servers to listen on multiple ports instead of creating separate virtual servers. If you want to configure content switching for a specific a virtual LAN, you can configure a content switching virtual server with a listen policy.
Configuring case sensitivity for policy evaluation

You can configure the content switching virtual server to treat URLs as case sensitive in URL-based policies. When case sensitivity is configured, the NetScaler appliance considers case when evaluating policies. For example, if case sensitivity is off, the URLs /a/1.htm and /A/1.HTM are treated as identical. If case sensitivity is on, those URLs are treated as separate and can be switched to different targets.

To configure case sensitivity by using the command line interface

At the command prompt, type:

```
set cs vserver \<name\> -caseSensitive (ON|OFF)
```

Example:

```
set cs vserver Vserver-CS-1 -caseSensitive ON
```

To configure case sensitivity by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Traffic Settings, and then select Case Sensitive.

Setting the precedence for policy evaluation

Precedence refers to the order in which policies that are bound to a virtual server are evaluated. You do not normally have to configure precedence: the default precedence works correctly in many cases. If you want to make sure that one policy or set of policies is applied first, however, and another policy or set of policies is applied only if the first set does not match a request, you can configure either URL-based precedence or rule-based precedence.

Precedence with URL-Based policies

If there are multiple matching URLs for the incoming request, the precedence (priority) for URL-based policies is:

1. Domain and exact URL
2. Domain, prefix, and suffix
3. Domain and suffix
4. Domain and prefix
5. Domain only
6. Exact URL
7. Prefix and suffix
8. Suffix only
9. Prefix only
10. Default

If you configure precedence based on URL, the request URL is compared to the configured URLs. If none of the configured URLs match the request URL, then rule-based policies are checked. If the request URL does not match any rule-based policies, or if the content group selected for the request is down, then the request is processed as follows:

- If you configure a default group for the content switching virtual server, then the request is forwarded to the default group.
- If the configured default group is down or if no default group is configured, then an “HTTP 404 Not Found” error message is sent to the client.

**Note**

You should configure URL-based precedence if the content type (for example, images) is the same for all clients. However, if different types of content must be served based on client attributes (such as Accept-Language), you must use rule-based precedence.

**Precedence with Rule-Based policies**

If you configure precedence based on rules, which is the default setting, the request is tested on the basis of the rule-based policies you have configured. If the request does not match any rule-based policies, or if the content group selected for the incoming request is down, the request is processed in the following manner:

- If a default group is configured for the content switching virtual server, the request is forwarded to the default group.
- If the configured default group is down or if no default group is configured, an “HTTP 404 Not Found” error message is sent to the client.

**To configure precedence by using the command line interface**

At the command prompt, type:

```bash
set cs vserver \<name\> -precedence ( RULE | URL )
```

**Example:**

```bash
set cs vserver Vserver-CS-1 -precedence RULE
```
To configure precedence by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Traffic Settings, and then specify Precedence.

Support for multiple ports for HTTP and SSL type content switching virtual servers

You can configure the NetScaler appliance so that HTTP and SSL content switching virtual servers listen on multiple ports, without having to configure separate virtual servers. This feature is especially useful if you want to base a content switching decision on a part of the URL and other L7 parameters. Instead of configuring multiple virtual servers with the same IP address and different ports, you can configure one IP address and specify the port as *. As a result, the configuration size is also reduced.

To configure an HTTP or SSL content switching virtual server to listen on multiple ports by using the command line

At the command prompt, type:

add cs vserver <name> <serviceType> <IPAddress> Port *

Example

```
1 > add cs vserver cs1 HTTP 10.102.92.215 *
2       Done
3 > sh cs vserver cs1
4       cs1 (10.102.92.215:*) - HTTP     Type: CONTENT
5       State: UP
6       Last state change was at Tue May 20 01:15:49 2014
7       Time since last state change: 0 days, 00:00:03.270
8       Client Idle Timeout: 180 sec
9       Down state flush: ENABLED
10      Disable Primary Vserver On Down : DISABLED
11      Appflow logging: ENABLED
12      Port Rewrite : DISABLED
13      State Update: DISABLED
14      Default:   Content Precedence: RULE
15      Vserver IP and Port insertion: OFF
16      L2Conn: OFF     Case Sensitivity: ON
17      Authentication: OFF
18      401 Based Authentication: OFF
19      Push: DISABLED   Push VServer:
20      Push Label Rule: none
```
To configure an HTTP or SSL content switching virtual server to listen on multiple ports by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, and create a virtual server of type HTTP or SSL.
2. Use an asterisk (*) to specify the port.

Configuring per-VLAN Wildcarded virtual servers

If you want to configure content switching for traffic on a specific virtual local area network (VLAN), you can create a wildcarded virtual server with a listen policy that restricts it to processing traffic only on the specified VLAN.

To configure a wildcarded virtual server that listens to a specific VLAN by using the command line interface

At the command prompt, type:

```
• add cs vserver <name> <serviceType> IPAddress * Port * -listenpolicy <expression> [-listenpriority <positive_integer>]
```

Example:

```
1 add cs vserver Vserver-CS-vlan1 ANY * *
2 -listenpolicy "CLIENT.VLAN.ID.EQ(2)" -listenpriority 10
```

To configure a wildcarded virtual server that listens to a specific VLAN by using the configuration utility

Navigate to Traffic Management > Content Switching > Virtual Servers, and configure a virtual server. Specify a listen policy that restricts it to processing traffic only on the specified VLAN.

After you have created this virtual server, you bind it to one or more services as described in Binding Services to the Virtual Server.
Configuring the Microsoft SQL server version setting

You can specify the version of Microsoft® SQL Server® for a content switching virtual server that is of type MSSQL. The version setting is recommended if you expect some clients to not be running the same version as your Microsoft SQL Server product. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server’s version.

To set the Microsoft SQL Server version parameter by using the command line interface

At the command prompt, type the following commands to set the Microsoft SQL Server version parameter for a content switching virtual server and verify the configuration:

- `set cs vserver \<name\> -mssqlServerVersion \<mssqlServerVersion\>`
- `show cs vserver \<name\>`

Example

```
1 > set cs vserver myMSSQLcsvip -mssqlServerVersion 2008R2 Done > show cs vserver myMSSQLcsvip myMSSQLcsvip (192.0.2.13:1433) - MSSQL Type: CONTENT State: UP . . . . . . MSsql Server Version: 2008R2 . . . . . . . Done >
```

To set the Microsoft SQL server version parameter by using the configuration utility

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, configure a virtual server and specify the protocol as MYSQL.
2. In **Advanced Settings**, select MySQL, and specify the Server Version.

Content switching for diameter protocol

January 6, 2019

For Diameter-protocol traffic, you can configure the NetScaler appliance (or virtual appliance) to act as a relay agent that load balances and forwards a packet to the appropriate destination on the basis of the message content (AVP value in the message). Since the appliance does not perform any application-level processing, it provides relaying services for all diameter applications as specified by the configured content switching policies. Therefore, the appliance advertises the Relay Application
ID in the capability exchange answer (CEA) message when the client establishes a diameter connection. You must configure a content switching virtual server, load balancing virtual servers, and services to represent the diameter nodes. When a request reaches the content switching virtual server, the virtual server applies the content switching policies associated with that type of request. After evaluating the policies, the content switching virtual server routes the request to the appropriate load balancing virtual server, which sends it to the appropriate service.

A diameter interface provides a connection between the different diameter nodes. The following sample deployment uses Cx and Rx interfaces. A Cx interface provides a connection between a CSCF and an HSS. An Rx interface provides a connection between a CSCF and a PCRF. All the messages reach the NetScaler appliance. Depending on whether the message is for a Cx or an Rx interface, and on the content switching policies defined, the NetScaler appliance selects an appropriate load balancing server pool.

**Sample Configuration**

1. For each entity, create a service, a load balancing server, and bind the service to the virtual server.

   1. add service svc_pcrf[1-3] 1.1.1.1[1-3] DIAMETER 3868
   2. add service svc_hss[1-3] 1.1.1.2[1-3] DIAMETER 3868
   3. add lb vserver vs_rx 1.1.1.2[1-3] DIAMETER -persistenceType DIAMETER -persistavpno 263
   4. add lb vserver vs_cx 1.1.1.1[1-3] DIAMETER -persistenceType DIAMETER -persistavpno 263
   5. bind lb vserver vs_rx svc_pcrf[1-3]
   6. bind lb vserver vs_cx svc_hss[1-3]

2. Create a content switching virtual server and two actions (one for each load balancing virtual server). Create two content switching policies and bind these policies to the content switching virtual server, specifying a priority for each policy.

   1. add cs vserver cs_diameter DIAMETER 10.1.1.10 3868
   2. add cs action cx_action -targetLBvserver vs_cx
   3. add cs action rx_action -targetLBvserver vs_rx
   4. add cs policy cx_policy -rule "DIAMETER.REQ.AUTH_APPLICATION_ID.EQ (16777216)" -action cx_action
   5. add cs policy rx_policy -rule "DIAMETER.REQ.AUTH_APPLICATION_ID.EQ (16777236)" -action rx_action
   6. bind cs vserver cs_diameter -policyName rx_policy -priority 100
   7. bind cs vserver cs_diameter -policyName cx_policy -priority 110
Protecting the content switching setup against failure

November 2, 2018

Content switching may fail when the content switching virtual server goes DOWN or fails to handle excessive traffic, or for other reasons. To reduce the chances of failure, you can take the following measures to protect the content switching setup against failure:

Configuring a Backup Virtual Server

If the primary content switching virtual server is marked DOWN or DISABLED, the NetScaler appliance can direct requests to a backup content switching virtual server. It can also send a notification message to the client regarding the site outage or maintenance. The backup content switching virtual server is a proxy and is transparent to the client.

When configuring the backup virtual server, you can specify the configuration parameter Disable Primary When Down to ensure that, when the primary virtual server comes back up, it remains the secondary until you manually force it to take over as the primary. This is useful if you want to ensure that any updates to the database on the server for the backup are preserved, enabling you to synchronize the databases before restoring the primary virtual server.

You can configure a backup content switching virtual server when you create a content switching virtual server or when you change the optional parameters of an existing content switching virtual server. You can also configure a backup content switching virtual server for an existing backup content switching virtual server, thus creating cascaded backup content switching virtual servers. The maximum depth of cascaded backup content switching virtual servers is 10. The appliance searches for a backup content switching virtual server that is up and accesses that content switching virtual server to deliver the content.

Note: If a content switching virtual server is configured with both a backup content switching virtual server and a redirect URL, the backup content switching virtual server takes precedence over the redirect URL. The redirect is used when the primary and backup virtual servers are down.

To set up a backup content switching virtual server by using the command line interface

At the command prompt, type:

```
set cs vserver <name> -backupVserver <string> -disablePrimaryOnDown (ON |OFF)
```
Example

```
set cs vserver Vserver-CS-1 -backupVserver Vserver-CS-2 -disablePrimaryOnDown ON
```

To set up a backup content switching virtual server by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, configure a virtual server and specify the protocol as MYSQL.
2. In Advanced Settings, select Protection, and specify a Backup Virtual Server.

Diverting Excess Traffic to a Backup Virtual Server

The spillover option diverts new connections arriving at a content switching virtual server to a backup content switching virtual server when the number of connections to the content switching virtual server exceeds the configured threshold value. The threshold value is dynamically calculated, or you can set the value. The number of established connections (in case of TCP) at the virtual server is compared with the threshold value. When the number of connections reaches the threshold, new connections are diverted to the backup content switching virtual server.

If the backup content switching virtual servers reach the configured threshold and are unable to take the load, the primary content switching virtual server diverts all requests to the redirect URL. If a redirect URL is not configured on the primary content switching virtual server, subsequent requests are dropped.

To configure a content switching virtual server to divert new connections to a backup virtual server by using the command line interface

At the command prompt, type:

```
set cs vserver \<name\> -soMethod \<methodType\> -soThreshold \<thresholdValue\> -soPersistence \<persistenceValue\> -soPersistenceTimeout \<timeoutValue\>
```

Example

```
set cs vserver Vserver-CS-1 -soMethod Connection -soThreshold 1000 -soPersistence enabled -soPersistenceTimeout 2
```
To set a content switching virtual server to divert new connections to a backup virtual server by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, configure a virtual server and specify the protocol as MYSQL.
2. In Advanced Settings, select Protection, and configure spillover.

Configuring a Redirection URL

You can configure a redirect URL to communicate the status of the NetScaler appliance in the event that a content switching virtual server of type HTTP or HTTPS is DOWN or DISABLED. This URL can be local or remote.

Redirect URLs can be absolute URLs or relative URLs. If the configured redirect URL contains an absolute URL, the HTTP redirect is sent to the configured location, regardless of the URL specified in the incoming HTTP request. If the configured redirect URL contains only the domain name (relative URL), the HTTP redirect is sent to a location after appending the incoming URL to the domain configured in the redirect URL.

Citrix recommends using an absolute URL. That is, a URL ending in /, for example www.example.com/ instead of a relative URL. A relative URL redirection might result in the vulnerability scanner reporting a false positive.

Note: If a content switching virtual server is configured with both a backup virtual server and a redirect URL, the backup virtual server takes precedence over the redirect URL. A redirect URL is used when the primary and backup virtual servers are down.

When redirection is configured and the content switching virtual server is unavailable, the appliance issues an HTTP 302 redirect to the user’s browser.

To configure a redirect URL for when the content switching virtual server is unavailable by using the command line interface

At the command prompt, type:

```
set cs vserver <name> -redirectURL <URLValue>
```

Example

```
set cs vserver Vserver-CS-1 -redirectURL http://www.newdomain.com/mysite/maintenance
```
To configure a redirect URL for when the content switching virtual server is unavailable by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, configure a virtual server and specify the protocol as MYSQL.
2. In Advanced Settings, select Protection, and specify a Redirect URL.

Configuring the State Update Option

The content switching feature enables the distribution of client requests across multiple servers on the basis of the specific content presented to the users. For efficient content switching, the content switching virtual server distributes the traffic to the load balancing virtual servers according to the content type, and the load balancing virtual servers distribute the traffic to the physical servers according to the specified load balancing method.

For smooth traffic management, it is important for the content switching virtual server to know the status of the load balancing virtual servers. The state update option helps to mark the content switching virtual server DOWN if the load balancing virtual server bound to it is marked DOWN. A load balancing virtual server is marked DOWN if all the physical servers bound to it are marked DOWN.

When State Update is disabled:

The status of the content switching virtual server is marked as UP. It remains UP even if there is no bound load balancing virtual server that is UP.

When State Update is enabled:

When you add a new content switching virtual server, initially, its status is shown as DOWN. When you bind a load balancing virtual server whose status is UP, the status of the content switching virtual server becomes UP.

If more than one load balancing virtual server is bound and if one of them is specified as the default, the status of the content switching virtual server reflects the status of the default load balancing virtual server.

If more than one load balancing virtual server is bound without any of them being specified as the default, the status of the content switching virtual server is marked UP only if all the bound load balancing virtual servers are UP.

To configure the state update option by using the command line interface

At the command prompt, type:
NetScaler 12.0

Example

```bash
add cs vserver csw_vserver HTTP 10.18.250.154 80 -stateupdate ENABLED -cltTimeout 180
```

To configure the state update option by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, configure a virtual server and specify the protocol as MYSQL.
2. In Advanced Settings, select Traffic Settings, and then select State Update.

Flushing the Surge Queue

When a physical server receives a surge of requests, it becomes slow to respond to the clients that are currently connected to it, which leaves users dissatisfied and disgruntled. Often, the overload also causes clients to receive error pages. To avoid such overloads, the NetScaler appliance provides features such as surge protection, which controls the rate at which new connections to a service can be established.

The appliance does connection multiplexing between clients and physical servers. When it receives a client request to access a service on a server, the appliance looks for an already established connection to the server that is free. If it finds a free connection, it uses that connection to establish a virtual link between the client and the server. If it does not find an existing free connection, the appliance establishes a new connection with the server, and establishes a virtual link between client and the server. However, if the appliance cannot establish a new connection with the server, it sends the client request to a surge queue. If all the physical servers bound to the load balancing or content switching virtual server reach the upper limit on client connections (max client value, surge protection threshold or maximum capacity of the service), the appliance cannot establish a connection with any server. The surge protection feature uses the surge queue to regulate the speed at which connections are opened with the physical servers. The appliance maintains a different surge queue for each service bound to the virtual server.

The length of a surge queue increases whenever a request comes for which the appliance cannot establish a connection, and the length decreases whenever a request in the queue gets sent to the server or a request gets timed out and is removed from the queue.
If the surge queue for a service or service group becomes too long, you may want to flush it. You can flush the surge queue of a specific service or service group, or of all the services and service groups bound to a load balancing virtual server. Flushing a surge queue does not affect the existing connections. Only the requests present in the surge queue get deleted. For those requests, the client has to make a fresh request.

You can also flush the surge queue of a content switching virtual server. If a content switching virtual server forwards some requests to a particular load balancing virtual server, and the load balancing virtual server also receives some other requests, when you flush the surge queue of the content switching virtual server, only the requests received from this content switching virtual server are flushed; the other requests in the surge queue of the load balancing virtual server are not flushed.

Note: You cannot flush the surge queues of cache redirection, authentication, VPN or GSLB virtual servers or GSLB services.

Do not use the Surge Protection feature if Use Source IP (USIP) is enabled.

To flush a surge queue by using the command line interface

The flush ns surgeQ command works in the following manner:

- You can specify the name of a service, service group, or virtual server whose surge queue has to be flushed.
- If you specify a name while executing the command, surge queue of the specified entity will be flushed. If more than one entity has the same name, the appliance flushes surge queues of all those entities.
- If you specify the name of a service group, and a server name and port while executing the command, the appliance flushes the surge queue of only the specified service group member.
- You cannot directly specify a service group member (<serverName> and <port>) without specifying the name of the service group (<name>) and you cannot specify <port> without a <serverName>. Specify the <serverName> and <port> if you want to flush the surge queue for a specific service group member.
- If you execute the command without specifying any names, the appliance flushes the surge queues of all the entities present on the appliance.
- If a service group member is identified with a server name, you must specify the server name in this command; you cannot specify its IP address.

At the command prompt, type:

```
flush ns surgeQ [-name <name>] [-serverName <serverName> <port>].
```

Examples
To flush a surge queue by using the configuration utility

Navigate to Traffic Management > Content Switching > Virtual Servers, select a virtual server and, in the Action list, select Flush Surge Queue.

Managing a content switching setup

January 6, 2019

After a content switching setup is configured, it may require periodic changes. When operating systems or software are updated, or hardware wears out and is replaced, you may need to take down your setup. Load on your setup may increase, requiring additional resources. You may also modify the configuration to improve performance.

These tasks may require unbinding policies from the content switching virtual server, or disabling or removing content switching virtual servers. After you have made changes to your setup, you may need to re-enable servers and rebind policies. You might also want to rename your virtual servers.

Unbinding Policies from the Content Switching Virtual Server

When you unbind a content switching policy from its virtual server, the virtual server no longer includes that policy when determining where to direct requests.

To unbind a policy from a content switching virtual server by using the command line interface

At the command prompt, type:

```
unbind cs vserver <name> -policyname <string>
```

Example:

```
1 unbind cs vserver Vserver-CS-1 -policyname Policy-CS-1
```
To unbind a policy from a content switching virtual server by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, and open the virtual server.
2. Click in the Policies section, select the policy, and click Unbind.

Removing Content Switching Virtual Servers

You normally remove a content switching virtual server only when you no longer require the virtual server. When you remove a content switching virtual server, the NetScaler appliance first unbinds all policies from the content switching virtual server, and then removes it.

To remove a content switching virtual server by using the command line interface

At the command prompt, type:

```
rm cs vserver <name>
```

Example:

```
1 rm cs vserver Vserver-CS-1
```

Disabling and Re-Enabling Content Switching Virtual Servers

Content switching virtual servers are enabled by default when you create them. You can disable a content switching virtual server for maintenance. If you disable the content switching virtual server, the state of the content switching virtual server changes to Out of Service. While out of service, the content switching virtual server does not respond to requests.

To disable or re-enable a virtual server by using the command line interface

At the command prompt, type one of the following commands:

- `disable cs vserver <name>`
- `enable cs vserver <name>`
Example:

```bash
1  disable cs vserver Vserver-CS-1
2
3  enable cs vserver Vserver-CS-1
```

To disable or re-enable a virtual server by using the configuration utility

Navigate to Traffic Management > Content Switching > Virtual Servers, select a virtual server and, in the Action list, select Enable or Disable.

Renaming Content Switching Virtual Servers

You can rename a content switching virtual server without unbinding it. The new name is propagated automatically to all affected parts of the NetScaler appliance configuration.

To rename a virtual server by using the command line interface

At the command prompt, type:

```
rename cs vserver <name> <newName>
```

Example:

```bash
1  rename cs vserver Vserver-CS-1 Vserver-CS-2
```

To rename a virtual server by using the configuration utility

Navigate to Traffic Management > Content Switching > Virtual Servers, select a virtual server and, in the Action list, select Rename.

Managing Content Switching Policies

You can modify an existing policy by configuring rules or changing the URL of the policy, or you can remove a policy. You can also rename an existing advanced content switching policy. You can create different policies based on the URL. URL-based policies can be of different types, as described in the following table.

For more information, see Examples of URL-Based Policies pdf.
Note
You can configure rule-based content switching using classical policy expressions or advanced policy expressions.

To modify, remove, or rename a policy by using the command line interface

At the command prompt, type one of the following commands:

- `set cs policy <policyName> [-domain <domainValue>] [-rule <ruleValue>] [-url <URLValue>]`
- `rm cs policy <policyName>`
- `rename cs policy <policyName> <newPolicyName>`

Example:

1. `set cs policy Policy-CS-1 -domain "www.domainxyz.com"`
2. `set cs policy Policy-CS-1 -rule "CLIENT.IP.SRC.SUBNET(22).EQ (10.100.148.0)"
3. `set cs policy Policy-CS-2 -rule "SYS.TIME.BETWEEN(GMT 2010 Jun,GMT 2010 Jul)"
4. `set cs policy Policy-CS-1 -url /sports/*`
5. `rename cs policy Policy-CS-1 Policy-CS-11`
6. `rm cs policy Policy-CS-1`

To modify, remove, or rename a policy by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Policies.
2. Select the policy, and either delete it, edit it or, in the Action list, click Rename.

Managing client connections

November 2, 2018

To ensure efficient management of client connections, you can configure the content switching virtual servers on the NetScaler appliance.
- Configuring the ICMP Response. You can configure the NetScaler appliance to send ICMP responses to PING requests according to your settings. On the IP address corresponding to the virtual server, set the ICMP RESPONSE to VSVR_CNTRLD, and on the virtual server, set the ICMP VSERVER RESPONSE.

The following settings can be made on a virtual server:
- When you set ICMP VSERVER RESPONSE to PASSIVE on all virtual servers, the NetScaler appliance always responds.
- When you set ICMP VSERVER RESPONSE to ACTIVE on all virtual servers, the NetScaler appliance responds even if one virtual server is UP.
- When you set ICMP VSERVER RESPONSE to ACTIVE on some and PASSIVE on others, NetScaler appliance responds even if one virtual server set to ACTIVE is UP.

Redirecting Client Requests to a Cache

The NetScaler appliance cache redirection feature redirects HTTP requests to a cache. You can significantly reduce the burden of responding to HTTP requests and improve your Web site performance through proper implementation of the cache redirection feature.

A cache stores frequently requested HTTP content. When you configure cache redirection on a virtual server, the NetScaler appliance sends cacheable HTTP requests to the cache and non-cacheable HTTP requests to the origin Web server. For more information on cache redirection, see “Cache Redirection.”

To configure cache redirection on a virtual server by using the command line interface

At the command prompt, type:

```
set cs vserver <name> -cacheable <Value>
```

Example

```
set cs vserver Vserver-CS-1 -cacheable yes
```

To configure cache redirection on a virtual server by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Traffic Settings, and select Cacheable.
Enabling Delayed Cleanup of Virtual Server Connections

Under certain conditions, you can configure the down state flush setting to terminate existing connections when a service or a virtual server is marked DOWN. Terminating existing connections frees resources and in certain cases speeds recovery of overloaded load balancing setups.

To configure the down state flush setting on a virtual server by using the command line interface

At the command prompt, type:

```
set cs vserver <name> -downStateFlush <Value>
```

Example

```
set cs vserver Vserver-CS-1 -downStateFlush enabled
```

To configure the down state flush setting on a virtual server by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Traffic Settings, and then select Down State Flush.

Rewriting Ports and Protocols for Redirection

Virtual servers and the services that are bound to them may use different ports. When a service responds to an HTTP connection with a redirect, you may need to configure the NetScaler appliance to modify the port and the protocol to ensure that the redirection goes through successfully. You do this by enabling and configuring the redirectPortRewrite setting.

To configure HTTP redirection on a virtual server by using the command line interface

At the command prompt, type:

```
set cs vserver <name> -redirectPortRewrite <Value>
```

Example

```
set cs vserver Vserver-CS-1 -redirectPortRewrite enabled
```
To configure HTTP redirection on a virtual server by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Traffic Settings and select Rewrite.

Inserting the IP Address and Port of a Virtual Server in the Request Header

If you have multiple virtual servers that communicate with different applications on the same service, you must configure the NetScaler appliance to add the IP address and port number of the appropriate virtual server to the HTTP requests that are sent to that service. This setting allows applications running on the service to identify the virtual server that sent the request.

If the primary virtual server is down and the backup virtual server is up, the configuration settings of the backup virtual server are added to the client requests. If you want the same header tag to be added, regardless of whether the requests are from the primary virtual server or backup virtual server, you must configure the required header tag on both virtual servers.

Note: This option is not supported for wildcarded virtual servers or dummy virtual servers.

To insert the IP address and port of the virtual server in the client requests by using the command line interface

At the command prompt, type:

```
set cs vserver <name> -insertVserverIPPort <vServerIPPort>
```

Example

```
set cs vserver Vserver-CS-1 -insertVserverIPPort 10.201.25.136:80
```

To insert the IP address and port of the virtual server in the client requests by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Traffic Settings and, in the Virtual Server IP Port Insertion list, select VIPADDR or V6TOV4MAPPING, and specify a port header in Virtual Server IP Port Insertion Value.
Setting a Time-out Value for Idle Client Connections

You can configure a virtual server to terminate any idle client connections after a configured time-out period elapses. When you configure this setting, the NetScaler appliance waits for the time you specify and, if the client is idle after that time, it closes the client connection.

To set a time-out value for idle client connections by using the command line interface

At the command prompt, type:

```
set cs vserver <name> -cltTimeout <Value>
```

Example

```
set cs vserver Vserver-CS-1 -cltTimeout 100
```

To set a time-out value for idle client connections by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Traffic Settings, and specify a Client Idle Time-Out value.

Identifying Connections with the 4-tuple and Layer 2 Connection Parameters

You can now set the L2Conn option for a content switching virtual server. With the L2Conn option set, connections to the content switching virtual server are identified by the combination of the 4-tuple (<source IP>:<source port>::<destination IP>:<destination port>) and Layer 2 connection parameters. The Layer 2 connection parameters are the MAC address, VLAN ID, and channel ID.

To set the L2Conn option for a content switching virtual server by using the command line interface

At the command line, type the following commands to configure the L2Conn parameter for a content switching virtual server and verify the configuration:

```
set cs vserver <name> -l2Conn (ON OFF)
```

```
show cs vserver <name>
```
Example

```
1  > set cs vserver mycsvserver -l2Conn ON
2  Done
3  > show cs vserver mycsvserver
4    mycsvserver (192.0.2.56:80) - HTTP   Type: CONTENT
5    State: UP
6      ...
7      ...
8    L2Conn: ON Case Sensitivity: ON
9      ...
10     ...
11  Done
12  >
```

To set the L2Conn option for a content switching virtual server by using the configuration utility

1. Navigate to Traffic Management > Content Switching > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Traffic Settings, and then select Layer 2 Parameters.

Troubleshooting

September 19, 2018

If the content switching feature does not work as expected after you have configured it, you can use some common tools to access NetScaler appliance resources and diagnose the problem.

Resources for Troubleshooting Content Switching

For best results, use the following resources to troubleshoot a content switching issue on a NetScaler appliance:

- Configuration file
- Relevant newnslog file
- Trace files
- Network topology diagram for the network setup of the customer
- Citrix documentation, such as release notes, Knowledge Center articles, and eDocs

In addition to the above resources, the following tools expedite troubleshooting:

- The iehttpheaders or a similar utility
- The Wireshark application customized for the NetScaler appliance trace files
• An SSH utility for command line access
• A HyperTerminal utility to access the console

Troubleshooting Content Switching Issues

The most common content switching issues involve the content switching feature not working at all, or working only intermittently, and Service Unavailable responses.

• Issue
  The content switching feature is not functioning.

  Resolution
  Check the configuration as follows:
  – Verify that the appliance is licensed for content switching.
  – Verify that the feature is enabled.
  – From the configuration file, verify that valid content switching policies are correctly bound to the load balancing virtual servers.

• Issue
  Client receives a 503 - Service Unavailable response.

  Resolution
  – Verify the URL and policy bindings. The client receives the 503 response when none of the policies you have configured is evaluated and no default load balancing virtual server is defined and bound to the content switching virtual server.
  – From the configuration, verify the policies and URL being accessed by the client.
  – Verify that for every type of request the respective policy is evaluated. If the policy is not evaluated, check the policy expression and update it if necessary.
  – Verify the URL and HTTP request and response headers. To do so, record an HTTPHeader trace and, if necessary, record the packet traces on the appliance and the client.

• Issue
  Intermittently, the content switching feature is not working as expected.

  Resolution
  – Study the network topology diagram, if available, of the setup to understand the various devices installed between the client and the server(s).
  – Verify the configuration and policy bindings. Make sure that the URL in the policy expression matches to the one in the client request.
- Verify that appropriate priorities are assigned to the policies. An incorrect precedence or priority assigned to a policy can cause a problem.
- Run the following commands to verify the bindings and the values of the policy hit counters in the output of the commands:
  
  ```shell
  show cs vserver <CS VServer>
  show cs policy <CS Policy>
  stat cs vserver <CS VServer>
  ```
- Using iehttpheaders or a similar utility, determine whether the HTTP headers for the requests or responses provide any pointers to the issue.
- Check the release notes and Knowledge Center articles.
- If the issue is still not resolved, contact Citrix Technical Support with appropriate data for further investigation.

DataStream

January 6, 2019

The NetScaler DataStream feature provides an intelligent mechanism for request switching at the database layer by distributing requests based on the SQL query being sent.

When deployed in front of database servers, a NetScaler appliance ensures optimal distribution of traffic from the application servers and Web servers. Administrators can segment traffic according to information in the SQL query and on the basis of database names, usernames, character sets, and packet size.

You can either configure load balancing to switch requests based on load balancing algorithms or elaborate the switching criteria by configuring content switching to make a decision based on an SQL query parameters. You can further configure monitors to track the state of database servers.

Note: NetScaler DataStream is supported only for MySQL and MS SQL databases. For information about the supported protocol version, character sets, special queries, and transactions, see DataStream Reference.

How DataStream Works

In DataStream, the ADC appliance is placed in-line between the application and/or Web servers and the database servers. On the appliance, the database servers are represented by services.

A typical DataStream deployment consists of the entities described in the following diagram.
As shown in this figure, a DataStream configuration can consist of an optional content switching virtual server (CS), a load balancing setup consisting of load balancing virtual servers (LB1 and LB2) and services (Svc1, Svc2, Svc3, and Svc4), and content switching policies (optional).

The clients (application or Web servers) send requests to the IP address of a content switching virtual server (CS) configured on the NetScaler appliance. The appliance, then, authenticates the clients using the database user credentials configured on the appliance. The content switching virtual server (CS) applies the associated content switching policies to the requests. After evaluating the policies, the content switching virtual server (CS) routes the requests to the appropriate load balancing virtual server (LB1 or LB2), which, then, distributes the requests to the appropriate database servers (represented by services on the appliance) based on the load balancing algorithm. The NetScaler appliance uses the same database user credentials to authenticate the connection with the database server.

If a content switching virtual server is not configured on the appliance, the clients (application or Web servers) send their requests to the IP address of a load balancing virtual server configured on the appliance. The NetScaler appliance authenticates the client by using the database user credentials configured on the appliance, and then uses the same credentials to authenticate the connection with the database server. The load balancing virtual server distributes the requests to the database servers according to the load balancing algorithm. The most effective load balancing algorithm for database switching is the least connection method.

DataStream uses connection multiplexing to enable multiple client-side requests to be made over the same server-side connection. The following connection properties are considered:

- User name
- Database name
- Packet size
- Character set

### Configuring Database Users

December 21, 2018

In databases, a connection is always stateful, which means that as soon as a connection is established, it must be authenticated.

You need to configure your database user name and password on the NetScaler appliance. For example, if you have a user John configured on the database, you need to configure the user John on the ADC too. When you add the database user names and passwords on the ADC, these are added to the nsconfig file.
Note

Names are case sensitive.

The ADC uses these user credentials to authenticate the clients, and then authenticate the server connections with the database servers.

To add a database user by using the command line interface

At the command prompt, type

```
add db user <username> - password <password>
```

Example:

```
1 add db user nsdbuser -password dd260427edf
```

To add a database user by using the configuration utility

Navigate to System > User Administration > Database Users, and configure a database user.

If you have changed the password of the database user on the database server, you must reset the password of the corresponding user configured on the ADC appliance.

To reset the password of a database user by using the command line interface

At the command prompt, type

```
set db user <username> -password <password>
```

Example:

```
1 set db user nsdbuser -password dd260538abs
```

To reset the password of database users by using the configuration utility

Navigate to System > User Administration > Database Users, select a user, and enter new values for the password.

If a database user no longer exists on the database server, you can remove the user from the ADC appliance. However, if the user continues to exist on the database server and you remove the user from the ADC appliance, any request from the client with this user name does not get authenticated, and therefore, does not get routed to the database server.
**To remove a database user by using the command line interface**

At the command prompt, type

```
1  rm db user <username>
```

**Example:**

```
1  rm db user nsdbuser
```

**To remove a database user by using the configuration utility**

Navigate to **System > User Administration > Database Users**, select a user, and click **Delete**.

**Configuring a Database Profile**

December 21, 2018

A database profile is a named collection of parameters that is configured once but applied to multiple virtual servers that require those particular parameter settings. After creating a database profile, you bind it to load balancing or content switching virtual servers. You can create as many profiles as you need.

**To create a database profile by using the command line interface**

At the command line, type the following commands to create a database profile and verify the configuration:

```
1  add db dbProfile <name> [-interpretQuery ( YES | NO )] [-stickiness ( YES | NO )] [-kcdAccount <string>]
2
3  show db dbProfile
```

**Example:**

```
1  > add dbProfile myDBProfile -interpretQuery YES -stickiness YES -
    kcdAccount mykcdacct
2  Done
3  > show dbProfile myDBProfile
4    Name: myDBProfile
5    Interpret Query: YES
```
To create a database profile by using the configuration utility

Navigate to System > Profiles and, on the Database Profiles tab, configure a database profile.

To bind a database profile to a load balancing or content switching virtual server by using the command line interface

At the command line, type:

```
1 set (lb | cs) vserver <name> -dbProfileName <string>
```

To bind a database profile to a load balancing or content switching virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers or Traffic Management > Content Switching > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Profiles and, in the DB Profile list, select a profile to bind to the virtual server. To create a new profile, click plus (+).

Configuring Load Balancing for DataStream

January 14, 2019

Before configuring a load balancing setup, you must enable the load balancing feature. Then, begin by creating at least one service for each database server in the load balancing group. With the services configured, you are ready to create a load balancing virtual server and bind the services to the virtual server.

Note:

For databases, the load balancing can only occur on homogenous database servers (database servers that contain the exact same databases). For a configuration that contains unique databases on different servers, you must use content switching. If some of your database
servers host identical content, you can use load balancing on those servers only. You can then use content switching policies to send requests to the load balancing virtual server that manages load balancing for those databases.

The NetScaler appliance currently stores the database name and login information during the database session. When a query is made to the database, it uses that information to connect to the specific database server.

Parameter values specific to DataStream

- **Protocol**
  

- **Port**
  
  Port on which the virtual server listens for client connections. Use port 3306 for MySQL database servers.

- **Method**
  
  It is recommended that you use the Least Connection method for better load balancing and lower server load. However, other methods, such as Round Robin, Least Response Time, Source IP Hash, Source IP Destination IP Hash, Least Bandwidth, Least Packets, and Source IP Source Port Hash, are also supported.

  Note: URL Hash method is not supported for DataStream.

- **MS SQL Server Version**
  
  If you are using the Microsoft SQL Server, and you expect some clients to not be running the same version as your Microsoft SQL Server product, set the Server Version parameter for the load balancing virtual server. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server’s version. For more information about setting the Server Version parameter, see [Configuring the MySQL and Microsoft SQL server version setting](#).

- **MySQL Server Version**
If you are using the MySQL Server, and you expect some clients to not be running the same version as your MySQL Server product, set the Server Version parameter for the load balancing virtual server. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server’s version. For more information about setting the Server Version parameter, see Configuring the MySQL and Microsoft SQL server version setting.

**Configuring Content Switching for DataStream**

January 14, 2019

You can segment traffic according to information in the SQL query, on the basis of database names, user names, character sets, and packet size.

You can configure content switching policies with default syntax expressions to switch content based on connection properties, such as user name and database name, command parameters, and the SQL query to select the server.

The default syntax expressions evaluate traffic associated with MYSQL and MS SQL database servers. You can use request-based expressions in default syntax policies to make request switching decisions at the content switching virtual server bind point and response-based expressions (expressions that begin with MYSQL.RES) to evaluate server responses to user-configured health monitors.

For information about default syntax expressions, see Default Syntax Expressions: DataStream.

**Note:**

For databases, the load balancing can only occur on homogenous database servers (database servers that contain the exact same databases). For a configuration that contains unique databases on different servers, you must use content switching. If some of your database servers host identical content, you can use load balancing on those servers only. You can then use content switching policies to send requests to the load balancing virtual server that manages load balancing for those databases.

The NetScaler appliance currently stores the database name and login information during the database session. When a query is made to the database, it uses that information to connect to the specific database server.

**Parameter values specific to DataStream**

- Protocol
Use the MySQL protocol type for MySQL databases and MSSQL protocol type for MS SQL databases while configuring virtual servers and services. The MySQL and TDS protocols are used by the clients to communicate with the respective database servers by using SQL queries. For information about the MySQL protocol, see http://dev.mysql.com/doc/internals/en/client-server-protocol.html. For information about the TDS protocol, see http://msdn.microsoft.com/en-us/library/dd304523(v=prot.13).aspx.

- Port

Port on which the virtual server listens for client connections. Use port 3306 for MySQL database servers.

- MS SQL Server Version

If you are using Microsoft SQL Server, and you expect some clients to not be running the same version as your Microsoft SQL Server product, set the Server Version parameter for the content switching virtual server. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server’s version. For more information about setting the Server Version parameter, see Configuring the Microsoft SQL Server Version Setting.

**Configuring Monitors for DataStream**

December 21, 2018

To track the state of each load balanced database server in real time, you need to bind a monitor to each service. The monitor is configured to test the service by sending periodic probes to the service. (This is sometimes referred to as performing a health check.) If the monitor receives a timely response to its probes, it marks the service as UP. If it does not receive a timely response to the designated number of probes, it marks the service as DOWN.

For DataStream, you need to use the built-in monitors, MYSQL-ECV and MSSQL-ECV. This monitor provides the ability to send an SQL request and parse the response for a string.

Before configuring monitors for DataStream, you must add database user credentials to your NetScaler appliance. For information about configuring monitors, see Configure monitors in a load balancing setup.

When you create a monitor, a TCP connection is established with the database server, and the connection is authenticated by using the user name provided while creating the monitor. You can then run
an SQL query to the database server and evaluate the server response to check whether it matches
the configured rule.

The following examples are for MYSQL servers.

**Examples:**

In the following example, the value of the error message is evaluated to determine the state of the
server.

```
1 add lb monitor lb_mon1 MYSQL-ECV -sqlQuery "select * from
table2;" -evalrule "mysql.res.error.message.contains("Invalid
User")" -database "NS" -userName "user1"
```

In the following example, the number of rows in the response is evaluated to determine the state of
the server.

```
1 add lb monitor lb_mon4 MYSQL-ECV -sqlQuery "select * from
table4;" -evalrule "mysql.res.atleast_rows_count(7)" -database "NS" -
userName "user2"
```

In the following example, the value of a particular column is evaluated to determine the state of the
server.

```
1 add lb monitor lb_mon3 MYSQL-ECV
2 -sqlQuery "select * from ABC;" -evalrule "mysql.res.row(1).double_elem
(2) == 345.12"
3 -database "NS" -userName "user3"
```

The following examples are for MSSQL servers.

**Examples:**

In the following example, the value of the error message is evaluated to determine the state of the
server.

```
1 add lb monitor lb_mon1 MSSQL-ECV -sqlQuery "select * from
table2;" -evalrule "mssql.res.error.message.contains("Invalid
User")" -database "NS" -userName "user1"
```

In the following example, the number of rows in the response is evaluated to determine the state of
the server.

```
1 add lb monitor lb_mon4 MSSQL-ECV -sqlQuery "select * from
table4;" -evalrule "mssql.res.atleast_rows_count(7)" -database "NS" -
userName "user2"
```
In the following example, the value of a particular column is evaluated to determine the state of the server.

```plaintext
1  add lb monitor lb_mon3 MSSQL-ECV
2  -sqlQuery "select * from ABC;" -evalrule "mssql.res.row(1).double_elem(2) == 345.12"
3  -database "NS" -userName "user3"
```

**Use Case 1: Configuring DataStream for a Master/Slave Database Architecture**

January 6, 2019

A commonly used deployment scenario is the master/slave database architecture where the master database replicates all information to the slave databases.

For master/slave database architecture, you may want all WRITE requests to be sent to the master database and all READ requests to the slave databases.

The following figure shows the entities and the values of the parameters you need to configure on the appliance.

Figure 1. DataStream Entity Model for Master/Slave Database Setup

In this example scenario, a service (Svc_mysql_1) is created to represent the master database and is bound to a load balancing virtual server (Lb_vsr_mysql_master). Three more services (Svc_mysql_2, Svc_mysql_3, and Svc_mysql_4) are created to represent the three slave databases, and they are bound to another load balancing virtual server (Lb_vsr_mysql_slave).

A content switching virtual server (Cs_vsr_mysql_1) is configured with associated policies to send all WRITE requests to the load balancing virtual server, Lb_vsr_mysql_master, and all READ requests to the load balancing virtual server, Lb_vsr_mysql_slave.

When a request reaches the content switching virtual server, the virtual server applies the associated content switching policies to that request. After evaluating the policies, the content switching virtual server routes the request to the appropriate load balancing virtual server, which sends it to the appropriate service.

The following table lists the names and values of the entities and the policy configured on the NetScaler appliance.

<table>
<thead>
<tr>
<th>Entity Type</th>
<th>Name</th>
<th>IP Address</th>
<th>Protocol</th>
<th>Port</th>
<th>Expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>Services</td>
<td>Svc_mysql_1</td>
<td>10.102.29.5</td>
<td>MYSQL</td>
<td>3306</td>
<td>NA</td>
</tr>
</tbody>

Table 1. Entity and Policy Names and Values

To configure DataStream for a master/slave database setup by using the command line interface

At the command prompt, type

```bash
1 add service Svc_mysql_1 10.102.29.5 mysql 3306
2 add service Svc_mysql_2 10.102.29.6 mysql 3306
3 add service Svc_mysql_3 10.102.29.7 mysql 3306
4 add service Svc_mysql_4 10.102.29.8 mysql 3306
5 add lb vserver Lb_vsr_mysql_master mysql 10.102.29.201 3306
6 add lb vserver Lb_vsr_mysql_slave mysql 10.102.29.202 3306
7 bind lb vserver Lb_vsr_mysql_master svc_mysql_1
8 bind lb vserver Lb_vsr_mysql_slave svc_mysql_2
```

Use Case 2: Configuring the Token Method of Load Balancing for DataStream

January 6, 2019

You can configure the token method of load balancing for DataStream to base the selection of database servers on the value of the token extracted from the client (application or web server) requests. These tokens are defined by using SQL expressions. For subsequent requests with the same token, the Citrix ADC appliance sends the requests to the same database server that handled the initial request. Requests with the same token are sent to the same database server until the maximum connection limit is reached or the session entry has aged out.

You can use the following sample SQL expressions to define tokens:

<table>
<thead>
<tr>
<th>MySQL</th>
<th>MS SQL</th>
</tr>
</thead>
<tbody>
<tr>
<td>MYSQL.REQ.QUERY.TEXT</td>
<td>MSSQL.REQ.QUERY.TEXT</td>
</tr>
<tr>
<td>MYSQL.REQ.QUERY.TEXT(n)</td>
<td>MSSQL.REQ.QUERY.TEXT(n)</td>
</tr>
<tr>
<td>MYSQL.REQ.QUERY.COMMAND</td>
<td>MSSQL.REQ.QUERY.COMMAND</td>
</tr>
<tr>
<td>MYSQL.CLIENT.USER</td>
<td>MSSQL.CLIENT.USER</td>
</tr>
<tr>
<td>MYSQL.CLIENT.DATABASE</td>
<td>MSSQL.CLIENT.DATABASE</td>
</tr>
<tr>
<td>MYSQL.CLIENT.CAPABILITIES</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how the Citrix ADC DataStream feature works when you configure the
token method of load balancing.

Figure 1. How DataStream Works with the Token Method of Load Balancing

In this example, the token is the name of the database. A request with token books is sent to Database Server1 and a request with token music is sent to Database Server2. All subsequent requests with token books are sent to Database Server1 and requests with token music are sent to Database Server2. This configuration provides pseudo persistence with the database servers.

To configure this example by using the command line interface

At the command prompt, type:

```
1  add service Service1 192.0.2.9 MYSQL 3306
2  add service Service2 192.0.2.11 MYSQL 3306
3  add lb vserver token_lb_vserver MYSQL 192.0.2.15 3306 -lbmethod token -
4  rule MYSQL.CLIENT.DATABASE
5  bind lb vserver token_lb_vserver Service1
6  bind lb vserver token_lb_vserver Service2
```

To configure this example by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, configure a virtual server and specify the protocol as MYSQL.
2. Click in the Service section, and configure two services specifying the protocol as MYSQL. Bind these services to the virtual server.
3. In Advanced Settings, click Method and, in the Load Balancing Method list, select TOKEN and specify the expression as MYSQL.CLIENT.DATABASE.

Use Case 3: Logging MSSQL Transactions in Transparent Mode

December 21, 2018

You can configure the Citrix ADC appliance to operate transparently between MSSQL clients and servers, and to only log or analyze details of all client-server transactions. Transparent mode is designed so that the Citrix ADC appliance only forwards MSSQL requests to the server, and then relays the server’s responses to the clients. As the requests and responses pass through the appliance,
the appliance logs information gathered from them, as specified by the audit logging or AppFlow configuration, or collects statistics, as specified by the Action Analytics configuration. You do not have to add database users to the appliance.

When operating in transparent mode, the Citrix ADC appliance does not perform load balancing, content switching, or connection multiplexing for the requests. However, it responds to a client’s pre-login packet on behalf of the server so that it can prevent encryption from being agreed upon during the pre-login handshake. The login packet and subsequent packets are forwarded to the server.

Summary of Configuration Tasks

For logging or analyzing MSSQL requests in transparent mode, you have to do the following:

- Configure the Citrix ADC appliance as the default gateway for both clients and servers.
- Do one of the following on the Citrix ADC appliance:
  - If you can configure the use source IP address (USIP) option globally, create a load balancing virtual server with a wildcard IP address and the port number on which the MSSQL servers listen for requests (a port-specific wildcard virtual server). Then, enable the USIP option globally. If you configure a port-specific wildcard virtual server, you do not have to create MSSQL services on the appliance. The appliance discovers the services on the basis of the destination IP address in the client requests.
  - If you do not want to configure the USIP option globally, create MSSQL services with the USIP option enabled on each of them. If you configure services, you do not have to create a port-specific wildcard virtual server.
- Configure audit logging, AppFlow, or Action Analytics to log or collect statistics about the requests. If you configure a virtual server, you can bind your policies either to the virtual server or to the global bind point. If you do not configure a virtual server, you can bind your policies to only the global bind point.

Configuring Transparent Mode by Using a Wildcard Virtual Server

You can configure transparent mode by configuring a port-specific wildcard virtual server and enabling Use Source IP (USIP) mode globally. When a client sends its default gateway (the Citrix ADC appliance) a request with the IP address of an MSSQL server in the destination IP address header, the appliance checks whether the destination IP address is available. If the IP address is available, the virtual server forwards the request to the server. Otherwise, it drops the request.
To create a wildcard virtual server by using the command line

At the command prompt, type the following commands to create a wildcard virtual server and verify the configuration:

```bash
1 add lb vserver <name> <serviceType> <IPAddress> <port>
2 show lb vserver <name>
```

Example:

```
1 > add lb vserver wildcardLbVs MSSQL * 1433
2 Done
3 > show lb vserver wildcardLbVs
4 wildcardLbVs (*:1433) - MSSQL  Type: ADDRESS
5     State: UP
6...
8 Done
9 >
```

To create a wildcard virtual server by using the GUI

Navigate to Traffic Management > Load Balancing > Virtual Servers, and create a virtual server. Specify MSSQL as the protocol and * as the IP address.

To enable Use Source IP (USIP) mode globally by using the CLI

At the command prompt, type the following commands to enable USIP mode globally and verify the configuration:

```bash
1 enable ns mode USIP
2 show ns mode
```

Example:

```
1 > enable ns mode USIP
2 Done
3 > show ns mode
4
5 | Mode | Acronym | Status |
6 | Mode | USIP   | Status |
7 Done
9 >
```
To enable USIP mode globally by using the GUI

1. Navigate to System > Settings and, in Modes and Features, select Configure Modes.
2. Select Use Source IP.

Configuring Transparent Mode by Using MSSQL Services

You can configure transparent mode by configuring MSSQL services and enabling USIP on each service. When a client sends its default gateway (the Citrix ADC appliance) a request with the IP address of an MSSQL server in the destination IP address header, the appliance forwards the request to the destination server.

To create an MSSQL service and enable USIP mode on the service by using the command line interface

At the command prompt, type the following commands to create an MSSQL service, with USIP enabled, and verify the configuration:

```plaintext
1  add service <name> (<IP> | <serverName>) <serviceType> <port> -usip YES
2
3  show service <name>
```

Example

```plaintext
1  > add service myDBservice 192.0.2.0 MSSQL 1433 -usip YES
2  Done
3  > show service myDBservice
4     myDBservice (192.0.2.0:1433) - MSSQL
5     State: UP
6     . . .
7     Use Source IP: YES    Use Proxy Port: YES
```

© 1999-2018 Citrix Systems, Inc. All rights reserved.
To create an MSSQL service, with USIP enabled, by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services, and configure a service.
2. Specify protocol as MSSQL and, in Settings, select Use Source IP.

Use Case 4: Database Specific Load Balancing

January 6, 2019

A database server farm should be load balanced not only on the basis of the states of the servers, but also on the basis of the availability of the database on each server. A service might be up, and a load balancing device might show it as being in the UP state, but the requested database might be unavailable on that service. If a query is forwarded to a service on which the database is unavailable, the request is not served. Therefore, a load balancing device must be aware of the availability of a database on each service and, when making a load balancing decision, it must consider only those services on which the database is available.

As an example, consider that database servers server1, server2, and server3 host databases mydatabase1 and mydatabase2. If mydatabase1 becomes unavailable on server2, the load balancing device must be aware of that change in state, and it must load balance requests for mydatabase1 across only server1 and server3. After mydatabase1 becomes available on server2, the load balancing device must include server2 in load balancing decisions. Similarly, if mydatabase2 becomes unavailable on server3, the device must load balance requests for mydatabase2 across only server1 and server2, and it must include server3 in its load balancing decisions only when mydatabase2 becomes available. This load balancing behavior must be consistent across all the databases that are hosted on the server farm.

The Citrix ADC appliance implements this behavior by retrieving a list of all the databases that are active on a service. To retrieve the list of active databases, the appliance uses a monitor that is configured with an appropriate SQL query. If the requested database is unavailable on a service, the appliance excludes the service from load balancing decisions until it becomes available. This behavior ensures uninterrupted service to clients.

Note
Database specific load balancing is currently supported for only MSSQL and MySQL service types. This support is also available for Microsoft SQL Server 2012 high availability deployment.

To set up database specific load balancing, you must enable the load balancing feature, configure a load balancing virtual server of type MSSQL or MySQL, configure the services that host the database, and bind the services to the virtual server. The monitor needs valid user credentials to log on to the database server, so you must configure a database user account on each of the servers and then add the user account to the Citrix ADC appliance. Then, you configure an MSSQL-ECV or MYSQL-ECV monitor and bind the monitor to each service. Finally, you must test the configuration to ensure that it is working as intended. Before you perform these configuration tasks, make sure you understand how database specific load balancing works.

**How Database Specific Load Balancing Works**

For database specific load balancing, you configure a monitor that periodically queries each database server for the names of all the active databases on it. The Citrix ADC appliance stores the results, and regularly updates the records on the basis of the information retrieved through monitoring. When a client queries a particular database, the appliance uses the configured load balancing method to select a service, and then checks its records to determine whether the database is available on that service. If the records indicate that the database is not available, it uses the configured load balancing method to select the next available service, and then repeats the check. The appliance forwards the query to the first available service on which the database is active.

**Enabling Load Balancing**

You can configure load balancing entities such as services and virtual servers when the load balancing feature is disabled, but they will not function until you enable the feature.

**To enable load balancing by using the command line interface**

At the command prompt, type the following command to enable load balancing and verify the configuration:

```
1 enable ns feature LB
2 show ns feature
```

**Example:**

```
1 > enable ns feature LoadBalancing
2 Done
```
To enable load balancing by using the configuration utility

Navigate to System > Settings and, in Configure Basic Features, select Load Balancing.

Configuring a Load Balancing Virtual Server for Database Specific Load Balancing

To configure a virtual server to load balance databases on the basis of availability, you enable the database specific load balancing parameter on the virtual server. Enabling the parameter modifies the load balancing logic so that the Citrix ADC appliance refers the results of the monitoring probe sent to the selected service, before forwarding the query to that service.

To configure a load balancing virtual server for database specific load balancing

At the command prompt, type the following command to configure a load balancing virtual server for database specific load balancing and verify the configuration:

```
1 add lb vserver <name> <serviceType> <ipAddress> <port> -dbsLb ENABLED
2 show lb vserver <name>
```

Configuring Services

After you enable the load balancing feature, you must create at least one service for each application server that is to be included in your load balancing setup. The services that you configure provide the connections between the Citrix ADC appliance and the load balanced servers. Each service has a name and specifies an IP address, a port, and the type of data that is served.
If you create a service without first creating a server object, the IP address of the service is also the name of the server that hosts the service. If you prefer to identify servers by name rather than IP address, you can create server objects and then specify a server’s name instead of its IP address when you create a service.

Configuring Database Users

In databases, a connection is always stateful, which means that as soon as a connection is established, it must be authenticated.

You need to configure your database user name and password on the Citrix ADC. For example, if you have a user John configured on the database, you need to configure the user John on the ADC too. When you add the database user names and passwords on the ADC, these are added to the nsconfig file.

Note
Names are case sensitive.

The ADC uses these user credentials to authenticate the clients, and then authenticate the server connections with the database servers.

To add a database user by using the command line interface

At the command prompt, type

```
add db user <username> - password <password>
```

Example:

```
add db user nsdbuser -password dd260427edf
```

To add a database user by using the configuration utility

Navigate to System > User Administration > Database Users, and configure a database user.

If you have changed the password of the database user on the database server, you must reset the password of the corresponding user configured on the Citrix ADC appliance.

To reset the password of a database user by using the command line interface

At the command prompt, type
To reset the password of database users by using the configuration utility

Navigate to System > User Administration > Database Users, select a user, and enter new values for the password.

If a database user no longer exists on the database server, you can remove the user from the Citrix ADC appliance. However, if the user continues to exist on the database server and you remove the user from the ADC appliance, any request from the client with this user name does not get authenticated, and therefore, does not get routed to the database server.

To remove a database user by using the command line interface

At the command prompt, type

```
1 rm db user <username>
```

Example:

```
1 rm db user nsdbuser
```

To remove a database user by using the configuration utility

Navigate to System > User Administration > Database Users, select a user, and click Delete.

Configuring a Monitor to Retrieve the Names of Active Databases

To retrieve a list of all the active databases on a database instance, you create a monitor that logs on to the database server by using a valid user credentials and runs an appropriate SQL query. The SQL query you need to use depends on your SQL server deployment. For example, in an MSSQL database mirroring setup, you can use the following query to retrieve a list of active databases available on a server instance.

```
1 select name from sys.databases where state=0
```
In a MySQL database setup you can use the following queries to retrieve a list of active databases available on a server instance.

**show databases:**

You also configure the monitor to evaluate the response for an error condition, and to store the results if there is no error. If the response contains an error, the monitor marks the service as DOWN, and the appliance excludes the service from load balancing decisions until an error is no longer returned.

Note

The database specific load balancing feature is supported only for the MSSQL and MySQL service types. Therefore, the monitor type must be MSSQL-ECV or MYSQL-ECV.

To configure a monitor to retrieve the names of all the active databases hosted on a service by using the command line

At the command prompt, type the following commands to retrieve the names of all the active databases hosted on a service and verify the configuration:

```
1 add lb monitor <monitorName> <type> -userName <string> -sqlQuery <text> -evalRule <expression> -storedb ENABLED
2 show lb monitor <monitorName>
```

To configure a monitor to retrieve the names of all the active databases hosted on a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors and configure a monitor of type MSSQL-ECV or MYSQL-ECV.
2. In Special Parameters, specify a user name, query, and a rule
   For example, for MSSQL-ECV, the query should be “select name from sys.databases where state=0”), and a rule should be MSSQL.RES.TYPE.NE(ERROR).
   For MSSQL-ECV, the query should be “show databases” and a rule should be MYSQL.RES.TYPE.NE(ERROR).

Availability Groups Deployment Support for MSSQL

Consider the following scenario in which database specific load balancing is configured in a high availability group deployment. S1 through S5 are the services on the ADC appliance. DB1 through DB4 are the databases on the servers represented by the services S1 through S5. AV1 and AV2 are the availability groups. Each availability group contains up to one primary database server instance and up to four secondary database server instances. A service, representing the servers in the availability group...
group, can be primary for one availability group and secondary for another availability group. Each availability group contains different databases and one listener, which is a service. All requests arrive on the listener service that resides on the primary database. AV1 contains databases DB1 and DB2. AV2 contains databases DB3 and DB4. L1 and L2 are the listeners on AV1 and AV2 respectively. S1 is the primary service for AV1 and S2 is the primary service for AV2.

<table>
<thead>
<tr>
<th>Service</th>
<th>List of Active Databases on the Service</th>
</tr>
</thead>
<tbody>
<tr>
<td>S1</td>
<td>DB1, DB2, DB3, DB4</td>
</tr>
<tr>
<td>S2</td>
<td>DB3, DB4</td>
</tr>
<tr>
<td>S3</td>
<td>DB3, DB4</td>
</tr>
<tr>
<td>S4</td>
<td>DB1, DB2</td>
</tr>
<tr>
<td>S5</td>
<td>DB1, DB2</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Availability Group</th>
<th>Databases</th>
<th>Services representing the Servers in Availability Group</th>
</tr>
</thead>
<tbody>
<tr>
<td>AV1</td>
<td>DB1, DB2</td>
<td>S1, S4, S5</td>
</tr>
<tr>
<td>AV2</td>
<td>DB3, DB4</td>
<td>S1, S2, S3</td>
</tr>
</tbody>
</table>

Queries flow as follows:
1. A READ query for AV1 is load balanced between S4 and S5. S1 is the primary for AV1.
2. A WRITE query for AV1 is directed to L1.
3. A READ query for AV2 is load balanced between S1 and S3. S2 is the primary for AV2.
4. A WRITE query for AV1 is directed to L2.

Sample Configuration

1. Configure load balancing and content switching virtual servers.
   - add lb vserver lbwrite -dbslb enabled
   - add lbvserver lbread MSSQL -dbslb enabled
   - add csrvserver csv MSSQL 1.1.1.10 1433
2. Configure two listener services, one for each availability group, and five services S1 through S5 representing databases DB1 through DB4.
   - add service L1 1.1.1.11 MSSQL 1433
   - add service L2 1.1.1.12 MSSQL 1433
   - add service s1 1.1.1.13 MSSQL 1433
• add service s2 1.1.1.14 MSSQL 1433
• add service s3 1.1.1.15 MSSQL 1433
• add service s4 1.1.1.16 MSSQL 1433
• add service s5 1.1.1.17 MSSQL 1433

3. Bind the services to the load balancing virtual servers.
• bind lbvserver lbwrite L1
• bind lbvserver lbwrite L2
• bind lbvserver lbread s1
• bind lbvserver lbread s2
• bind lbvserver lbread s3
• bind lbvserver lbread s4
• bind lbvserver lbread s5

4. Configure database users.
• add db user nsdbuser1 -password dd260427edf
• add db user nsdbuser2 -password ccd1234xyzw

5. Configure two monitors, monitor_L1 and monitor_L2 for each listener service, to retrieve the list of active databases in that availability group. Add a monitor, monitor1 to retrieve the list of databases for the secondary database server instance.
• add lb monitor monitor_L1 MSSQL-ECV -userName user1 -sqlQuery “SELECT name FROM sys.databases a INNER JOIN sys.dm_hadr_availability_replica_states b ON a.replica_id=b.replica_id INNER JOIN sys.availability_group_listeners c on b.group_id = c.group_id INNER JOIN sys.availability_group_listener_ip_addresses d on c.listener_id = d.listener_id WHERE b.role = 1 and d.ip_address like ‘1.1.1.11’” -evalRule “MSSQL.RES.TYPE.NE(ERROR)” –storedb ENABLED
• add lb monitor monitor_L2 MSSQL-ECV -userName user1 -sqlQuery “SELECT name FROM sys.databases a INNER JOIN sys.dm_hadr_availability_replica_states b ON a.replica_id=b.replica_id INNER JOIN sys.availability_group_listeners c on b.group_id = c.group_id INNER JOIN sys.availability_group_listener_ip_addresses d on c.listener_id = d.listener_id WHERE b.role = 1 and d.ip_address like ‘1.1.1.12’” -evalRule “MSSQL.RES.TYPE.NE(ERROR)” -storedb ENABLED
• add lb monitor monitor1 MSSQL-ECV -userName user1 -sqlQuery “SELECT name FROM sys.databases a INNER JOIN sys.dm_hadr_availability_replica_states b ON a.replica_id=b.replica_id WHERE b.role = 2” -evalRule “MSSQL.RES.TYPE.NE(ERROR)” -storedb ENABLED

6. Configure read and write policies.
• add cs policy pol_write -rule “MSSQL.REQ.QUERY.TEXT.CONTAINS(‘insert’)”
• add cs policy pol_read -rule “MSSQL.REQ.QUERY.TEXT.CONTAINS(‘select’)”

7. Bind the policies to the content switching virtual server.
• bind csvserver csv -targetLBVserver lbwrite -policyName pol_write -priority 11
8. Bind monitors to the services. Bind monitors to services L1 and L2 to get the list of active
databases for the availability group for which it is the listener. Bind monitors to all the services
that are bound to the read-only virtual server.

- bind service L1 -monitorName monitor_L1
- bind service L2 -monitorName monitor_L2
- bind service s1 -monitorName monitor1
- bind service s2 -monitorName monitor1
- bind service s3 -monitorName monitor1
- bind service s4 -monitorName monitor1
- bind service s5 -monitorName monitor1

**Configuration examples for MSSQL virtual server**

To configure a load balancing virtual server for database specific load balancing:

```plaintext
1  add lb vserver DBSpecificLB1 MSSQL 192.0.2.10 1433 -dbsLb ENABLED
2  Done
3
4  show lb vserver DBSpecificLB1
5
6  DBSpecificLB1 (192.0.2.10:1433) - MSSQL Type: ADDRESS
7  ...  DBS_LB: ENABLED
8  Done
```

To configure services:

`add service msservice1 5.5.5.5 MSSQL 1433`

To configure a monitor to retrieve the names of all the active databases hosted on a service by
using the command line:

```plaintext
1  add lb monitor mssql-monitor1 MSSQL-ECV -userName user1 -sqlQuery "
   select name from sys.databases where state=0" -evalRule "MSSQL.RES.
   TYPE.NE(ERROR)" -storedb EN
2  Done
3
4  show lb monitor mssql-monitor1
5
6  1) Name.......: mssql-monitor1 Type.......: MSSQL-ECV
```
### Configuration examples for MySQL virtual server

To configure a load balancing virtual server for database specific load balancing:

```plaintext
add lb vserver DBSpecificLB1 MYSQL 192.0.2.10 3306 -dbsLb ENABLED
Done

show lb vserver DBSpecificLB1
DBSpecificLB1 (192.0.2.10:3306) - MYSQL Type: ADDRESS
... 
DBS_LB: ENABLED
Done
```

To configure services:

```plaintext
add service msservice1 5.5.5.5 MYSQL 3306
```

To configure a monitor to retrieve the names of all the active databases hosted on a service by using the command line:

```plaintext
add lb monitor mysql-monitor1 MYSQL-ECV -userName user1 -sqlQuery "show databases" -evalRule "MYSQL.RES.TYPE.NE(ERROR)" -storedb ENABLED
Done
```
show lb monitor mysql-monitor1

1) Name........: mysql-monitor1  Type........: MYSQL-ECV  State.....: ENABLED

... Special parameters: Database.......:"

User name.....:"user1" Query...:show databases

EvalRule....:MYSQL.RES.TYPE.NE(ERROR) STORE_DB....:ENABLED

Done

DataStream Reference

December 21, 2018

This reference describes the MySQL and TDS protocols, the database versions, the authentication methods, and the character sets supported by the DataStream feature. It also describes how the Citrix ADC handles transaction requests and special queries that modify the state of a connection.

You can also configure the Citrix ADC appliance to generate audit log messages for the DataStream feature.

Supported Database Versions, Protocols, and Authentication Methods

<table>
<thead>
<tr>
<th></th>
<th>MySQL Database</th>
<th>MS SQL Database</th>
</tr>
</thead>
<tbody>
<tr>
<td>Protocols</td>
<td>MySQL protocol version 10. For information about the MySQL protocol, see MySQL Client/Server Protocol</td>
<td>Tabular Data Stream (TDS) protocol version 7.1 and higher. For information about the TDS protocol, see Tabular Data Stream Protocol</td>
</tr>
</tbody>
</table>
Authentication Methods

<table>
<thead>
<tr>
<th>MySQL Database</th>
<th>MS SQL Database</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL native authentication is supported.</td>
<td>SQL server authentication and Windows Authentication (Kerberos/NTLM) are supported.</td>
</tr>
</tbody>
</table>

Character Sets

The DataStream feature supports only the UTF-8 charset.

The character set used by the client while sending a request may be different from the character set used in the database server responses. Although the charset parameter is set during the connection establishment, it can be changed at any time by sending an SQL query. The character set is associated with a connection, and therefore, requests on connections with one character set cannot be multiplexed onto a connection with a different character set.

The Citrix ADC appliance parses the queries sent by the client and the responses sent by the database server.

The character set associated with a connection can be changed after the initial handshake by using the following two queries:

```
1) SET NAMES <charset> COLLATION <collation>
2) SET CHARACTER SET <charset>
```

Transactions

In MySQL, transactions are identified by using the connection parameter AUTOCOMMIT or the BEGIN:COMMIT queries. The AUTOCOMMIT parameter can be set during the initial handshake, or after the connection is established by using the query SET AUTOCOMMIT.

The Citrix ADC appliance explicitly parses each and every query to determine the beginning and end of a transaction.

In MySQL protocol, the response contains two flags to indicate whether the connection is a transaction, the TRANSACTION and AUTOCOMMIT flags.

If the connection is a transaction, the TRANSACTION flag is set. Or, if the AutoCommit mode is OFF, the AUTOCOMMIT flag is not set. The ADC appliance parses the response, and if either the TRANSACTION flag is set or the AUTOCOMMIT flag is not set, it does not do connection multiplexing. When these conditions are no longer true, the ADC appliance begins connection multiplexing.
Special Queries

There are special queries, such as SET and PREPARE, that modify the state of the connection and may break request switching, and therefore, these need to be handled differently.

On receiving a request with special queries, the Citrix ADC appliance sends an OK response to the client and additionally, stores the request in the connection.

When a non-special query, such as INSERT and SELECT, is received along with a stored query, the Citrix ADC appliance first, looks for the server-side connection on which the stored query has already been sent to the database server. If no such connections exist, the ADC appliance creates a new connection, and sends the stored query first, and then, sends the request with the non-special query.

In case of SET, USE db, and INIT_DB special queries, the appliance modifies a field in the server side connection corresponding to the special query. This results in better reuse of the server side connection.

Only 16 queries are stored in each connection.

The following is a list of the special queries for which the ADC appliance has a modified behavior.

- **SET query**
  The SET SQL queries define variables that are associated with the connection. These queries are also used to define global variables, but as of now, the ADC appliance is unable to differentiate between local and global variables. For this query, the ADC appliance uses the ‘store and forward’ mechanism.

- **USE <db> query**
  Using this query, the user can change the database associated with a connection. In this case, the ADC appliance parses the <db> value sent and modifies a field in the server side connection to reflect the new database to be used.

- **INIT_DB command**
  Using this query, the user can change the database associated with a connection. In this case, ADC appliance parses the value sent and modifies a field in the server side connection to reflect the new database to be used.

- **COM_PREPARE**
  The ADC appliance stops request switching on receiving this command.
• PREPARE query

This query is used to create prepared statements that are associated with a connection. For this query, the ADC appliance uses the ‘store and forward’ mechanism.

**Audit Log Message Support**

You can now configure the Citrix ADC appliance to generate audit log messages for the DataStream feature. Audit log messages are generated when client-side and server-side connections are established, closed, or dropped. The categories of messages that you can log and view are ERROR and INFO. Error messages for client-side connections begin with “CS” and error messages for server-side connections begin with “SS.” Additional information is provided where necessary. For example, log messages for closed connections (CS_CONN_CLOSED) include only the connection ID. However, log messages for established connections (CS_CONN_ESTD) include information such as the user name, database name, and the client IP address in addition to the connection ID.

**Domain Name System**

January 6, 2019

You can configure the NetScaler appliance to function as an authoritative domain name server (ADNS server) for a domain. You can add the DNS resource records that belong to the domain for which the appliance is authoritative and configure resource record parameters. You can also configure the NetScaler appliance as a proxy DNS server that load balances a farm of DNS name servers that are either within your network or outside your network. You can configure the appliance as an end resolver and forwarder. You can configure DNS suffixes that enable name resolution when fully qualified domain names are not configured. The appliance also supports the DNS ANY query that retrieves all the records that belong to a domain.

You can configure the NetScaler appliance to concurrently function as an authoritative DNS server for one domain and a DNS proxy server for another domain. When you configure the NetScaler appliance as the authoritative DNS server or DNS proxy server for a zone, you can enable the appliance to use the Transmission Control Protocol (TCP) for response sizes that exceed the size limit specified for the User Datagram Protocol (UDP).

**How DNS Works on the NetScaler**

You can configure the NetScaler appliance to function as an ADNS server, DNS proxy server, end resolver, and forwarder. You can add DNS resource records on the NetScaler appliance, including service (SRV) records, IPv6 (AAAA) records, address (A) records, mail exchange (MX) records, canonical
name (CNAME) records, pointer (PTR) records, start of authority (SOA) records, and text (TXT) records. Also, you can configure the NetScaler to load balance external DNS name servers.

The NetScaler appliance can be configured as the authority for a domain. To do this, you add valid SOA and NS records for the domain.

An ADNS server is a DNS server that contains complete information about a zone.

To configure the NetScaler appliance as an ADNS server for a zone, you must add an ADNS service, and then configure the zone. To do so, you add valid SOA and NS records for the domain. When a client sends a DNS request, the NetScaler appliance searches the configured resource records for the domain name. You can configure the ADNS service to be used with the NetScaler Global Server Load Balancing (GSLB) feature.

You can delegate a subdomain, by adding NS records for the subdomain to the zone of the parent domain. You can then make the NetScaler authoritative for the subdomain, by adding a “glue record” for each of the subdomain name servers. If GSLB is configured, the NetScaler makes a GSLB load balancing decision based on its configuration and replies with the IP address of the selected virtual server.

The following figure shows the entities in an ADNS GSLB setup and a DNS proxy setup.

Figure 1. DNS Proxy Entity Model

The NetScaler appliance can function as a DNS proxy. Caching of DNS records, which is an important function of a DNS proxy, is enabled by default on the NetScaler appliance. This enables the NetScaler appliance to provide quick responses for repeated translations. You must also create a load balancing DNS virtual server, and DNS services, and then bind these services to the virtual server.

The NetScaler provides two options, minimum time to live (TTL) and maximum TTL for configuring the lifetime of the cached data. The cached data times out as specified by your settings for these two options. The NetScaler checks the TTL of the DNS record coming from the server. If the TTL is less than the configured minimum TTL, it is replaced with the configured minimum TTL. If the TTL is greater than the configured maximum TTL, it is replaced with the configured maximum TTL.

The NetScaler also allows caching of negative responses for a domain. A negative response indicates that information about a requested domain does not exist, or that the server cannot provide an answer for the query. The storage of this information is called negative caching. Negative caching helps speed up responses to queries on a domain, and can optionally provide the record type.

A negative response can be one of the following:

- **NXDOMAIN error message** - If a negative response is present in the local cache, the NetScaler returns an error message (NXDOMAIN). If the response is not in the local cache, the query is forwarded to the server, and the server returns an NXDOMAIN error to the NetScaler. The NetScaler caches the response locally, then returns the error message to the client.
- **NODATA error message** - The NetScaler sends a NODATA error message, if the domain name in query is valid but records of the given type are not available.
The NetScaler supports recursive resolution of DNS requests. In recursive resolution, the resolver (DNS client) sends a recursive query to a name server for a domain name. If the queried name server is authoritative for the domain, it responds with the requested domain name. Otherwise, the NetScaler queries the name servers recursively until the requested domain name is found.

Before you can apply the recursive query option, you must first enable it. You can also set the number of times the DNS resolver must send a resolution request (DNS retries) if a DNS lookup fails.

You can configure the NetScaler as a DNS forwarder. A forwarder passes DNS requests to external name servers. The NetScaler allows you to add external name servers and provides name resolution for domains outside the network. The NetScaler also allows you to set the name lookup priority to DNS or Windows Internet Name Service (WINS).

**Round Robin DNS**

When a client sends a DNS request to find the DNS resource record, it receives a list of IP addresses resolving to the name in the DNS request. The client then uses one of the IP addresses in the list, generally, the first record or IP address. Hence, a single server is used for the total TTL of the cache and is overloaded when a large number of requests arrive.

When the NetScaler receives a DNS request, it responds by changing the order of the list of DNS resource records in a round robin method. This feature is called *round robin DNS*. Round robin distributes the traffic equally between data centers. The NetScaler performs this function automatically. You do not have to configure this behavior.

**Functional Overview**

If the NetScaler is configured as an ADNS server, it returns the DNS records in the order in which the records are configured. If the NetScaler is configured as a DNS proxy, it returns the DNS records in the order in which it receives the records from the server. The order of the records present in the cache matches the order in which records are received from the server.

The NetScaler then changes the order in which records are sent in the DNS response in a round robin method. The first response contains the first record in sequence, the second response contains the second record in sequence, the third response contains the third record in sequence, and the order continues in the same sequence. Thus, clients requesting the same name can connect to different IP addresses.

**Round Robin DNS Example**

As an example of round robin DNS, consider DNS records that have been added as follows:
The domain, abc.com is linked to an NS record as follows:

```
add dns addRec ns1 1.1.1.1  
add dns addRec ns1 1.1.1.2  
add dns addRec ns1 1.1.1.3  
add dns addRec ns1 1.1.1.4
```

When the NetScaler receives a query for the A record of ns1, the Address records are served in a round robin method as follows. In the first DNS response, 1.1.1.1 is served as the first record:

```
ns1. IN A 1.1.1.1  
ns1. IN A 1.1.1.2  
ns1. IN A 1.1.1.3  
ns1. IN A 1.1.1.4
```

In the second DNS response, the second IP address, 1.1.1.2 is served as the first record:

```
ns1. IN A 1.1.1.2  
ns1. IN A 1.1.1.3  
ns1. IN A 1.1.1.4  
ns1. IN A 1.1.1.1
```

In the third DNS response, the third IP address, 1.1.1.2 is served as the first record:

```
ns1. IN A 1.1.1.3  
ns1. IN A 1.1.1.4  
ns1. IN A 1.1.1.1  
ns1. IN A 1.1.1.2
```

### Configure DNS resource records

September 14, 2018

You configure resource records on the NetScaler ADC appliance when you configure the appliance as an ADNS server for a zone. You can also configure resource records on the appliance if the resource records belong to a zone for which the appliance is a DNS proxy server. On the appliance, you can configure the following record types:

- Service records
- AAAA records
- Address records
- Mail Exchange records
NetScaler 12.0

- Name Server records
- Canonical records
- Pointer records
- NAPTR records
- Start of Authority records
- Text records

The following table lists the record types that you can configure for a domain name record on the NetScaler appliance. For example, you can configure a maximum of 25 IP addresses for one record.

Table 1. Record Type and Number Configurable

<table>
<thead>
<tr>
<th>Record Type</th>
<th>Number of Records</th>
</tr>
</thead>
<tbody>
<tr>
<td>Address (A)</td>
<td>25</td>
</tr>
<tr>
<td>IPv6 (AAAA)</td>
<td>5</td>
</tr>
<tr>
<td>Mail exchange (MX)</td>
<td>12</td>
</tr>
<tr>
<td>Name server (NS)</td>
<td>16</td>
</tr>
<tr>
<td>Service (SRV)</td>
<td>8</td>
</tr>
<tr>
<td>Pointer (PTR)</td>
<td>20</td>
</tr>
<tr>
<td>Canonical name (CNAME)</td>
<td>1</td>
</tr>
<tr>
<td>Start of Authority (SOA)</td>
<td>1</td>
</tr>
<tr>
<td>Text (TXT)</td>
<td>20</td>
</tr>
<tr>
<td>Naming Authority Pointer (NAPTR)</td>
<td>20</td>
</tr>
</tbody>
</table>

Note:
The maximum number of IP addresses for a specific hostname is 25. However, the number of different address records can be more than 25.

Create SRV records for a service

September 11, 2018

The SRV record provides information about the services available on the NetScaler appliance. An SRV record contains the following information: name of the service and the protocol, domain name, TTL, DNS class, priority of the target, weight of records with the same priority, port of the service, and hostname of the service. The NetScaler chooses the SRV record that has the lowest priority setting first.
If a service has multiple SRV records with the same priority, clients use the weight field to determine which host to use.

**Add an SRV record by using the CLI**

At the command prompt, type the following commands to add an SRV record and verify the configuration:

1. `add dns srvRec <domain> <target> -priority <positive_integer> -weight <positive_integer> -port <positive_integer> [-TTL <secs>]`
2. `sh dns srvRec <domain>`

**Example:**

```
1 > add dns srvRec _http._tcp.example.com nameserver1.com -priority 1 -weight 1 -port 80
2  Done
3 > show dns srvRec _http._tcp.example.com
4 1) Domain Name : _http._tcp.example.com
5   Target Host : nameserver1.com
6   Priority : 1   Weight : 1
7   Port : 80     TTL : 3600 secs
8  Done
```

**Modify or remove an SRV record by using the CLI**

- To modify an SRV record, type the `set dns srvRec` command, the name of the domain for which the SRV record is configured, the name of the target host that hosts the associated service, and the parameters to be changed, with their new values.
- To remove an SRV record, type the `rm dns srvRec` command, the name of the domain for which the SRV record is configured, and the name of the target host that hosts the associated service.

**Configure an SRV record by using the GUI**

Navigate to Traffic Management > DNS > Records > SRV Records and create an SRV record.

**Creating AAAA Records for a Domain Name**

September 11, 2018
An AAAA resource record stores a single IPv6 address.

**Add an AAAA record by using the CLI**

At the command prompt, type the following commands to add an AAAA record and verify the configuration:

```bash
1 - add dns aaaaRec <hostName> <IPv6Address> ... [-TTL <secs>]
2 - show dns aaaaRec <hostName>
```

**Example:**

```bash
1 > add dns aaaaRec www.example.com 2001:0db8:0000:0000:0000:0000:1428:57ab
2 Done
3 > show dns aaaaRec www.example.com
4 1) Host Name : www.example.com
5 Record Type : ADNS TTL : 5 secs
6 IPV6 Address : 2001:db8::1428:57ab
7 Done
```

To remove an AAAA record and all of the IPv6 addresses associated with the domain name, type the `rm dns aaaaRec` command and the domain name for which the AAAA record is configured. To remove only a subset of the IPv6 addresses associated with the domain name in an AAAA record, type the `rm dns aaaaRec` command, the domain name for which the AAAA record is configured, and the IPv6 addresses that you want to remove.

**Add an AAAA record by using the GUI**

Navigate to Traffic Management > DNS > Records > AAAA Records and create an AAAA record.

**Creating address records for a Domain Name**

September 11, 2018

Address (A) records are DNS records that map a domain name to an IPv4 address.

You cannot delete Address records for a host participating in global server load balancing (GSLB). However, the NetScaler deletes Address records added for GSLB domains when you unbind the domain from a GSLB virtual server. Only user-configured records can be deleted manually. You cannot delete a record for a host referenced by records such as NS, MX, or CNAME.
Add an Address record by using the CLI

At the command prompt, type the following commands to add an Address record and verify the configuration:

```
1 - add dns addRec <hostName> <IPAddress> [-TTL <secs>]
2 - show dns addRec <hostName>
```

Example:

```
1 > add dns addRec ns.example.com 192.0.2.0
2 Done
3 > show dns addRec ns.example.com
4 1) Host Name : ns.example.com
5 Record Type : ADNS
6 IP Address : 192.0.2.0
7 Done
```

To remove an Address record and all of the IP addresses associated with the domain name, type the `rm dns addRec` command and the domain name for which the Address record is configured. To remove only a subset of the IP addresses associated with the domain name in an Address record, type the `rm dns addRec` command, the domain name for which the Address record is configured, and the IP addresses that you want to remove.

Add an Address record by using the GUI

Navigate to Traffic Management > DNS > Records > Address Records and create an Address record.

Create MX records for a mail exchange server

September 11, 2018

Mail Exchange (MX) records are used to direct email messages across the Internet. An MX record contains an MX preference that specifies the MX server to be used. The MX preference values range from 0 through 65536. An MX record contains a unique MX preference number. You can set the MX preference and the TTL values for an MX record.

When an email message is sent through the Internet, a mail transfer agent sends a DNS query requesting the MX record for the domain name. This query returns a list of host names of mail exchange servers for the domain, along with a preference number. If there are no MX records, the request is made for the Address record of that domain. A single domain can have multiple mail exchange servers.
**Add an MX record by using the CLI**

At the command prompt, type the following commands to add an MX record and verify the configuration:

```
1 - add dns mxRec <domain> -mx <string> -pref <positive_integer> [-TTL <secs>]
2 - show dns mxRec <domain>
```

**Example:**

```
1 > add dns mxRec example.com -mx mail.example.com -pref 1
2  Done
3 > show dns mxRec example.com
4  1) Domain : example.com   MX Name : mail.example.com
5  Preference :  1  TTL : 5 secs
6  Done
```

**Modify or remove an MX record by using the CLI**

- To modify an MX record, type the set dns mxRec command, the name of the domain for which the MX record is configured, the name of the MX record, and the parameters to be changed, with their new values.
- To set the TTL parameter to its default value, type the unset dns mxRec command, the name of the domain for which the MX record is configured, the name of the MX record, and -TTL without any TTL value. You can use the unset dns mxRec command to unset only the TTL parameter.
- To remove an MX record, type the rm dns mxRec command, the name of the domain for which the MX record is configured, and the name of the MX record.

**Add an MX record by using the GUI**

Navigate to Traffic Management > DNS > Records > Mail Exchange Records and create an MX record.

**Create NS Records for an authoritative server**

September 11, 2018

Name Server (NS) records specify the authoritative server for a domain. You can configure a maximum of 16 NS records. You can use an NS record to delegate the control of a subdomain to a DNS server.
Create an NS record by using the CLI

At the command prompt, type the following commands to create an NS record and verify the configuration:

```
1 - add dns nsRec <domain> <nameServer> [-TTL <secs>]
2 - show dns nsRec <domain>
```

Example:

```
1 > add dns nsRec example.com nameserver1.example.com
  2   Done
3 > show dns nsRec example.com
  4   1) Domain : example.com   NameServer : nameserver1.example.com
  5     TTL : 5 sec
  6   Done
```

To remove an NS record, type the `rm dns nsRec` command, the name of the domain to which the NS record belongs, and the name of the name server.

Create an NS record by using the GUI

Navigate to Traffic Management > DNS > Records > Name Server Records and create an NS record.

Create CNAME records for a subdomain

September 11, 2018

A canonical name record (CNAME record) is an alias for a DNS name. These records are useful when multiple services query the DNS server. The host that has an address (A) record cannot have a CNAME record.

In some cases, a NetScaler appliance in proxy mode requests an address record from the cache instead of the server.

Add a CNAME record by using the CLI

At the command prompt, type the following commands to create a CNAME record and verify the configuration:
NetScaler 12.0

```
1 - add dns cnameRec <aliasName> <canonicalName> [-TTL <secs>]
2 - show dns cnameRec <aliasName>
```

Example:

```
1 > add dns cnameRec www.example.com www.examplenw.com
2 Done
3 > show dns cnameRec www.example.com
4  1) www.example.com      www.examplenw.com      5 secs
6 Done
```

To remove a CNAME record for a given domain, type the `rm dns cnameRec` command and the alias of the domain name.

**Add a CNAME record by using the GUI**

Navigate to Traffic Management > DNS > Records > Canonical Records and create a CNAME record.

**Cache CNAME records**

NetScaler when deployed in a proxy mode does not always send the query for an address record to the back-end server. This happens when for an answer to a query for an address record, a partial CNAME chain is present in the cache. There are few conditions in which the ADC caches the partial CNAME record and serves the query from the cache. Following are the conditions:

- NetScaler should be deployed in a proxy mode
- The response from the back-end server should have a CNAME chain, for which the record type of the last entry in the answer section must be a CNAME and the question type not a CNAME
- The response from the back-end server cannot be a No-data or NX-Domain
- The response from the back-end server has to be an authoritative response

**Create NAPTR records for telecommunications domain**

September 11, 2018

NAPTR (Naming Address Pointer) is one of the most commonly used DNS record in telecommunications domain. NAPTR records map the Internet telephony address space to the Internet address space. They therefore enable a mobile device to send a request to the correct server. The combination of NAPTR records with Service Records (SRV) allows the chaining of multiple records to form complex
rewrite rules that produce new domain labels or uniform resource identifiers (URIs). The DNS code for NAPTR is 35.

NetScalers support NAPTR in two modes: ADNS mode and proxy mode. In proxy mode, the ADC caches the response from the servers and uses the cached records to server future queries. A maximum of 20 NAPTR records can be added for a particular domain in NetScaler. NetScaler caches the reply to a DNS NAPTR record query. Any subsequent requests for the NAPTR record is served from the cache.

Create a NAPTR record by using CLI

At the command prompt, type the following commands to add a NAPTR record and verify the configuration:

```
add dns naptrRec <order> <preference>[flags<string>][services<string>](regexp<expressions>|-replacement<string>)[-TTL<secs>]
```

Remove a NAPTR record by using CLI

```
rm dns naptrRec <domain> (<order> <preference> [-flags <string>] [-services <string>] (-regexp <expression> | -replacement <string>))| -recordId <positive_integer>@
```

Configure a NAPTR record using GUI

Navigate to Traffic Management > DNS > Records > NAPTR Records and create an NAPTR record.

Create PTR records for IPv4 and IPv6 addresses

September 11, 2018

A pointer (PTR) record translates an IP address to its domain name. IPv4 PTR records are represented by the octets of an IP address in reverse order with the string “in-addr.arpa.” appended at the end. For example, the PTR record for the IP address 1.2.3.4 is 4.3.2.1.in-addr.arpa.

IPv6 addresses are reverse mapped under the domain IP6.ARPA. IPv6 reverse-maps use a sequence of nibbles separated by dots with the suffix “.IP6.ARPA” as defined in RFC 3596. For example, the reverse lookup domain name corresponding to the address, 4321:0:1:2:3:4:567:89ab would be b.a.9.8.7.6.5.0.4.0.0.0.3.0.0.2.0.0.0.1.0.0.0.0.0.1.2.3.4.IP6.ARPA.
Add a PTR record by using the CLI

At the command prompt, type the following commands to add a PTR record and verify the configuration:

```
1 - add dns ptrRec <reverseDomain> <domain> [<-TTL <secs>]
2 - show dns ptrRec <reverseDomain>
```

Example:

```
1 > add dns ptrRec 0.2.0.192.in-addr.arpa example.com
2   Done
3 > show dns ptrRec 0.2.0.192.in-addr.arpa
4 1) Reverse Domain Name : 0.2.0.192.in-addr.arpa
5     Domain Name : example.com     TTL : 3600 secs
6   Done
```

To remove a PTR record, type the `rm dns ptrRec` command and the reverse domain name associated with the PTR record.

Add a PTR record by using the GUI

Navigate to Traffic Management > DNS > Records > PTR Records and create a PTR record.

Create SOA records for authoritative information

September 11, 2018

A Start of Authority (SOA) record is created only at the zone apex and contains information about the zone. The record includes, among other parameters, the primary name server, contact information (e-mail), and default (minimum) time-to-live (TTL) values for records.

Create an SOA record by using the CLI

At the command prompt, type the following commands to add an SOA record and verify the configuration:

```
1 - add dns soaRec <domain> -originServer \originServerName\ -contact \contactName\n2 - sh dns soaRec \do\ main\n```

Example:
Modify or remove an SOA record by using the CLI

- To modify an SOA record, type the `set dns soaRec` command, the name of the domain for which the record is configured, and the parameters to be changed, with their new values.
- To remove an SOA record, type the `rm dns soaRec` command and the name of the domain for which the record is configured.

Configure an SOA record by using the GUI

Navigate to Traffic Management > DNS > Records > SOA Records and create an SOA record.

Create TXT records for holding descriptive text

Domain hosts store TXT records for informative purposes. A TXT record’s RDATA component, which consists of one or more character strings of variable length, can store practically any information that a recipient might need to know about the domain, including information about the service provider, contact person, email addresses, and associated details. SPF (Sender Policy Framework) protection has been the most prominent use case for the TXT record.

All configuration types (authoritative DNS, DNS proxy, end resolver, and forwarder configurations) on the NetScaler appliance support TXT records. You can add a maximum of 20 TXT resource records to a domain. Each resource record is stored with a unique, internally generated record ID. You can view the ID of a record and use it to delete the record. However, you cannot modify a TXT resource record.
Create a TXT resource record by using the CLI

At the command prompt, type the following commands to create a TXT resource record and verify the configuration:

```
1 - add dns txtRec <domain> <string> ... [-TTL <secs>]
2 - show dns txtRec [<domain> | -type <type>]
```

Example:

```
1 > add dns txtRec www.example.com "Contact: Mark" "Email: mark@example.com" -TTL 36000
2 Done
3 > show dns txtRec www.example.com
4 1) Domain: www.example.com Record id: 13783 TTL: 36000 secs
   Record Type: ADNS
   "Contact: Mark"
   "Email: mark@example.com"
7 Done
```

Remove a TXT resource record by using the CLI

At the command prompt, type the following commands to remove a TXT resource record and verify the configuration:

```
1 - rm dns txtRec <domain> (<string> ... | -recordId <positive_integer>)
2 - show dns txtRec [<domain> | -type <type>]
```

Example:

You can use the show dns txtRec command first to view the record ID of the TXT resource record that you want to remove, as shown:

```
1 > show dns txtRec www.example.com
2 1) Domain: www.example.com Record id: 36865 TTL: 36000 secs
   Record Type: ADNS
   "Contact: Evan"
   "Email: evan@example.com"
5 2) Domain: www.example.com Record id: 14373 TTL: 36000 secs
   Record Type: ADNS
   "Contact: Mark"
   "Email: mark1@example.com"
8 Done
```
The simpler method of deleting a TXT record is to use the record ID. If you want to provide the strings, enter them in the order in which they are stored in the record. In the following example, the TXT record is deleted by using its record ID.

```
> rm dns txtRec www.example.com -recordID 36865
Done
> show dns txtRec www.example.com
1) Domain: www.example.com Record id: 14373 TTL : 36000 secs
  Record Type : ADNS
  "Contact: Mark"
  "Email: mark1@example.com"
Done
```

**Configure a TXT record by using the GUI**

Navigate to Traffic Management > DNS > Records > TXT Records and create a TXT record.

**Viewing DNS statistics**

September 14, 2018

You can view the DNS statistics generated by the NetScaler appliance. The DNS statistics include runtime, configuration, and error statistics.

**View DNS records statistics by using the CLI**

At the command prompt, type:

```
stat dns
```

**Example:**

```
1) > stat dns
2) DNS Statistics
3) 
4) Runtime Statistics
5) Dns queries 21
6) NS queries 8
7) SOA queries 18
8) 
9) 
10) 
```
View DNS records statistics by using the GUI

1. Navigate to Traffic Management > DNS.
2. In the details pane, click Statistics.

Configure a DNS zone

September 14, 2018

A DNS zone entity on the NetScaler ADC appliance facilitates the ownership of a domain on the appliance. A zone on the appliance also enables you to implement DNS Security Extensions (DNSSEC) for the zone, or to offload the zone’s DNSSEC operations from the DNS servers to the appliance. DNSSEC sign operations are performed on all the resource records in a DNS zone. Therefore, if you want to sign a zone, or if you want to offload DNSSEC operations for a zone, you must first create the zone on the NetScaler appliance.

You must create a DNS zone on the appliance in the following scenarios:

- The NetScaler appliance owns all the records in a zone, that is, the appliance is operating as the authoritative DNS server for the zone. The zone must be created with the proxyMode parameter set to NO.
- The NetScaler appliance owns only a subset of the records in a zone, and all the other resource records in the zone are hosted on a set of back-end name servers for which the appliance is configured as a DNS proxy server. A typical configuration where the NetScaler appliance owns only a subset of the resource records in the zone is a global server load balancing (GSLB) configuration. Only the GSLB domain names are owned by the NetScaler appliance, while all the
other records are owned by the back-end name servers. The zone must be created with the proxyMode parameter set to YES.

- You want to offload DNSSEC operations for a zone from your authoritative DNS servers to the appliance. The zone must be created with the proxyMode parameter set to YES. You might need to configure additional settings for the zone.

The current topic describes how to create a zone for the first two scenarios. For more information about how to configure a zone for offloading DNSSEC operations to the appliance, see Offload DNSSEC operations to the NetScaler appliance.

**Note**

If the NetScaler is operating as the authoritative DNS server for a zone, you must create Start of Authority (SOA) and name server (NS) records for the zone before you create the zone. If the NetScaler is operating as the DNS proxy server for a zone, SOA and NS records must not be created on the NetScaler appliance. For more information about creating SOA and NS records, see Configure DNS resource records.

When you create a zone, all existing domain names and resource records that end with the name of the zone are automatically treated as a part of the zone. Additionally, any new resource records created with a suffix that matches the name of the zone are implicitly included in the zone.

**Create a DNS zone on the NetScaler appliance by using the CLI**

At the command prompt, type the following command to add a DNS zone to the NetScaler appliance and verify the configuration:

```
1  - add dns zone <zoneName> -proxyMode ( YES | NO )
2  - show dns zone [<zoneName> | -type <type>]
```

**Example:**

```
1  > add dns zone example.com -proxyMode Yes
2  Done
3  > show dns zone example.com
4       Zone Name : example.com
5       Proxy Mode : YES
6  Done
```

**Modify or remove a DNS zone by using the CLI**

- To modify a DNS zone, type the `set dns zone` command, the name of the DNS zone, and the parameters to be changed, with their new values.
To remove a DNS zone, type the `rm dns zone` command and the name of the dns zone.

**Configure a DNS zone by using the GUI**

Navigate to Traffic Management > DNS > Zones and create a DNS zone.

**Configure the NetScaler as an ADNS server**

January 6, 2019

You can configure the NetScaler appliance to function as an authoritative domain name server (ADNS) for a domain. As an ADNS server for a domain, the NetScaler resolves DNS requests for all types of DNS records that belong to the domain. To configure the NetScaler to function as an ADNS server for a domain, you must create an ADNS service and configure NS and Address records for the domain on the NetScaler. The ADNS service can be configured using the subnet IP address (SNIP) or a separate IP address. The following topology diagram shows a sample configuration and the flow of requests and responses.

Figure 1. NetScaler as an ADNS

The following table shows the parameters that are configured for the ADNS service illustrated in the preceding topology diagram.

<table>
<thead>
<tr>
<th>Entity type</th>
<th>Name</th>
<th>IP address</th>
<th>Type</th>
<th>Port</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADNS Service</td>
<td>Service-ADNS-1</td>
<td>10.102.29.51</td>
<td>ADNS</td>
<td>53</td>
</tr>
</tbody>
</table>

Table 1. Example of ADNS Service Configuration

To configure an ADNS setup, you must configure the ADNS service. For instructions on configuring the ADNS service, see “Load balancing”.

During DNS resolution, the ADNS server directs the DNS proxy or local DNS server to query the NetScaler for the IP address of the domain. Because the NetScaler is authoritative for the domain, it sends the IP address to the DNS proxy or local DNS server. The following diagram describes the placement and role of the ADNS server in a GSLB configuration.

Figure 2. GSLB Entity Model

Note: In ADNS mode, if you remove SOA and ADNS records, the following do not function for the domain hosted by the NetScaler: ANY query (for more information about the ANY query, see
**DNS ANY query**, and negative responses, such as NODATA and NXDOMAIN.

**Create an ADNS service**

An ADNS service is used for global service load balancing. For more information about creating a GSLB setup, see “Global server load balancing”. You can add, modify, enable, disable, and remove an ADNS service. For instructions on creating an ADNS service, see Configure services.

**Note:** You can configure the ADNS service to use SNIP or any new IP address.

When you create an ADNS service, the NetScaler responds to DNS queries on the configured ADNS service IP and port.

You can verify the configuration by viewing the properties of the ADNS service. You can view properties such as name, state, IP address, port, protocol, and maximum client connections.

**Configure the ADNS setup to use TCP**

By default, some clients use the User Datagram Protocol (UDP) for DNS, which specifies a limit of 512 bytes for the payload length of UDP packets. To handle payloads that exceed 512 bytes in size, the client must use the Transmission Control Protocol (TCP). To enable DNS communications over TCP, you must configure the NetScaler appliance to use the TCP protocol for DNS. The NetScaler then sets the truncation bit in the DNS response packets. The truncation bit specifies that the response is too large for UDP and that the client must send the request over a TCP connection. The client then uses the TCP protocol on port 53 and opens a new connection to the NetScaler. The NetScaler listens on port 53 with the IP address of the ADNS service to accept the new TCP connections from the client.

To configure the NetScaler to use the TCP protocol, you must configure an ADNS_TCP service. For instructions on creating an ADNS_TCP service, see Load balancing.

---

**Important**

To configure the NetScaler to use UDP for DNS and use TCP only when the payload length of UDP exceeds 512 bytes, you need to configure the ADNS and ADNS_TCP services. The IP address of the ADNS_TCP service must be same as the IP address of the ADNS service.

**Add DNS resource records**

After you create an ADNS service, you can add DNS records. For instructions on adding DNS records, see Configure DNS resource records.
Remove ADNS services

For instructions on removing services, see Load balancing

Configure domain delegation

Domain delegation is the process of assigning responsibility for a part of the domain space to another name server. Therefore, during domain delegation, the responsibility for responding to the query is delegated to another DNS server. Delegation uses NS records.

In the following example, sub1.abc.com is the subdomain for abc.com. The procedure describes the steps to delegate the subdomain to the name server ns2.sub1.abc.com and add an Address record for ns2.sub1.abc.com.

To configure domain delegation, you need to perform the following tasks, which are described in the sections that follow:

1. Create an SOA record for a domain.
2. Create an NS record to add a name server for the domain.
3. Create an Address record for the name server.
4. Create an NS record to delegate the subdomain.
5. Create a glue record for the name server.

Create an SOA record

For instructions on configuring SOA records, see Create SOA records for authoritative information.

Create an NS record for a name server

For instructions on configuring an NS record, see Create NS records for an authoritative server. In the Name Server drop-down list, select the primary authoritative name server, for example, ns1.abc.com.

Create an address record

For instructions on configuring Address records, see Create address records for a domain name. In the Host Name and IP address text boxes, type the domain name for the DNS Address record and the IP address, for example, ns1.abc.com and 10.102.11.135, respectively.
Create an NS record for domain delegation

For instructions on configuring NS records, see Create NS records for an authoritative server. In the Name Server drop-down list, select the primary authoritative name server, for example, ns2.sub1.abc.com.

Create a glue record

NS records are usually defined immediately after the SOA record (but this is not a restriction.) A domain must have at least two NS records. If an NS record is defined within a domain, it must have a matching Address record. This Address record is referred to as a glue record. Glue records speed up DNS queries.

For instructions on adding glue records for a subdomain, see the procedure for adding an Address (A) record, Configure DNS resource records.

For instructions on configuring Address records, see [Create address records for a domain name](/en-us/netscaler/12/dns/configure-dns-resource-records/create-address-records.html). In Host Name and IP address text boxes, type the domain name for the DNS Address record and the IP address, for example, ns2.sub1.abc.com and 10.102.12.135, respectively.

Configure the NetScaler appliance as a DNS proxy server

January 6, 2019

As a DNS proxy server, the NetScaler ADC appliance can function as a proxy for either a single DNS server or a group of DNS servers. The flow of requests and responses is illustrated in the following sample topology diagram.

Figure 1. NetScaler as DNS proxy

By default, the NetScaler appliance caches responses from DNS name servers. When the appliance receives a DNS query, it checks for the queried domain in its cache. If the address for the queried domain is present in its cache, the NetScaler returns the corresponding address to the client. Otherwise, it forwards the query to a DNS name server that checks for the availability of the address and returns it to the NetScaler. The NetScaler then returns the address to the client.

For requests for a domain that has been cached earlier, the NetScaler serves the Address record of the domain from the cache without querying the configured DNS server.

The appliance discards a record stored in its cache when the time-to-live (TTL) value of the record reaches the configured value. A client that requests an expired record has to wait until the NetScaler
retrieves the record from the server and updates its cache. To avoid this delay, the NetScaler proactively updates the cache by retrieving the record from the server before the record expires.

The following table lists sample names and the values of the entities that need to be configured on the NetScaler.

Table 1. Example of DNS Proxy Entity Configuration

<table>
<thead>
<tr>
<th>Entity type</th>
<th>Name</th>
<th>IP address</th>
<th>Type</th>
<th>Port</th>
</tr>
</thead>
<tbody>
<tr>
<td>LB virtual server</td>
<td>Vserver-DNS-1</td>
<td>10.102.29.40</td>
<td>DNS</td>
<td>53</td>
</tr>
<tr>
<td>Services</td>
<td>Service-DNS-1</td>
<td>10.102.29.50</td>
<td>DNS</td>
<td>53</td>
</tr>
<tr>
<td>Services</td>
<td>Service-DNS-2</td>
<td>10.102.29.51</td>
<td>DNS</td>
<td>53</td>
</tr>
</tbody>
</table>

The following diagram shows the entities of a DNS Proxy and the values of the parameters to be configured on the NetScaler.

Figure 2. DNS Proxy Entity Model

Note

To configure DNS proxy, you need to know how to configure load balancing services and virtual servers.

Create a load balancing virtual server

To configure a DNS Proxy on the NetScaler, configure a load balancing virtual server of type DNS. To configure a DNS virtual server to load balance a set of DNS servers that support recursive queries, you must set the Recursion Available option. With this option, the RA bit is set to ON in the DNS replies from the DNS virtual server.

For instructions on creating a load balancing virtual server, see “Load Balancing”.

Create DNS services

After creating a load balancing virtual server of type DNS, you must create DNS services. You can add, modify, enable, disable, and remove a DNS service. For instructions on creating a DNS service, see “Load Balancing”.
**Bind a load balancing virtual server to DNS services**

To complete the DNS Proxy configuration, you must bind the DNS services to the load balancing virtual server. For instructions on binding a service to a load balancing virtual server, see “Load Balancing”.

**Configure the DNS proxy setup to use TCP**

Some clients use the User Datagram Protocol (UDP) for DNS communications. However, UDP specifies a maximum packet size of 512 bytes. When payload lengths exceed 512 bytes, the client must use the Transmission Control Protocol (TCP). When a client sends the NetScaler ADC appliance a DNS query, the appliance forwards the query to one of the name servers. If the response is too large for a UDP packet, the name server sets the truncation bit in its response to the NetScaler. The truncation bit indicates that the response is too large for UDP and that the client must send the query over a TCP connection. The NetScaler relays the response to the client with the truncation bit intact and waits for the client to initiate a TCP connection with the IP address of the DNS load balancing virtual server, on port 53. The client sends the request over a TCP connection. The NetScaler appliance then forwards the request to the name server and relays the response to the client.

To configure the NetScaler to use the TCP protocol for DNS, you must configure a load balancing virtual server and services, both of type DNS_TCP. You can configure monitors of type DNS_TCP to check the state of the services. For instructions on creating DNS_TCP virtual servers, services, and monitors, see “Load Balancing.”

For updating the records proactively, the NetScaler uses a TCP connection to the server to retrieve the records.

**Important** To configure the NetScaler to use UDP for DNS and use TCP only when the payload length of UDP exceeds 512 bytes, you need to configure DNS and DNS_TCP services. The IP address of the DNS_TCP service must be same as that of the DNS service.

**Configure time-to-live values for DNS entries**

The TTL is the same for all DNS records with the same domain name and record type. If the TTL value is changed for one of the records, the new value is reflected in all records of the same domain name and type. The default TTL value is 3600 seconds. The minimum is 0, and the maximum is 604800. If a DNS entry has a TTL value less than the minimum or greater than the maximum, it is saved as the minimum or maximum TTL value, respectively.
Specify the minimum and/or maximum TTL by using the CLI

At the NetScaler command prompt, type the following commands to specify the minimum and maximum TTL and verify the configuration:

```
1 - set dns parameter [-minTTL <secs>] [-maxTTL <secs>]
2 - show dns parameter
```

Example:

```
1 > set dns parameter -minTTL 1200 -maxTTL 1800
2   Done
3 > show dns parameter
4       DNS parameters:
5           DNS retries: 5
6           Minimum TTL: 1200   Maximum TTL: 1800
7    .
8    .
9    .
10 Done
11 >
```

Specify the minimum and/or maximum TTL by using the GUI

1. Navigate to Traffic Management > DNS.
2. In the details pane, under Settings, click Change DNS settings.
3. In the Configure DNS Parameters dialog box, in TTL, in the Minimum and Maximum text boxes, type the minimum and maximum time to live (in seconds), respectively, and then click OK.

Note: When the TTL expires, the record is deleted from the cache. The NetScaler proactively contacts the servers and obtains the DNS record just before the DNS record expires.

Flush DNS records

You can delete all DNS records present in the cache. For example, you might want to flush DNS records when a server is restarted after modifications are made.

Delete all proxy records by using the CLI

At the NetScaler command prompt, type:

```
flush dns proxyRecords
```
Delete all proxy records by using the GUI

1. Navigate to Traffic Management > DNS > Records.
2. In the details pane, click Flush Proxy Records.

Add DNS resource records

You can add DNS records to a domain for which the NetScaler ADC appliance is configured as a DNS proxy server. For information about adding DNS records, see Configuring DNS Resource Records.

Remove a load balancing DNS virtual server

For information about removing a load balancing virtual server, see Load Balancing.

Limit the number of concurrent DNS requests on a client connection

You can limit the number of concurrent DNS requests on a single client connection, which is identified by the `<clientip:port>-<vserver ip:port>` tuple. Concurrent DNS requests are those requests that the NetScaler appliance has forwarded to the name servers and for which the appliance is awaiting responses. Limiting the number of concurrent requests on a client connection enables you to protect the name servers when a hostile client attempts a Distributed Denial of Service (DDoS) attack by sending a flood of DNS requests. When the limit for a client connection is reached, subsequent DNS requests on the connection are dropped till the outstanding request count goes below the limit. This limit does not apply to the requests that the NetScaler appliance serves out of its cache.

The default value for this parameter is 255. This default value is sufficient in most scenarios. If the name servers serve a large number of concurrent DNS requests under normal operating conditions, you can specify either a large value or a value of zero (0). A value of 0 disables this feature and specifies that there is no limit to the number of DNS requests that are allowed on a single client connection. This is a global parameter and applies to all the DNS virtual servers that are configured on the NetScaler appliance.

Specify the maximum number of concurrent DNS requests allowed on a single client connection by using the CLI

At the command prompt, type the following commands to specify the maximum number of concurrent DNS requests allowed on a single client connection and verify the configuration:

```
1 - set dns parameter -maxPipeline <positive_integer>
2 - show dns parameter
```
Example:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><code>&gt; set dns parameter -maxPipeline 1000</code></td>
</tr>
<tr>
<td>2</td>
<td>Done</td>
</tr>
<tr>
<td>3</td>
<td><code>&gt; show dns parameter</code></td>
</tr>
<tr>
<td>4</td>
<td>DNS parameters:</td>
</tr>
<tr>
<td>5</td>
<td>DNS retries: 5</td>
</tr>
<tr>
<td>6</td>
<td>.</td>
</tr>
<tr>
<td>7</td>
<td>.</td>
</tr>
<tr>
<td>8</td>
<td>.</td>
</tr>
<tr>
<td>9</td>
<td>Max DNS Pipeline Requests: 1000</td>
</tr>
<tr>
<td>10</td>
<td>Done</td>
</tr>
</tbody>
</table>

**Specify the maximum number of concurrent DNS requests allowed on a single client connection by using the GUI**

1. Navigate to Traffic Management > DNS.
2. In the details pane, click Change DNS settings.
3. In the Configure DNS Parameters dialog box, specify a value for Max DNS Pipeline Requests.
4. Click OK.

**Configure the NetScaler as an end resolver**

January 6, 2019

A resolver is a procedure that is invoked by an application program that translates a domain/host name to its resource record. The resolver interacts with the LDNS, which looks up the domain name to obtain its IP address. The NetScaler can provide end-to-end resolution for DNS queries.

In recursive resolution, the NetScaler appliance queries different name servers recursively to access the IP address of a domain. When the NetScaler receives a DNS request, it checks its cache for the DNS record. If the record is not present in the cache, it queries the root servers configured in the ns.conf file. The root name server reports back with the address of a DNS server that has detailed information about the second-level domain. The process is repeated until the required record is found.

When you start the NetScaler appliance for the first time, 13 root name servers are added to the ns.conf file. The NS and Address records for the 13 root servers are also added. You can modify the ns.conf file, but the NetScaler does not allow you to delete all 13 records; at least one name server entry is required for the appliance to perform name resolution. The following diagram illustrates the process of name resolution.

Figure 1. Recursive resolution
In the process shown in the diagram, when the name server receives a query for the address of s1.s2.s3.com, it first checks the root name servers for s1.s2.s3.com. A root name server reports back with the address of the .com name server. If the address of s1.s2.s3.com is found in the name server, it responds with a suitable IP address. Otherwise, it queries other name servers for s3.com, then for s2.s3.com to retrieve the address of s1.s2.s3.com. In this way, resolution always starts from root name servers and ends with the domain’s authoritative name server.

Note: For recursive resolution functionality, caching should be enabled.

Enable recursive resolution

To configure the NetScaler appliance to function as an end resolver, you must enable recursive resolution on the appliance.

Enable recursive resolution by using the CLI

At the command prompt, type the following commands to enable recursive resolution and verify the configuration:

```
1 - set dns parameter -recursion ENABLED
2 - show dns parameter
```

Example:

```
1 > set dns parameter -recursion ENABLED
2   Done
3 > show dns parameter
4   DNS parameters:
5     .
6     .
7     .
8   Recursive Resolution : ENABLED
9     .
10    .
11    .
12   Done
```

Enable recursive resolution by using the GUI

1. Navigate to Traffic Management > DNS.
2. In the details pane, under Settings, click Change DNS settings.
3. In the Configure DNS Parameters dialog box, select the Enable recursion check box, and then click OK.

**Set the Number of Retries**

The NetScaler appliance can be configured to make a preconfigured number of attempts (called DNS retries) when it does not receive a response from the server to which it sends a query. By default, the number of DNS retries is set to 5.

**Set the number of DNS retries by using the CLI**

At the command prompt, type the following commands to set the number of retries and verify the configuration:

```
1 - set dns parameter -retries <positive_integer>
2 - show dns parameter
```

**Example:**

```
1 > set DNS parameter -retries 3
2   Done
3 > show dns parameter
4   DNS parameters:
5     DNS retries: 3
6     .
7     .
8     .
9   Done
```

**Set the number of retries by using the GUI**

1. Navigate to Traffic Management > DNS.
2. In the details pane, under Settings, click Change DNS settings.
3. In the Configure DNS Parameters dialog box, in the DNS Retries text box, type the DNS resolver request retry count, and then click OK.

**Configure the NetScaler appliance as a forwarder**

September 11, 2018
A forwarder is a server that forwards DNS queries to DNS servers that are outside the forwarder server’s network. Queries that cannot be resolved locally are forwarded to other DNS servers. A forwarder accumulates external DNS information in its cache as it resolves DNS queries. To configure the NetScaler appliance as a forwarder, you must add an external name server.

The NetScaler appliance allows you to add external name servers to which it can forward the name resolution queries that cannot be resolved locally. To configure the NetScaler appliance as a forwarder, you must add the name servers to which it must forward name resolution queries. You can specify the lookup priority to specify the name service that the NetScaler appliance must use for name resolution.

**Add a name server**

September 18, 2018

You can create a name server by specifying its IP address or by configuring an existing virtual server as the name server.

While adding name server, you can provide an IP address or a virtual server IP address. If you add IP address based name servers, the NetScaler appliance load balances requests to the configured name servers in round robin method. If you add a virtual server, you can configure any load balancing method.

To verify the configuration, you can use the `sh dns <recordtype> <domain>` command. If the queried records are not present in the cache, the resource records are fetched from the configured external name servers.

**Add a name server (when the NetScaler appliance acts as a forwarder) by using the CLI**

At the command prompt, type;

```
1 add dns nameServer ((<IP>) | <dnsVserverName>)
```

**Example:**

```
1 add dns nameServer 192.0.2.10
2 add dns nameServer dnsVirtualNS
```

**Add a name server (when the NetScaler appliance acts as a resolver) by using the CLI**

At the command prompt, type:
NetScaler 12.0

Example:

```
1 add dns nameServer ((<IP> [-local]) | <dnsVserverName>)
```

```
Example:
1 add dns nameServer 10.102.9.19 -local
```

Note:
- To remove a name server, at the NetScaler CLI, type the `rm dns nameServer` command followed by the IP address of the name server.
- To view the details of the DNS nameserver, at the NetScaler CLI, type `show dns nameServer` command followed by the IP address of the name server.

Add a name server by using the GUI

Navigate to Traffic Management > DNS > Name Servers and create a name server.

Set DNS lookup priority

September 11, 2018

You can set the lookup priority to either DNS or WINS. This option is used in the SSL VPN mode of operation.

Set the lookup priority to DNS by using the CLI

At the command prompt, type the following commands to set the lookup priority to DNS and verify the configuration:

```
1 - set dns parameter -nameLookupPriority (DNS | WINS)
2 - show dns parameter
```

Example:

```
1 > set dns parameter -nameLookupPriority DNS
2    Done
3 > show dns parameter
4    .
5    .
6    .
7    Name lookup priority : DNS
```
Set lookup priority to DNS by using the GUI

1. Navigate to Traffic Management > DNS.
2. In the details pane, under Settings, click Change DNS settings.
3. In the Configure DNS Parameters dialog box, under Name Lookup Priority, select DNS or WINS, and then click OK.

Note
If the DNS virtual server that you have configured is DOWN and if you set the -nameLookupPriority to DNS, the NetScaler does not attempt WINS lookup. Therefore, if a DNS virtual server is not configured or is disabled, set the -nameLookupPriority to WINS.

Disable and enable name servers

September 11, 2018

The following procedure describes the steps to enable or disable an existing name server.

Enable or disable a name server by using the CLI

At the command prompt, type the following commands to enable or disable a name server and verify the configuration:

```
1  - (enable | disable) dns nameServer <IPAddress>
2  - show dns nameServer <IPAddress>
```

Example:

```
1  > disable dns nameServer 10.102.9.19
2  Done
3  > show dns nameServer 10.102.9.19
4  1) 10.102.9.19: LOCAL - State: OUT OF SERVICE
5  Done
```
Enable or disable a name server by using the GUI

1. Navigate to Traffic Management > DNS > Name Servers.
2. In the details pane, select the name server that you want to enable or disable.
3. Click Enable or Disable. If a name server is enabled, the Disable option is available. If a name server is disabled, the Enable option is available.

Configure DNS logging

September 12, 2018

You can configure the NetScaler appliance to log the DNS requests and responses that it handles. The appliance logs the DNS requests and responses in SYSLOG format. You can choose to log either DNS requests or DNS responses, or both, and send the syslog messages to a remote log server. The log messages can be used to:

- Audit the DNS responses to the client
- Audit DNS clients
- Detect and prevent DNS attacks
- Troubleshoot

A NetScaler appliance can log the following sections in the DNS request or response, on the basis of your configuration:

- Header Section
- Questions Section
- Answer Section
- Authority Section
- Additional Section

DNS profiles

You can use a DNS profile to configure various DNS parameters that you want the DNS endpoint to apply to the DNS traffic. In the profile, you can enable logging, caching and negative caching.

Important: From NetScaler 11.0 release, enabling DNS caching using global DNS parameters has been deprecated. You can enable or disable DNS caching using DNS profiles. You can now enable DNS caching for an individual virtual server by enabling DNS caching in a DNS profile and setting the DNS profile to the individual virtual server.

DNS profiles support the following types of DNS logging:

- DNS Query Logging
DNS query logging

You can configure a NetScaler appliance to log only the DNS queries that are received by the DNS endpoints on the appliance.

**Note:** If errors occur during processing of a query, they are logged if this option is set in the DNS profile.

Following is an example of a query log message:

```
1 DNS DNS_QUERY 143 0 : U:10.102.27.70#61297:10.102.27.73#53/22142/Q/
2 (RD)/NO/1/0/0/0#test.com./1#
```

DNS answer section logging

You can configure a NetScaler appliance to log all the Answer sections in the DNS responses that appliance sends to the client. DNS Answer Section logging is very useful when NetScaler is configured as a DNS resolver, or in GLSB use cases.

Following is an example of a DNS answer section log:

```
1 DNS DNS_RESPONSE 6678 0 : U:100.100.100.210#32776:100.100.100.10#
2 53/61373/Q/(RD,AA,RA,R)/NO/1/1/2/4#n1.citrix.com1./
3 28#ANS#AAAA/120/1111:2345:6789:ffab:abcd:effa:1234:3212#
```

DNS extended logging

To configure a NetScaler appliance to log Authority and Additional sections in the DNS responses, enable Extended logging with Answer Section logging.

**Note:** If errors occur during processing of either queries or responses, the errors are logged if this option is set in the DNS profile.

Following is an example of a message logged when the cache lookup is completed and the response is embedded in the packet:

```
1 DNS DNS_RESPONSE 2252 0 : T:100.100.100.118#21411:100.100.100.10
2 #53/48537/Q/(RD,AA,CD,RA,R)/NO/1/1/2/6#a1.citrix.com1./1#ANS/A/
3 120/1.1.1.1##AUTH#citrix.com1/NS/120/n2.citrix.com1#n1.citrix.com1##ADD
   #n1.citrix.com1
```
DNS error logging

You can configure a NetScaler appliance to log the errors or failures that occur when it processes a DNS query or response. For these errors, the appliance logs the DNS header, Question sections and OPT records.

Following is an example of a message logged when an error occurs during processing of a DNS request or response:

```
DNS DNS_ERROR 149 0 : U:10.102.27.70#27832:10.102.27.73#53/61153/Q/
(RD)/NO/1/0/0/0#test.com./1140#Packet Dropped
```

Policy based logging

You can configure custom logging based on DNS expressions by configuring the logAction on DNS policies, Rewrite, or Responder policies. You can specify that logging occurs only when a particular DNS policy evaluates to true. For more information, see Configure policy based logging for DNS.

Understand the NetScaler syslog log message format

NetScaler appliance log DNS requests and responses in the following Syslog format:

```
<transport> :<client IP#echo><client ephemeral port>:<DNS endpoint IP>#<port>
: <query id> /opcode/header flags/rcode/question section count/answer section count
/ auth section count / additional section count #<queried domain name>
/<queried type>###
```

- **<transport>:**
  - T = TCP
  - U = UDP
- **<client IP>#< client ephemeral port >:**
  DNS client IP address and port number
- `<DNS endpoint IP>#<port>`:
  NetScaler DNS endpoint IP address and port number

- `<query id>`:
  Query ID

- `<opcode>`:
  Operation code. Supported Values:
  - Q: query
  - I: inverse query
  - S: status
  - X0: unassigned
  - N: notify
  - U: update
  - X1-10: unassigned values

- `<headerflags>`:
  Flags. Supported Values:
  - RD: recursion desired
  - TC: truncated
  - AA: authoritative response
  - CD: check disabled
  - AD: authenticated data
  - Z: unassigned
  - RA: recursion available
  - R: response

- `<rcode>`:
  Response Code. Supported Values:
  - NO: no error
  - F: format error
  - S: server failure
  - NX: non-existent domain
  - NI: not implemented
  - R: query refused
  - YX: Name Exists when it should not
  - YXR: RR Set Exists when it should not
  - NXR: RR Set that should exist does not
  - NAS: Server Not Authoritative for zone
  - NA: Not Authorized
  - NZ: Name not contained in zone
- X1-5: unassigned

- **/question section count/answer section count/auth section count/additional section count:**
  Question section, Authority section count, and Additional section count in the DNS request

- **<queried domain name>/<queried type>:**
  Queried domain and queried type in the DNS request

- **#ANS#/<record type>/<ttl>/..#AUTH#/<domain name>/<record type>/<ttl>..#ADD#/<domain name>/<record type>/<ttl>…:**
  In case of DNS responses:
  Answer Section is logged if answer section logging is enabled in the DNS profile.
  Authority and Additional sections are logged if extended logging is enabled in the DNS profile.
  The log format would differ depending on the type of record. For more information see Understanding the Record Logging Format.
  - ANS: answer section
  - AUTH: authority
  - ADD: Additional section

- **OPT/<edns version>/UDP max payload size/DO:**
  OPT record format in the DNS log

- **OPT/<EDNS version>/UDP payload size>/<“DO”or empty based on whether DNSSEC OK bit is set or not>/<value of RDLEN>/ECS/<Q/R>/<option length>/<Family>/<Source Prefix-Length>/<Scope Prefix-Length>/<ECS Address>:**
  If the DNS query or response includes the EDNS Client Subnet (ECS) option, then that is also logged in the OPT record format in the DNS log file.
  When a DNS query with ECS option that includes either IPv4 or IPv6 address is sent, the ECS option is logged with either “ECS/Q” indicating that the values in the log are from the query or “ECS/R” indicating that the values in the log are from the response.
  The value of Scope Prefix-Length is also set appropriately. In case of the DNS Query, it is set to zero, and for response, it is set to the calculated value.
  The following table describes the logged details in various scenarios:
<table>
<thead>
<tr>
<th>Scenario</th>
<th>ECS option set in the DNS Query</th>
<th>ECS option set in the DNS Response</th>
<th>Logged Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Both query logging and extended logging enabled</td>
<td>Yes</td>
<td>Yes</td>
<td>ECS option is logged with the string “ECS/R/” and the Scope Prefix-Length is set to the calculated value.</td>
</tr>
<tr>
<td>Both query logging and extended logging enabled</td>
<td>Yes</td>
<td>No</td>
<td>ECS option is logged with the string “ECS/Q” and the Scope Prefix-Length is set to zero.</td>
</tr>
<tr>
<td>Query logging is enabled, but extended logging is not enabled</td>
<td>Yes</td>
<td>Yes</td>
<td>ECS option is logged with the string “ECS/Q/” and the Scope Prefix-Length is set to zero.</td>
</tr>
<tr>
<td>Query logging &amp; extended logging are not enabled</td>
<td>Yes</td>
<td>Yes</td>
<td>ECS option is not logged.</td>
</tr>
<tr>
<td>Query logging is enabled, but extended logging is not enabled</td>
<td>Yes</td>
<td>No</td>
<td>ECS option is logged with the string “ECS/Q/” and the Scope Prefix-Length is set to zero.</td>
</tr>
<tr>
<td>Query logging is not enabled, but extended logging is enabled</td>

</tr>
<tr>
<td>Query logging is not enabled, but extended logging is enabled</td>
<td>Yes</td>
<td>No</td>
<td>ECS option is not logged.</td>
</tr>
</tbody>
</table>
Understand the record logging format

Following is an example of the record logging format in a Syslog message:

```
1 <domainname>/<record type>/ <record ttl> / <resource record data>##<resource record data>######
```

where:

<table>
<thead>
<tr>
<th>Record Type</th>
<th>Sample Format</th>
<th>Resource Record Data / Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Address (A) record</td>
<td>A/5/1.1.1.1#1.1.1.2#1.1.1.3##</td>
<td>IPv4 address</td>
</tr>
<tr>
<td>AAAA record</td>
<td>AAAA/5/1::1#1::2#1::3##</td>
<td>IPv6 address</td>
</tr>
<tr>
<td>SOA record</td>
<td>SOA/3600/ns1.dnslogging.test./</td>
<td>Origin server, contact, and other details. Resource record format is: 3/3600/5##</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>NS record</td>
<td>NS/5/ns1.dnslogging.test</td>
<td>Host name of the nameserver.</td>
</tr>
<tr>
<td>MX record</td>
<td>#MX/5/10/host1.dnslogging.test.#</td>
<td>Exchange server host name</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>CNAME record logging</td>
<td>CNAME/5/host1.dnslogging.test</td>
<td>Canonical name</td>
</tr>
<tr>
<td>SRV record</td>
<td>SRV/5/1/2/3/host1.dnslogging.test.#</td>
<td>Resource record format: # latency=dnslogging by tail &lt;priority&gt;/&lt;weight&gt;/&lt;port&gt;/&lt;target&gt;#</td>
</tr>
<tr>
<td>TXT record</td>
<td>TXT/5/dns+logging##</td>
<td>Data comprises all the texts.</td>
</tr>
<tr>
<td>NAPTR record</td>
<td>NAPTR/5/10/11//dnslogging#20/dnslogging#20/#</td>
<td>Resource record format: # latency=dnslogging by tail &lt;flags&gt;##</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>DNSKEY record</td>
<td>DNSKEY/5/1/3/5/AwEAAanP0K+</td>
<td>Resource record format: IZgiDBZhSONI&lt;flags&gt;## &lt;protocol&gt;/&lt;algorithm&gt; &lt;public key in base64 encoding&gt;##</td>
</tr>
<tr>
<td>PTR record</td>
<td>PTR/3600/test.com.#test4.com.#</td>
<td>Domain name</td>
</tr>
</tbody>
</table>
Limitations of DNS logging

DNS logging has the following limitations:

- If response logging is enabled, only the following record types are logged:
  - Address (A) record
  - AAAA record
  - SOA record
  - NS record
  - MX record
  - CNAME record
  - SRV record
  - TXT record
  - NAPTR record
  - DNSKEY record
  - PTR record

  For all other record types, only L3/L4 parameters, DNS Header, and Question section are logged.

- RRSIG records are not logged even if response logging is enabled.

- DNS64 is not supported.

- DNS proactive update requests or responses are logged according to the settings in the default profile.

- On the virtual server, if sessionless option and response logging is enabled, L3/L4 parameters, DNS Header, and DNS Question section are logged instead of the response.

- The maximum size of the syslog message is 1024 bytes.

- If you have set DNS profile for a DNS policy with action type Rewrite Response, NetScaler appliance does not log the query or the manipulated responses. To log the required information you need to use audit message action in the DNS policy.

- DNS transactions that are due to DNS monitoring traffic are not logged.

Configuring DNS logging

Following is an overview of configuring DNS logging:

1. Create a Syslog action and enable DNS in the action.
2. Create a Syslog policy and specify the Syslog action in the policy.
3. Globally bind the Syslog policy to enable logging of all NetScaler system events. Or, bind the Syslog policy to a specific load balancing virtual server.
4. Create a DNS profile and define any of the following type of logging that you want to enable:
NetScaler 12.0

- DNS Query Logging
- DNS Answer Section Logging
- DNS Extended Logging
- DNS Error Logging

5. Configure any of the following, based on your requirement:

- DNS service and virtual server for DNS
- ADNS service
- NetScaler as a forwarder
- NetScaler as a resolver

6. Set the created DNS profile to one of the DNS entities.

**Configure DNS logging for NetScaler configured as DNS Proxy by using the CLI**

1. Add a syslog action and enable DNS in the action. At the command prompt, type:

   ```
   add audit syslogAction <name> (<serverIP> | -lbVserverName <string> | -serverPort <port> | -logLevel <logLevel> ... [-dateFormat <dateFormat>] [-logFacility <logFacility>] [-tcp ( NONE | ALL )] [-acl ( ENABLED | DISABLED )] [-timeZone ( GMT_TIME | LOCAL_TIME )] [-userDefinedAuditlog ( YES | NO )] [-appFlowExport ( ENABLED | DISABLED )] [-lsn ( ENABLED | DISABLED )] [-alg ( ENABLED | DISABLED )] [-transport ( TCP | UDP )] [-tcpProfileName <string>] [-maxLogDataSizeToHold <positive_integer>] [-dns ( ENABLED | DISABLED)]
   ```

   **Example:**

   ```
   add audit syslogAction nssyslogact1 10.102.151.136 -logLevel CRITICAL ERROR WARNING NOTICE INFORMATIONAL DEBUG -logFacility LOCAL4 -timeZone LOCAL_TIME -dns ENABLED
   ```

2. Create a syslog policy and specify the created syslog action in the policy. At the command prompt, type:

   ```
   add audit syslogPolicy <name> <rule> <action>
   ```

   **Example:**

   ```
   add audit syslogPolicy syslogpoll ns_true nssyslogact1
   ```

3. Bind the syslog policy globally. At the command prompt, type:

   ```
   bind system global [/<policyName> [ -priority <positive_integer>]]
   ```

   **Example:**

   ```
   bind system global syslogpoll
   ```
4. Create a DNS profile and enable any of the following type of logs that you want to configure:
   
   - DNS Query Logging
   - DNS Answer Section Logging
   - DNS Extended Logging
   - DNS Error Logging

   At the command prompt, type:

   ```
   add dns profile <dnsProfileName> [-dnsQueryLogging ( ENABLED | DISABLED )] [-dnsAnswerSecLogging ( ENABLED | DISABLED )] [-dnsExtendedLogging ( ENABLED | DISABLED )] [-dnsErrorLogging ( ENABLED | DISABLED )] [-cacheRecords ( ENABLED | DISABLED )] [-cacheNegativeResponses ( ENABLED | DISABLED )]
   ```

   **Example:**

   ```
   add dns profile dnsprofile1 -dnsQueryLogging ENABLED
   ```

5. Configure service of type DNS. At the command prompt, type:

   ```
   add service <name> <serviceName> <serverName> <serviceType> <port>
   ```

   **Example:**

   ```
   add service svc1 10.102.84.140 dns 53
   ```

6. Configure a load balancing virtual server of service type DNS.

   ```
   add lb vserver <name> <serviceType> <ip> <port>
   ```

   **Example:**

   ```
   add lb vserver lb1 dns 100.100.100.10 53
   ```

7. Bind the service to the virtual server. At the command prompt, type:

   ```
   bind lb vserver <name> <serviceName>
   ```

   **Example:**

   ```
   bind lb vserver lb1 svc1
   ```

8. Set the created DNS profile to the virtual server. At the command prompt, type:

   ```
   set lb vserver <name> [ -dnsProfileName <string>]
   ```

   **Example:**

   ```
   set lb vserver lb1 -dnsProfileName dnsprofile1
Sample DNS logging configuration for NetScaler appliance configured as DNS proxy

```
> add audit syslogAction nssyslogact1 10.102.151.136 -logLevel CRITICAL ERROR WARNING NOTICE INFORMATIONAL DEBUG -logFacility LOCAL4 -timeZone LOCAL_TIME -dns ENABLED
Done
> add audit syslogPolicy syslogpol1 ns_true nssyslogact1
Done
> bind system global syslogpol1
Done
> add dns profile dnsprofile1 -dnsqueryLogging ENABLED
Done
> add lb vserver lb1 dns 100.100.100.10 53 -dnsProfileName dnsprofile1
Done
> add service svc1 10.102.84.140 dns 53
Done
> bind lb vserver lb1 svc1
Done
```

Sample DNS logging configuration for NetScaler appliance configured as ADNS

```
> add audit syslogAction nssyslogact1 10.102.151.136 -logLevel CRITICAL ERROR WARNING NOTICE INFORMATIONAL DEBUG -logFacility LOCAL4 -timeZone LOCAL_TIME -dns ENABLED
Done
> add audit syslogPolicy syslogpol1 ns_true nssyslogact1
Done
> bind system global syslogpol1
Done
> add dns profile dnsprofile1 -dnsqueryLogging ENABLED
Done
> add lb vserver lb1 dns 100.100.100.10 53 -dnsProfileName dnsprofile1
Done
> add service svc1 10.102.84.140 dns 53
Done
> bind lb vserver lb1 svc1
Done
```

Sample DNS logging configuration for NetScaler appliance configured as a forwarder
Sample DNS logging configuration for NetScaler appliance configured as a sesolver

```
> add audit syslogAction nssyslogact1 10.102.151.136 -logLevel CRITICAL ERROR WARNING NOTICE INFORMATIONAL DEBUG -logFacility LOCAL4 -timeZone LOCAL_TIME -dns ENABLED
Done
> add audit syslogPolicy syslogpol1 ns_true nssyslogact1
Done
> bind system global syslogpol1
Done
> add dns profile dnsprofile1 -dnsqueryLogging ENABLED
Done
> add dns nameserver 8.8.8.8 -dnsProfileName dnsprofile1
Done
```

Configure policy based logging for DNS

Policy based logging enables you to specify a format for log messages. The contents of a log message are defined by using a default syntax expression. When the message action specified in the policy is performed, the NetScaler appliance constructs the log message from the expression and writes the message to the log file. You can configure the appliance to log only when a particular DNS policy evaluates to True.
NetScaler 12.0

Note

If you have set a DNS policy with a DNS profile for the request side, NetScaler appliance logs only the query.

To configure policy based logging for a DNS policy, you must first configure an audit message action. For more information about configuring an audit message action, see Configure the NetScaler appliance for audit logging. After configuring the audit message action, specify the message action in a DNS policy.

Configure policy based logging for a DNS policy by using the CLI

At the command prompt, type the following commands to configure policy based logging for a DNS policy and verify the configuration:

1. `add dns action <actionName> <actionType> [-IPAddress <ip_addr> ipv6_addr> ...] [-TTL <secs>] [-preferredLocList <string> ...] [-dnsProfileName <string>]
2. `set dns policy <name> [<rule>] [-actionName <string>] [-logAction <string>]
3. `show dns policy [<name>]

Example 1:

In a GSLB deployment, if you want to respond with different IP addresses to the client requests coming from a particular subnet, instead of responding with IP addresses used for general purposes (such as the IP addresses of internal users), you can configure a DNS policy with the action type as DNS view. In this case, you can configure DNS logging on the specified DNS action such that you can log the specific responses.

1. `add dns profile dns_prof1 -dnsqueryLogging enABLED -dnsanswerSecLogging enABLED
2. Done
3. `add dns view dns_view1
4. Done
5. `add dns action dns_act1 viewName -view dns_view1 -dnsprofilename dns_prof1
6. Done
7. `add dns policy dns_pol1 "CLIENT.IP.SRC.APPLY_MASK(255.255.255.0).EQ(100.100.100.0)"
   dns_act1
8. Done
9. `bind dns global dns_pol1 100 -gotoPriorityExpression END -type REQ_DEFAULT

© 1999-2018 Citrix Systems, Inc. All rights reserved. 2001
NetScaler 12.0

11 Done
12 > bind gslb service site_1_svc -viewName dns_view1 123.1.1.1
13 Done
14 > bind gslb service site_5_svc -view dns_view1 132.1.1.1
15 Done

**Note:** In the above configuration, if you query for the domain configured on a GSLB virtual server, for example, *sampletest.com*, all the internal users of subnet 100.100.100.0/24 are served with the DNS view IP addresses, and the responses are logged. Client requests for other subnets are not logged.

**Example 2:**

If you want to log only the queries for the domain *example.com*, you can create a DNS profile with query logging enabled and set the DNS profile to a DNS action with the action type *NOOP*, and then create a DNS policy and set the DNS action. For example:

```bash
1 > add dns profile query_logging -dnsqueryLogging ENABLED
2 Done
3 > add dns action dns_act1 NOOP -dnsprofileName query_logging
4 Done
5 > add dns policy dns_pol1 DNS.REQ.QUESTION.DOMAIN.EQ("example.com")
        dns_act1
6 Done
```

**Configuring DNS suffixes**

September 11, 2018

You can configure DNS suffixes that enable the NetScaler appliance to complete non-fully qualified domain names (non-FQDNs) during name resolution. For example, during the process of resolving the domain name *abc* (which is not fully qualified), if a DNS suffix *example.com* is configured, the appliance appends the suffix to the domain name (*abc.example.com*) and resolves it. If DNS suffixes are not configured, the appliance appends a period to the non-FQDNs and resolves the domain name.

**Create DNS suffixes**

DNS suffixes have significance and are valid only when the NetScaler is configured as an end resolver or forwarder. You can specify a suffix of up to 127 characters.
Create DNS suffixes by using the CLI

At the command prompt, type the following commands to create a DNS suffix and verify the configuration:

1 - add dns suffix <dnsSuffix>
2 - show dns suffix <dnsSuffix>

Example:

1 > add dns suffix example.com
2 Done
3 > show dns suffix example.com
4 1) Suffix: example.com
5 Done

To remove a DNS suffix by using the NetScaler command line, at the NetScaler command prompt, type the rm dns suffix command and the name of the DNS suffix.

Create DNS suffixes by using the GUI

Navigate to Traffic Management > DNS > DNS Suffix and create DNS suffixes.

DNS ANY query

September 11, 2018

An ANY query is a type of DNS query that retrieves all records available for a domain name. The ANY query must be sent to a name server that is authoritative for a domain.

Behavior in ADNS mode

In the ADNS mode, the NetScaler appliance returns the records held in its local cache. If there are no records in the cache, the appliance returns the NXDOMAIN (negative) response.

If the NetScaler can match the domain delegation records, it returns the NS records. Otherwise, it returns the NS records of the root domain.

Behavior in DNS proxy mode

In proxy mode, the NetScaler appliance checks its local cache. If there are no records in the cache, the appliance passes the query to the server.
**Behavior for GSLB domains**

If a GSLB domain is configured on the NetScaler appliance and an ANY query is sent for the GSLB domain (or GSLB site domain), the appliance returns the IP address of the GSLB service that it selects through the Load Balancing decision. If the multiple IP response (MIR) option is enabled, the IP addresses of all GSLB services are sent.

For the NetScaler to return these records when it responds to the ANY query, all records corresponding to a GSLB domain must be configured on the NetScaler.

**Note**

If records for a domain are distributed between the NetScaler and a server, only records configured on the NetScaler are returned.

The NetScaler provides the option to configure DNS views and DNS policies. These are used for performing global server load balancing. For more information, see [Global Server Load Balancing](#).

**Configure negative caching of DNS records**

September 11, 2018

The NetScaler appliance supports caching of negative responses for a domain. A negative response indicates that information about a requested domain does not exist, or that the server cannot provide an answer for the query. The storage of this information is called negative caching. Negative caching helps speed up responses to queries about a domain.

**Note:**

Negative caching is supported only when the back-end server is configured as an authoritative DNS (ADNS) server for the queried domain.

A negative response can be one of the following:

- **NXDOMAIN error message**—If a negative response is present in the local cache, the NetScaler returns an error message (NXDOMAIN). If the response is not in the local cache, the query is forwarded to the server, and the server returns an NXDOMAIN error to the NetScaler appliance. The appliance caches the response locally, then returns the error message to the client.

- **NODATA error message**—If the domain name in query is valid but records of the given type are not available, the appliance sends a NODATA error message.

When negative caching is enabled, the appliance caches the negative response from the DNS server and serves the future requests from the cache only. This helps speed up responses to queries and also to reduce the DNS traffic. Negative caching can be used in all deployments, that is, when a NetScaler appliance is serving as a proxy, as an end resolver, or as a forwarder.
You can enable or disable negative caching using DNS profile, for more information see, DNS profiles. By default, negative caching is enabled in the default DNS profile (default-dns-profile) that are bound by default to a DNS virtual server or in the newly created DNS profile.

Enable or disable negative caching by using the CLI

At the command prompt, type the following commands to enable or disable negative caching and verify the configuration:

1. `add dns profile <dnsProfileName> [-cacheRecords ( ENABLED | DISABLED )] [-cacheNegativeResponses (ENABLED | DISABLED )]`

Example of a default DNS profile:

```
1 > sh dns profile default-dns-profile
2  1) default-dns-profile
3    Query logging : DISABLED     Answer section logging :
4      DISABLED
5    Extended logging : DISABLED     Error logging : DISABLED
6    Cache Records : ENABLED   Cache Negative Responses: ENABLED
7 Done
```

Example of a newly created DNS profile:

```
1 > add dnsprofile dns_profile1 -cacheRecords ENABLED -cacheNegativeResponses ENABLED
2   Done
3 > show dns profile dns_profile1
4  1) dns_profile1
5    Query logging : DISABLED     Answer section logging :
6      DISABLED
7    Extended logging : DISABLED     Error logging : DISABLED
8    Cache Records : ENABLED   Cache Negative Responses: ENABLED
9 Done
```

Specify service or virtual server level DNS parameters by using the CLI

At the command prompt, perform the following:

1. Configure the DNS profile.

```
add dns profile <dnsProfileName> [-cacheRecords ( ENABLED | DISABLED )]
  [-cacheNegativeResponses (ENABLED | DISABLED )]
```
2. Bind the DNS profile to the service or virtual server.

To bind the DNS profile to the service:

```
set service <name> [-dnsProfileName <string>]
```

Example:

```
1 >set service service1 -dnsProfileName dns_profile1
2 Done
```

To bind the DNS profile to the virtual server:

```
set lb vserver <name> [-dnsProfileName <string>]
```

Example:

```
1 >set lb vserver lbvserver1 -dnsProfileName dns_profile1
2 Done
```

Specify service or virtual server level DNS parameters by using the GUI

1. Configure the HTTP profile.

   Navigate to **System > Profiles > DNS Profile**, and create the DNS profile.

2. Bind the HTTP profile to the service or virtual server.

   Navigate to **Traffic Management > Load Balancing > Services/Virtual Servers**, and create the DNS profile, which should be bound to the service/virtual server.

Cache EDNS0 client subnet data when the NetScaler appliance is in proxy mode

January 6, 2019

In NetScaler Proxy mode, if a back-end server that supports EDNS0 Client Subnet (ECS) sends a response containing the ECS option, the NetScaler appliance forwards the response as-is to the client and stores it in the cache, along with the client subnet information. Further DNS requests that are from the same subnet of the same domain, and for which the server would send the same response, are then served from the cache instead of being directed to the server.

**Note:**

- ECS caching is disabled by default. You have to enable caching of EDNS0 client-subnet data in the associated DNS profile.
The number of subnets that you can cache for a domain is limited to the available subnet IDs, that is, 1270 in the NetScaler appliance. Optionally, you can set the limit to a lower number (minimum value: 1 ipv4/ipv6).

Enable caching of ECS responses by using the CLI

At the command prompt, type:

```
set dns profile <dnsProfileName> -cacheECSSubnet ( ENABLED | DISABLED )
```

Limit the number of subnets that can be cached per domain by using the CLI

At the command prompt, type:

```
set dns profile <dnsProfileName> -maxSubnetsPerDomain <positive_integer>
```

**Example:**

In the example shown in the above figure, the client at IP address 2.2.2.2 sends a query for www.example.com to the DNS resolver, and the DNS resolver sends the following response:

```
www.example.com IN A, IP is 2.2.2.11, and ECS 2.2.2.0/24/24
```

At this point, the response and the client-subnet identifier (2.2.2.0/24) are cached. Further requests from the same subnet and domain will be served from the cache.

For example, if the client’s IP address is 2.2.2.100 and the query is for www.example.com, the query is served from the cache instead of being sent to the backend server.

Domain name system security extensions

September 12, 2018

DNS Security Extensions (DNSSEC) is an Internet Engineering Task Force (IETF) standard that aims to provide data integrity and data origin authentication in communications between name servers and clients while still transmitting User Datagram Protocol (UDP) responses in clear text. DNSSEC specifies a mechanism that uses asymmetric key cryptography and a set of new resource records that are specific to its implementation.

You can configure DNSSEC on the NetScaler ADC. You can generate and import keys for signing DNS zones. You can configure DNSSEC for zones for which the NetScaler is authoritative. You can configure the ADC as a DNS proxy server for signed zones hosted on a farm of backend name servers. If the ADC is authoritative for a subset of the records belonging to a zone for which the ADC is configured as a DNS proxy server, you can include the subset of records in the DNSSEC implementation.

**Configure DNSSEC**

September 14, 2018

Configuring DNSSEC involves enabling DNSSEC on the NetScaler ADC appliance, creating a Zone Signing Key and a Key Signing Key for the zone, adding the two keys to the zone, and then signing the zone with the keys.

The NetScaler appliance does not act as a DNSSEC resolver. DNSSEC on the ADC is supported only in the following deployment scenarios:

1. ADNS—NetScaler is the ADNS and generates the signatures itself.
2. Proxy—NetScaler acts as a DNSSEC proxy. It is assumed that the NetScaler is placed in front of the ADNS/LDNS servers in a trusted mode. The ADC acts only as a proxy caching entity and does not validate any signatures.

**Enable and disable DNSSEC**

You must enable DNSSEC on the NetScaler for the ADC to respond to DNSSEC-aware clients. By default, DNSSEC is enabled.

You can disable the DNSSEC feature if you do not want the NetScaler to respond to clients with DNSSEC-specific information.

**Enable or disable DNSSEC by using the CLI**

At the command prompt, type the following commands to enable or disable DNSSEC and verify the configuration:

```
1 - set dns parameter -dnssec ( ENABLED | DISABLED )
2 - show dns parameter
```

**Example:**

```
1 > set dns parameter -dnssec ENABLED
2  Done
```
Enable or disable DNSSEC by using the GUI

1. Navigate to Traffic Management > DNS.
2. In the details pane, click Change DNS settings.
3. In the Configure DNS Parameters dialog box, select or clear the Enable DNSSEC Extension check box.

Create DNS keys for a zone

For each DNS zone that you want to sign, you must create two pairs of asymmetric keys. One pair, called the Zone Signing Key, is used to sign all the resource record sets in the zone. The second pair is called the Key Signing Key and is used to sign only the DNSKEY resource records in the zone.

When the Zone Signing Key and Key Signing Key are created, the suffix .key is automatically appended to the names of the public components of the keys and the suffix .private is automatically appended to the names of their private components.

Additionally, the NetScaler also creates a Delegation Signer (DS) record and appends the suffix .ds to the name of the record. If the parent zone is a signed zone, you must publish the DS record in the parent zone to establish the chain of trust.

When you create a key, the key is stored in the /nsconfig/dns/ directory, but it is not automatically published in the zone. After you create a key by using the create dns key command, you must explicitly publish the key in the zone by using the add dns key command. The process of generating a key has been separated from the process of publishing the key in a zone to enable you to use alternative means to generate keys. For example, you can import keys generated by other key-generation programs (such as bind-keygen) by using Secure File Transfer Protocol (SFTP) and then publish the keys in the zone. For more information about publishing a key in a zone, see Publish a DNS key in a zone.

Perform the steps described in this topic to create a Zone Signing Key and then repeat the steps to create a Key Signing Key. The example that follows the command syntax first creates a Zone Signing
Key pair for the zone example.com. The example then uses the command to create a Key Signing Key pair for the zone.

Create a DNS key by using the CLI

At the NetScaler command prompt, type the following command to create a DNS key:

```bash
create dns key -zoneName <string> -keyType <keyType> -algorithm RSASHA1 -keySize <positive_integer> -fileNamePrefix <string>
```

Example:

```
1 > create dns key -zoneName example.com -keyType zsk -algorithm RSASHA1 -keySize 1024 -fileNamePrefix example.com.zsk.rsasha1.1024
2 File Name: /nsconfig/dns/example.com.zsk.rsasha1.1024.key (public); /
   nsconfig/dns/example.com.zsk.rsasha1.1024.private (private); /
   nsconfig/dns/example.com.zsk.rsasha1.1024.ds (ds)
3 This operation may take some time, Please wait...
4 Done
5 > create dns key -zoneName example.com -keyType ksk -algorithm RSASHA1 -keySize 4096 -fileNamePrefix example.com.ksk.rsasha1.4096
6 File Name: /nsconfig/dns/example.com.ksk.rsasha1.4096.key (public); /
   nsconfig/dns/example.com.ksk.rsasha1.4096.private (private); /
   nsconfig/dns/example.com.ksk.rsasha1.4096.ds (ds)
7 This operation may take some time, Please wait...
8 Done
```

Create a DNS key by using the GUI

1. Navigate to Traffic Management > DNS.
2. In the details area, click **Create DNS Key** and create a DNS key.
   
   Note: For File Name Prefix, if you want to modify the file name prefix of an existing key, click the arrow next to the Browse button, click either Local or Appliance (depending on whether the existing key is stored on your local computer or in the /nsconfig/dns/ directory on the appliance), browse to the location of the key, and then double-click the key. The File Name Prefix box is populated with only the prefix of the existing key. Modify the prefix accordingly.
Publish a DNS key in a zone

A key (Zone Signing Key or Key Signing Key) is published in a zone by adding the key to the NetScaler. A key must be published in a zone before you sign the zone.

Before you publish a key in a zone, the key must be available in the /nsconfig/dns/ directory. Therefore, if you used other means to generate the key—means other than the create dns key command on the NetScaler (for example, by using the bind-keygen program on another computer)—make sure that the key is added to the /nsconfig/dns/ directory before you publish the key in the zone.

If the key has been generated by another program, you can import the key to your local computer and use the NetScaler configuration utility to add the key to the /nsconfig/dns/ directory. Or, you can use other means to import the key to the directory, such as the Secure File Transfer Protocol (SFTP).

You must use the add dns key command for each public-private key pair that you want to publish in a given zone. If you created a Zone Signing Key pair and a Key Signing Key pair for a zone, use the add dns key command to first publish one of the key pairs in the zone and then repeat the command to publish the other key pair. For each key that you publish in a zone, a DNSKEY resource record is created in the zone.

The example that follows the command syntax first publishes the Zone Signing Key pair (that was created for the example.com zone) in the zone. The example then uses the command to publish the Key Signing Key pair in the zone.

Publish a key in a zone by using the CLI

At the command prompt, type the following command to publish a key in a zone and verify the configuration:

```
1 - add dns key <keyName> <publickey> <privatekey> [-expires <positive_integer> [units]] [-notificationPeriod <positive_integer> [units]] [-TTL <secs>]
2 - show dns zone [<zoneName> | -type <type>]
```

Example:

```
1 > add dns key example.com.zsk example.com.zsk.rsasha1.1024.key example.com.zsk.rsasha1.1024.private
   Done
2 > add dns key example.com.zsk example.com.zsk.rsasha1.1024.key example.com.zsk.rsasha1.1024.private
   Done
3 > add dns key example.com.zsk example.com.zsk.rsasha1.4096.key example.com.zsk.rsasha1.4096.private
   Done
4 > show dns zone example.com
   Zone Name : example.com
```
Publish a key in a DNS zone by using the GUI

Navigate to
Traffic Management > DNS > Keys.

**Note:** For Public Key and Private Key, to add a key that is stored on your local computer, click the arrow next to the Browse button, click Local, browse to the location of the key, and then double-click the key.

Configure a DNS key

You can configure the parameters of a key that has been published in a zone. You can modify the key’s expiry time period, notification period, and time-to-live (TTL) parameters. If you change the expiry time period of a key, the NetScaler automatically re-signs all the resource records in the zone with the key, provided that the zone is currently signed with the particular key.

Configure a key by using the CLI

At the command prompt, type the following command to configure a key and verify the configuration:

```
1 - set dns key <keyName> [-expires <positive_integer> [units]] [-notificationPeriod <positive_integer> [units]] [-TTL <secs>]
2 - show dns key [<keyName>]
```

**Example:**

```
1 > set dns key example.com.ksk -expires 30 DAYS -notificationPeriod 3 DAYS -TTL 3600
2   Done
3 > show dns key example.com.ksk
```
Configure a key by using the GUI

1. Navigate to Traffic Management > DNS > Keys.
2. In the details pane, click the key that you want to configure, and then click Open.
3. In the Configure DNS Key dialog box, modify the values of the following parameters as shown:
   - Expires—expires
   - Notification Period—notificationPeriod
   - TTL—TTL
4. Click OK.

Sign and unsign a DNS zone

To secure a DNS zone, you must sign the zone with the keys that have been published in the zone. When you sign a zone, the NetScaler creates a Next Secure (NSEC) resource record for each owner name. Then, it uses the Key Signing Key to sign the DNSKEY resource record set. Finally, it uses the Zone Signing Key to sign all the resource record sets in the zone, including the DNSKEY resource record sets and NSEC resource record sets. Each sign operation results in a signature for the resource record sets in the zone. The signature is captured in a new resource record called the RRSIG resource record.

After you sign a zone, you must save the configuration.

Sign a zone by using the CLI

At the command prompt, type the following command to sign a zone and verify the configuration:

```
1 - sign dns zone <zoneName> [-keyName <string> ...]
2 - show dns zone [<zoneName> | -type (ADNS | PROXY | ALL)]
3 - save config
```

Example:

```
1 > sign dns zone example.com -keyName example.com.zsk example.com.ksk
2 Done
```
Unsign a zone by using the CLI

At the command prompt, type the following command to unsign a zone and verify the configuration:

```
1 - unsign dns zone <zoneName> [-keyName <string> ...]
2 - show dns zone [<zoneName> | -type (ADNS | PROXY | ALL)]
```

Example:

```
1 > unsign dns zone example.com -keyName example.com.zsk example.com.ksk
2 Done
3 > show dns zone example.com
   Zone Name : example.com
   Proxy Mode : NO
   Domain Name : example.com
   Record Types : NS SOA DNSKEY RRSIG NSEC
4 Domain Name : ns1.example.com
   Record Types : A RRSIG NSEC
5 Domain Name : ns2.example.com
   Record Types : A RRSIG
6 Domain Name : ns2.example.com
   Record Types : RRSIG NSEC
7 Done
```

Sign or unsign a zone by using the GUI

1. Navigate to Traffic Management > DNS > Zones.
2. In the details pane, click the zone that you want to sign, and then click Sign/Unsign.
3. In the Sign/Unsign DNS Zone dialog box, do one of the following:
• To sign the zone, select the check boxes for the keys (Zone Signing Key and Key Signing Key) with which you want to sign the zone.
  You can sign the zone with more than one Zone Signing Key or Key Signing Key pair.
• To unsign the zone, clear the check boxes for the keys (Zone Signing Key and Key Signing Key) with which you want to unsign the zone.
  You can unsign the zone with more than one Zone Signing Key or Key Signing Key pair.
  4. Click OK.

**View the NSEC records for a given record in a zone**

You can view the NSEC records that the NetScaler automatically creates for each owner name in the zone.

**View the NSEC record for a given record in a zone by using the CLI**

At the command prompt, type the following command to view the NSEC record for a given record in a zone:

```bash
show dns nsecRec [<hostName> | -type (ADNS | PROXY | ALL)]
```

**Example:**

```
1 > show dns nsecRec example.com
2 1) Domain Name : example.com
3       Next Nsec Name: ns1.example.com
4       Record Types : NS SOA DNSKEY RRSIG NSEC
5       Done
```

**View the NSEC record for given record in a zone by using the GUI**

2. In the details pane, click the name of the record for which you want to view the NSEC record.
   The NSEC record for the record you select is displayed in the Details area.

**Remove a DNS key**

You remove a key from the zone in which it is published when the key has expired or if the key has been compromised. When you remove a key from the zone, the zone is automatically unsigned with the key. Removing the key with this command does not remove the key files present in the /nsconfig/dns/ directory. If the key files are no longer needed, they have to be explicitly removed from the directory.
Remove a key from the NetScaler by using the CLI

At the command prompt, type the following command to remove a key and verify the configuration:

```
1 - rm dns key <keyName>
2 - show dns key <keyName>
```

Example:

```
1 > rm dns key example.com.zsk
2   Done
3 > show dns key example.com.zsk
4 ERROR: No such resource [keyName, example.com.zsk]
```

Remove a key from the NetScaler by using the GUI

1. Navigate to Traffic Management > DNS > Keys.
2. In the details pane, click the name of the key that you want to remove from the ADC, and then click Remove.

Configure DNSSEC when the NetScaler is authoritative for a zone

September 14, 2018

When the NetScaler ADC is authoritative for a given zone, all the resource records in the zone are configured on the ADC. To sign the authoritative zone, you must create keys (the Zone Signing Key and the Key Signing Key) for the zone, add the keys to the ADC, and then sign the zone, as described in Create DNS keys for a zone, Publish a DNS key in a zone, and Sign and unsign a DNS zone, respectively.

If any global server load balancing (GSLB) domains configured on the ADC belong to the zone being signed, the GSLB domain names are signed along with the other records that belong to the zone.

After you sign a zone, responses to requests from DNSSEC-aware clients include the RRSIG resource records along with the requested resource records. DNSSEC must be enabled on the ADC. For more information about enabling DNSSEC, see Enable and disable DNSSEC.

Finally, after you configure DNSSEC for the authoritative zone, you must save the NetScaler configuration.
Configure DNSSEC for a zone for which the NetScaler is a DNS proxy server

October 24, 2018

The procedure for signing a zone for which the NetScaler ADC is configured as a DNS proxy server depends on whether or not the ADC owns a subset of the zone information owned by the backend name servers. If it does, the configuration is considered a partial zone ownership configuration. If the ADC does not own a subset of the zone information, the NetScaler configuration for managing the backend servers is considered a zone-less DNS proxy server configuration. The basic DNSSEC configuration tasks for both NetScaler configurations are the same. However, signing the partial zone on the NetScaler requires some additional configuration steps.

Note: The terms zone-less proxy server configuration and partial zone are used only in the context of the NetScaler appliance.

Important: When configured in proxy mode, the ADC does not perform signature verification on DNSSEC responses before updating the cache.

If you configure the ADC as a DNS proxy to load balance DNSSEC aware resolvers (servers), you must set the Recursion Available option while configuring the DNS virtual server. If a DNSSEC query arrives with Checking Disabled (CD) bit set, the query is passed on to the server with the CD bit retained, and the response from the server is not cached. In releases prior to 10.5.e build xx.x, the ADC unset the CD bit before passing it to the server and also cached the server response.

Configure DNSSEC for a zone-less DNS proxy server configuration

For a zone-less DNS proxy server configuration, zone signing must be performed on the backend name servers. On the NetScaler, you configure the ADC as a DNS proxy server for the zone. You create a load balancing virtual server of protocol type DNS, configure services on the ADC to represent the name servers, and then bind the services to the load balancing virtual server. For more information about these configuration tasks, see Configure the NetScaler as a DNS proxy server.

When a client sends the ADC a DNS request with the DNSSEC OK (DO) bit set, the ADC checks its cache for the requested information. If the resource records are not available in its cache, the ADC forwards the request to one of the DNS name servers, and then relays the response from the name server to the client. Additionally, the ADC caches the RRSIG resource records along with the response from the name server. Subsequent requests from DNSSEC-aware clients are served from the cache (including the RRSIG resource records), subject to the time-to-live (TTL) parameter. If a client sends a DNS request without setting the DO bit, the ADC responds with only the requested resource records, and does not include the RRSIG resource records that are specific to DNSSEC.
Configure DNSSEC for a partial zone ownership configuration

In some NetScaler configurations, even though the authority for a zone lies with the backend name servers, a subset of the resource records that belong to the zone might be configured on the NetScaler. The ADC owns (or is authoritative for) only this subset of records. Such a subset of records can be considered to constitute a **partial zone** on the ADC. The ADC owns the partial zone. All other records are owned by the backend name servers.

A typical partial zone configuration on the NetScaler is seen when global server load balancing (GSLB) domains are configured on the ADC, and the GSLB domains are a part of a zone for which the backend name servers are authoritative.

Signing a zone that includes only a partial zone on the ADC involves including the partial zone information in the backend name server zone files, signing the zone on the backend name servers, and then signing the partial zone on the ADC. The same key set must be used to sign the zone on the name servers and the partial zone on the ADC.

**Sign the zone on the backend name servers**

1. Include the resource records that are contained in the partial zone, in the zone files of the name servers.
2. Create keys and use the keys to sign the zone on the backend name servers.

**Sign the partial zone on the NetScaler**

1. Create a zone with the name of the zone that is owned by the backend name servers. When configuring the partial zone, set the proxyMode parameter to YES. This zone is the partial zone that contains the resource records owned by the ADC.

   For example, if the name of the zone that is configured on the backend name servers is example.com, you must create a zone named example.com on the ADC, with the proxyMode parameter set to YES. For more information about adding a zone, see Configure a DNS zone.

   **Note**

   Do not add SOA and NS records for the zone. These records should not exist on the ADC for a zone for which the ADC is not authoritative.

2. Import the keys (from one of the backend name servers) to the ADC and then add them to the /nsconfig/dns/ directory. For more information about how you can import a key and add it to the ADC, see Publish a DNS key in a zone.

3. Sign the partial zone with the imported keys. When you sign the partial zone with the keys, the ADC generates RRSIG and NSEC records for the resource record sets and individual resource...
records in the partial zone, respectively. For more information about signing a zone, see sign and unsign a DNS zone.

**Configure DNSSEC for GSLB domain names**

September 14, 2018

If global server load balancing (GSLB) is configured on the NetScaler ADC and the ADC is authoritative for the zone to which the GSLB domain names belong, all GSLB domain names are signed when the zone is signed. For more information about signing a zone for which the ADC is authoritative, see Configure DNSSEC when the NetScaler appliance is authoritative for a zone.

If the GSLB domains belong to a zone for which the backend name servers are authoritative, you must first sign the zone on the name servers, and then sign the partial zone on the ADC to complete the DNSSEC configuration for the zone. For more information, see Configure DNSSEC for a partial zone ownership configuration.

**Zone Maintenance**

September 14, 2018

From a DNSSEC perspective, zone maintenance involves rolling over Zone Signing Keys and Key Signing Keys when key expiry is imminent. These zone maintenance tasks have to be performed manually. The process of re-signing a zone is performed automatically and does not require manual intervention.

**Re-sign an updated zone**

When a zone is updated, that is, when new records are added to the zone or existing records are changed, the process of re-signing the new (or modified) record is performed automatically by the NetScaler ADC. If a zone contains multiple Zone Signing Keys, the ADC re-signs the new (or modified) record with the key with which the zone is signed at the point in time when the re-signing is to be performed.

**Roll over DNSSEC keys**

On the NetScaler, you can use the pre-publish and double signature methods to perform a rollover of the Zone Signing Key and Key Signing Key. More information about these two rollover methods is available in RFC 4641, “DNSSEC Operational Practices.”
The following topics map commands on the ADC to the steps in the rollover procedures discussed in RFC 4641.

The key expiry notification is sent through an SNMP trap called dnskeyExpiry. Three MIB variables, dnskeyName, dnskeyTimeToExpire, and dnskeyUnitsOfExpiry are sent along with the dnskeyExpiry SNMP trap. For more information, see Citrix NetScaler SNMP OID Reference at NetScaler 12.0 SNMP OID Reference.

Pre-publish key rollover

RFC 4641, “DNSSEC Operational Practices” defines four stages for the pre-publish key rollover method: initial, new DNSKEY, new RRSIGs, and DNSKEY removal. Each stage is associated with a set of tasks that you must perform on the ADC. Following are the descriptions of each stage and the tasks that you must perform. The rollover procedure described here can be used for both Key Signing Keys and Zone Signing Keys.

- **Stage 1: Initial.** The zone contains only those key sets with which the zone has currently been signed. The state of the zone in the initial stage is the state of the zone just before you begin the key rollover process.

  **Example:**

  Consider the key, example.com.zsk1, with which the zone example.com is currently signed. The zone contains only those RRSIGs that were generated by the example.com.zsk1 key, which is due for expiry. The Key Signing Key is example.com.ksk1.

- **Stage 2: New DNSKEY.** A new key is created and published in the zone (that is, the key is added to the ADC), but the zone is not signed with the new key until the pre-roll phase is complete. In this stage, the zone contains the old key, the new key, and the RRSIGs generated by the old key. Publishing the new key for the complete duration of the pre-roll phase gives the DNSKEY resource record (that corresponds to the new key) enough time to propagate to the secondary name servers.

  **Example:**

  A new key example.com.zsk2 is added to the example.com zone. The zone is not signed with example.com.zsk2 until the pre-roll phase is complete. The example.com zone contains DNSKEY resource records for both example.com.zsk1 and example.com.zsk2.

  **NetScaler commands:**

  Perform the following tasks on the ADC:

  - Create a new DNS key by using the create dns key command.

    For more information about creating a DNS key, including an example, see Create DNS keys for a zone.
Publish the new DNS key in the zone by using the add dns key command.

For more information about publishing the key in the zone, including an example, see Publish a DNS key in a zone.

• **Stage 3: New RRSIGs.** The zone is signed with the new DNS key and then unsigned with the old DNS key. The old DNS key is not removed from the zone and remains published until the RRSIGs that were generated by the old key expire.

**Example:**
The zone is signed with example.com.zsk2 and then unsigned with example.com.zsk1. The zone continues to publish example.com.zsk1 until the RRSIGs that were generated by example.com.zsk1 expire.

**NetScaler commands:**
Perform the following tasks on the ADC:
- Sign the zone with the new DNS key by using the sign dns zone command.
- Unsign the zone with the old DNS key by using the unsign dns zone command.

For more information about signing and unsigning a zone, including examples, see Sign and unsign a DNS zone.

• **Stage 4: DNSKEY Removal.** When the RRSIGs that were generated by the old DNS key expire, the old DNS key is removed from the zone.

**Example:**
The old DNS key example.com.zsk1 is removed from the example.com zone.

**NetScaler commands**
On the ADC, you remove the old DNS key by using the rm dns key command. For more information about removing a key from a zone, including an example, see Remove a DNS key.

**Double signature key rollover**

RFC 4641, “DNSSEC Operational Practices” defines three stages for double signature key rollover: initial, new DNSKEY, and DNSKEY removal. Each stage is associated with a set of tasks that you must perform on the ADC. Following are the descriptions of each stage and the tasks that you must perform. The rollover procedure described here can be used for both Key Signing Keys and Zone Signing Keys.

• **Stage 1: Initial.** The zone contains only those key sets with which the zone has currently been signed. The state of the zone in the initial stage is the state of the zone just before you begin the key rollover process.
Example:

Consider the key, example.com.zsk1, with which the zone example.com is currently signed. The zone contains only those RRSIGs that were generated by the example.com.zsk1 key, which is due for expiry. The Key Signing Key is example.com.ksk1.

- **Stage 2:** **New DNSKEY.** The new key is published in the zone and the zone is signed with the new key. The zone contains the RRSIGs that are generated by the old and the new keys. The minimum duration for which the zone must contain both sets of RRSIGs is the time required for all the RRSIGs to expire.

  Example:

  A new key example.com.zsk2 is added to the example.com zone. The zone is signed with example.com.zsk2. The example.com zone now contains the RRSIGs generated from both keys.

**NetScaler commands**

Perform the following tasks on the ADC:

- Create a new DNS key by using the create dns key command.
  
  For more information about creating a DNS key, including an example, see [Create DNS keys for a zone](#).

- Publish the new key in the zone by using the add dns key command.
  
  For more information about publishing the key in the zone, including an example, see [Publish a DNS key in a zone](#).

- Sign the zone with the new key by using the sign dns zone command.
  
  For more information about signing a zone, including examples, see [Sign and unsign a DNS zone](#).

- **Stage 3:** **DNSKEY Removal.** When the RRSIGs that were generated by the old DNS key expire, the old DNS key is removed from the zone.

  Example:

  The old DNS key example.com.zsk1 is removed from the example.com zone.

**NetScaler commands:**

On the ADC, you remove the old DNS key by using the rm dns key command.

For more information about removing a key from a zone, including an example, see [Remove a DNS key](#).
Offload DNSSEC operations to the NetScaler

September 11, 2018

For DNS zones for which your DNS servers are authoritative, you can offload DNSSEC operations to the NetScaler. In a DNSSEC offloading deployment, a DNS server sends unsigned responses. The ADC signs the response on the fly before relaying it to the client. The ADC also caches the signed response. Apart from reducing the load on the DNS servers, offloading DNSSEC operations to the ADC gives you the following benefits:

- You can sign records that the DNS servers generate programmatically. Such records cannot be signed by routine zone signing operations performed on the DNS servers.
- You can serve signed responses to clients even if you have not implemented DNSSEC on your servers.

For setting up DNSSEC offloading, you must configure a DNS load balancing virtual server, configure services that represent the DNS servers, and then bind the services to the virtual server. For information about configuring a DNS load balancing virtual server, configuring services, and binding the services to the virtual server, see Configure a DNS zone.

You must create a zone entity on the ADC for each DNS zone whose DNSSEC operations you want to offload. For each DNS zone, you must enable the Proxy Mode and DNSSEC Offload parameters. You can optionally configure NSEC record generation for an offloaded zone. To create a DNS zone entity for DNSSEC offloading, follow the instructions in this topic.

To complete the configuration, you must generate DNS keys for the zone, add the keys to the zone, and then sign the zone with the keys. This process is the same as for normal DNSSEC. For information about creating keys, adding keys to a zone, and signing the zone, see Domain name system security extensions.

After you configure DNS offloading, you must flush the DNS cache on the NetScaler. Flushing the DNS cache ensures that any unsigned records in the cache are removed and subsequently replaced by signed records. For information about flushing the DNS cache, see Flush DNS records.

Enable DNSSEC offloading for a zone by using the CLI

At the command line, type the following commands to enable DNSSEC offloading for a zone and verify the configuration:

1. add dns zone <zoneName> -proxyMode YES -dnssecOffload ENABLED [-nsec ( ENABLED | DISABLED )]
2. show dns zone

Example:
Enable DNSSEC offloading for a zone by using the GUI

1. Navigate to Traffic Management > DNS > Zones.
2. In the details pane, do one of the following:
   • To create a zone on the NetScaler, click Add.
   • To configure DNSSEC offloading for an existing zone, double-click the zone.
3. In the Create DNS Zone or Configure DNS Zone dialog box, select the Proxy Mode and DNSSEC Offload check boxes.
4. Optionally, if you want the NetScaler to generate NSEC records for the zone, select the NSEC check box.

Admin partition support for DNSSEC

September 11, 2018

In a partitioned NetScaler appliance, the DNS keys that are generated are stored in the following locations:

• Default partition: /nsconfig/dns/
• Non-default partition: /nsconfig/partitions/<partitionname>/dns/

You can now add a password to the DNS key. To add a password to the DNS key, you must first add the password in the create dns key command and then provide the same password in the add dns key command when adding the DNS key to the NetScaler appliance. For example:

create dns key -zoneName com -keytype ksK -algorithm rsASHA1 -keysize 4096 -fileNamePrefix com.ksk.rsasha1.4096 -password 1jsfd3Wa

add dns key com.zsk.4096 /nsconfig/dns/com.zsk.rsasha1.4096.private -password 1jsfd3Wa

Note:
- For default partitioned environment, the keys are read from default location/nsconfig/dns/. However, if the keys are stored in a different location, the path name has to be provided in the `add dns key -private` command. Example, `add dns key -private <path name>`.
- For non-default partitioned environment, the keys are read from the default location/nsconfig/partitions/<partitionname>/dns/.

### Supporting wildcard DNS domains

**September 11, 2018**

Wildcard DNS domains are used to handle requests for nonexistent domains and subdomains. In a zone, if you want to redirect queries for all nonexistent domains or subdomains to a particular server, you can use wildcard domains rather than creating a separate Resource Record (RR) for each such domain. The most common use of a wildcard DNS domain is to create a zone that can be used to forward mail from the internet to some other mail system.

In DNS resolution, the wildcard domain is supported by wildcard RRs. The wildcard RRs are used to synthesize the responses to queries for a nonexistent domain name. For example, if you queried `http://image.example.com`, and the subdomain “image” did not exist, you could be redirected to `example.com`.

A wildcard record has an asterisk (*) character as the leftmost label of a domain name. For example, `*.example.com`. An asterisk at any other place in the domain name does signify a wildcard DNS record. For example, `new.*.example.com` is not a valid wildcard DNS record.

**Note**

- Wildcard domain is supported only when the NetScaler appliance is authoritative for the zone and is configured as an ADNS or a DNS proxy server.
- Wildcard domain is not supported for NS and SOA records.
- Wildcard domain cannot be applied when the query is in another zone.
- Wildcard domain cannot be applied when the QNAME or a name between the wildcard domain and the QNAME is known to exist.

**Example configuration**

```plaintext
1  add dns soaRec example.com -originServer n1.example.com -contact admin.example.com
2
3  add dns nsRec example.com n1.example.com
4
5  add dns nsRec example.com n2.example.com
```
In the example, wildcard domain name is added for A and AAAA record.

When a query is received for a domain name that exists in the zone, say www.example.com, the NetScaler appliance responds with the corresponding response; that is 2.2.2.2 in the example.

For a nonexistent domain name that matches with a wildcard type, a synthesized response is delivered.

In the example, the NetScaler appliance responds with 10.10.10.10 and 10.10.10.11 for domain name nonexistent.example.com or xyz.example.com.

Wildcard synthesize is not applicable for a domain name that exists in the zone.

For example, for the query www.example.com and type AAAA, the NetScaler appliance does not synthesize with wildcard, because www.example.com exists with type A. In the example, the NetScaler appliance responds with a NODATA response.

For a query say abc.example.com and type AAAA, the NetScaler appliance responds with a synthesized response; that is 2001::1 in the example.

**Mitigate DNS DDoS attacks**

September 11, 2018

DNS servers are one of the most critical components of a network, and they must be defended against attacks. One of the most basic types of DNS attacks is the DDoS attack. Attacks of this type are on the rise and can be extremely destructive. To mitigate DDoS attacks, you can flush negative records, restrict the time to live (TTL) of negative records, preserve NetScaler memory by limiting the memory consumed by the DNS cache, retain DNS records in the cache, and enable DNS cache bypass. You can also limit DNS queries to a single packet and thereby prevent Slowloris attacks.
Flush negative records

A DNS attack fills the cache with negative records (NXDOMAIN and NODATA). As a result, responses to legitimate requests are not cached, so new requests are sent to a back-end server for DNS resolution. Responses are therefore delayed.

You can now flush the negative DNS records from the NetScaler appliance’s DNS cache.

Flush negative cache records by using the CLI

At the command prompt, type:

```
flush dns proxyrecords -type (dnsRecordType | negRecType)NXDOMAIN | NODATA
```

Example:

```
flush dns proxyrecords -negRecType NODATA
```

Flush of negative cache records by using the GUI

2. In the details pane, click Flush Proxy Records.
3. In the Flush Type box, select Negative Records.
4. In the Negative Records Type box, select either NXDOMAIN or NODATA.

Protection against random subdomain and NXDOMAIN attacks

To prevent random subdomain and NXDOMAIN attacks, you can restrict the DNS cache memory, and you can adjust the TTL values for negative records.

To limit the amount of memory consumed by the DNS cache, you can specify the maximum cache size (in MB), and also the cache size (in MB) for storing negative responses. When either limit is reached, no more entries are added to the cache. Also, syslog messages are logged and, if you have configured SNMP traps, SNMP traps are generated. If these limits are not set, caching continues until the system memory is exhausted.

A higher TTL value for negative records can result in storing records that are not valuable for a long period of time. A lower TTL value results in sending more requests to the back-end server.

The TTL of the negative record is set to a value that can be lesser of the TTL value or the "Expires" value of the SOA record.

Note:
• This limitation is added per packet engine. For example, if the maxCacheSize is set to 5 MB and the appliance has 3 packet engines, the total cache size is 15 MB.
• The cache size for the negative records must be less than or equal to the maximum cache size.
• If you reduce the DNS cache memory limit to a value lower than the amount of data already cached, the cache size remains above the limit until data ages out (exceeds its TTL or is flushed (flush dns proxyrecords command, or Flush Proxy Records in the NetScaler GUI).
• To configure SNMP traps, see Configuring the NetScaler to Generate SNMP Traps.

Limit the memory consumed by the DNS Cache by using the CLI

At the command prompt, type:

set dns parameter -maxCacheSize <MBytes> -maxNegativeCacheSize <MBytes>

Example:

set dns parameter -maxCacheSize 100 -maxNegativeCacheSize 25

Limit the memory consumed by the DNS Cache by using the GUI

Navigate to Configuration > Traffic Management > DNS, click Change DNS Settings, and set the following parameters:

• Max Cache Size in MB
• Max Negative Cache Size in MB

Restrict TTL of negative records by using the CLI

At the command prompt, type:

set dns parameter -maxnegcacheTTL <secs>

Example:

set dns parameter -maxnegcacheTTL 360

Restrict TTL of negative records by using the GUI

1. Navigate to Configuration > Traffic Management > DNS.
2. Click Change DNS Settings and set the Max Negative Cache TTL in sec parameter.
Retain DNS records in the cache

An attack can flood the DNS cache with entries that are not valuable but can cause flushing of the already cached legitimate records to make room for the new entries. To prevent attacks from filling the cache with invalid data, you can retain the legitimate records even after they exceed their TTL values.

If you enable the cacheNoExpire parameter, the records currently in the cache are retained until you disable the parameter.

**Note:**

- This option can be used only when the maximum cache size is specified (maxCacheSize parameter).
- If maxnegcacheTTL is configured and cacheNoExpire is enabled, cacheNoExpire takes priority.

Retain DNS records in the cache by using the CLI

At the command prompt, type:

```bash
set dns parameter -cacheNoExpire ( ENABLED | DISABLED )
```

**Example:**

```bash
set dns parameter -cacheNoExpire ENABLED
```

Retain DNS records in the cache by using the GUI

1. Navigate to **Configuration > Traffic Management > DNS** and click **Change DNS Settings**.
2. Select **Cache No Expire**.

Enable DNS cache bypass

For greater visibility and control of DNS requests arriving at the NetScaler appliance, you can set the cacheHitBypass parameter to forward all requests to the back-end servers and allow cache to be built but not used. After the cache is built, you can disable the parameter so that requests are served from the cache.

Enable DNS cache bypass by using the CLI

At the command prompt, type:

```bash
set dns parameter -cacheHitBypass ( ENABLED | DISABLED )
```
**Example:**

```
set dns parameter -cacheHitBypass ENABLED
```

Enable DNS cache bypass by using the GUI

1. Navigate to **Configuration > Traffic Management > DNS** and click **Change DNS Settings**.
2. Select **Cache Hit Bypass**.

**Prevent the Slowloris attack**

A DNS query spanning multiple packets presents the potential threat of a Slowloris attack. The NetScaler appliance can silently drop DNS queries that are split into multiple packets.

You can set the `splitPktQueryProcessing` parameter to `ALLOW` or `DROP` a DNS query if the query is split into multiple packets.

**Note:** This is applicable only for DNS TCP.

**Limit the DNS queries to a single packet by using the CLI**

At the command prompt, type:

```
set dns parameter -splitPktQueryProcessing ( ALLOW | DROP )
```

**Example:**

```
set dns parameter -splitPktQueryProcessing DROP
```

**Limit DNS queries to a single packet by using the GUI**

1. Navigate to **Configuration > Traffic Management > DNS** and click **Change DNS Settings**.
2. In the **Split Packet Query Processing** box, choose **ALLOW** or **DROP**.

**Collect statistics of the DNS responses served from the cache**

You can collect statistics of the DNS responses served from cache and use these statistics to create a threshold beyond which additional DNS traffic is dropped, and enforce this threshold with a bandwidth based policy. Previously, bandwidth calculation for a DNS load balancing virtual server was not accurate, because the number of cache hits was not reported.
In proxy mode, the statistics for Request bytes, Response bytes, Total Packets rcvd, and Total Packets sent statistics are continuously updated. Previously, these statistics were not always updated, particularly for a DNS load balancing virtual server.

Proxy mode also now enables you to determine the number of DNS responses served from the cache. To help collect these statistics, the following options have been added to the stat lb vserver <DNSvirtualServerName> command:

- Requests – Total number of requests received by the DNS or DNS_TCP vserver. Includes the requests forwarded to the back end and the requests answered from the cache.
- Vserver hits – Total number of requests forwarded to the back end. The total number of cache hits is the difference between Requests and Vserver hits.
- Responses – Total number of responses sent by this vserver. For example, if a DNS LB virtual server received 5 DNS requests, forwarded 3 of them to the back end, and served 2 of them from the cache, the corresponding value of each of these statistics would be as follows:
  - Vserver hits: 3
  - Requests: 5
  - Responses: 5

**Firewall Load Balancing**

September 14, 2018

Firewall load balancing distributes traffic across multiple firewalls, providing fault tolerance and increased throughput. Firewall load balancing protects your network by:

- Dividing the load between the firewalls, which eliminates a single point of failure and allows the network to scale.
- Increasing high availability.

Configuring a NetScaler appliance for firewall load balancing is similar to configuring load balancing, with the exception that the recommended service type is ANY, recommended monitor type is PING, and the load balancing virtual server mode is set to MAC.

You can set up firewall load balancing in a sandwich, an enterprise, or multiple-firewall environment configuration. The sandwich environment is used for load balancing traffic entering the network from outside and traffic leaving the network to the internet and involves configuring two NetScaler appliances, one on each side of a set of firewalls. You configure an enterprise environment for load balancing traffic leaving the network to the internet. The enterprise environment involves configuring a single NetScaler appliance between the internal network and the firewalls that provide access to the Internet. The multiple-firewall environment is used for load balance traffic coming from another firewall. Having firewall load balancing enabled on both the sides of NetScaler appliance improves the traffic flow in both the egress and ingress direction and ensures faster processing of the traffic. The
multiple-firewall environment involves configuring a NetScaler appliance sandwiched between two firewalls.

Important: If you configure static routes on the NetScaler appliance for the destination IP address and enable L3 mode, the NetScaler appliance uses its routing table to route the traffic instead of sending the traffic to the load balancing vserver.

Note: For FTP to work, an additional virtual server or service should be configured on the NetScaler appliance with IP address and port as * and 21 respectively, and the service type specified as FTP. In this case, the NetScaler appliance manages the FTP protocol by accepting the FTP control connection, modifying the payload, and managing the data connection, all through the same firewall.

Firewall Load Balancing supports only some of the load balancing methods supported on the NetScaler appliance. Also, you can configure only a few types of persistence and monitors.

**Firewall Load Balancing Methods**

The following load balancing methods are supported for firewall load balancing.

- Least Connections
- Round Robin
- Least Packets
- Least Bandwidth
- Source IP Hash
- Destination IP Hash
- Source IP Destination IP Hash
- Source IP Source Port hash
- Least Response Time Method (LRTM)
- Custom Load

**Firewall Persistence**

Only SOURCEIP, DESTIP, and SOURCEIPDESTIP based persistence are supported for firewall load balancing.

**Firewall Server Monitoring**

Only PING and transparent monitors are supported in firewall load balancing. You can bind a PING monitor (default) to the backend service that represents the firewall. If a firewall is configured not to respond to ping packets, you can configure transparent monitors to monitor hosts on the trusted side through individual firewalls.
A NetScaler deployment in a sandwich mode is capable of load balancing network traffic through firewalls in both directions: ingress (traffic entering the network from the outside, such as the internet) and egress (traffic leaving the network to the internet).

In this setup, a NetScaler is located on each side of a set of firewalls. The NetScaler placed between the firewalls and the Internet, called the external NetScaler that handles ingress traffic selects the best firewall, based on the configured method. The NetScaler between the firewalls and the private network, called the internal NetScaler tracks the firewall from which the initial packet for a session is received. It then makes sure that all subsequent packets for that session are sent to the same firewall.

The internal NetScaler can be configured as a regular traffic manager to load balance traffic across the private network servers. This configuration also allows traffic originating from the private network (egress) to be load balanced across the firewalls.

The following diagram shows the sandwich firewall load balancing environment.

Figure 1. Firewall Load Balancing (Sandwich)

The service type ANY configures the NetScaler to accept all traffic.

To avail benefits related to HTTP and TCP, configure the service and virtual server with type HTTP or TCP. For FTP to work, configure the service with type FTP.

### Configuring the External NetScaler in a Sandwich Environment

Perform the following tasks to configure the external NetScaler in a sandwich environment:

- Enable the load balancing feature.
- Configure a wildcard service for each firewall.
- Configure a monitor for each wildcard service.
- Configure a wildcard virtual server for traffic coming from the Internet.
- Configure the virtual server in MAC rewrite mode.
- Bind services to the wildcard virtual server.
- Save and Verify the Configuration.

### Enable the load balancing feature

To enable load balancing by using the command line interface

At the command prompt, type the following command to enable load balancing and verify the configuration:
To enable load balancing by using the configuration utility

Navigate to System > Settings and, in Configure Basic Features, select Load Balancing.

Configure a wildcard service for each firewall

To configure a wildcard service for each firewall by using the command line interface

At the command prompt, type:

```
add service <name> <serverName> ANY *
```

Example:

```
add service Service-HTTP-1 10.102.29.5 ANY *
```

To configure a wildcard service for each firewall by using the configuration utility

Navigate to Traffic Management > Load Balancing > Services and add a service. Specify ANY in the Protocol field and * in the Port field.
Configure a monitor for each wildcard service

A PING monitor is bound by default to the service. You will need to configure a transparent monitor to monitor hosts on the trusted side through individual firewalls. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the NetScaler appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the firewall is UP but one of the next hop devices from that firewall is down, the appliance includes the firewall while performing load balancing and forwards the packet to the firewall. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor, if any of the devices (including the firewall) are down, the service is marked as DOWN and the firewall is not included when the appliance performs firewall load balancing.

Binding a transparent monitor will override the PING monitor. To configure a PING monitor in addition to a transparent monitor, after you create and bind a transparent monitor, you need to bind a PING monitor to the service.

To configure a transparent monitor by using the command line interface

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

1. `add lb monitor <monitorName> <type> [-destIP <ip_addr|ipv6_addr|*>] [-transparent (YES | NO )]`
2. `bind lb monitor <monitorName> <serviceName>`

Example:

1. `add monitor monitor-HTTP-1 HTTP -destip 10.10.10.11 -transparent YES`
2. `bind monitor monitor-HTTP-1 fw-svc1`
3. To bind a PING monitor, type the following command:
4. `bind monitor PING fw-svc1`

To create and bind a transparent monitor by using the configuration utility

Navigate to
Traffic Management > Load Balancing > Monitors, and then create and bind a transparent monitor.
Configure a wildcard virtual server for traffic coming from the Internet

To configure a wildcard virtual server for traffic coming from the Internet by using the command line interface

At the command prompt, type:

```bash
add lb vserver <name> ANY * *
```

Example:

```bash
add lb vserver Vserver-LB-1 ANY * *
```

To configure a wildcard virtual server for traffic coming from the Internet by using the configuration utility

Navigate to Traffic Management > Load Balancing > Virtual Servers and create a wildcard virtual server. Specify `ANY` in the `Protocol` field and `*` in the Port field.

Configure the virtual server in MAC rewrite mode

To configure the virtual server in MAC rewrite mode by using the command line interface

At the command prompt, type:

```bash
set lb vserver <name> -m <RedirectionMode>
```

Example:

```bash
set lb vserver Vserver-LB-1 -m MAC
```

To configure the virtual server in MAC rewrite mode by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers and select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB-1).
2. Edit the `Basic Settings` section and click `more`.
3. From the `Redirection Mode` drop-down list, select `MAC Based`.

Bind services to the wildcard virtual server

To bind a service to the wildcard virtual server by using the command line interface

At the command prompt, type:

```bash
bind lb vserver <name> <serviceName>
```

**Example:**

```bash
bind lb vserver Vserver-LB-1 Service-HTTP-1
```

### To bind a service to the wildcard virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers and select the virtual server for which you want to bind the service.
2. Click in the **Services** section and select a service to bind.

### Save and Verify the Configuration

When you've finished the configuration tasks, be sure to save the configuration. You should also check to make sure that the settings are correct.

### To save and verify the configuration by using the command line interface

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

```bash
save ns config
show vserver
```

**Example:**

```bash
save config
sh lb vserver FWLBVIP1
FWLBVIP1 (**) - ANY  Type: ADDRESS
  State: UP
  Last state change was at Mon Jun 14 06:40:14 2010
  Time since last state change: 0 days, 00:00:11.240
  Effective State: UP  ARP:DISABLED
  Client Idle Timeout: 120 sec
  Down state flush: ENABLED
  Disable Primary Vserver On Down: DISABLED
  No. of Bound Services: 2 (Total) 2 (Active)
  Configured Method: SRCIPDESTIPHASH
  Mode: MAC
  Persistence: NONE
  Connection Failover: DISABLED
```
NetScaler 12.0

1) fw_svc_1 (10.102.29.251:*) - ANY State: UP Weight: 1
2) fw_svc_2 (10.102.29.18:*) - ANY State: UP Weight: 1
Done

show service fw-svc1
fw_svc1 (10.102.29.251:*) - ANY
State: DOWN
Last state change was at Thu Jul 8 10:04:50 2010
Time since last state change: 0 days, 00:00:38.120
Server Name: 10.102.29.251
Server ID: 0 Monitor Threshold: 0
Max Conn: 0 Max Req: 0 Max Bandwidth: 0 kbits
Use Source IP: NO
Client Keepalive (CKA): NO
Access Down Service: NO
TCP Buffering (TCPB): YES
HTTP Compression (CMP): NO
Idle timeout: Client: 120 sec Server: 120 sec
Client IP: DISABLED
Cacheable: NO
SC: OFF
SP: OFF
Down state flush: ENABLED

1) Monitor Name: monitor-HTTP-1
   State: DOWN Weight: 1
   Probes: 5 Failed [Total: 5 Current: 5]
   Last response: Failure - Time out during TCP connection establishment stage
   Response Time: 2000.0 millisec
2) Monitor Name: ping
   State: UP Weight: 1
   Probes: 3 Failed [Total: 0 Current: 0]
   Last response: Success - ICMP echo reply received.
   Response Time: 1.415 millisec
Done

Configuring the Internal NetScaler in a Sandwich Environment

Perform the following tasks to configure the internal NetScaler in a sandwich environment

For traffic from the server (egress)

- Enable the load balancing feature.
• Configure a wildcard service for each firewall.
• Configure a monitor for each wildcard service.
• Configure a wildcard virtual server to load balance the traffic sent to the firewalls.
• Configure the virtual server in MAC rewrite mode.
• Bind firewall services to the wildcard virtual server.

For traffic across private network servers
• Configure a service for each virtual server.
• Configure a monitor for each service.
• Configure an HTTP virtual server to balance traffic sent to the servers.
• Bind HTTP services to the HTTP virtual server.
• Save and Verify the Configuration.

Enable the load balancing feature

You can configure load balancing entities such as services and virtual servers when the load balancing feature is disabled, but they will not function until you enable the feature.

To enable load balancing by using the command line interface

At the command prompt, type the following command to enable load balancing and verify the configuration:

```
1 enable ns feature LB
2 show ns feature
```

Example:

```
1 > enable ns feature LoadBalancing
Done
2 > show ns feature

<table>
<thead>
<tr>
<th>Feature</th>
<th>Acronym</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>1) Web Logging</td>
<td>WL</td>
<td>OFF</td>
</tr>
<tr>
<td>2) Surge Protection</td>
<td>SP</td>
<td>ON</td>
</tr>
<tr>
<td>3) Load Balancing</td>
<td>LB</td>
<td>ON</td>
</tr>
<tr>
<td>24) NetScaler Push</td>
<td>push</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Done
```
To enable load balancing by using the configuration utility

Navigate to System > Settings and, in Configure Basic Features, select Load Balancing.

Configure a wildcard service for each firewall

To configure a wildcard service for each firewall by using the command line interface

At the command prompt, type:

```
add service <name> <serverName> ANY *
```

Example:

```
add service Service-HTTP-1 10.102.29.5 ANY *
```

To configure a wildcard service for each firewall by using the configuration utility

Navigate to Traffic Management > Load Balancing > Services and add a service. Specify ANY in the Protocol field and * in the Port field.

Configure a monitor for each wildcard service

A PING monitor is bound by default to the service. You will need to configure a transparent monitor to monitor hosts on the trusted side through individual firewalls. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the NetScaler appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the firewall is UP but one of the next hop devices from that firewall is down, the appliance includes the firewall while performing load balancing and forwards the packet to the firewall. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor, if any of the devices (including the firewall) are down, the service is marked as DOWN and the firewall is not included when the appliance performs firewall load balancing.

Binding a transparent monitor will override the PING monitor. To configure a PING monitor in addition to a transparent monitor, after you create and bind a transparent monitor, you need to bind a PING monitor to the service.

To configure a transparent monitor by using the command line interface

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:
Example:

<table>
<thead>
<tr>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>add lb monitor &lt;monitorName&gt; &lt;type&gt; [-destIP &lt;ip_addr</td>
</tr>
<tr>
<td>bind lb monitor &lt;monitorName&gt; &lt;serviceName&gt;</td>
</tr>
</tbody>
</table>

To create and bind a transparent monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors and create a monitor.
2. In the Create Monitor dialog box, enter the required parameters and select Transparent.

Configure a wildcard virtual server to load balance the traffic sent to the firewalls

To configure a wildcard virtual server to load balance the traffic sent to the firewalls by using the command line interface

At the command prompt, type:

```
add lb vserver <name> ANY * *
```

Example:

```
add lb vserver Vserver-LB-1 ANY * *
```

To configure a wildcard virtual server for traffic coming from the Internet by using the configuration utility

Navigate to Traffic Management > Load Balancing > Virtual Servers and create a wildcard virtual server. Specify ANY in the Protocol field and * in the Port field.

To configure a wildcard virtual server to load balance the traffic sent to the firewalls by using the configuration utility

2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters as shown:
• Name—name
4. In Protocol, select ANY, and in IP Address and Port, select *.
5. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

Configure the virtual server in MAC rewrite mode

To configure the virtual server in MAC rewrite mode by using the command line interface

At the command prompt, type:

```
set lb vserver <name>@ -m <RedirectionMode>
```

Example:

```
set lb vserver Vserver-LB-1 -m MAC
```

To configure the virtual server in MAC rewrite mode by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers and select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB-1).
2. Edit the Basic Settings section and click more.
3. From the Redirection Mode drop-down list, select MAC Based.

To configure the virtual server in MAC rewrite mode by using the configuration utility

2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB-1), and then click Open.
3. On the Advanced tab, under Redirection Mode, click MAC-Based.
4. Click OK.

Bind firewall services to the wildcard virtual server

To bind firewall services to the wildcard virtual server by using the command line interface

At the command prompt, type:

```
bind lb vserver <name> <serviceName>
```

Example:

```
bind lb vserver Vserver-LB-1 Service-HTTP-1
```
To bind firewall services to the wildcard virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and select a virtual server.
2. Click in the Service section, and select a service to bind.

Note: You can bind a service to multiple virtual servers.

Configure a service for each virtual server

To configure a service for each virtual server by using the command line interface

At the command prompt, type:

```
 1 add service <name> <serverName> HTTP <port>
```

Example:

```
 1 add service Service-HTTP-1 10.102.29.5 HTTP 80
```

To configure a service for each virtual server by using the configuration utility

Navigate to Traffic Management > Load Balancing > Services and configure a service for each virtual server. Specify HTTP in the Protocol field and select HTTP under Available Monitors.

To configure a service for each virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters as shown:
   - Service Name—name
   - Server—serverName
   - Port—port
4. In Protocol, specify HTTP. Under Available Monitors, select HTTP.
5. Click Create, and then click Close. The service you created appears in the Services pane.

Configure a monitor for each service

To bind a monitor to a service by using the command line interface

At the command prompt, type:

```
 1 bind lb monitor <monitorName> <ServiceName>
```
Example:

```
bind mon monitor-HTTP-1 Service-HTTP-1
```

To bind a monitor to a service by using the configuration utility

Navigate to Traffic Management > Load Balancing > Services, double-click a service and add a monitor.

To bind a monitor to a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open the service, and add a monitor.

Configure an HTTP virtual server to balance traffic sent to the servers

To configure an HTTP virtual server to balance traffic sent to the servers by using the command line interface

At the command prompt, type:

```
add lb vserver <name> HTTP <ip> <port>
```

Example:

```
add lb vserver Vserver-LB-1 HTTP 10.102.29.60 80
```

To configure an HTTP virtual server to balance traffic sent to the servers by using the configuration utility

To configure an HTTP virtual server to balance traffic sent to the servers by using the configuration utility

2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters as shown:
   - Name—name
• IP Address—IPAddress
  Note: If the virtual server uses IPv6, select the IPv6 check box and enter the address in IPv6 format (for example, 1000:0000:0000:0000:0005:0600:700a:888b).
• Port—port

4. Under Protocol, select HTTP.
5. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

Save and Verify the Configuration

When you’ve finished the configuration tasks, be sure to save the configuration. You should also check to make sure that the settings are correct.

To save and verify the configuration by using the command line interface

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

- save ns config
- show vserver

Example:

```
1) save config
2) show lb vserver FWLBVIP2
   FWLBVIP2 (*:*): ANY Type: ADDRESS
   State: UP
   Last state change was at Mon Jun 14 07:22:54 2010
   Time since last state change: 0 days, 00:00:32.760
   Effective State: UP
   Client Idle Timeout: 120 sec
   Down state flush: ENABLED
   Disable Primary Vserver On Down: DISABLED
   No. of Bound Services: 2 (Total) 2 (Active)
   Configured Method: LEASTCONNECTION
   Current Method: Round Robin, Reason: A new service is bound
   Mode: MAC
   Persistence: NONE
   Connection Failover: DISABLED

1) fw-int-svc1 (10.102.29.5: *) - ANY State: UP Weight: 1
2) fw-int-svc2 (10.102.29.9: *) - ANY State: UP Weight: 1
Done
```
show service fw-int-svc1
fw-int-svc1 (10.102.29.5:* ) - ANY
State: DOWN

Last state change was at Thu Jul 8 14:44:51 2010
Time since last state change: 0 days, 00:01:50.240

Server Name: 10.102.29.5
Server ID: 0
Monitor Threshold: 0
Max Conn: 0
Max Req: 0
Max Bandwidth: 0 kbits

Use Source IP: NO
Client Keepalive (CKA): NO

SC: OFF
SP: OFF

Down state flush: ENABLED

1) Monitor Name: monitor-HTTP-1
   State: DOWN
   Weight: 1
   Probes: 9
   Failed [Total: 9 Current: 9]
   Last response: Failure - Time out during TCP connection establishment stage
   Response Time: 2000.0 millisec

2) Monitor Name: ping
   State: UP
   Weight: 1
   Probes: 3
   Failed [Total: 0 Current: 0]
   Last response: Success - ICMP echo reply received.
   Response Time: 1.275 millisec

Done

To save and verify the configuration by using the configuration utility

1. In the details pane, click Save.
2. In the Save Config dialog box, click Yes.
4. In the details pane, select the virtual server that you created in step 5 and verify that the settings displayed in the Details pane are correct.
6. In the details pane, select the service that you created in step 5 and verify that the settings displayed in the Details pane are correct.
Monitoring a Firewall Load Balancing Setup in a Sandwich Environment

After the configuration is up and running, you should view the statistics for each service and virtual server to check for possible problems.

Viewing the Statistics of a Virtual Server

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the NetScaler appliance. You can display a summary of statistics for all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name
- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of hits

To display virtual server statistics by using the command line interface

To display a summary of the statistics for all the virtual servers currently configured on the NetScaler, or for a single virtual server, at the command prompt, type:

```
stat lb vserver [-detail] [<name>]
```

Example:

```
>stat lb vserver -detail
Virtual Server(s) Summary
vsrvIP  port      Protocol  State  Req/s
  Hits/s
One     *  80       HTTP     UP     5/s
     0/s
Two     *  0        TCP      DOWN   0/s
     0/s
Three   * 2598     TCP      DOWN   0/s
     0/s
dnsVirtualNS  10.102.29.90  53  DNS      DOWN   0/s
     0/s
BRVSERVER  10.10.1.1  80   HTTP     DOWN   0/s
     0/s
```
To display virtual server statistics by using the configuration utility

2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server, and click Statistics.

Viewing the Statistics of a Service

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in surge queue, current server connections, and so forth using the service statistics.

To view the statistics of a service by using the command line interface

At the command prompt, type:

```
stat service <name>
```

Example:

```
stat service Service-HTTP-1
```

To view the statistics of a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services > Statistics.
2. If you want to display the statistics for only one service, select the service, and click Statistics.

Enterprise Environment

January 6, 2019

In the enterprise setup, the NetScaler is placed between the firewalls connecting to the public Internet and the internal private network and handles egress traffic. The NetScaler selects the best firewall based on the configured load balancing policy.

The following diagram shows the enterprise firewall load balancing environment

Figure 1. Firewall Load Balancing (Enterprise)
The service type ANY configures the NetScaler to accept all traffic.

To avail benefits related to HTTP and TCP, configure the service and vserver with type HTTP or TCP. For FTP to work, configure the service with type FTP.

**Configuring the NetScaler in an Enterprise Environment**

Perform the following tasks to configure a NetScaler in an enterprise environment.

For traffic from the server (egress)

- Enable the load balancing feature.
- Configure a wildcard service for each firewall.
- Configure a monitor for each wildcard service.
- Configure a wildcard virtual server to load balance the traffic sent to the firewalls.
- Configure the virtual server in MAC rewrite mode.
- Bind firewall services to the wildcard virtual server.

For traffic across private network servers

- Configure a service for each virtual server.
- Configure a monitor for each service.
- Configure an HTTP virtual server to balance traffic sent to the servers.
- Bind HTTP services to the HTTP virtual server.
- Save and Verify the Configuration.

**Enable the load balancing feature**

You can configure load balancing entities such as services and virtual servers when the load balancing feature is disabled, but they will not function until you enable the feature.

**To enable load balancing by using the command line interface**

At the command prompt, type the following command to enable load balancing and verify the configuration:

- `enable ns feature LB`
- `show ns feature`

**Example:**

```
1 > enable ns feature LoadBalancing
2   Done
3 > show ns feature
```

</tbody>
</table>

To enable load balancing by using the configuration utility

Navigate to System > Settings and, in Configure Basic Features, select Load Balancing.

Configure a wildcard service for each firewall

To configure a wildcard service for each firewall by using the command line interface

At the command prompt, type:

```
add service <name> <serverName> ANY *
```

Example:

```
add service Service-HTTP-1 10.102.29.5 ANY *
```

To configure a wildcard service for each firewall by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters as shown:
   - Service Name—name
   - Server—serverName
4. In Protocol, select ANY, and in Port, select *.
5. Click Create, and then click Close. The service you created appears in the Services pane.

Configure a monitor for each wildcard service

A PING monitor is bound by default to the service. You will need to configure a transparent monitor to monitor hosts on the trusted side through individual firewalls. You can then bind the transparent
monitor to services. The default PING monitor monitors the connectivity only between the NetScaler appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the firewall is UP but one of the next hop devices from that firewall is down, the appliance includes the firewall while performing load balancing and forwards the packet to the firewall. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor, if any of the devices (including the firewall) are down, the service is marked as DOWN and the firewall is not included when the appliance performs firewall load balancing.

Binding a transparent monitor will override the PING monitor. To configure a PING monitor in addition to a transparent monitor, after you create and bind a transparent monitor, you need to bind a PING monitor to the service.

To configure a transparent monitor by using the command line interface

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

```
1 add lb monitor <monitorName> <type> [-destIP <ip_addr|ipv6_addr|*>] [-transparent (YES | NO )]
2 bind lb monitor <monitorName> <serviceName>
```

Example:

```
1 add monitor monitor-HTTP-1 HTTP -destip 10.10.10.11 -transparent YES
2 bind monitor monitor-HTTP-1 fw-svc1
```

To create and bind a transparent monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.

2. In the details pane, click Add.

3. In the Create Monitor dialog box, specify values as shown:
   - Name*
   - Type*—type
   - Destination IP
   - Transparent

   * A required parameter

4. Click Create, and then click Close. In the Monitors pane, select the monitor that you just configured and verify that the settings displayed at the bottom of the screen are correct.
Configure a wildcard virtual server to load balance the traffic sent to the firewalls

To configure a wildcard virtual server to load balance the traffic sent to the firewalls by using the command line interface

At the command prompt, type:

```
1 add lb vserver <name> ANY * *
```

Example:

```
1 add lb vserver Vserver-LB-1 ANY * *
```

To configure a wildcard virtual server to load balance the traffic sent to the firewalls by using the configuration utility

2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters as shown:
   - Name—name
4. In Protocol, select ANY, and in IP Address and Port, select *.
5. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

Configure the virtual server in MAC rewrite mode

To configure the virtual server in MAC rewrite mode by using the command line interface

At the command prompt, type:

```
1 set lb vserver <name>@ -m <RedirectionMode>
```

Example:

```
1 set lb vserver Vserver-LB-1 -m MAC
```

To configure the virtual server in MAC rewrite mode by using the configuration utility

2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB-1), and then click Open.
3. On the Advanced tab, under Redirection Mode, click MAC-Based.
4. Click OK.

Bind firewall services to the wildcard virtual server

To bind firewall services to the wildcard virtual server by using the command line interface

At the command prompt, type:

```
bind lb vserver <name> <serviceName>
```

Example:

```
bind lb vserver Vserver-LB-1 Service-HTTP-1
```

To bind firewall services to the wildcard virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and select a virtual server.
2. Click in the Service section, and select a service to bind.

Note: You can bind a service to multiple virtual servers.

Configure a service for each virtual server

To configure a service for each virtual server by using the command line interface

At the command prompt, type:

```
add service <name> <serverName> HTTP <port>
```

Example:

```
add service Service-HTTP-1 10.102.29.5 HTTP 80
```

To configure a service for each virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters as shown:
   - Service Name—name
   - Server—serverName
   - Port—port
4. In Protocol, specify HTTP. Under Available Monitors, select HTTP.
5. Click Create, and then click Close. The service you created appears in the Services pane.

**Configure a monitor for each service**

**To bind a monitor to a service by using the command line interface**

At the command prompt, type:

```
bind lb monitor <monitorName> <ServiceName>
```

**Example:**

```
bind mon monitor-HTTP-1 Service-HTTP-1
```

**To bind a monitor to a service by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open the service, and add a monitor.

**Configure an HTTP virtual server to balance traffic sent to the servers**

**To configure an HTTP virtual server to balance traffic sent to the servers by using the command line interface**

At the command prompt, type:

```
add lb vserver <name> HTTP <ip> <port>
```

**Example:**

```
add lb vserver Vserver-LB-1 HTTP 10.102.29.60 80
```

**To configure an HTTP virtual server to balance traffic sent to the servers by using the configuration utility**

2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters as shown:
   - Name—name
• IP Address—IPAddress
  Note: If the virtual server uses IPv6, select the IPv6 check box and enter the address in IPv6 format (for example, 1000:0000:0000:0005:0600:700a:888b).
• Port—port
4. Under Protocol, select HTTP.
5. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

Bind HTTP services to the HTTP virtual server

To bind HTTP services to the wildcard virtual server by using the command line interface

At the command prompt, type:

`bind lb vserver <name> <serviceName>`

Example:

```
bind lb vserver Vserver-LB-1 Service-HTTP-1
```

To bind HTTP services to the wildcard virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and select a virtual server.
2. Click in the Service section, and select a service to bind.

Note: You can bind a service to multiple virtual servers.

Save and Verify the Configuration

When you’ve finished the configuration tasks, be sure to save the configuration. You should also check to make sure that the settings are correct.

To save and verify the configuration by using the command line interface

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

• `save ns config`
• `show vserver`

Example:
save config
show lb vserver FWLBVIP2

FWLBVIP2 (*:**) - ANY  Type: ADDRESS
State: UP
Last state change was at Mon Jun 14 07:22:54 2010
Time since last state change: 0 days, 00:00:32.760

establishment stage
Response Time: 2000.0 millisec

2) Monitor Name: ping

State: UP Weight: 1
Probes: 3 Failed [Total: 0 Current: 0]
Last response: Success - ICMP echo reply received.

Response Time: 1.275 millisec

To save and verify the configuration by using the configuration utility

1. In the details pane, click Save.
2. In the Save Config dialog box, click Yes.
4. In the details pane, select the virtual server that you created in step 5 and verify that the settings displayed in the Details pane are correct.
6. In the details pane, select the service that you created in step 5 and verify that the settings displayed in the Details pane are correct.

Monitoring a Firewall Load Balancing Setup in an Enterprise Environment

After the configuration is up and running, you should view the statistics for each service and virtual server to check for possible problems.

Viewing the Statistics of a Virtual Server

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the NetScaler appliance. You can display a summary of statistics for all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name
- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of hits
To display virtual server statistics by using the command line interface

To display a summary of the statistics for all the virtual servers currently configured on the NetScaler appliance, or for a single virtual server, at the command prompt, type:

```
stat lb vserver [-detail] [<name>]
```

Example:

```
>stat lb vserver -detail

Virtual Server(s) Summary

<table>

```

To display virtual server statistics by using the configuration utility

2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server, and click Statistics.

Viewing the Statistics of a Service

Updated: 2013-08-28

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in surge queue, current server connections, and so forth using the service statistics.

To view the statistics of a service by using the command line interface

At the command prompt, type:
To view the statistics of a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services > Statistics.
2. If you want to display the statistics for only one service, select the service, and click Statistics.

Multiple-Firewall Environment

January 6, 2019

In a multiple-firewall environment, the NetScaler appliance is placed between two sets of firewalls, the external set connecting to the public Internet, and the internal set connecting to the internal private network. The external set typically handles the egress traffic. These firewalls mainly implement access control lists to allow or deny access to external resources. The internal set typically handles the ingress traffic. These firewalls implement security to safeguard the intranet from malicious attacks apart from load-balancing the ingress traffic. The multiple-firewall environment allows you to load-balance traffic coming from another firewall. By default, the traffic coming from a firewall is not load balanced on the other firewall across a NetScaler appliance. Having firewall load balancing enabled on both the sides of NetScaler improves the traffic flow in both the egress and ingress direction and ensures faster processing of the traffic.

The following figure shows a multiple-firewall load balancing environment

Figure 1. Firewall Load Balancing (multiple-firewall)

With a configuration like the one shown in Figure 1, you can configure the NetScaler to load balance the traffic through the an internal firewall even if it is load balanced by an external firewall. For example, with this feature configured, the traffic coming from the external firewalls (firewalls 1, 2, and 3) is load balanced on the internal firewalls (firewalls 4, 5, and 6) and vice versa.

Firewall load balancing is supported only for MAC mode LB virtual server.

The service type ANY configures the NetScaler to accept all traffic.

To avail benefits related to HTTP and TCP, configure the service and virtual server with type HTTP or TCP. For FTP to work, configure the service with type FTP.
Configuring the NetScaler in a Multiple-Firewall Environment

To configure a NetScaler appliance in a multiple-firewall environment, you have to enable the load balancing feature, configure a virtual server to load balance the egress traffic across the external firewalls, configure a virtual server to load balance the ingress traffic across the internal firewalls, and enable firewall load balancing on the NetScaler appliance. To configure a virtual server to load balance traffic across a firewall in the multiple-firewall environment, you need to:

1. Configure a wildcard service for each firewall
2. Configure a monitor for each wildcard service
3. Configure a wildcard virtual server to load balance the traffic sent to the firewalls
4. Configure the virtual server in MAC rewrite mode
5. Bind firewall services to the wildcard virtual server

Enabling the load balancing feature

To configure and implement load balancing entities such as services and virtual servers, you need to enable the load balancing feature on the NetScaler device.

To enable load balancing by using the CLI:

At the command prompt, type the following command to enable load balancing and verify the configuration:

```
1 enable ns feature <featureName>
2 show ns feature
```

Example:

```
1 enable ns feature LoadBalancing
2 Done
3 show ns feature
4 Feature Acronym Status
5 -------- -------- ------
6 1) Web Logging WL OFF
7 2) Surge Protection SP ON
8 3) Load Balancing LB ON
9 .
10 .
11 .
12 24) NetScaler Push push OFF
13 Done
```

To enable load balancing by using the GUI:
1. In the navigation pane, expand System, and then click Settings.
2. In the Settings pane, under Modes and Features, click Change basic features.
3. In the Configure Basic Features dialog box, select the Load Balancing check box, and then click Ok.

**Configuring a wildcard service for each firewall**

To accept traffic from all the protocols, you need to configure wildcard service for each firewall by specifying support for all the protocols and ports.

**To configure a wildcard service for each firewall by using the CLI:**

At the command prompt, type the following command to configure support for all the protocols and ports:

```
1 add service <name>@ <serverName> <serviceType> <port_number>
```

Example:

```
1 add service fw-svc1 10.102.29.5 ANY *
```

**To configure a wildcard service for each firewall by using the GUI:**

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Services dialog box, specify values for the following parameters as shown:
   - Service Name—name
   - Server—serverName
   - * A required parameter
4. In Protocol, select Any and in Port, select *.
5. Click Create, and then click Close. The service you created appears in the Services pane.

**Configuring a monitor for each service**

A PING monitor is bound by default to the service. You will need to configure a transparent monitor to monitor hosts on the trusted side through individual firewalls. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the NetScaler appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the firewall is UP but one of the next hop
devices from that firewall is down, the appliance includes the firewall while performing load balancing and forwards the packet to the firewall. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor, if any of the devices (including the firewall) are down, the service is marked as DOWN and the firewall is not included when the appliance performs firewall load balancing.

Binding a transparent monitor will override the PING monitor. To configure a PING monitor in addition to a transparent monitor, after you create and bind a transparent monitor, you need to bind a PING monitor to the service.

**To configure a transparent monitor by using the CLI:**

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

```
1  add lb monitor <monitorName> <type> [-destIP <ip_addr|ipv6_addr|*>] [-transparent (YES | NO )]
2  bind lb monitor <monitorName> <serviceName>
```

**Example:**

```
1  add monitor monitor-HTTP-1 HTTP -destip 10.10.10.11 -transparent YES
2  bind monitor monitor-HTTP-1 fw-svc1
```

**To create and bind a transparent monitor by using the GUI:**

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. In the details pane, click Add.
3. In the Create Monitor dialog box, specify values for the following parameters as shown:
   - Name*
   - Type*—type
   - Destination IP
   - Transparent
   - * A required parameter
4. Click Create, and then click Close. In the Monitors pane, select the monitor that you just configured and verify that the settings displayed at the bottom of the screen are correct.

**Configuring a virtual server to load balance the traffic sent to the firewalls**

To load balance any kind of traffic, you need to configure a wildcard virtual server specifying the protocol and port as any value.
NetScaler 12.0

To configure a virtual server to load balance the traffic sent to the firewalls by using the CLI:

At the command prompt, type the following command:

```
add lb vserver <name>@<serviceType> <IPAddress> <port_number>
```

**Example:**

```
add lb vserver Vserver-LB-1 ANY * *
```

To configure a virtual server to load balance the traffic sent to the firewalls by using the GUI:

2. In the details pane, click Add.
3. In Protocol, select Any, and in IP Address and Port, select *.
4. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

Configuring the virtual server to MAC rewrite mode

To configure the virtual server to use MAC address for forwarding the incoming traffic, you need to enable the MAC rewrite mode.

To configure the virtual server in MAC rewrite mode by using the CLI:

At the command prompt, type the following command:

```
set lb vserver <name>@-m<RedirectionMode>
```

**Example:**

```
set lb vserver Vserver-LB-1 -m MAC
```

To configure the virtual server in MAC rewrite mode by using the GUI:

2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB1), and then click Open.
3. On the Advanced tab, under the Redirection Mode mode, click Open.
4. Click Ok.

Binding firewall services to the virtual server

To access a service on NetScaler appliance, you need to bind it to a wildcard virtual server.
To bind firewall services to the virtual server by using the CLI:

At the command prompt, type the following command:

```
bind lb vserver <name>@<serviceName>
```

Example:

```
bind lb vserver Vserver-LB-1 Service-HTTP-1
```

To bind firewall services to the virtual server by using the GUI:

2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB1), and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Services tab, select the Active check box next to the service that you want to bind to the virtual server (for example, Service-HTTP-1).
4. Click Ok.

Configuring the multiple-firewall load balancing on the NetScaler appliance

To load balance traffic on both the sides of a NetScaler using firewall load balancing, you need to enable multiple-firewall load balancing by using the vServerSpecificMac parameter.

To configure multiple-firewall load balancing by using the CLI:

At the command prompt, type the following command:

```
set lb parameter -vServerSpecificMac <status>
```

Example:

```
set lb parameter -vServerSpecificMac ENABLED
```

To configure multiple-firewall load balancing by using the GUI:

2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Configure Load Balancing parameters).
3. In the Set Load Balancing Parameters dialog box, select the Virtual Server Specific MAC check box.
4. Click Ok.
**Saving and Verifying the Configuration**

When you’ve finished the configuration tasks, be sure to save the configuration. You should also check to make sure that the settings are correct.

**To save and verify the configuration by using the CLI:**

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

- `save ns config`
- `show vserver`

**Example:**

```
1 save config
2 show lb vserver FWLBVIP2
   FWLBVIP2 (**:*) - ANY  Type: ADDRESS
   State: UP
   Last state change was at Mon Jun 14 07:22:54 2010
   Time since last state change: 0 days, 00:00:32.760
   Effective State: UP
   Client Idle Timeout: 120 sec
   Down state flush: ENABLED
   Disable Primary Vserver On Down : DISABLED
   No. of Bound Services : 2 (Total)  2 (Active)
   Configured Method: LEASTCONNECTION
   Current Method: Round Robin, Reason: A new service is bound
   Mode: MAC
   Persistence: NONE
   Connection Failover: DISABLED

1) fw-int-svc1 (10.102.29.5: *) - ANY State: UP Weight: 1

**Done**

**To save and verify the configuration by using the GUI:**

1. In the details pane, click Save.
2. In the Save Config dialog box, click Yes.
4. In the details pane, select the virtual server that you created in step 5 and verify that the settings displayed in the Details pane are correct.
6. In the details pane, select the service that you created in step 5 and verify that the settings displayed in the Details pane are correct.

**Monitoring a Firewall Load Balancing Setup in a Multiple-Firewall Environment**

After the configuration is up and running, you should view the statistics for each service and virtual server to check for possible problems.

**Viewing the Statistics of a Virtual Server**

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the NetScaler appliance. You can display a summary of statistics for
all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name
- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of hits

To display virtual server statistics by using the CLI:

To display a summary of the statistics for all the virtual servers currently configured on the NetScaler appliance, or for a single virtual server, at the command prompt, type:

```
stat lb vserver [-detail] [<name>]
```

**Example:**

```
>stat lb vserver -detail
Virtual Server(s) Summary

</tr>
</tbody>
</table>
```

To display virtual server statistics by using the GUI:

2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server, and click Statistics.
NetScaler 12.0

Viewing the Statistics of a Service

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in surge queue, current server connections, and so forth using the service statistics.

To view the statistics of a service by using the CLI:

At the command prompt, type:

```
stat service <name>
```

Example:

```
stat service Service-HTTP-1
```

To view the statistics of a service by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Services > Statistics.
2. If you want to display the statistics for only one service, select the service, and click Statistics.

Global Server Load Balancing

September 14, 2018

Note

This feature is available as an option with a NetScaler standard edition license, but is included with the enterprise and platinum edition licenses.

NetScaler appliances configured for global server load balancing (GSLB) provide for disaster recovery and ensure continuous availability of applications by protecting against points of failure in a wide area network (WAN). GSLB can balance the load across data centers by directing client requests to the closest or best performing data center, or to surviving data centers in case of an outage.

In a typical configuration, a local DNS server sends client requests to a GSLB virtual server, to which are bound GSLB services. A GSLB service identifies a load balancing or content switching virtual server, which can be at the local site or a remote site. If the GSLB virtual server selects a load balancing or content switching virtual server at a remote site, it sends the virtual server’s IP address to the DNS server, which sends it to the client. The client then resends the request to the new virtual server at the new IP.

The GSLB entities that you must configure are the GSLB sites, the GSLB services, the GSLB virtual servers, load balancing or content switching virtual servers, and authoritative DNS (ADNS) services. You must also configure MEP. You can also configure DNS views to expose different parts of your network to clients accessing the network from different locations.
Note
To take full advantage of the NetScaler GSLB features, you should use NetScaler appliances for load balancing or content switching at each data center, so that your GSLB configuration can use the proprietary Metric Exchange Protocol (MEP) to exchange site metrics.

GSLB deployment types

September 12, 2018

NetScaler appliances configured for global server load balancing (GSLB) provide for disaster recovery and ensure continuous availability of applications by protecting against points of failure in a wide area network (WAN). GSLB can balance the load across data centers by directing client requests to the closest or best performing data center, or to surviving data centers in the event of an outage.

The following are some of the typical GSLB deployment types:

- Active-active site deployment
- Active-passive site deployment
- Parent-child topology deployment

Active-active site deployment

January 6, 2019

An active-active site consists of multiple active data centers. Client requests are load balanced across active data centers. This deployment type can be used when you have a need for global distribution of traffic in a distributed environment.

All the sites in an active-active deployment are active, and all the services for a particular application/domain are bound to the same GSLB vserver. Sites exchange metrics through the Metrics Exchange Protocol (MEP). Site metrics exchanged between the sites include the status of each load balancing and content switching virtual server, current number of connections, current packet rate, and current bandwidth usage. The NetScaler appliance needs this information to perform load balancing across the sites.

An active-active deployment can include a maximum of 32 GSLB sites, because MEP cannot synchronize more than 32 sites. No backup sites are configured in this deployment type.

The NetScaler appliance sends client requests to the appropriate GSLB site as determined by the GSLB method specified in the GSLB configuration.

For an active-active deployment, you can configure the following GSLB methods.
• Round Robin
• Least Connections
• Least Response Time
• Least Bandwidth
• Least Packets
• Source IP Hash
• Custom Load
• Round Trip Time (RTT)
• Static Proximity

Note:

• If MEP is disabled, the following algorithm methods default to Round Robin.
  – RTT
  – Least Connections
  – Least Bandwidth
  – Least Packets
  – Least Response Time
• In the static proximity GLSB method, the appliance sends the request to the IP address of the site that best matches the proximity criteria.
• In the Round Trip Time method, the dynamic round trip time (RTT) values are to select the IP address of the best performing site. RTT is a measure of the delay in the network between the client’s local DNS server and a data resource.

**GSLB active-active datacenter topology**

In the diagram, Site 1 and Site 2 are active GLSB sites.

When the client sends a DNS request, it lands in one of the active sites.

If Site 1 receives the client request, the GSLB virtual server in Site 1 selects a load balancing or content switching virtual server and sends the virtual server’s IP address to the DNS server, which sends it to the client. The client then resends the request to the new virtual server at the new IP address.

As both sites are active, the GSLB algorithm evaluates the services at both sites when making a selection as determined by the configured GSLB method.

**Active-passive site deployment**

January 6, 2019

An active-passive site consists of an active and a passive data center. This deployment type is ideal for disaster recovery.
In this type of deployment, some of the sites (remote sites) are reserved only for disaster recovery. These sites do not participate in any decision making until all the active sites are DOWN. A passive site does not become operational unless a disaster event triggers a failover.

Once you have configured the primary data center, replicate the configuration for the backup data center and designate it as the passive GSLB site by designating a GSLB virtual server at that site as the backup virtual server.

An active-passive deployment can include a maximum of 32 GSLB sites, because MEP cannot synchronize more than 32 sites.

For an active-passive deployment, you can configure the following GSLB methods.

- Round Robin
- Least Connections
- Least Response Time
- Least Bandwidth
- Least Packets
- Source IP Hash
- Custom Load
- Round Trip Time (RTT)
- Static Proximity

**Note:**

- If MEP is disabled, the following algorithm methods default to Round Robin.
  - RTT
  - Least Connections
  - Least Bandwidth
  - Least Packets
  - Least Response Time
- In the static proximity GLSB method, the appliance sends the request to the IP address of the site that best matches the proximity criteria.
- In the Round Trip Time method, the dynamic round trip time (RTT) values are to select the IP address of the best performing site. RTT is a measure of the delay in the network between the client’s local DNS server and a data resource.

**GSLB active-passive datacenter topology**

In the diagram, Site 1 is an active site and Site 2 is a passive site, which has the same configuration as that of Site 1.

If Site 1 goes DOWN, Site 2 becomes operational.
When the client sends a DNS request, the request can land in any of the sites. However, the services are selected only from the active site (Site1) as long as it is UP.

Services from the passive site (Site 2) are selected only if the active site (Site 1) is DOWN.

**Parent-child topology deployment using the MEP protocol**

January 6, 2019

NetScaler GSLB provides global server load balancing and disaster recovery by creating mesh connections between all the involved sites and making intelligent load balancing decisions. Each site communicates with the others to exchange server and network metrics through Metric Exchange Protocol (MEP), at regular intervals. However, with the increase in number of peer sites, the volume of MEP traffic increases exponentially because of the mesh topology. To overcome this, you can use a parent-child topology. The parent-child topology also supports larger deployments. In addition to the 32 parent sites, you can configure 1024 child sites.

The GSLB parent-child topology is a two-level hierarchical design with the following characteristics:

- At the top level are parent sites, which have peer relationships with other parents.
- Each parent can have multiple child sites.
- Each parent site exchanges health information with its child sites and with other parent sites.
- A child site communicates only with its parent site.
- In a parent-child relationship for GSLB, only the parent site responds to ADNS queries. The child sites act as normal load balancing sites.
- An ADNS service or DNS load balancing virtual servers should be configured only in the parent site.
- A parent site can have a normal GSLB configuration, that is, services from local and all remote sites, but a child site can have local services only. Also, only the parent sites have GSLB virtual servers configured.

**Note**

- In a parent-child topology, the exchange of site metrics is initiated from the lower of two IP addresses. However, from NetScaler release 11.1 build 51.x, the parent sites initiate connections to the child sites, and not vice versa, because the parent sites have information about all the child sites in the GSLB setup.

- In a parent-parent connection, the exchange of site metrics is still initiated from the lower IP of two IP addresses.

- In a parent-child topology, GSLB services are not always required to be configured on a child site. However, if you have additional configuration such as client authentication, client IP address
insertion, or other SSL-specific requirement, you must add an explicit GSLB service on the child site and configure it accordingly.

- In a parent-child topology, the parent site and the child site can be on different NetScaler software versions. However, to use the GSLB automaticConfigSync option to synchronize the configuration across the parent sites, all parent sites must be on the same NetScaler software versions. If you are not using the automaticConfigSync option, then the parent site and the child site can be on different NetScaler software versions but make sure that you are not using any of the new features in the latest release. This is also applicable, in general, to two NetScaler nodes participating in GSLB.

**Basic parent-child topology**

In the diagram, Site P1 and Site P2 are parent sites in a peer relationship. Site P1C1 and P2C1 are the child sites of P1 and P2 respectively.

**Setting up a parent-child configuration for GSLB**

If you have a firewall configured at a GSLB site, make sure that port 3011 is open.

The following diagram displays a sample parent-child configuration.

- The configuration of a child site includes the child site and its parent site, but no other parent or child sites.
- Network metrics, such as RTT and persistence session information, are synchronized only across the parent sites. Therefore, parameters such as nwMetricExchange and sessionExchange are disabled by default on all the child sites.
- To verify correct parent-child configuration, check the states of all the GSLB services bound to the parent sites.

**To set up a parent-child configuration for GSLB by using the CLI:**

1. On each parent site, enter the following commands:

   ```bash
   add gslb site <siteName> <siteIPAddress> [-publicIP <ip_addr|ipv6_addr] [►]
   ```

   ```bash
   add gslb site <siteName> <siteIPAddress> [-publicIP <ip_addr|ipv6_addr] [►] [-parentSite <string>]
   ```

**Example:**

```bash
add gslb site GSLB_Site1 10.1.1.1 - publicIP 10.1.1.1
```
1 add gslb site Site1_child1 1 10.1.1.2 -publicIP 10.1.1.2 -parentSite GSLB_Site1

2. On each child site, enter the following commands:

   1 add gslb site <siteName> <siteIPAddress> [-publicIP <ip_addr|ipv6_addr |*>]
   2 add gslb site <siteName> <siteIPAddress> [-publicIP <ip_addr|ipv6_addr |*>] [-parentSite <string>]

Example:

   1 add gslb site GSLB_Site1 10.1.1.1 -publicIP 10.1.1.1
   2 add gslb site Site1_child1 1 10.1.1.2 -publicIP 10.1.1.2 -parentSite GSLB_Site1

For a complete example of a parent-child configuration, using the command line interface, see Example of a Complete Parent-Child Configuration, Using the CLI

**Note**

If the load balancing virtual server IP address is a private IP address and the public IP address is different from this IP address, you need to configure a GSLB service for the local load balancing virtual server on the child site. This is required for statistics collection between the parent and the child site.

On the child site, at the command prompt, type:

   add gslb service <name> <private IP/lb vserver IP> http 80 -sitename <childsite name> -publicip <public IP of LB vserver>

Example:

   add gslb service Service-GSLB 192.168.1.3 http 80 -GSLB_Site1 site 11_lb1 172.16.1.1

Where 192.168.1.3 is a private IP address of the load balancing virtual server and 172.16.1.1 is a public IP address of the load balancing virtual server.

**Backing up a parent site**

**Note**: This feature was introduced in NetScaler release 11.1 build 51.x. To use the backup parent site topology, make sure that the parent site and the child sites are on NetScaler 11.1 build 51.x and later.
The backup parent site topology is useful in scenarios wherein a large number of child sites are associated with a parent site. If this parent site goes DOWN, all of its child sites become unavailable. To prevent this, you can now configure a backup parent site to which the child sites can connect if the original parent site is DOWN. The parent site sends the backup parent list to the child sites through the MEP messages.

When a parent site is DOWN, the other parent sites in the GSLB get to know that a particular parent site is DOWN through MEP because MEP to that parent site is DOWN. The other parent sites in the GSLB setup look up the backup chain of the peer parent. The parent site with the highest preference adopts the child sites of the parent that went DOWN. The new parent then initiates a connection with the child site. A child site can accept or reject the connection after evaluating its existing connections and the information in the backup list.

When the original parent site is back UP, it tries to establish connections with its child sites that have migrated to a different parent. When a connection attempt is successful, the child site is reassigned to its original parent site.

**Note:**

- Only parent sites can be configured as backups, and this configuration can only be done at the parent site.
- All child sites use the backup parent set.
- Synchronization is done only on the parent sites. GSLB child sites’ configuration is not affected by synchronization. This is because the parent site and the child site configurations are not identical. The child sites configuration consists only of its own and its parent site’s details. Also, GSLB services are not always required to be configured in the child sites.

Consider the configuration shown in the following figure, in which:

- SiteP1, SiteP2, and SiteP3 are the parent sites.
- Child_site1, Child_site2, and Child_site3 are the child sites of SiteP1, SiteP2, and SiteP3 respectively.
- Backup parent sites;
  - SiteP1 backup parents - SiteP2 (higher preference) and Site P3
  - SiteP2 backup parents – SiteP3 (higher preference) and Site P1
  - SiteP3 backup parents – SiteP1 (higher preference) and Site P2

**Note:** For illustration purposes, the figure shows only one backup parent for each parent site.

The following list summarizes the behavior of the parent and child sites under various scenarios:

- **Scenario 1: SiteP1 goes DOWN.**
  - SiteP2 and SiteP3 detect that SiteP1’s MEP connection is DOWN. SiteP2 is higher in the preference list of backup parents for SiteP1, so it tries to initiate a connection to Child_site1. SiteP3 assumes that Child_site1 is now the child site of parent SiteP2.
NetScaler 12.0

- SiteP2 sends Child_Site1 the list of SiteP1’s backup parents (SiteP2 and SiteP3) to Child_site1. Child_site1 uses the list to decide whether to accept or reject the connection from SiteP2. It accepts the connection and becomes a child of SiteP2.
- When SiteP1 is back UP, it sends Child_site1 a connection request. The new request takes precedence and Child_site1 migrates to SiteP1.

- Scenario 2: Only the MEP connection between SiteP1 and SiteP2 has gone DOWN. Child_site1 rejects SiteP2’s connection request, because its parent, SiteP1, is still UP.
- Scenario 3: SiteP3 and Child_Site1 detect that SiteP1 is DOWN, and the MEP connection between SiteP3 and SiteP2 is also DOWN. However, Site P2 detects that SiteP1 is UP, and the MEP connection between SiteP1 and SiteP2 is UP.
  - SiteP2 does not take any action.
  - SiteP3 checks SiteP1’s backup list and finds that SiteP2 has a higher preference than SiteP3. But SiteP2 is DOWN, so SiteP3 tries to establish a connection with Child_site1. Child_site1 has detected that SiteP1 is DOWN, so it accepts SiteP3’s connection request.
  - Now the connection between SiteP1 and SiteP2 goes DOWN. SiteP2 checks SiteP1’s backup list and finds itself as the most preferred backup, so it tries to connect to Child_site1. Child_site1 evaluates the new connection request based on SiteP1’s list and finds SiteP2 as the most preferred backup, so it migrates to SiteP2 from SiteP3.

To configure a backup parent site by using the command line interface

At the command prompt type:

```
set gslb site <sitename> -backupParentlist <bkp_site1> <bkp_site2> ... <bkp_site5>
```

<sitename> is the current parent site.

**Note:**

- You cannot add a new site as a backup parent. You must first add all the sites, and then configure the site as a backup parent.
- To remove a backup parent, you must use the unset command, which unsets all the sites that were previously configured as backup parent sites.

To configure a backup parent site by using the GUI

1. Navigate to **Configuration > Traffic Management > GSLB > Sites**.
2. Add a new site or select an existing site.
3. Choose the **Backup Parent Sites** option box while creating or configuring the GSLB site.
**GSLB configuration entities**

September 12, 2018

A GSLB configuration consists of a group of GSLB entities on each appliance in the configuration. These entities include the following:

- GSLB Sites
- GSLB Services
- GSLB Virtual Servers
- Load Balancing or Content Switching Virtual Servers
- ADNS Services
- DNS VIPs

**GSLB Sites**

A typical GSLB setup consists of data centers, each of which has various network appliances that may or may not be NetScaler appliances. The data centers are called GSLB sites. Each GSLB site is managed by a NetScaler appliance that is local to that site. Each of these appliances treats its own site as the local site and all other sites, managed by other appliances, as remote sites.

If the appliance that manages a site is the only NetScaler appliance in that data center, the GSLB site hosted on that appliance acts as a bookkeeping placeholder for auditing purposes, because no metrics can be collected. Typically, this happens when the appliance is used only for GSLB, and other products in the data center are used for load balancing or content switching.

**Relationships among GSLB Sites**

The concept of sites is central to NetScaler GSLB implementations. Unless otherwise specified, sites form a peer relationship among themselves. This relationship is used first to exchange health information and then to distribute load as determined by the selected algorithm. In many situations, however, a peer relationship among all GSLB sites is not desirable. Reasons for not having an all-peer implementation could be:

- To clearly separate GSLB sites. For example, to separate sites that participate in resolving DNS queries from the traffic management sites.
- To reduce the volume of Metric Exchange Protocol (MEP) traffic, which increases exponentially with an increasing number of peer sites.

These goals can be achieved by using parent and child GSLB sites.
**GSLB Services**

A GSLB service is usually a representation of a load balancing or content switching virtual server, although it can represent any type of virtual server. The GSLB service identifies the virtual server’s IP address, port number, and service type. GSLB services are bound to GSLB virtual servers on the NetScaler appliances managing the GSLB sites. A GSLB service bound to a GSLB virtual server in the same data center is local to the GSLB virtual server. A GSLB service bound to a GSLB virtual server in a different data center is remote from that GSLB virtual server.

**Note**

Sites and services are inherently linked to indicate proximity between the two. That is, all services must belong to a site, and are assumed to be in the same location as the GSLB site for proximity purposes. Likewise, services and virtual servers are linked, so that the logic is linked to the resources that are available.

**GSLB Virtual Servers**

A GSLB virtual server has one or more GSLB services bound to it, and load balances traffic among those services. It evaluates the configured GSLB methods (algorithms) to select the appropriate service to which to send a client request. Because the GSLB services can represent either local or remote servers, selecting the optimal GSLB service for a request has the effect of selecting the data center that should serve the client request.

The domain for which global server load balancing is configured must be bound to the GSLB virtual server, because one or more services bound to the virtual server will serve requests made for that domain.

Unlike other virtual servers configured on a NetScaler appliance, a GSLB virtual server does not have its own virtual IP address (VIP).

**Load Balancing or Content Switching Virtual Servers**

A load balancing or content switching virtual server represents one or many physical servers on the local network. Clients send their requests to the load balancing or content switching virtual server’s virtual IP (VIP) address, and the virtual server balances the load across the physical servers. After a GSLB virtual server selects a GSLB service representing either a local or a remote load balancing or content switching virtual server, the client sends the request to that virtual server’s VIP address.

For more information about load balancing or content switching virtual servers and services, see Load Balancing or Content Switching.
**ADNS Services**

An ADNS service is a special kind of service that responds only to DNS requests for domains for which the NetScaler appliance is authoritative. When an ADNS service is configured, the appliance owns that IP address and advertises it. Upon reception of a DNS request by an ADNS service, the appliance checks for a GSLB virtual server bound to that domain. If a GSLB virtual server is bound to the domain, it is queried for the best IP address to which to send the DNS response.

**DNS VIPs**

A DNS virtual IP is a virtual IP (VIP) address that represents a load balancing DNS virtual server on the NetScaler appliance. DNS requests for domains for which the NetScaler appliance is authoritative can be sent to a DNS VIP.

**GSLB methods**

September 12, 2018

Unlike traditional DNS servers that simply respond with the IP addresses of the configured servers, a NetScaler appliance configured for GSLB responds with the IP addresses of the services, as determined by the configured GSLB method. By default, the GSLB virtual server is set to the least connection method. If all GSLB services are down, the appliance responds with the IP addresses of all the configured GSLB services.

GSLB methods are algorithms that the GSLB virtual server uses to select the best-performing GSLB service. After the host name in the Web address is resolved, the client sends traffic directly to the resolved service IP address.

The NetScaler appliance provides the following GSLB methods:

- Round Robin
- Least Connections
- Least Response Time
- Least Bandwidth
- Least Packets
- Source IP Hash
- Custom Load
- Round Trip Time (RTT)
- Static Proximity
For GSLB methods to work with a remote site, either MEP must be enabled or explicit monitors must be bound to the remote services. If MEP is disabled, RTT, Least Connections, Least Bandwidth, Least Packets and Least Response Time methods default to Round Robin.

The Static Proximity and RTT load balancing methods are specific to GSLB.

**Specifying a GSLB method other than static proximity or dynamic RTT**

For information about the Round Robin, Least Connections, Least Response Time, Least Bandwidth, Least Packets, Source IP Hash, or Custom Load method, see “Load Balancing.”

**To change the GSLB method by using the CLI**

At the command prompt, type:

```
set gslb vserver <name> -lbMethod GSLBMethod
```

**Example:**

```
set gslb vserver Vserver-GSLB-1 -lbMethod ROUNDROBIN
```

**To change the GSLB method by using the GUI**

1. Navigate to **Traffic Management > GSLB > Virtual Servers**.
2. In the details pane, select a GSLB virtual server and click **Open**.
3. In the Configure GSLB Virtual Server dialog box, on the Method and Persistence tab, under Method, select a method from the Choose Method list.
4. Click **OK**, and verify that the method you selected appears under Details at the bottom of the screen.

**GSLB algorithms**

September 12, 2018

The following algorithm are supported for GSLB.

- **Round Robin**: When a GSLB virtual server is configured to use the round robin method, it continuously rotates a list of the services that are bound to it. When the virtual server receives a request, it assigns the connection to the first service in the list, and then moves that service to the bottom of the list.
**Least Response Time:** When the GSLB virtual server is configured to use the least response time method, it selects the service with the fewest active connections and the lowest average response time. You can configure this method for HTTP and Secure Sockets Layer (SSL) services only. The response time (also called Time to First Byte, or TTFB) is the time interval between sending a request packet to a service and receiving the first response packet from the service. The NetScaler appliance uses response code 200 to calculate TTFB.

**Least Connections:** When a GSLB virtual server is configured to use the least connection GSLB algorithm (or method), it selects the service with the fewest active connections. This is the default method, because, in most circumstances, it provides the best performance.

**Least Bandwidth:** A GSLB virtual server configured to use the least bandwidth method selects the service that is currently serving the least amount of traffic, measured in megabits per second (Mbps). The following example shows how the virtual server selects a service for GSLB by using the least bandwidth method.

**Least Packets:** A GSLB virtual server configured to use the least packets method selects the service that has received the fewest packets in the last 14 seconds.

**Source IP Hash:** A GSLB virtual server configured to use the source IP hash method uses the hashed value of the client IPv4 or IPv6 address to select a service. To direct all requests from source IP addresses that belong to a particular network to a specific destination server, you must mask the source IP address. For IPv4 addresses, use the netMask parameter. For IPv6 addresses, use the v6NetMaskLength parameter.

**Custom Load:** Custom load balancing is performed on server parameters such as CPU usage, memory, and response time. When using the custom load method, the NetScaler appliance usually selects a service that is not handling any active transactions. If all of the services in the GSLB setup are handling active transactions, the appliance selects the service with the smallest load. A special type of monitor, known as a load monitor, calculates the load on each service in the network. The load monitors do not mark the state of a service, but they do take services out of the GSLB decision when those services are not UP.

For more details, see Load Balancing.

---

**Static proximity**

September 12, 2018

The static proximity method for GSLB uses an IP-address based static proximity database to determine the proximity between the client’s local DNS server and the GSLB sites. The NetScaler appliance responds with the IP address of a site that best matches the proximity criteria.

If two or more GSLB sites at different geographic locations serve the same content, the NetScaler appliance maintains a database of IP address ranges and uses the database for decisions about the GSLB sites to which to direct incoming client requests.
For the static proximity method to work, you must either configure the NetScaler appliance to use an existing static proximity database populated through a location file or add custom entries to the static proximity database. After adding custom entries, you can set their location qualifiers. After configuring the database, you are ready to specify static proximity as the GSLB method.

For details about configuring static proximity, see Configuring Static Proximity.

Dynamic round trip time method

September 20, 2018

Dynamic round trip time (RTT) is a measure of time or delay in the network between the client’s local DNS server and a data resource. To measure dynamic RTT, the NetScaler appliance probes the client’s local DNS server and gathers RTT metric information. The appliance then uses this metric to make its load balancing decision. Global server load balancing monitors the real-time status of the network and dynamically directs the client request to the data center with the lowest RTT value.

When a client’s DNS request for a domain comes to the NetScaler appliance configured as the authoritative DNS for that domain, the appliance uses the RTT value to select the IP address of the best performing site to send it as a response to the DNS request.

The NetScaler appliance uses different mechanisms, such as ICMP echo request / reply (PING), UDP, and TCP to gather the RTT metrics for connections between the local DNS server and participating sites. The appliance first sends a ping probe to determine the RTT. If the ping probe fails, a DNS UDP probe is used. If that probe also fails, the appliance uses a DNS TCP probe.

These mechanisms are represented on the NetScaler appliance as Load Balancing Monitors and are easily identified due to their use of the “ldns” prefix. The three monitors, in their default order, are:

- ldns-ping
- ldns-dns
- ldns-tcp

These monitors are built in to the appliance and are set to safe defaults, but may be customized just like any other monitor on the appliance.

The default order may also be changed by setting it explicitly as a GSLB parameter. For example, to set the order to be the DNS UDP query followed by the PING and then TCP, type the following command:

```
set gslb parameter -ldnsprobeOrder DNS PING TCP
```

Unless they have been customized, the NetScaler appliance performs UDP and TCP probing on port 53, however unlike regular load balancing monitors the probes need not be successful in order to provide valid RTT information. ICMP port unavailable messages, TCP Resets and DNS error responses, which would usually constitute a failure are all acceptable for calculating the RTT value.
Once the RTT data has been compiled, the appliance uses the proprietary metrics exchange protocol (MEP) to exchange RTT values between participating sites. After calculating RTT metrics, the appliance sorts the RTT values to identify the data center with the best (smallest) RTT metric.

If RTT information is not available (for example, when a client’s local DNS server accesses the site for the first time), the NetScaler appliance selects a site by using the round robin method and directs the client to the site.

To configure the dynamic method, you configure the site’s GSLB virtual server for dynamic RTT. You can also set the interval at which local DNS servers are probed to a value other than the default.

**Configure a GSLB virtual server for dynamic RTT**

To configure a GSLB virtual server for dynamic RTT, you specify the RTT load balancing method.

The NetScaler appliance regularly validates the timing information for a given local server. If a change in latency exceeds the configured tolerance factor, the appliance updates its database with the new timing information and sends the new value to other GSLB sites by performing a MEP exchange. The default tolerance factor is 5 milliseconds (ms).

The RTT tolerance factor must be the same throughout the GSLB domain. If you change it for a site, you must configure identical RTT tolerance factors on all NetScaler appliances deployed in the GSLB domain.

**To configure a GSLB virtual server for dynamic RTT by using the command line interface**

At the command prompt, type:

```
set gslb vserver <name> -lbMethod RTT -tolerance <value>
```

**Example:**

```
set gslb vserver Vserver-GSLB-1 -lbMethod RTT -tolerance 10
```

**To configure a GSLB virtual server for dynamic RTT by using the configuration utility**

Navigate to **Traffic Management > GSLB > Virtual Servers** and double-click the virtual server.

**Set the probing interval of local DNS servers**

The NetScaler appliance uses different mechanisms, such as ICMP echo request / reply (PING), TCP, and UDP to obtain RTT metrics for connections between the local DNS server and participating GSLB
NetScaler 12.0

sites. By default, the appliance uses a ping monitor and probes the local DNS server every 5 seconds. The appliance then waits 2 seconds for the response and, if a response is not received in that time, it uses the TCP DNS monitor for probing.

However, you can modify the time interval for probing the local DNS server to accommodate your configuration.

To modify the probing interval by using the command line interface

At the command prompt, type:

```
set lb monitor <monitorName> <type> -interval <integer> <units> -resptimeout <integer> <units>
```

Example:

```
set lb monitor monitor-HTTP-1 HTTP -interval 10 sec -resptimeout 5 sec
```

To modify the probing interval by using the configuration utility

Navigate to Traffic Management > Load Balancing > Monitors, and double-click the monitor that you want to modify (for example, PING).

Configure static proximity

September 12, 2018

For the static proximity method to work, you must either configure the NetScaler appliance to use an existing static proximity database populated through a location file or add custom entries to the static proximity database. After adding custom entries, you can set their location qualifiers. After configuring the database, you are ready to specify static proximity as the GSLB method.

This document includes the following information:

- Adding a Location File to Create a Static Proximity Database
- Adding Custom Entries to a Static Proximity Database
- Setting the Location Qualifiers
- Specifying the Proximity Method
- Synchronizing GSLB Static Proximity Database
Add a location file to create a static proximity database

September 12, 2018

A static proximity database is a UNIX-based ASCII file. Entries added to this database from a location file are called static entries. Only one location file can be loaded on a NetScaler appliance. Adding a new location file overrides the existing file. The number of entries in the static proximity database is limited by the configured memory in the NetScaler appliance.

The static proximity database can be created in the default format or in a format derived from commercially configured third party databases (such as www.maxmind.com and www.ip2location.com).

The NetScaler appliance includes the following two IP geolocation database files. These are GeoLite2 files, published by MaxMind.

- Citrix_Netscaler_InBuilt_GeoIP_DB_IPv4
- Citrix_Netscaler_InBuilt_GeoIP_DB_IPv6

These database files are available in a format supported by the NetScaler appliance in the directory /var/netscaler/inbuilt_db.

You can use these IP geolocation databases as the location file for the static proximity based GSLB method, or in location based policies.

These databases vary in the details they provide. There is no strict enforcement of the database file format, except that the default file has format tags. The database files are ASCII files that use a comma as the field delimiter. There are differences in the structure of fields and the representation of IP addresses in the locations.

The format parameter describes the structure of the file to the NetScaler appliance. Specifying an incorrect value for the format option can corrupt the internal data.

**Note**

- After an upgrade, if the /var/netscaler/inbuilt_db/ directory contains the database file (Citrix_Netscaler_InBuilt_GeoIP_DB.csv) from the earlier NetScaler software versions, the file is retained.
- The default location of the database file is /var/netscaler/locdb, and on a high availability (HA) setup, an identical copy of the file must be present in the same location on both NetScaler appliances.

The following abbreviations are used in this section:

**CSHN.** Short name of a country based on the country code standard of ISO-3166.

**LCN.** Long name of the country.

**RC.** Region code based on ISO-3166-2 (for US and Canada). The region code “FIPS-10-4” is used.
Some databases provide short country names according to ISO-3166 and long country names as well. The NetScaler uses short names when storing and matching qualifiers.

To create a static proximity database, log on to the UNIX shell of the NetScaler appliance and use an editor to create a file with the location details in one of the NetScaler-supported formats.

**To add a static location file by using the CLI**

At the command prompt, type:

```
1  add locationFile <locationFile> [-format <format>]
2  -  show locationFile
```

**Example:**

```
1  add locationFile /var/nmap/locdb/nsgeo1.0 -format netscaler
2  Done
3
4  show locationFile
5  Location File: /var/nmap/locdb/nsgeo1.0
6  Format: netscaler
7  Done
8  >
```

**To add a static location file by using the GUI**

1. Navigate to AppExpert > Location, click the Static Database tab.
2. Click Add to add a static location file.

You can view an imported location file database by using the View Database dialog box in the configuration utility. There is no CLI equivalent.

**To view a static location file by using the GUI**

1. Navigate to AppExpert > Location, click the Static Database tab.
2. Select a static location file, and from the Action list, click View Database.
NetScaler 12.0

To convert a location file into the NetScaler format

By default, when you add a location file, it is saved in the NetScaler format. You can convert a location file of other formats into the NetScaler format.

**Note:** The nsmap option can be accessed only from the command line interface. The conversion is possible only into the NetScaler format.

To convert the static database format, At the CLI prompt, type the following command:

```bash
nsmap -f <inputFileFormat> -o <outputFileName> <inputFileName>
```

**Example:**

```bash
nsmap -f ip-country-region-city -o nsfile.ns ip-country-region-city.csv
```

Add custom entries to a static proximity database

September 12, 2018

Custom entries take precedence over static entries in the proximity database. You can add a maximum of 500 custom entries. For a custom entry, denote all omitted qualifiers with an asterisk (*) and, if qualifiers have a period or space in the name, enclose the parameter in double quotation marks. The first 31 characters are evaluated for each qualifier. You can also provide the longitude and latitude of the geographical location of the IP address-range for selecting a service with the static proximity GSLB method.

To add custom entries by using the command line interface

At the command prompt, type the following commands to add a custom entry to the static proximity database and verify the configuration:

```bash
add location <IPfrom> <IPto> <preferredLocation> [-longitude <integer>] [-latitude <integer>]
show location
```

**Example:**

```bash
>add location 192.168.100.1 192.168.100.100 *.us.ca.mycity

>show location
```
Parameters for adding custom entries

- **IPfrom**
  First IP address in the range, in dotted decimal notation. This is a mandatory argument.

- **IPto**
  Last IP address in the range, in dotted decimal notation. This is a mandatory argument.

- **preferredLocation**
  String of qualifiers, in dotted notation, describing the geographical location of the IP address range. Each qualifier is more specific than the one that precedes it, as in continent.country.region.city.isp.organization. For example, “NA.US.CA.San Jose.ATT.citrix”. Note: A qualifier that includes a dot (.) or space ( ) must be enclosed in double quotation marks. This is a mandatory argument. Maximum Length: 197

- **longitude**
  Numerical value, in degrees, specifying the longitude of the geographical location of the IP address-range. Note: Longitude and latitude parameters are used for selecting a service with the static proximity GSLB method. If they are not specified, selection is based on the qualifiers specified for the location. Maximum value: 180

- **latitude**
  Numerical value, in degrees, specifying the latitude of the geographical location of the IP address-range. Note: Longitude and latitude parameters are used for selecting a service with the static proximity GSLB method. If they are not specified, selection is based on the qualifiers specified for the location. Maximum value: 180

To add custom entries by using the configuration utility

Navigate to **AppExpert > Location**, click the **Custom Entries** tab, and add the custom entries.

Set location qualifiers

September 12, 2018
The database used to implement static proximity contains the location of the GSLB sites. Each location contains an IP address range and up to six qualifiers for that range. The qualifiers are literal strings and are compared in a prescribed order at run time. Every location must have at least one qualifier. The meaning of the qualifiers (context) is defined by the qualifier labels, which are user defined. NetScaler has two built-in contexts:

Geographic context, which has the following qualifier labels:

- Qualifier 1 – “Continent”
- Qualifier 2 – “Country”
- Qualifier 3 – “State”
- Qualifier 4 – “City”
- Qualifier 5 – “ISP”
- Qualifier 6 – “Organization”

Custom entries, which have the following qualifier labels:

- Qualifier 1 – “Qualifier 1”
- Qualifier 2 – “Qualifier 2”
- Qualifier 3 – “Qualifier 3”
- Qualifier 4 – “Qualifier 4”
- Qualifier 5 – “Qualifier 5”
- Qualifier 6 – “Qualifier 6”

If the geographic context is set with no Continent qualifier, Continent is derived from Country. Even the built-in qualifier labels are based on the context, and the labels can be changed. These qualifier labels specify the locations mapped with the IP addresses used to make static proximity decisions.

To perform a static proximity-based decision, the NetScaler appliance compares the location attributes (qualifiers) derived from the IP address of the local DNS server resolver with the location attributes of the participating sites. If only one site matches, the appliance returns the IP address of that site. If there are multiple matches, the site selected is the result of a round robin on the matching GSLB sites. If there is no match, the site selected is a result of a round robin on all configured sites. A site that does not have any qualifiers is considered a match.

**To set the location qualifiers by using the command line interface**

At the command prompt, type:

```
set locationparameter -context <context> -q1label <string> [-q2label <string>] [-q3label <string>] [-q4label <string>] [-q5label <string>] [-q6label <string>]
```

**Example:**

© 1999-2018 Citrix Systems, Inc. All rights reserved.
To set the location qualifiers by using the configuration utility

1. Navigate to AppExpert > Location.
2. From the Action list, click Location Parameters and set the location qualifiers.

Specify proximity method

September 12, 2018

When you have configured the static proximity database, you are ready to specify static proximity as the GLSB method.

To specify static proximity by using the command line interface

At the command prompt, type the following commands to configure static proximity and verify the configuration:

```
1 set gslb vserver <name> -lbMethod STATICPROXIMITY
2 show gslb vserver <name>
```

Example:

```
1 set gslb vserver Vserver-GSLB-1 -lbMethod STATICPROXIMITY
2 show gslb vserver
```

To specify static proximity by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the virtual server.
2. Click the Method section and from the Choose Method drop-down list, select STATICPROXIMITY.

Synchronize GSLB static proximity database

September 12, 2018
Synchronizing a global server load balancing (GSLB) static proximity database requires that one of the sites be identified as the master GSLB node. Any site in the topology can be designated as the master node. The rest of the GSLB nodes are automatically designated as slave nodes.

Synchronizing GSLB static proximity databases synchronizes the files in the /var/netscaler/locdb directory across the slave nodes. During the synchronization process, the master node fetches the running configuration from each of the slave nodes and compares it to the configuration on the master node. The master GSLB node uses the rsync program to synchronize the static proximity database across the slave nodes. To speed up the synchronization process, the rsync program makes only enough changes to eliminate the differences between the two files. The synchronization process cannot be rolled back.

The following example synchronizes Site2, which is a slave site, to master site Site1. The administrator enters the `sync gslb config` command on Site1:

```
1       sync gslb config -nowarn
2       Sync Time: Feb 24 2014 14:56:16
3       Retrieving local site info: ok
4       Retrieving all participating gslb sites info:
5       0 bytes in 0 blocks
6       ok
7       site1[Master]:
8       Getting Config: ok
9       site2[Slave]:
10      Syncing gslb static proximity database: ok
11      Getting Config: ok
12      Comparing config: ok
13      Applying changes: ok
14      Done
```

**Configure site-to-site communication**

September 12, 2018

GSLB site-to-site communication is between the remote procedure call (RPC) nodes that are associated with the communicating sites. A master GSLB site establishes connections with slave sites to synchronize GSLB configuration information and to exchange site metrics.

An RPC node is created automatically when a GSLB site is created, and is assigned an internally generated user name and password. The NetScaler appliance uses this user name and password to authenticate itself to remote GSLB sites during connection establishment. No configuration steps are necessary for an RPC node, but you can specify a password of your choice, enhance security by encrypting the information that GSLB sites exchange, and specify a source IP address for the RPC node.
NetScaler 12.0

The appliance needs a NetScaler owned IP address to use as the source IP address when communicating with other GSLB sites. By default, the RPC nodes use either a subnet IP (SNIP) address, but you might want to specify an IP address of your choice.

The following topics describe the behavior and configuration of RPC nodes on the NetScaler appliance:

**Changing the password of an RPC node**

You can secure the communication between sites in your GSLB setup by changing the password of each RPC node. After you change the password for the RPC node of the local site, you must manually propagate the change to the RPC node at each of the remote sites.

The password is stored in encrypted form. You can verify that the password has changed by using the show rpcNode command to compare the encrypted form of the password before and after the change.

**To change the password of an RPC node by using the command line interface**

At the command line, type the following commands to change the password of an RPC node:

```
set ns rpcNode <IPAddress> { -password }
```

Example:

```n
> set rpcNode 192.0.2.4 -password mypassword
Done
> show ns rpcNode
```

To unset the password of an RPC node by using the command line interface

To unset the password of an RPC node by using the CLI, type the unset rpcNode command, the IP address of the RPC node, and the password parameter, without a value.
To change the password of an RPC node by using the configuration utility

Navigate to System > Network > RPC, select the RPC node, and change the password.

Encrypt the exchange of site metrics

You can secure the information that is exchanged between GSLB sites by setting the secure option for the RPC nodes in the GSLB setup. With the secure option set, the NetScaler appliance encrypts all communication sent from the node to other RPC nodes.

To encrypt the exchange of site metrics by using the command line interface

At the command prompt, type the following commands to encrypt the exchange of site metrics and verify the configuration:

```
1  set ns rpcNode <IPAddress> [-secure ( YES | NO )]
2  show rpcNode
```

Example:

```
1 > set rpcNode 192.0.2.4 -secure YES
2   Done
3 >
4 > show rpcNode
5 .
6 .
7 .
8 3) IPAddress: 192.0.2.4 Password: d336004164d4352ce39e SrcIP: 192.0.2.3 Secure: ON
9   Done
10 >
```

To unset the secure parameter by using the command line interface

To unset the secure parameter by using the CLI, type the unset rpcNode command, the IP address of the RPC node, and the secure parameter, without a value.

To encrypt the exchange of site metrics by using the NetScaler configuration utility

1. Navigate to System > Network > RPC and double-click a RPC node.
2. Select the Secure option, and click OK.
**Configure source IP address for an RPC node**

By default, the NetScaler appliance uses a NetScaler owned subnet IP (SNIP) address as the source IP address for an RPC node, but you can configure the appliance to use a specific SNIP address. If a SNIP address is not available, the GSLB site cannot communicate with other sites. In such a scenario, you must configure either the NSIP address or a virtual IP (VIP) address as the source IP address for an RPC node. A VIP address can be used as the source IP address of an RPC node only if the RPC node is a remote node. If you configure a VIP address as the source IP address and remove the VIP address, the appliance uses a SNIP address.

**Note**

From NetScaler 11.0.64.x release onwards, you can configure the appliance to use GSLB Site IP address as the source IP address for an RPC node.

**To specify a source IP address for an RPC node by using the command line interface**

At the command prompt, type the following commands to change the source IP address for an RPC node and verify the configuration:

```bash
1 set ns rpcNode <IPAddress> [-srcIP <ip_addr|ipv6_addr|*]]
2 show ns rpcNode
```

**Example:**

```bash
1 set rpcNode 192.0.2.4 -srcIP 192.0.2.3
2 Done
3 show rpcNode
```

```
1 IPAddress: 192.0.2.4 Password: d336004164d4352ce39e SrcIP: 192.0.2.3 Secure: OFF
2 Done
```

**To unset the source IP address parameter by using the command line interface**

To unset the source IP address parameter by using the CLI, type the unset rpcNode command, the IP address of the RPC node, and the srcIP parameter, without a value.

**To specify a source IP address for an RPC node by using the NetScaler configuration utility**

1. Navigate to System > Network > RPC and double-click a RPC node.
2. In the Source IP Address field, enter the IP address that you want the RPC node to use as the source IP address and click OK.

Important
The source IP address cannot be synchronized across the sites participating in GSLB because the source IP address for a RPC node is specific to each NetScaler appliance. Therefore, after you force a synchronization (using the sync gslb config –forceSync command or by selecting the ForceSync option in the GUI), you have to manually change the source IP addresses on the other NetScaler appliances.

Configure metrics exchange protocol

September 12, 2018

The data centers in a GSLB setup exchange metrics with each other through the metrics exchange protocol (MEP), which is a proprietary protocol for NetScaler appliance. The exchange of the metric information begins when you create a GSLB site. These metrics comprise load, network, and persistence information.

MEP is required for health checking of data centers to ensure their availability. A connection for exchanging network metric (round-trip time) can be initiated by either of the data centers involved in the exchange, but a connection for exchanging site metrics is always initiated by the data center with the lower IP address. By default, the data center uses a subnet IP address (SNIP) to establish a connection to the IP address of a different data center. However, you can configure a specific SNIP, virtual IP (VIP) address, or the NSIP address, as the source IP address for metrics exchange. The communication process between GSLB sites uses TCP port 3011 or 3009, so this port must be open on firewalls that are between the NetScaler appliances.

Note: You cannot configure a GSLB site IP address as the source IP address for site metrics exchange.

If the source and target sites (the site that initiates a MEP connection and the site that receives the connection request, respectively) have both private and public IP addresses configured, the sites exchange MEP information by using the public IP addresses.

You can also bind monitors to check the health of remote services as described in “Monitoring GSLB Services.” When monitors are bound, metric exchange does not control the state of the remote service. If a monitor is bound to a remote service and metric exchange is enabled, the monitor controls the health status. Binding the monitors to the remote service enables the NetScaler appliance to interact with a non NetScaler load balancing device. The NetScaler appliance can monitor non NetScaler devices but cannot perform load balancing on them unless monitors are bound to all GSLB services and only static load balancing methods (such as the round robin, static proximity, or hash-based methods) are used.
With NetScaler release 11.1.51.x or later, to avoid unnecessary disruption of services, you can set a time delay for marking GSLB services as DOWN when a MEP connection goes DOWN.

**Enable site metrics exchange**

Site metrics exchanged between the GSLB sites include the status of each load balancing, or content switching virtual server, the current number of connections, the current packet rate, and current bandwidth usage information.

The NetScaler appliance needs this information to perform load balancing between the sites. The site metric exchange interval is 1 second. A remote GSLB service must be bound to a local GSLB virtual server to enable the exchange of site metrics with the remote service.

**To enable or disable site metrics exchange by using the command line interface**

At a command prompt, type the following commands to enable or disable site metric exchange and verify the configuration:

```bash
1 set gslb site <siteName> -metricExchange (ENABLED|DISABLED)
2 show gslb site** <siteName>
```

**Example:**

```bash
1 set gslb site Site-GSLB-East-Coast -metricExchange ENABLED
2 set gslb site Site-GSLB-East-Coast -metricExchange DISABLED
3 show gslb site Site-GSLB-East-Coast
```

**To enable or disable site metric exchange by using the GUI**

1. Navigate to Traffic Management > GSLB > Sites, and select the site.
2. In the Configure GSLB Site dialog box, select the Metric Exchange option.

**Enable network metric exchange**

If your GSLB sites use the round-trip time (RTT) load balancing method, you can enable or disable the exchange of RTT information about the client's local DNS service. This information is exchanged every 5 seconds.

For details about changing the GSLB method to a method based on RTT, see “GSLB Methods.”
To enable or disable network metric information exchange by using the command line interface

At the command prompt, type the following commands to enable or disable network metric information exchange and verify the configuration:

```
1  set gslb site <siteName> -nwmetricExchange (ENABLED|DISABLED)
2  show gslb site <<siteName>
```

Example:

```
1  set gslb site Site-GSLB-East-Coast -nwmetricExchange ENABLED
2  set gslb site Site-GSLB-East-Coast -nwmetricExchange DISABLED
3  show gslb site Site-GSLB-East-Coast
```

To enable or disable network metric information exchange by using the GUI

1. Navigate to Traffic Management > GSLB > Sites.
2. In the Configure GSLB Site dialog box, select the Network Metric Exchange option.

Configuring a time delay for the GSLB services to be marked as DOWN when a MEP connection goes DOWN

If the status of a MEP connection to a remote site changes to DOWN, the status of every GSLB service on that remote site is marked as DOWN, although the site might not actually be DOWN.

You can now set a delay to allow some time for reestablishment of the MEP connection before the site is marked as DOWN. If the MEP connection is back UP before the delay expires, the services are not affected.

For example, if you set the delay 10, the GSLB services are marked as DOWN until the MEP connection has been DOWN for 10 seconds. If the MEP connection is back UP within 10 seconds, the GSLB services remain in the UP state.

Note: This delay is applicable only to services not bound to a monitor. The delay does not affect the trigger monitors.

To set a time delay by using the command line interface

At the command prompt, type the following command:

```
1  set gslb parameter** - GSLBSvcStateDelayTime <sec>
```
Example:

```
set gslb parameter - GSLBSvcStateDelayTime 10
```

To set a time delay by using the GUI

1. Navigate to Configuration > Traffic Management > GSLB > Change GSLB Settings.
2. In the GSLB Service State Delay Time (secs) box, type the time delay in seconds.

Enable persistence information exchange

You can configure NetScaler appliance to provide persistent connections, so that a client transmission to any virtual server in a group can be directed to a server that has received previous transmissions from the same client.

You can enable or disable the exchange of persistence information at each site. This information is exchanged once every 5 seconds between NetScaler appliances participating in GSLB.

For details about configuring persistence, see Configuring Persistent Connections.

To enable or disable persistence information exchange by using the command line interface

At the command prompt, type the following commands to enable or disable persistence-information exchange and verify the configuration:

```
1 set gslb site <siteName> -sessionExchange (ENABLED|DISABLED)
2 show gslb site** <siteName>
```

Example:

```
1 set gslb site Site-GSLB-East-Coast -sessionExchange  ENABLED
2 set gslb site Site-GSLB-East-Coast -sessionExchange  DISABLED
3 show gslb site Site-GSLB-East-Coast
```

To enable or disable persistence information exchange by using the GUI

1. Navigate to Traffic Management > GSLB > Sites, and double-click the site.
2. In the Configure GSLB Site dialog box, select or clear the Persistence Session Entry Exchange check box.
Configure GSLB by using a wizard

September 12, 2018

You can now use a wizard to configure the GSLB deployment types: active-active, active-passive, and parent-child.

This wizard is available in the GUI. To access the wizard, navigate to Configuration > Traffic Management > GSLB and click Get Started.

You can also access this wizard from the GSLB dashboard. Navigate to Configuration > Traffic Management > GSLB > Dashboard and click Configure GSLB.

Note: You can also configure the GSLB entities individually.

- Active-Active Site Configuration
- Active-Passive Site Configuration
- Parent-Child Topology Configuration

Important

This feature is supported in High Availability deployment and not in Admin Partition and Cluster deployments.

Configure active-active site

January 6, 2019

The following figure shows the workflow involved in a GSLB active-active site configuration.

Before you begin configuring an active-active site, make sure you have configured a standard load balancing setup for each server farm or data center.

Also, for synchronizing the GSLB configuration across the GSLB sites in the deployment, make sure that:

- Local GLSB Sites are configured on all the appliances in the GSLB configuration.
- You have enabled management access on all the GSLB Sites in the configuration.
- You have configured the firewall to accept the auto synchronization and MEP connections.
- The master and slave NetScaler appliances are running the same NetScaler software versions.
- All the NetScaler appliances participating as sites should have the same NetScaler software version (the sites are not in a master-slave relationship).
- The RPC node password is same across all the GSLB sites in the GSLB configuration.
To configure an active-active site by using the wizard

On the Configuration tab, do the following:

1. Navigate to **Traffic Management > GSLB**, and then click **Get Started**.
2. If you have not configured an ADNS service or a DNS virtual server for the site, you can do it now.
   a) Click **View** and then click **Add**.
      b) Enter the service name, IP address and select the protocol (ADNS/ADNS_TCP) through which the data is exchanged with the service.
3. Select **Active-Active Site**.
4. Enter the fully qualified domain name and specify the time period for which the record must be cached by DNS proxies.
5. Configure the GSLB sites. Each site must be configured with a local GSLB site, and each site’s configuration must include all the other sites as remote GSLB sites. There can be only one local site and all other sites are remote sites.
   a) Enter the site details, such as the site name and site IP address.
   b) Select either REMOTE or LOCAL site type.
   c) Optionally, change the RPC password and, if necessary, secure it.
   d) If a monitor is to be bound to the GSLB service, select the condition under which the monitor is to monitor the service. This will be effective only after a monitor is bound to the services. The possible conditions are:
      - **ALWAYS**: Monitor the GSLB service at all times.
      - **MEP Fails**: Monitor the GSLB service only when the exchange of metrics through MEP fails.
      - **MMEP Fails and Service ID Down**: Exchange of metrics through MEP is enabled but the status of the service, updated through metrics exchange, is DOWN.
6. Configure the GSLB services. To create an active-active site you must add at least two GSLB services.
   a) Enter the service details, such as service name, service type, and port number.
   b) Associate the service with a site (local or remote) by selecting the GSLB site where the GSLB service belongs.
   c) Select the monitor that must be bound to the service when MEP fails, if required. The service can be an existing server, or you can create a new server or a virtual server.
   d) To associate an existing server, select the server name. The service IP address is automatically populated.
      - If the public IP address is different from the server IP, which can happen in a NAT environment, enter the public IP address and the port number of the public port.
      - To associate a new server, create a server by entering the server IP details and its public IP address and the public port number.
      - To associate a virtual server, select an already existing virtual server, or click + and add
a new virtual server. This vserver is the load balancing vserver with which this GSLB service will be associated.

7. Configure the GSLB virtual servers.
   a) Enter the name of the GSLB virtual server name and select the DNS record type.
   b) Click > in the Select Service box and choose the GSLB services to be bound to the GSLB virtual server.
   c) Click > in the Domain Binding box to select the domain to be bound to this GSLB virtual server.
   d) Choose the GSLB method for selecting the best-performing GSLB service. The default values are auto-populated, by default. You can change them if required.
      • If you choose the Algorithm based method, select the primary and backup methods and also specify the dynamic weight option.
      • If you choose the Static Proximity method, select the backup method and the dynamic weight method. Also, provide the location of the database file by clicking the > icon or add a new location by clicking + in the Select a location database box.
      • If you choose the Dynamic Proximity (RTT) method, select the backup method and specify the dynamic weight option and the round-trip time value based on which the best-performing service is to be selected.

8. Click Done if the configuration is complete. The GSLB dashboard appears.

9. If you have modified the GSLB site configuration, click Auto Synchronize GSLB in the dashboard to synchronize the configuration to other sites in the GSLB setup.
   • Before synchronization, make sure that the local site’s configuration includes information about the remote sites. Also, for the synchronization to be successful, the local site must be configured on the other NetScaler appliances.
   • If real-time synchronization is enabled, you do not have to click Auto Synchronize GSLB. The synchronization happens automatically. To enable real time synchronization, do the following:
      a) Navigate to Traffic Management > GSLB > Dashboard and click Change GSLB Settings.
      b) Select the Automatic Config Sync check box.

10. Click Test GSLB Setup to make sure that the ADNS services or the DNS servers are responding with the correct IP address for the domain name that is configured in the GSLB setup.

Configure active-passive site

January 6, 2019
The following figure shows the workflow involved in the active-passive site configuration.
Before you begin configuring an active-passive site, make sure you have configured a standard load balancing setup for each server farm or data center.

Also, for synchronizing the GSLB configuration across the GSLB sites in the deployment, make sure that:

- Local GLSB Sites are configured on all the appliances in the GSLB configuration.
- You have enabled management access on all the GSLB Sites in the configuration.
- You have configured the firewall to accept the auto synchronization and MEP connections.
- The master and slave NetScaler appliances are running the same NetScaler software versions.
- All the NetScaler appliances participating as sites should have the same NetScaler software version (the sites are not in a master-slave relationship).
- The RPC node password is same across all the GSLB sites in the GSLB configuration.

To configure an active-passive site by using the wizard

On the Configuration tab, do the following:

1. Navigate to Traffic Management > GSLB, and then click Get Started.
2. If you have not configured an ADNS service or a DNS virtual server for the site, you can do it now.
   a) Click View and then click Add.
   b) Enter the service name, IP address and select the protocol (ADNS/ADNS_TCP) through which the data is exchanged with the service.
3. Select Active-Passive Site.
4. Enter the fully qualified domain name and specify the time period for which the record must be cached by DNS proxies.
5. Configure the GSLB sites. Each site must be configured with a local GSLB site, and each site's configuration must include all the other sites as remote GSLB sites. There can be only one local site and all other sites are remote sites.
   a) Enter the site details, such as the site name and site IP address.
   b) Select either REMOTE or LOCAL site type.
   c) Optionally, change the RPC password and, if necessary, secure it.
   d) If a monitor is to be bound to the GSLB service, select the condition under which the monitor is to monitor the service. This will be effective only after a monitor is bound to the services. The possible conditions are:
      - **ALWAYS**. Monitor the GSLB service at all times.
      - **MEP Fails**. Monitor the GSLB service only when the exchange of metrics through MEP fails.
      - **MEP Fails and Service ID Down**. Exchange of metrics through MEP is enabled but the status of the service, updated through metrics exchange, is DOWN.
6. Configure the GSLB services.
a) Enter the service details, such as service name, service type, and port number.

b) Associate the service with a site (local or remote) by selecting the GSLB site where the GSLB service belongs.

c) Select the monitor that must be bound to the service when MEP fails, if required. The service can be an existing server, or you can create a new server or a virtual server.

d) To associate an existing server, select the server name. The service IP address is automatically populated.
   • If the public IP address is different from the server IP, which can happen in a NAT environment, enter the public IP address and the port number of the public port.
   • To associate a new server, create a server by entering the server IP details and its public IP address and the public port number.
   • To associate a virtual server, select an already existing virtual server, or click + and add a new virtual server. This vserver is the load balancing vserver with which this GSLB service will be associated.

7. Configure the GSLB backup virtual servers. The GSLB backup virtual servers become operational only when the primary GSLB virtual servers is inaccessible or it is marked DOWN for any reason.

   a) Enter the name of the GSLB virtual server name and select the DNS record type.
   b) Click > in Service Binding, and choose the GSLB services that must be bound to the GSLB virtual server.
   c) Choose the GSLB method for selecting the best-performing GSLB service. The default values for GSLB method, backup method, and dynamic weight are auto-populated, by default. You can change them if required.
      • If you choose the Algorithm based method, select the primary and backup methods.
      • If you choose the Static Proximity method, select the backup method and provide the location of the database file.
      • If you choose the Dynamic Proximity (RTT) method, select the backup method and specify the service weight and the RTT value based on which the best-performing service is to be selected.

8. Configure the GSLB virtual servers.

   a) Enter the name of the GSLB virtual server name and select the DNS record type.
   b) Click > in the Select Service box and choose the GSLB services to be bound to the GSLB virtual server.
   c) Click > in the Domain Binding box to select the domain to be bound to this GSLB virtual server.
   d) Choose the GSLB method for selecting the best-performing GSLB service. The default values for GSLB method, backup method, and dynamic weight are auto-populated, by default. You can change them if required.
      • If you choose the Algorithm based method, select the primary and backup methods
and also specify the dynamic weight option.

- If you choose the **Static Proximity** method, select the backup method and the dynamic weight method. Also, provide the location of the database file by clicking the > icon or add a new location by clicking + in the Select a location database box.
- If you choose the **Dynamic Proximity (RTT)** method, select the backup method and specify the dynamic weight option and the round-trip time value based on which the best-performing service is to be selected.

9. Click **Done** if the configuration is complete. The GSLB dashboard appears.

10. If you have modified the GSLB site configuration, click **Auto Synchronize GSLB** in the dashboard to synchronize the configuration to other sites in the GSLB setup.

    - Before synchronization, make sure that the local site's configuration includes information about the remote sites. Also, for the synchronization to be successful, the local site must be configured on the other NetScaler appliances.
    - If real-time synchronization is enabled, you do not have to click **Auto Synchronize GSLB**. The synchronization happens automatically. To enable real-time synchronization, do the following:
      a) Navigate to **Traffic Management > GSLB > Dashboard** and click **Change GSLB Settings**.
      b) Select the **Automatic Config Sync** check box.

11. Click **Test GSLB Setup** to make sure that the ADNS services or the DNS servers are responding with the correct IP address for the domain name that is configured in the GSLB setup.

**Note**

For details about configuring GSLB entities of an active-passive GSLB setup for disaster recovery, see *Configuring GSLB for Disaster Recovery*.

---

**Configure parent-child topology**

January 6, 2019

In a parent-child topology, at the top level are parent sites, which have peer relationships with other parents. Each parent can have multiple child sites, and each parent site exchanges health information with its child sites and with other parent sites. However, a child site communicates only with its parent site.

The following figure shows the workflow involved in a GSLB parent-child topology configuration.

Before you begin configuring the parent-child topology deployment, make sure you have configured a standard load balancing setup for each server farm or data center.

Also, for synchronizing the GSLB configuration across the GSLB sites in the deployment, make sure that:
• Local GLSB Sites are configured on all the appliances in the GSLB configuration.
• You have enabled management access on all the GSLB Sites in the configuration.
• You have configured the firewall to accept the auto synchronization and MEP connections.
• All the NetScaler appliances participating as sites should have the same NetScaler software version (the sites are not in a master-slave relationship).
• The RPC node password is same across all the GSLB sites in the GSLB configuration.

To configure a parent-child deployment by using the wizard

On the Configuration tab, do the following:

1. Navigate to Traffic Management > GSLB, and then click Get Started.
2. If you have not configured an ADNS server or a DNS virtual server for the site, you can do it now.
   a) Click View and then click Add.
   b) Enter the service name, IP address and select the protocol (ADNS/ADNS_TCP) through which the data is exchanged with the service.
4. In the Select the site type field, choose;
   • Parent – When configuring the parent site, you must configure its associated child sites and also configure the other parent sites in the GSLB setup.
   • Child – When configuring the child site, you must configure only the child site and its parent site.

To configure a parent site

1. Enter the fully qualified domain name and specify the time period for which the record must be cached by DNS proxies.
2. Configure the GSLB sites. Each site must be configured with a local GSLB site, and each site’s configuration must include all the other sites as remote GSLB sites. There can be only one local site. All other sites are remote sites. If the specified site IP address is owned by the appliance (for example, a MIP address or SNIP address), the site is a local site. Otherwise, it is a remote site.
3. Enter the site details, such as the site name and site IP address.
   a) Select the site type.
   b) Optionally, change the RPC password and, if necessary, secure it.
   c) If a monitor is to be bound to the GSLB service, select the condition under which the monitor is to monitor the service. This will be effective only after a monitor is bound to the services. The possible conditions are:
      • Always. Monitor the GSLB service at all times.
• MEP Fails. Monitor the GSLB service only when the exchange of metrics through MEP fails.

• MEP Fails and Service is DOWN. Exchange of metrics through MEP is enabled but the status of the service, updated through metrics exchange, is DOWN.

4. Configure the GSLB services.
   a) Enter the service details such as service name, service type, and port number.
   b) Associate the service with a site (local or remote) by selecting the GSLB site to which the GSLB service belongs.
   c) Select the monitor that must be bound to the service when MEP fails, if required. The service can be an existing server, or you can create a new server or a virtual server.
      • To associate an existing server, select the server name. The service IP address is auto-populated.
      • To associate a new server, create a server by entering the server IP details and its public IP address and the public port number.
      • To associate a virtual server, select an already existing virtual server or click + and add a new virtual server. This vservers is the load balancing vserver to which this GSLB service will be associated. If the public IP address is different from the server IP, which can happen in a NAT environment, enter the public IP address and the public port number.

5. Configure the GSLB virtual servers.
   a) Enter the name of the GSLB virtual server name and select the DNS record type.
   b) Click > in the Select Service box and choose the GSLB services to be bound to the GSLB virtual server.
   c) Click > in the Domain Binding box to view the domain name that is bound to the GSLB virtual server.
   d) Choose the GSLB method for selecting the best-performing GSLB service. The default values for GSLB method, backup method, and dynamic weight are automatically populated by default. You can change them if required.
      • If you choose the Algorithm based method, select the primary and backup methods and also specify the dynamic weight option.
      • If you choose the Static Proximity method, select the backup method and the dynamic weight method. Also, provide the location of the database file by clicking the > icon or add a new location by clicking + in the Select a location database box.
      • If you choose the Dynamic Proximity (RTT) method, select the backup method and specify the service weight and the RTT value based on which the best-performing service is to be selected.

6. Click Done if the configuration is complete. The GSLB dashboard appears.

7. If you have modified the GSLB parent-site configuration, click Auto Synchronize GSLB to synchronize the configuration to the other parent sites in the GSLB setup. In a parent-child topol-
ogy, synchronization for the child sites is skipped.

- Before synchronization, make sure that the local site’s configuration includes information about the remote sites.
- If real-time synchronization is enabled, you do not have to click Auto Synchronize GSLB. The synchronization happens automatically. To enable real time synchronization, do the following:
  a) Navigate to Traffic Management > GSLB > Dashboard and click Change GSLB Settings.
  b) Select the Automatic Config Sync check box.

8. Click Test GSLB Setup to make sure that the ADNS services or the DNS servers are responding with the correct IP address for the domain name that is configured in the GSLB setup.

To configure a child site

1. Configure the GSLB sites.
   a) Enter the site details, such as the site name and site IP address.
   b) Select the site type.
   c) Optionally, change the RPC password and, if necessary, secure it. 4. If a monitor is bound to the GSLB service, select the condition under which the monitor is to monitor the service. The possible conditions are:
      • Always. Monitor the GSLB service at all times.
      • MEP Fails. Monitor the GSLB service only when the exchange of metrics through MEP fails.
      • MEP Fails and Service is DOWN. Exchange of metrics through MEP is enabled but the status of the service, updated through metrics exchange, is DOWN.

2. Click Done if the configuration is complete. The GSLB dashboard appears.

3. Click Test GSLB Setup to make sure that the ADNS services or the DNS servers are responding with the correct IP address for the domain name that is configured in the GSLB setup.

Configure GSLB entities individually

January 6, 2019

Global server load balancing is used to manage traffic flow to a web site hosted on two separate server farms that ideally are in different geographic locations. For example, consider a Web site, www.mycompany.com, which is hosted on two geographically separated server farms or data centers. Both server farms use NetScaler appliances. The NetScaler appliances in these server farms are set up in one-arm mode and function as authoritative DNS servers for the www.mycompany.com domain. The following figure illustrates this configuration.
To configure such a GSLB setup, you must first configure a standard load balancing setup for each server farm or data center. This enables you to balance load across the different servers in each server farm. Then, configure both NetScaler appliances as authoritative DNS (ADNS) servers. Next, create a GSLB site for each server farm, configure GSLB virtual servers for each site, create GLSB services, and bind the GSLB services to the GSLB virtual servers. Finally, bind the domain to the GSLB virtual servers. The GSLB configurations on the two appliances at the two different sites are identical, although the load-balancing configurations for each site is specific to that site.

Note: To configure a GSLB site in a NetScaler cluster setup, see Setting Up GSLB in a Cluster.

**Configuring a Standard Load Balancing Setup**

A load balancing virtual server balances the load across different physical servers in the data center. These servers are represented as services on the NetScaler appliance, and the services are bound to the load balancing virtual server.

For details on configuring a basic load balancing setup, see Load Balancing.

**Configure an authoritative DNS service**

September 12, 2018

When you configure the NetScaler appliance as an authoritative DNS server, it accepts DNS requests from the client and responds with the IP address of the data center to which the client should send requests.

Note: For the NetScaler appliance to be authoritative, you must also create SOA and NS records. For more information about SOA and NS records, see Domain Name System.

**To create an ADNS service by using the command line interface**

At the command prompt, type the following commands to create an ADNS service and verify the configuration:

```
1 add service <name> <IP>@ ADNS <port>
2
3 show service <name>
```
Example:

<table>
<thead>
<tr>
<th></th>
<th>add service Service-ADNS-1 10.14.39.21 ADNS 53</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>show service Service-ADNS-1</td>
</tr>
</tbody>
</table>

To modify an ADNS service by using the command line interface

At the command prompt, type the following command:

```
set service <name> <IPAddress> ADNS <port>
```

Example:

```
set service Service-ADNS-1 10.14.39.21 ADNS 53
```

To remove an ADNS service by using the command line interface

At the command prompt, type the following command:

```
rm service <name>
```

Example:

```
rm service Service-ADNS-1
```

To configure an ADNS service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. Add a new ADNS service, or select an existing service and edit its settings.

Configure a basic GSLB site

September 12, 2018

A GSLB site is a representation of a data center in your network and is a logical grouping of GSLB virtual servers, services, and other network entities. Typically, in a GSLB set up, there are many GSLB sites that are equipped to serve the same content to a client. These are usually geographically separated to ensure that the domain is active even if one site goes down completely. All of the sites in the GSLB
configuration must be configured on every NetScaler appliance hosting a GSLB site. In other words, at each site, you configure the local GSLB site and each remote GSLB site.

Once GSLB sites are created for a domain, the NetScaler appliance sends client requests to the appropriate GSLB site as determined by the GSLB algorithms configured.

**To create a GSLB site by using the command line interface**

At the command prompt, type the following commands to create a GSLB site and verify the configuration:

```bash
1 add gslb site <siteName> <siteIPAddress>
2 show gslb site <siteName>
```

**Example:**

```bash
1 add gslb site Site-GSLB-East-Coast 10.14.39.21
2 show gslb site Site-GSLB-East-Coast
```

**To modify or remove a GSLB Site by using the command line interface**

- To modify a GSLB site, use the set gslb site command, which is just like using the add gslb site command, except that you enter the name of an existing GSLB Site.
- To unset a site parameter, use the unset gslb site command, followed by the siteName value and the name of the parameter to be reset to its default value.
- To remove a GSLB site, use the rm gslb site command, which accepts only the `<name>` argument.

**To configure a basic GSLB site by using the configuration utility**

1. Navigate to Traffic Management > GSLB > Sites.
2. Add a new GSLB site, or select an existing GSLB site and edit its settings.

**To view the statistics of a GSLB site by using the command line interface**

At the command prompt, type:

```bash
1 stat gslb site <siteName>
```

**Example:**

```bash
1 stat gslb site Site-GSLB-East-Coast
```
To view the statistics of a GSLB site by using the configuration utility

1. Navigate to Traffic Management > GSLB > Sites.
2. Select the GSLB site and click Statistics.

Configure a GSLB service

November 9, 2018

A GSLB service is a representation of a load balancing or content switching virtual server. A local GSLB service represents a local load balancing or content switching virtual server. A remote GSLB service represents a load balancing or content switching virtual server configured at one of the other sites in the GSLB setup. At each site in the GSLB setup, you can create one local GSLB service and any number of remote GSLB services.

Important

If the load balancing virtual server is either in a GSLB node itself or is in a child node (in parent-child deployment) and no monitors are bound to the GSLB service, then make sure the following:

- The GSLB service IP address, port number, and protocol match the virtual server that the service is representing. Else, the service state is marked as DOWN.

To create a GSLB service by using the command line interface

At the command prompt, type the following commands to create a GSLB service and verify the configuration:

```
1. add gslb service <serviceName> <serverName | IP> <serviceType> <port>-siteName <string>
2. show gslb service <serviceName>
```

Example:

```
1. add gslb service Service-GSLB-1 10.14.39.14 HTTP 80 -siteName Site-GSLB-East-Coast
2. show gslb service Service-GSLB-1
```

To modify or remove a GSLB service by using the command line interface

- To modify a GSLB service, use the set gslb service <serviceName> command. For this command, specify the name of the GSLB service whose configuration you want to modify. You can
change the existing values of the parameters either specified by you or set by default. You can change the value of more than one parameter in the same command. Refer to the add gslb service command for details about the parameters. Example

```
> set gslb service SKP_GSLB_NOTCNAME_SVC2 -maxBandWidth 25 -maxClient 8
Done
> sh gslb service SKP_GSLB_NOTCNAME_SVC2
SKP_GSLB_NOTCNAME_SVC2 (21.211.21.21: 80) - HTTP
...
Max Conn: 8  Max Bandwidth: 25 kbits
```

- To reset a parameter to its default value, you can use the unset gslb service <serviceName> command and the parameters to be unset. Example

```
> unset gslb service SKP_GSLB_NOTCNAME_SVC2 maxBandWidth
Done
> sh gslb service SKP_GSLB_NOTCNAME_SVC2
SKP_GSLB_NOTCNAME_SVC2 (21.211.21.21: 80) - HTTP
...
Max Conn: 8  Max Bandwidth: 0 kbits
```

- To remove a GSLB service, use the rm gslb service <serviceName> command.

**To create a GSLB service by using the configuration utility**

1. Navigate to **Traffic Management > GSLB > Services**.
2. Add a new GSLB service, or select an existing service and edit its settings.

**To view the statistics of a GSLB service by using the command line interface**

At the command prompt, type:

```
stat gslb service <serviceName>
```

**Example:**

```
stat gslb service Service-GSLB-1
```

**To view the statistics of a GSLB service by using the configuration utility**

1. Navigate to **Traffic Management > GSLB > Services**.
2. Select the GSLB Service and click **Statistics**.
Configure a GSLB service group

November 9, 2018

Service group enables you to manage a group of services as easily as a single service. For example, if you enable or disable an option, such as compression, health monitoring, or graceful shutdown, for a service group, the option gets enabled or disabled for all the members of the service group.

After creating a service group, you can bind it to a virtual server, and you can add services to the group. You can also bind monitors to the service groups.

Important

If the load balancing virtual server is either in a GSLB node itself or in a child node (in parent-child deployment) and no monitors are bound to the GSLB service, then make sure the following:

- The GLSB service group IP address, port number, and protocol match the virtual server that the service is representing. Else, the service state is marked as DOWN.

The NetScaler supports the following types of GSLB service groups.

- IP address based service groups
- Domain name based service groups
- Domain name based autoscale service groups

GSLB domain name based autoscale service groups

The NetScaler hybrid and multi-cloud global server load balancing (GSLB) solution enables customers to distribute application traffic across multiple data centers in hybrid clouds, multiple clouds, and on premises. The NetScaler GSLB solution supports various load balancing solutions, such as the NetScaler load balancer, Elastic Load Balancing (ELB) for Amazon Web Services (AWS), and other third-party load balancers. Also, the GSLB solution performs global load balancing even if the GSLB and load balancing layers are independently managed.

In cloud deployments, users are given a domain name as a reference when accessing the load balancing solution for management purposes. It is recommended that external entities do not use the IP addresses that these domain names resolve to. Also, the load balancing layers scale up or down based on the load, and the IP addresses are not guaranteed to be static. Therefore, it is recommended to use the domain name to refer to the load balancing endpoints instead of IP addresses. This requires the GSLB services to be referred using the domain name instead of IP addresses and it must consume all the IP addresses returned for the load balancing layer domain name and have a representation for the same in GSLB.

To use domain names instead of IP addresses when referring to the load balancing endpoints, you can use the domain name based service groups for GSLB.
Monitor GSLB domain name based service groups

The NetScaler appliance has two built-in monitors that monitor TCP-based applications; tcp-default and ping-default. The tcp-default monitor is bound to all TCP services and the ping-default monitor is bound to all non-TCP services. The built-in monitors are bound by default to the GSLB service groups. However, it is recommended to bind an application specific monitor to the GSLB service groups.

Recommendation for setting the trigger monitors option to MEPDOWN

The Trigger Monitors option can be used to indicate if the GSLB site must use the monitors always, or use monitors when metrics exchange protocol (MEP) is DOWN.

The Trigger Monitors option is set to ALWAYS by default.

When the Trigger Monitors option is set to ALWAYS, each GSLB node triggers the monitors independently. If each GSLB node triggers the monitors independently, then each GSLB node might operate on different set of GSLB services. This might result in discrepancies in the DNS responses for the DNS requests landing on these GSLB nodes. Also, if each GSLB node is monitoring independently, then the number of monitor probes reaching the load balancer entity increases. The persistence entries also become incompatible across the GSLB nodes.

Therefore, it is recommended that the Trigger Monitors option on GSLB site entity is set to MEPDOWN. When the Trigger Monitors option is set to MEPDOWN, the load balancing domain resolution and monitoring ownership lies with the local GSLB node. When Trigger Monitors option is set to MEPDOWN, the load balancing domain resolution and subsequent monitoring is done by the local GSLB node of a GSLB service group. The results are then propagated to all other nodes participating in GSLB by using the metrics exchange protocol (MEP).

Also, whenever the set of IP addresses associated with a load balancing domain are updated, it is notified through MEP.

Limitations of GSLB service groups

- For a load balancing domain, the IP address that is returned in the DNS response is generally the public IP address. The private IP address cannot be applied dynamically when the load balancing domain is resolved. Therefore, public IP port and private IP port for the GSLB domain name based autoscale service groups IP port bindings are the same. These parameters cannot be set explicitly for the domain name based autoscale service groups.
- Site persistence, DNS views, and clustering are not supported for GSLB service groups.
Configure and manage GSLB service groups by using the CLI
<table>
<thead>
<tr>
<th>Operation</th>
<th>CLI Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>To add a GSLB service group</td>
<td>`add gslb serviceGroup &lt;serviceGroupName&gt;@ &lt;serviceType&gt; [-autoScale (DISABLED</td>

<tr>
<td></td>
<td>Example: `add gslb serviceGroup Service-Group-1 http -siteName Site1</td>
</tr>
<tr>
<td></td>
<td>-autoScale DNS`</td>
</tr>
<tr>
<td>To bind a GSLB service group to a</td>
<td>`bind gslb serviceGroup (&lt;serverName&gt;@</td>
</tr>
<tr>
<td>virtual server</td>
<td>Example: `bind gslb serviceGroup Service-Group-1 203.0.113.2; bind gslb</td>
</tr>
</tbody>
</table>
|                                   | `serviceGroup Service-Group-1 S1 80; bind gslb serviceGroup Service-Group-1-`
<p>|                                   | <code>monitorName Mon1</code>                                                         |
| To unbind a GSLB service group to   | <code>unbind gslb serviceGroup (&lt;serverName&gt;@ | ((&lt;monitorName &lt;string&gt;@)</code> |
| a virtual server                  | Example: <code>unbind gslb serviceGroup Service-Group-1 -monitorName Mon1</code>       |</p>
<table>
<thead>
<tr>
<th>Operation</th>
<th>CLI Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>To set parameters for a GSLB service group</td>
<td>`set gslb serviceGroup &lt;serviceGroupName&gt;@ [(&lt;serverName&gt;@&lt;port&gt; [-weight &lt;positive_integer&gt;] [-hashId &lt;positive_integer&gt;] [-publicIP &lt;ip_addr</td>
</tr>
<tr>
<td>To enable a GSLB service group</td>
<td><code>enable gslb serviceGroup &lt;serviceGroupName&gt;@ [&lt;serverName&gt;@&lt;port&gt;]</code></td>
</tr>
<tr>
<td>Example: <code>enable gslb serviceGroup SG1 S1 80</code></td>
<td></td>
</tr>
<tr>
<td>To disable a GSLB service group</td>
<td>`disable gslb serviceGroup &lt;serviceGroupName&gt;@ [&lt;serverName&gt;@&lt;port&gt;] [-delay &lt;secs&gt;] [-graceful ( YES</td>
</tr>
</tbody>
</table>
Example: `disable gslb serviceGroup` SRG2 S1 80

**Note:** The service group that has to be disabled must be a DBS service group and not an autoscale service group.

**To remove a GSLB service group**

`rm gslb serviceGroup` <serviceGroupName>

Example: `rm gslb serviceGroup` Service-Group-1

**To view the statistics of a GSLB service group**

`stat gslb serviceGroup` [<serviceGroupName>]

Example: `stat gslb serviceGroup` Service-Group-1

**To view the properties of a GSLB service group**

`show gslb serviceGroup` [<serviceGroupName> -includeMembers]

Example: `show gslb serviceGroup` SG1; `show gslb serviceGroup` -includeMembers

### Changes to the existing GSLB CLI commands

The following table lists some of the changes that are done to the existing GSLBs commands after the introduction of the GSLB service groups.

<table>

**Configure GSLB service groups by using the GUI**

1. Navigate to **Traffic Management > GSLB > Service Groups.**
2. Create a service group and set the AutoScale Mode to DNS.
Tip
For deployment scenario and example configuration of GSLB service groups, see the following topics:

- Use Case: Deployment of Domain Name Based Autoscale Service Group
- Use Case: Deployment of IP Address Based Autoscale Service Group

Configure a GSLB virtual server

September 12, 2018

A GSLB virtual server is an entity that represents one or more GSLB services and balances traffic between them. It evaluates the configured GSLB methods or algorithms to select a GSLB service to which to send the client request.

Note
A GSLB virtual server protocol requirement is mainly to create a relation between the virtual server and the services that are bound to the virtual server. This also keeps CLI/APIs consistent with respect to other types of virtual servers. The Service Type parameter on a service or a virtual server is not leveraged while serving the DNS requests. It is instead referenced during site persistence, monitoring, and for the purpose of doing lookups via MEP.

To create a GSLB virtual server by using the command line interface

At the command prompt, type the following commands to add a GSLB virtual server and verify the configuration:

```
1 - add gslb vserver <name> <serviceType> -ipType (IPv4 | IPv6)
2 - show gslb vserver <name>
```

Example:

```
1 add gslb vserver Vserver-GSLB-1 HTTP -ipType IPv4
2 add gslb vserver Vserver-GSLB-2 HTTP -ipType IPv6
3 show gslb vserver Vserver-GSLB-1
4 show gslb vserver Vserver-GSLB-2
```
To modify or remove a GSLB virtual server by using the command line interface

- To modify a GSLB virtual server, use the set gslb vserver command, which is just like using the add gslb vserver command, except that you enter the name of an existing GSLB virtual server.
- To reset a parameter to its default value, you can use the unset gslb vserver command followed by the vserverName value and the name of the parameter to be unset.
- To remove a GSLB virtual server, use the rm gslb vserver command, which accepts only the name argument.

To configure a GSLB virtual server by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers.
2. Add a new GSLB virtual server, or select an existing GSLB virtual server and edit its settings.

To view the statistics of a GSLB virtual server by using the command line interface

At the command prompt, type:

```
stat gslb vserver <name>
```

Example:

```
stat gslb vserver Vserver-GSLB-1
```

To view the statistics of a GSLB virtual server by using the configuration utility

Navigate to Traffic Management > GSLB > Virtual Servers, select the virtual server and click Statistics.

Statistics of a GSLB service

When you run the stat gslb service command from the command line or click on the Statistics link from the configuration utility, the following details of the service will be displayed:

- **Request bytes.** Total number of request bytes received on this service or virtual server.
- **Response bytes.** Number of response bytes received by this service or virtual server.
- **Current client established connections.** Number of client connections in ESTABLISHED state.
- **Current load on the service.** Load on the service (Calculated from the load monitor bound to the service).
The data of number of requests and responses, and the number of current client and server connections may not be displayed or may not be synchronized with the data of the corresponding load balancing virtual server.

**Clearing the GSLB virtual server or service statistics**

Note: This feature is available in NetScaler release 10.5.e.

You can now clear the statistics of a GSLB virtual server and service. NetScaler provides the following two options to clear the statistics:

- **Basic**: Clears the statistics that are specific to the virtual server but retains the statistics that are contributed by the bound GLSB service.
- **Full**: Clears both the virtual server and the bound GSLB service statistics.

**To clear the statistics of a GSLB virtual server by using the command line interface**

At the command prompt, type:

```
stat gslb vserver <name> -clearstats <basic | full>
```

*Example:*

```
stat gslb vserver Vserver-GSLB-1 -clearstats basic
```

**To clear the statistics of a GSLB service by using the command line interface**

At the command prompt, type:

```
stat gslb service <name> -clearstats <basic | full>
```

*Example:*

```
stat gslb service service-GSLB-1 -clearstats basic
```

**To clear the statistics of a GSLB virtual server by using the configuration utility**

1. Navigate to **Traffic Management > GSLB > Virtual Servers**.
2. Select the GSLB virtual server and, click **Statistics**, and then click **Clear**.
3. From the **Clear** drop-down list, select **Basic** or **Full**, and then click **OK**.
To clear the statistics of a GSLB service by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services.
2. Select the GSLB service and, click Statistics, and then click Clear.
3. From the Clear drop-down list, select Basic or Full, and then click OK.

Enabling and Disabling GSLB Virtual Servers

When you create a GSLB virtual server, it is enabled by default. If you disable it, it cannot process traffic. A disabled GSLB virtual server is not included in GSLB configuration but is not removed from the NetScaler appliance.

To enable or disable a GSLB virtual server by using the command line interface

At the command prompt, type one of the following commands:

```
1 enable gslb vserver <name>@
2 disable gslb vserver <name>@
```

Example:

```
1 enable gslb vserver Vserver-GSLB-1
2 disable gslb vserver Vserver-GSLB-1
```

To enable or disable a GSLB virtual server by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers.
2. Select a virtual server and, from the Action list, select enable or disable.

Bind GSLB services to a GSLB virtual server

September 12, 2018

Once the GSLB services and virtual server are configured, relevant GSLB services must be bound to the GSLB virtual server to activate the configuration.
To bind a GSLB service to a GSLB virtual server by using the command line interface

At the command prompt, type the following commands to bind a GSLB service to a GSLB virtual server and verify the configuration:

```
1  bind gslb vserver <name> -serviceName <string>
2  show gslb vserver <name>
```

Example:

```
1  bind gslb vserver Vserver-GSLB-1 -serviceName Service-GSLB-1
2  show gslb vserver Vserver-GSLB-1
```

To unbind a GSLB service from a GSLB virtual server by using the command line interface

At the command prompt, type:

```
1  unbind gslb vserver <name> -serviceName <string>
```

To bind GSLB services by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click a virtual server.
2. Click in the Domains section, and configure a domain and bind the domain.

Bind a domain to a GSLB virtual server

September 12, 2018

To make a NetScaler appliance the authoritative DNS server for a domain, you must bind the domain to the GSLB virtual server. When you bind a domain to a GSLB virtual server, the NetScaler appliance adds an address record for the domain, containing the name of the GSLB virtual server. The start of authority (SOA) and name server (NS) records for the GSLB domain must be added manually.

For details on configuring SOA and NS records, see Domain Name System.

To bind a domain to a GSLB virtual server by using the command line interface

At the command prompt, type the following commands to bind a domain to a GSLB virtual server and verify the configuration:
1 \texttt{bind gslb vserver <name> -domainName <string>}
2 \texttt{show gslb vserver <name>}

Example:

1 \texttt{bind gslb vserver Vserver-GSLB-1 -domainName www.mycompany.com}
2 \texttt{show gslb vserver Vserver-GSLB-1}

To unbind a GSLB domain from a GSLB virtual server by using the command line interface

At the command prompt, type:

1 \texttt{unbind gslb vserver <name> -domainName <string>}

To bind a domain to a GSLB virtual server by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers.
2. In GSLB Virtual Servers pane, select the GSLB Virtual Server to which you want to bind the domain (for example, Vserver-GSLB-1) and click Open.
3. In the Configure GSLB Virtual Server dialog box, on the Domains tab, do one of the following:
   - To create a new Domain, click Add.
   - To modify an existing Domain, select the domain, and then click Open.
4. In the Create GSLB Domain or Configure GSLB Domain dialog box, specify values for the following parameters as shown:
   - Domain Name*—domainName (for example, www.mycompany.com)
     /* A required parameter
5. Click Create.
6. Click OK.

To view the statistics of a domain by using the command line interface

At the command prompt, type:

1 \texttt{stat gslb domain <name>}

© 1999-2018 Citrix Systems, Inc. All rights reserved. 2125
Example:

```bash
stat gslb domain www.mycompany.com
```

Note: To view statistics for a particular GSLB domain, enter the name of the domain exactly as it was added to the NetScaler appliance. If you do not specify the domain name, or if you specify an incorrect domain name, statistics for all configured GSLB domains are displayed.

**To view the statistics of a domain by using the configuration utility**

1. Navigate to **Traffic Management > GSLB > Virtual Servers**.
2. In GSLB Virtual Servers pane, select the GSLB Virtual Server (for example, Vserver-GSLB-1) and click Open.
3. In the Configure GSLB Virtual Server dialog box, on the Domains tab, select the domain, and then click **Statistics**.

**To view the configuration details of the entities bound to a GSLB domain using the command line**

Note: This feature is available in NetScaler release 10.5.e.

At the command prompt, type:

```bash
show gslb domain <name>
```

Example:

```bash
show gslb domain gslb1.com
gslb1.com
gvs1 - HTTP state: DOWN
DNS Record Type: A
Configured Method: LEASTCONNECTION
Backup Method: ROUNDROBIN
Persistence Type: NONE
Empty Down Response: DISABLED
Multi IP Response: DISABLED
Dynamic Weights: DISABLED

gsvc1 (10.102.239.165: 80) - HTTP State: DOWN Weight: 1
  Dynamic Weight: 0 Cumulative Weight: 1
  Effective State: DOWN
  Threshold : BELOW
```
Monitor Name: http
State: DOWN   Weight: 1
Probes: 144   Failed [Total: 144 Current: 144]
Last response: Failure - TCP syn sent, reset received.
Response Time: 2000 millisecond

gsvc2 (10.102.239.179: 80) - HTTP State: DOWN   Weight: 1
Dynamic Weight: 0   Cumulative Weight: 1
Effective State: DOWN
Threshold : BELOW

Monitor Name: http-ecv
State: DOWN   Weight: 1
Probes: 141   Failed [Total: 141 Current: 141]
Last response: Failure - TCP syn sent, reset received.
Response Time: 2000 millisecond

To view the configuration details of the entities bound to a GSLB domain by using the configuration utility

Note: This feature is available in NetScaler release 10.5.e.

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click a virtual server.
2. Click the field below the Domains pane.
3. In the GSLB Virtual Server Domain Binding dialog box, select a domain, and then click Show Bindings.

Example of a GSLB setup and configuration

January 14, 2019

An organization has a geographically dispersed network and has three data centers located in the United States, Mexico, and Colombia. In the configuration related to these locations, these are referred to as US, MX, and CO respectively. At each location, the company has a server farm, which provides the same content and the setup is working as expected. The NetScaler appliance at each location is configured through a virtual server with the HTTP protocol on port 80.

The organization has implemented the GSLB setup by adding a site identifier at each site. The site identifier includes a site name and an IP address that is owned by the NetScaler appliance and is used
for the GSLB communications.
Each site has a site local to the appliance. Also, each site has two sites remote to the local appliance. On each site, a GSLB virtual server is created with the same name. This virtual server identifies the website of the organization globally and does not have any IP address associated with it. The setup also has GSLB services configured that point to the load balancing virtual servers configured on each GSLB site by specifying the IP address, protocol, and port number of the respective virtual server. These services are bound to the GSLB virtual server.

**Note:** In the procedure below, the commands use private IP addresses for the GSLB sites. For public sites and GSLB services, ensure that you use public IP addresses for these sites.

The following table lists the IP addresses and locations used in the example:

<table>
<thead>
<tr>
<th>IP Address</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.3.1.101</td>
<td>Site IP of local NetScaler.</td>
</tr>
<tr>
<td>172.16.1.101</td>
<td>Site IP of remote location site-MX.</td>
</tr>
<tr>
<td>192.168.1.101</td>
<td>Site IP of remote location site-CO.</td>
</tr>
<tr>
<td>172.16.1.100</td>
<td>Service IP of remote location site-MX.</td>
</tr>
<tr>
<td>10.3.1.100</td>
<td>Service IP of local NetScaler.</td>
</tr>
<tr>
<td>192.168.1.100</td>
<td>Service IP of remote location site-CO.</td>
</tr>
</tbody>
</table>

When adding a GSLB site, if the site communicates over the internet only then use the “Public IP” field. For example, when there is no site to site VPN connectivity between the GSLB sites.

**To configure the GSLB setup with NetScaler appliances by using the CLI commands**

1. Enable the GSLB feature, if not already done.

   ```
   1 enable ns feature gslb
   ```

2. Identify a SNIP that for adding local GSLB site.

3. Add the GSLB site for the local NetScaler appliance.

   ```
   1 add gslb site site-US 10.3.1.101
   ```

4. Add the GSLB sites for the remote NetScaler appliances.

   ```
   1 add gslb site site-MX 172.16.1.101
   2 add gslb site site-CO 192.168.1.101
   ```
NetScaler 12.0

5. Add the GSLB virtual server that references a service being used in the GSLB setup:

```
add gslb vserver gslb-lb HTTP
```

6. Add the GSLB services for each site participating in the GSLB setup:

```
1 add gslb service gslb_SVC30 172.16.1.100 HTTP 80 -siteName site-MX
2 add gslb service gslb_SVC10 10.3.1.100 HTTP 80 -siteName site-US
3 add gslb service gslb_SVC20 192.168.1.100 HTTP 80 -siteName site-CO
```

7. Bind the GSLB services to the GSLB virtual server:

```
1 bind gslb vserver gslb-lb -serviceName gslb_SVC10
2 bind gslb vserver gslb-lb -serviceName gslb_SVC20
3 bind gslb vserver gslb-lb -serviceName gslb_SVC30
```

8. Bind the domain to the GSLB virtual server.

```
1 bind gslb vserver gslb-lb -domainName www.mycompany.com -TTL 30
```

9. Add an ADNS service that listens to the DNS queries.

```
1 set service Service-ADNS-1 10.14.39.21 ADNS 53
```

**Synchronize the configuration in a GSLB setup**

January 14, 2019

Typically, a GSLB setup has a few data centers with a GSLB site configured for each data center. In each NetScaler, participating in GSLB, configure one GSLB site as a local site and the others as remote sites. When you add another GSLB site at a later point, you must ensure that the configuration across all GSLB sites is identical. You can use the NetScaler’s GSLB configuration synchronization option to synchronize the configuration across the GSLB sites.

The NetScaler appliance from which you use the synchronization option is referred to as the ‘master node’ and the GSLB sites on which the configuration is copied as ‘slave nodes.’ When you synchronize a GSLB configuration, the configurations on all the GSLB sites participating in the GSLB setup are made similar to that on the master node.

Synchronization (may also be referred to as ‘auto sync’) is carried out in the following manner:

- The master node finds the differences between the configuration of the master node and slave node, and changes the configuration of the slave node to make it similar to the master node.
If you force a synchronization (use the ‘force sync’ option), the appliance deletes the GSLB configuration from the slave node and then configures the slave to make it similar to the master node.

- During synchronization, if a command fails, synchronization is not aborted and the error message are logged into a .err file in the /var/netscaler/gslb directory.

- Synchronization is done only on the parent sites. GSLB child sites’ configuration is not affected by synchronization. This is because the parent site and the child site configurations are not identical. The child sites configuration consists only of its own and its parent site’s details. Also, GSLB services are not always required to be configured in the child sites.

- If you disable the internal user login, the GSLB auto sync uses the SSH keys to synchronize the configuration. But, to use GSLB auto sync in partition environment, you need to enable the internal user login and make sure that the partition username in the local and remote GSLB sites is same.

**Note**

- On the remote GSLB site RPC node, configure the firewall to accept auto-sync connections by specifying the remote site IP (cluster IP address for cluster setup) and port (3010 for RPC and 3008 for secure RPC). If the default route to reach the remote sites is in management subnet, as in most cases, then NSIP is used as the source IP address.

  To configure a different source IP address, you must have the GSLB site IP address and the SNIP in a different subnet. Also, you must have an explicit route defined to the remote site IP address through GSLB site IP subnet.

- The source IP address cannot be synchronized across the sites participating in GSLB because the source IP address for a RPC node is specific to each NetScaler appliance. Therefore, after you force a synchronization (using the sync gslb config -forceSync command or by selecting the ForceSync option in the GUI), you have to manually change the source IP addressess on the other NetScaler appliances.

- Port 22 is also required for synchronizing the database files to the remote site.

If you use the saveconfig option, the sites that participate in the synchronization process automatically save their configuration, in the following way:

1. The master node saves its configuration immediately before it initiates the process of synchronization.

2. After the process of synchronization is complete, the slave nodes save their configuration. A slave node saves its configuration only if the configuration difference was applied successfully on it. If synchronization fails on a slave node, you must manually investigate the cause of the failure and take corrective action.

**Limitations of synchronization:**
On the master node, the names of the remote GSLB sites must be identical to the names of sites configured on the NetScaler appliances hosting those sites. During the synchronization, traffic disruptions may occur. NetScaler can synchronize only up to 80000 lines of the configuration. Synchronization may fail:
- If the spill over method is changed from CONNECTION to DYNAMIC CONNECTION.
- If you interchange the site prefix of the GSLB services bound to a GSLB virtual server on the master node and then try to synchronize.
- If the RPC node passwords are different for NSIP and loopback IP address.
- If you have configured the GSLB sites as High Availability (HA) pairs, the RPC node passwords of primary and secondary nodes should be same.
- If you rename any GSLB entity that are part of your GSLB configuration (use “show gslb running-Config” command to display the GSLB configuration). You need to use the force sync option to synchronize the configuration to other GSLB sites.

Note: To overcome the limitations due to some settings in the GSLB configuration, you can use the force sync option. But, if you use the force sync option the GSLB entities are removed and re-added to the configuration and the GSLB statistics are reset to zero. Hence the traffic is disrupted during the configuration change.

Before you start the synchronization of a GSLB setup, make sure that:
- On all the GSLB sites including the master node, management access and SSH should be enabled for the IP address of the corresponding GSLB site. The IP address of a GSLB site must be an IP address owned by the NetScaler appliance. For more information about adding the GSLB site IP addresses and enabling Management Access, see “Configuring a Basic GSLB Site”.
- The GSLB configuration on the NetScaler appliance that is considered as the master node is complete and appropriate to be copied on all the sites.
- If you are synchronizing the GSLB configuration for the first time, all the sites participating in GSLB need to have the GSLB site entity of their respective local sites.
- You are not synchronizing sites that, by design, do not have the same configuration.

**Important**

The following directories are synchronized as part of the GSLB configuration synchronization.
- /var/netscaler/locdb/
- /var/netscaler/ssl/

**Manual synchronization between sites participating in GSLB**

September 12, 2018
**Important:** After a GSLB configuration is synchronized, the configuration cannot be rolled back on any of the GSLB sites. Perform the synchronization only if you are sure that the synchronization process will not overwrite the configuration on the remote site. Site synchronization is undesirable when the local and remote sites have different configurations by design, and can lead to site outage. If some commands fail and some commands succeed, the successful commands cannot be rolled back.

**To synchronize a GSLB configuration by using the CLI:**

At the command prompt, type the following commands to synchronize GSLB sites and verify the configuration:

```bash
1  sync gslb config [-preview | -forceSync <string> | -nowarn | -saveconfig] [-debug]
2  show gslb syncStatus
```

**Example:**

```bash
1  sync gslb config
2
3  [WARNING]: Syncing config may cause configuration loss on other site.
4  Please confirm whether you want to sync-config (Y/N)? [N]:y
5  Sync Time: Dec 9 2011 10:56:9
6
7  Retrieving local site info: ok
8  Retrieving all participating gslb sites info: ok
9
10  Gslb_site1[Master]:
11    Getting Config: ok
12
13  Gslb_site2[Slave]:
14    Getting Config: ok
15
16  Comparing config: ok
17  Applying changes: ok
18
19  Done
```

**To synchronize a GSLB configuration by using the GUI:**

1. Navigate to **Traffic Management > GSLB > Dashboard**.
2. Click Auto Synchronization GSLB and select ForceSyn.
3. In GSLB Site Name, select the GSLB sites that are to be synchronized with the master node configuration.

**Previewing GSLB synchronization**

By previewing the GSLB synchronization operation, you can see the differences between the master node and each slave node. If there are any discrepancies, you can troubleshoot before synchronizing the GSLB configuration.

**To preview the GSLB synchronization output by using the CLI:**

At the command prompt, type the following command:

```
1 sync gslb config -preview
```

**To preview the GSLB synchronization output by using the GUI:**

1. Navigate to Configuration > Traffic Management > GSLB > Dashboard.
2. Click Auto Synchronization GSLB and select Preview.
3. Click Run.
   
   A progress window displays any discrepancies in the configuration.

**Debugging the commands triggered during synchronization process**

You can view the status (success or failure) of each command triggered during the synchronization process and troubleshoot accordingly.

**To debug the GSLB synchronization commands by using the CLI:**

At the command prompt, type the following command:

```
1 sync gslb config -debug
```

**To debug the GSLB synchronization commands by using the GUI:**

1. Navigate to Configuration > Traffic Management > GSLB > Dashboard.
2. Click Auto Synchronization GSLB and select Debug.
3. Click Run.

   A progress window displays the status of each command triggered during synchronization.

**Real-time synchronization between sites participating in GSLB**

September 12, 2018
If you want to synchronize GSLB configuration across slave sites automatically when the commands are executed on master sites, you can now use the AutomaticConfigSync option to automatically synchronize the real-time GSLB configuration. You do not have to manually trigger the AutoSync option to synchronize the configuration.

If you attempt to manually synchronize (with the sync gslb config command) a site while it is being autosynchronized, a “Sync in progress” error message appears. Autosynchronization cannot be triggered for a site that is in the process of being synchronized manually.

Attention:
Starting with NetScaler 12.1 build xx.xx, SNMP traps are generated when you synchronize the GSLB configuration. Note that in real-time synchronization, the synchronization status in the first SNMP trap is captured as failure. You can ignore this status because a second SNMP trap is automatically generated immediately after the first trap with the actual synchronization status. However, if the synchronization failed in the second attempt also, SNMP trap is not generated because the synchronization status has not changed from the previous synchronization status.

For details on configuring NetScaler appliance to generate traps, see Configuring the NetScaler to generate SNMP traps.

Notes:

• All logs related to real-time sync are stored in the /var/netscaler/gslb/periodic_sync.log file.
• The sync status file and default configuration file are stored in the location /var/netscaler/gslb_sync.
• Enabling AutomaticConfigSync from default partition of a partitioned appliance is not supported. However, it can be enabled from all other partitions. The sync status file and default configuration file are stored in the location /var/partitions/<partition name>/netscaler/gslb_sync.

Best practices for using the real-time synchronization feature

• It is recommended that all the NetScaler appliances participating as sites have the same NetScaler software version.
• To change the RPC node password, first change the password on the slave site and then on the master site.
• Configure local GSLB sites on each site participating in GSLB.
• Enable automaticConfigSync on one of the sites where the configuration is performed. This site eventually gets synchronized to other GSLB sites.
• If there is a new configuration or changes are made to the existing configuration, make sure to check the status using the “show gslb syncStatus” command to confirm if the changes are synchronized across all sites or if there was any error.
To enable real-time synchronization by using the CLI

At the command prompt, type:

```
1 set gslb parameter -automaticConfigSync (ENABLED | DISABLED)
```

Example:

```
1 set gslb parameter -automaticConfigSync ENABLED
```

To enable real-time synchronization by using the GUI

1. Navigate to Configuration > Traffic Management > GSLB > Change GSLB Settings.
2. Select Automatic ConfigSync.

   Note: This option must be enabled only in the site where the configuration is performed.

Tip

For information on the following topics, see Manual synchronization between sites participating in GSLB.
- Previewing GSLB synchronization
- Debugging the commands triggered during synchronization process

GSLB dashboard

September 12, 2018

You can view the overall status of the GSLB sites participating in GSLB on the GSLB dashboard.

You can access the GSLB settings from the dashboard. You can also start the GSLB configuration wizard from the dashboard. Additionally, you can perform the synchronization and test the GSLB setup from the dashboard.

To access the GSLB dashboard, navigate to Configuration > Traffic Management > GSLB > Dashboard.

Monitor GSLB services

September 12, 2018
When you bind a remote service to a GSLB virtual server, the GSLB sites exchange metric information, including network metric information, which is the round-trip-time and persistence Information. If a metric exchange connection is momentarily lost between any of the participating sites, the remote site is marked as DOWN and load balancing is performed on the remaining sites that are UP. When metric exchange for a site is DOWN, the remote services belonging to the site are marked DOWN as well.

The NetScaler appliance periodically evaluates the state of the remote GSLB services by using either MEP or monitors that are explicitly bound to the remote services. Binding explicit monitors to local services is not required, because the state of the local GSLB service is updated by default using the MEP. However, you can bind explicit monitors to a remote service. When monitors are explicitly bound, the state of the remote service is not controlled by the metric exchange.

By default, when you bind a monitor to a remote GSLB service, the NetScaler appliance uses the state of the service reported by the monitor. However, you can configure the NetScaler appliance to use monitors to evaluate services in the following situations:

- Always use monitors (default setting).
- Use monitors when MEP is DOWN.
- Use monitors when remote services and MEP are DOWN.

The second and third of the above settings enable the appliance to stop monitoring when MEP is UP. For example, in a hierarchical GSLB setup, a GSLB site provides the MEP information about its child sites to its parent site. Such an intermediate site may evaluate the state of the child site as DOWN because of network issues, though the actual state of the site is UP. In this case, you can bind monitors to the services of the parent site and disable MEP to determine the actual state of the remote service. This option enables you to control the manner in which the states of the remote services are determined.

To use monitors, first create them, and then bind them to GSLB services.

**Configure monitor trigger**

You can configure a GSLB site to always use monitors (the default), use monitors when MEP is down, or use monitors when both the remote service and MEP are down. In the latter two cases, the NetScaler appliance stops monitoring when MEP returns to the UP state.

**To configure monitor triggering by using the command line interface**

At the command prompt, type:

```
set gslb site <siteName> -triggerMonitor (ALWAYS | MEPDOWN | MEPDOWN_SVCDOWN)
```
To configure monitor triggering by using the configuration utility

1. Navigate to Traffic Management > GSLB > Sites, and double-click the site.
2. In the Trigger Monitors drop-down list, select an option for when to trigger monitoring.

Add or remove monitors

To add a monitor, you specify the type and the port. You cannot remove a monitor that is bound to a service. You must first unbind the monitor from the service.

To add a monitor by using the command line interface

At the command prompt, type the following commands to create a monitor and verify the configuration:

```
1 add lb monitor <monitorName> -type <monitorType> -destPort <portNumber>
2 show lb monitor <monitorName>
```

Example:

```
1 add lb monitor monitor-HTTP-1 -type HTTP -destPort 80
2 show lb monitor monitor-HTTP-1
```

To remove a monitor by using the command line interface

At the command prompt, type:

```
1 rm lb monitor <monitorName>
```

To add a monitor by using the configuration utility

Navigate to
Traffic Management > Load Balancing > Monitors, and add or delete a monitor.
Bind monitors to a GSLB service

Once you create monitors, you must bind them to GSLB services. When binding monitors to the services, you can specify a weight for the monitor. After binding one or more weighted monitors, you can configure a monitor threshold for the service. This threshold takes the service down if the sum of the bound monitor weights falls below the threshold value.

Note: In the configuration utility, you can set both the weight and the monitoring threshold at the same time that you bind the monitor. When using the command line, you must issue a separate command to set the service’s monitoring threshold.

To bind the monitor to the GSLB service by using the command line interface

At the command prompt, type:

```
bind monitor <name> <serviceName> [ -state (Enabled | Disabled) ] -weight <positiveInteger>
```

Example:

```
bind monitor monitor-HTTP-1 service-GSLB-1 -state enabled -weight 2
```

To set the monitoring threshold for a GSLB service by using the command line interface

At the command prompt, type:

```
set gslb service <ServiceName> -monThreshold <PositiveInteger>
```

Example:

```
set gslb service service-GSLB-1 -monThreshold 9
```

To bind the monitor to the GSLB service by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services.
2. Click the Monitor section and bind the monitor to the GSLB service.

To set the monitoring threshold for a GSLB service by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services.
2. Click the Monitor Threshold section and enter a threshold value.
Use case: Deployment of domain name based autoscale service group

September 12, 2018

Tip

For information about the GSLB service groups, see Configuring a GSLB Service Group

Deployment scenario

Two datacenters are deployed in two AWS regions, one in Sydney and one in North Virginia. Another datacenter is deployed in Azure. An AWS ELB in each AWS region is used to load balance the application servers. ALB is used for Azure to load balancing the application server. The NetScaler appliances are configured for GSLB for the ELBs and ALB using GSLB domain name based autoscale service group.

Important

You must configure the required security groups in AWS and attach it to the GSLB instance. Port 53 must be allowed in the security group inbound and outbound rules. Also, ports (3009 or 3011 depending on secure MEP configuration) for MEP communication must be open. For application monitoring, the corresponding ports must be allowed in the security group outbound rules.

The configuration steps for the above deployment scenario and the corresponding CLI commands are as follows:

1. Create datacenters (represented by GSLB sites).

```
1 add gslb site aws-sydney 192.0.2.2
2 add gslb site aws-nvirginia 198.51.100.111
3 add gslb site alb-southindia 203.0.113.6
```

2. Add a name server with the DNS gateway IP address where the GSLB node is added. This must be done in all datacenters.

```
1 add dns nameServer 8.8.8.8
```

3. Add servers for ELB and ALB.

```
1 add server aws-sydney_server lb-sydney-1052691850.ap-southeast-2.elb.amazonaws.com
2 add server aws-nvirginia_server LB-nvirginia-860559595.us-east-1.elb.amazonaws.com
```
4. Add GSLB autoscale service groups for each ELB and ALB and bind each server to the respective service group.

```
4 add server alb-southindia_server alb.southindia.cloudapp.azure.com

1 add gslb serviceGroup aws-nvirginia_sg HTTP -autoScale DNS -siteName aws-nvirginia
2 add gslb serviceGroup aws-sydney_sg HTTP -autoScale DNS -siteName aws-sydney
3 add gslb serviceGroup alb-southindia_sg HTTP -autoScale DNS -siteName alb-southindia
4 bind gslb serviceGroup aws-nvirginia_sg aws-nvirginia_server 80
5 bind gslb serviceGroup aws-sydney_sg aws-sydney_server 80
6 bind gslb serviceGroup alb-southindia_sg alb-southindia_server 80
```

5. Add a GSLB virtual server and bind the application domain and the service groups to this virtual server.

```
1 add gslb vserver gv1 HTTP
2 bind gslb vserver gv1 -serviceGroupName aws-nvirginia_sg
3 bind gslb vserver gv1 -serviceGroupName aws-sydney_sg
4 bind gslb vserver gv1 -serviceGroupName alb-southindia_sg
```

**Use case: Deployment of IP address based autoscale service group**

September 12, 2018

**Tip**

For information about the GSLB service groups, see [Configuring a GSLB Service Group](#).
Deployment scenario

If there are multiple applications hosted on the same application server, the GSLB should probe these applications to see if the applications are responding or not. If an application is not responding, the user must be directed to the server on which the application is UP. Also, if one of the applications is DOWN, then the server should not be marked DOWN, because the other applications are UP.

In the following example, multiple applications (HTTPS) are hosted on one server in each GSLB site and hence all these applications resolve to one IP address of the respective site.

Using the GSLB service groups, you can have the same server with an IP address and port bound to multiple service groups where each service group represents a different application.

An application specific monitor is bound to the service groups that marks the service group as DOWN if the application is DOWN. Thus, whenever an application is DOWN, only that application is taken out from the setup and not the server.

```
1  add gslb serviceGroup app1_site1 HTTP -maxClient 0 -cip DISABLED -
   cltTimeout 180 -svrTimeout 360 -siteName s1
2
3  add gslb serviceGroup app2_site1 HTTP -maxClient 0 -cip DISABLED -
   cltTimeout 180 -svrTimeout 360 -siteName s1
4
5  add gslb serviceGroup app1_site2 HTTP -maxClient 0 -cip DISABLED -
   cltTimeout 180 -svrTimeout 360 -siteName s2
6
7  add gslb serviceGroup app2_site2 HTTP -maxClient 0 -cip DISABLED -
   cltTimeout 180 -svrTimeout 360 -siteName s2
8
9  add lb monitor http_app2 HTTP -respCode 200 -httpRequest "GET /tests
   site/app2.html"
10
11 add lb monitor http_app1 HTTP -respCode 200 -httpRequest "GET /tests
   site/app1.html"
12
13 bind gslb serviceGroup app1_site1 192.0.2.140 80
14
15 bind gslb serviceGroup app1_site1 -monitorName http_app1
16
17 bind gslb serviceGroup app2_site1 192.0.2.140 80
18
19 bind gslb serviceGroup app2_site1 -monitorName http_app2
20
21 bind gslb serviceGroup app1_site2 192.0.2.142 80
22
23 bind gslb serviceGroup app1_site2 -monitorName http_app1
```
How-to articles

September 12, 2018

The GSLB how-to articles contain information about some of the important GSLB configurations such as customizing GSLB configuration, configuring persistent connections, disaster recovery, and so on.

Customizing Your GSLB Configuration

Configuring Persistent Connections

Managing Client Connections

Configuring GSLB for Proximity

Protecting the GSLB Setup Against Failure

Configuring GSLB for Disaster Recovery

Overriding Static Proximity Behavior by Configuring Preferred Locations

Configuring GSLB Service Selection Using Content Switching

Configuring Global Server Load Balancing for DNS Queries with NAPTR records

Using the EDNS0 Client Subnet Option for Global Server Load Balancing

Example of a Complete Parent-Child Configuration Using the Metrics Exchange Protocol

Customize your GSLB configuration

September 12, 2018

Once your basic GSLB configuration is operational, you can customize it by modifying the bandwidth of a GSLB service, configuring CNAME based GSLB services, static proximity, dynamic RTT, persistent connections, or dynamic weights for services, or changing the GSLB Method.

You can also configure monitoring for GSLB services to determine their states.

These settings depend on your network deployment and the types of clients you expect to connect to your servers.
Modify maximum connections or maximum bandwidth for a GSLB service

You can restrict the number of new clients that can simultaneously connect to a load balancing or content switching virtual server by configuring the maximum number of clients and/or the maximum bandwidth for the GSLB service that represents the virtual server.

To modify the maximum clients or bandwidth of a GSLB service by using the command line interface

At the command prompt, type the following command to modify the maximum number of client connections or the maximum bandwidth of a GSLB service and verify the configuration:

```
1 set gslb service <serviceName> [-maxClients <positive_integer>] [-maxBandwidth <positive_integer>]
2 show gslb service <serviceName>
```

Example:

```
1 set gslb service Service-GSLB-1 -maxBandwidth 100 -maxClients 100
2 show gslb service Service-GSLB-1
```

To modify the maximum clients or bandwidth of a GSLB service by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services, and double-click a service.
2. Click in the Other Settings section and set the following parameters:
   - Max Clients—maxClients
   - Max Bandwidth—maxBandwidth

Create CNAME-based GSLB services

To configure a GSLB service, you can use the IP address of the server or a canonical name of the server. If you want to run multiple services (like an FTP and a Web server, each running on different ports) from a single IP address or run multiple HTTP services on the same domain, example.com, you can use canonical names (CNAMEs) for the services.

For example, you can have two entries in DNS as ftp.example.com and www.example.com for FTP services and HTTP services on the same domain, example.com. CNAME-based GSLB services are useful in a multilevel domain resolver configuration or in multilevel domain load balancing. Configuring a CNAME-based GSLB service can also help if the IP address of the physical server is likely to change.
If you configure CNAME-based GSLB services for a GSLB domain, when a query is sent for the GSLB domain, the NetScaler appliance provides a CNAME instead of an IP address. If the A record for this CNAME record is not configured, the client must query the CNAME domain for the IP address. If the A record for this CNAME record is configured, the NetScaler appliance provides the CNAME with the corresponding A record (IP address). The NetScaler appliance handles the final resolution of the DNS query, as determined by the GSLB method. The CNAME records can be maintained on a different NetScaler appliance or on a third-party system.

In an IP-address-based GSLB service, the state of a service is determined by the state of the server that it represents. However, a CNAME-based GSLB service has its state set to UP by default; the virtual server IP (VIP) address or metric exchange protocol (MEP) are not used for determining its state. If a desktop-based monitor is bound to a CNAME-based GSLB service, the state of the service is determined according to the result of the monitor probes.

You can bind a CNAME-based GSLB service only to a GSLB virtual server that has the DNS Record Type as CNAME. Also, a NetScaler appliance can contain at most one GSLB service with a given CNAME entry.

The following are some of the features supported for a CNAME-based GSLB service:

- GSLB-policy based site affinity is supported, with the CNAME as the preferred location.
- Source IP persistence is supported. The persistency entry contains the CNAME information instead of the IP address and port of the selected service.

The following are the limitations of CNAME-based GSLB services:

- Site persistence is not supported, because the service referenced by a CNAME can be present at any third-party location.
- Multiple-IP-address response is not supported because one domain cannot have multiple CNAME entries.
- Source IP Hash and Round Robin are the only load balancing methods supported. The Static Proximity method is not supported because a CNAME is not associated with an IP address and static proximity can be maintained only according to the IP addresses.

Note: The Empty-Down-Response feature should be enabled on the GSLB virtual server to which you bind the CNAME-based GSLB service. If you enable the Empty-Down-Response feature, when a GSLB virtual server is DOWN or disabled, the response to a DNS query, for the domains bound to this virtual server, contains an empty record without any IP addresses, instead of an error code.

**To create a CNAME-based GSLB service by using the command line interface**

At the command prompt, type:
To create a CNAME-based GSLB service by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services.
2. Create a service, and set the Type to Canonical Name Based.

Configure transition Out-Of-Service State (TROFS) in GSLB

When you configure persistence on a GSLB virtual server to which a service is bound, the service continues to serve requests from the client even after it is disabled, accepting new requests or connections only to honor persistence. After a configured period of time, known as the graceful shutdown period, no new requests or connections are directed to the service, and all of the existing connections are closed.

When disabling a service, you can specify a graceful shutdown period, in seconds, by using the delay argument. During the graceful shutdown period, if the service is bound to a virtual server, its state appears as Out of Service.

Configure dynamic weights for services

In a typical network, there are servers that have a higher capacity for traffic than others. However, with a regular load balancing configuration, the load is evenly distributed across all services even though different services represent servers with different capacities.

To optimize your GSLB resources, you can configure dynamic weights on a GSLB virtual server. The dynamic weights can be based on either the total number of services bound to the virtual server or the sum of the weights of the individual services bound to the virtual server. Traffic distribution is then based on the weights configured for the services.

When dynamic weights are configured on the GSLB virtual server, requests are distributed according to the load balancing method, the weight of the GSLB service, and the dynamic weight. The product of the weight of the GSLB service and the dynamic weight is known as the cumulative weight. Therefore,
when dynamic weight is configured on the GSLB virtual server, requests are distributed on the basis of the load balancing method and the cumulative weight.

When dynamic weight for a virtual server is disabled, the numerical value is set to 1. This ensures that the cumulative weight is a non-zero integer at all times.

Dynamic weight can be based on the total number of active services bound to load balancing virtual servers or on the weights assigned to the services.

Consider a configuration with two GSLB sites configured for a domain and each site has two services that can serve the client. If a service at either site goes down, the other server in that site has to handle twice as much traffic as a service at the other site. If dynamic weight is based on the number of active services, the site with both services active has twice the weight of the site with one service down and therefore receives twice as much traffic.

Alternatively, consider a configuration in which the services at the first site represent servers that are twice as powerful as servers at the second site. If dynamic weight is based on the weights assigned to the services, twice as much traffic can be sent to the first site as to the second.

Note: For details on assigning weights to load balancing services, see “Assigning Weights to Services”.

As an illustration of how dynamic weight is calculated, consider a GSLB virtual server that has a GSLB service bound to it. The GSLB service represents a load balancing virtual server that in turn has two services bound to it. The weight assigned to the GSLB service is 3. The weights assigned to the two services are 1 and 2 respectively. In this example, when dynamic weight is set to:

- **Disabled**: The cumulative weight of the GSLB virtual server is the product of the dynamic weight (disabled = 1) and the weight of the GSLB service (3), so the cumulative weight is 3.
- **SERVICECOUNT**: The count is the sum of the number of services bound to the load balancing virtual servers corresponding to the GSLB service (2), and the cumulative weight is the product of the dynamic weight (2) and the weight of the GSLB service (3), which is 6.
- **SERVICEWEIGHT**: The dynamic weight is the sum of the number of services bound to the GSLB service (2), and the cumulative weight is the product of the dynamic weight (2) and the weight of the GSLB service (3), which is 6.

Note: Dynamic weights are not applicable when content switching virtual servers are configured.

To configure a GSLB virtual server to use dynamic weights by using the command line interface

At the command prompt, type:

```
set gsbl vserver <name> -dynamicWeight SERVICECOUNT | SERVICEWEIGHT
```

**Example:**
To set GSLB virtual server to use dynamic weights by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers, double-click the GSLB virtual server whose method you want to change (for example, vserver-GSLB-1).
2. Click the Method section and, from the Dynamic Weight drop-down list, select SERVICECOUNT or SERVICEWEIGHT.

Configure persistent connections

September 12, 2018

Persistence ensures that a series of client requests for a particular domain name is sent to the same data center instead of being load balanced. If persistence is configured for a particular domain, it takes precedence over the configured GSLB method. Persistence is useful for deployments that deal with e-commerce, such as shopping card usage, where the server needs to maintain the state of the connection to track the transaction. To maintain the state of connection, you must configure persistence on a virtual server. With persistence configured, the NetScaler appliance selects a data center to process a client request and forwards the IP address of the selected data center for all subsequent DNS requests. If the configured persistence applies to a site that is down, the NetScaler appliance uses a GSLB method to select a new site, and the new site becomes persistent for subsequent requests from the client.

The GSLB virtual server is responsible for DNS-based site persistence, and it controls the site persistence for a remote GSLB service. The NetScaler appliance supports persistence based on the source IP address or on HTTP cookies.

When you bring a physical service DOWN with a delay time, the physical service goes into the transition out of service (TROFS) state. Site persistence is supported as long as the service is in the TROFS state. That is, if the same client sends a request for the same service within the specified delay time after a service is marked TROFS, the same GSLB site (data center) services the request.

Note: If connection proxy is specified as the site persistence method and if you also want to configure persistence of the physical servers, do not configure SOURCEIP persistence. When the connection is proxied, an IP address owned by the appliance is used, and not the actual IP address of the client. Configure methods such as cookie persistence or rule-based persistence on the load balancing virtual server.
Configure persistence based on source IP address

With source-IP persistence, when a DNS request is received at a data center, the NetScaler appliance first looks for an entry in the persistence table and, if an entry for the local DNS server exists and the server mentioned in the entry is configured, the IP address of that server is sent as the DNS response.

For the first request from a particular client, the NetScaler appliance selects the best GSLB site for the request and sends its IP address to the client. Since persistence is configured for the source IP address of the client, all subsequent requests by that client or another local DNS server in the same IP subnet are sent the IP address of the GSLB site that was selected for the first request.

For source-IP address based persistence, the same set of persistence identifiers must be configured on the GSLB virtual servers in all data centers. A persistence identifier is a number used by the data centers to identify a particular GSLB virtual server. A cookie transmits the persistence identifier, enabling the NetScaler appliance to identify the domain so that it can forward all appropriate requests to the same domain. When persistence is enabled, the persistence information is also exchanged as part of metrics exchange.

For the NetScaler appliance to support persistence across sites, persistence must be enabled on the GSLB virtual servers of all participating sites. When you use source IP address persistence on the network identifier, you must configure a subnet mask. For any domain, persistence takes precedence over any other configured GSLB method.

To configure persistence based on source IP address by using the command line interface

At the command prompt, type:

```
set gslb vserver <name> -persistenceType (SOURCEIP|NONE) -persistenceId <positive_integer> [-persistMask <netmask>] - [timeout <mins>]
```

Example:

```
set gslb vserver vserver-GSLB-1 -persistenceType SOURCEIP -persistenceId 23 -persistMask 255.255.255.255 - timeout 2
```

To configure persistence based on source IP address by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the GSLB virtual server whose method you want to change (for example, vserver-GSLB-1).
2. Click the Persistence section and, from the Persistence drop-down list, select SOURCEIP and set the following parameters:
   - Persistence Id—persistenceID
Configure persistence based on HTTP cookies

The NetScaler appliance provides persistence at the HTTP-request level by using connection proxy and HTTP redirect. With these persistence methods, the appliance uses an HTTP cookie (known as a “site cookie”) to reconnect the client to the same server. The appliance inserts the site cookie in the first HTTP response.

The site cookie contains information about the selected GSLB service on which the client has a persistent connection. The cookie expiration is based on the cookie timeout configured on the NetScaler appliance. If the virtual server names are not identical on all the sites, you must use the persistence identifier. Cookies inserted are compliant with RFC 2109.

When the NetScaler appliance responds to a client DNS request by sending the IP address of the selected GSLB site, the client sends an HTTP request to that GSLB site. The physical server in that GSLB site adds a site cookie to the HTTP header, and connection persistence is in effect.

If the DNS entry in the client cache expires, and then the client sends another DNS query and is directed to a different GSLB site, the new GSLB site uses the site cookie present in the client request header to implement persistence. If the GSLB configuration at the new site uses connection-proxy persistence, the new site creates a connection to the GSLB site that inserted the site cookie, proxies the client request to the original site, receives a response from the original GSLB site, relays that response back to the client, and closes the connection. If the GSLB configuration uses HTTP redirect persistence, the new site redirects the request to the site that originally inserted the cookie.

Note: Connection proxy persistence can be configured only for local services. However, connection proxy persistence must be enabled on both local and remote GSLB services that are configured for the GSLB virtual server.

Connection proxy occurs when the following conditions are satisfied:

- Requests are sent from a domain participating in GSLB. The domain is obtained from the URL/Host header.
- Requests are sent from a local GSLB service whose public IP address matches the public IP address of an active service bound to the GSLB virtual server.
- The local GSLB service has connection proxy enabled.
- The request includes a valid cookie that contains the IP address of an active remote GSLB service.

If one of the conditions is not met, connection proxy does not occur, but a site cookie is added if the local GSLB service has connection proxy enabled AND:

- No site cookie is supplied; OR,
• The site cookie refers to an IP address that is not an active GSLB remote service; OR,
• The cookie refers to the IP address of the virtual server on which the request is received.

The following are the limitations of using connection proxy site cookies:
• Site cookies do not work for non-HTTP(S) protocols.
• If an HTTP request is sent to a back-up virtual server, the virtual server does not add a cookie.
• Site cookies do not work if SSL client authentication is required.
• At the local site, the statistics for a GSLB service on a remote site are not the same as the statistics recorded for that service at the remote site. At the local site, the statistics for a remote GSLB service are slightly higher than the statistics that the remote site records for that same service.

Redirect persistence can be used only:
• For HTTP or HTTPS protocols.
• If the domain name is present in the request (either in the URL or in the HOST header), and the domain is a GSLB domain.
• When the request is received on a backup VIP or a GSLB local service that is in the down state.

Note
In a GSLB parent-child configuration, connection proxy works as intended even when a GSLB service is not configured on a child site. However, if you have additional configuration such as client authentication, client IP address insertion, or other SSL-specific requirement, you must add an explicit GSLB service on the site and configure it accordingly.

For more information about parent-child topology, see Parent-Child Topology Deployment Using the MEP Protocol.

To set persistence based on HTTP cookies by using the command line interface

At the command prompt, type:

1 set gslb service <serviceName> -sitePersistence (ConnectionProxy [-sitePrefix <prefix>] | HTTPRedirect -sitePrefix <prefix>)

Example:

1 set gslb service service=GSLB-1 -sitePersistence ConnectionProxy
2 set gslb service service=GSLB-1 -sitePersistence HTTPRedirect -sitePrefix vserver=GSLB-1
To set persistence based on cookies by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services and select the service that you want to configure for site persistence (for example, service-GSLB-1).
2. Click the Site Persistence section and set persistence based on cookies.

Manage client connections

October 26, 2018

To facilitate management of client connections, you can enable delayed cleanup of connections to the virtual server. You can then manage local DNS traffic by configuring DNS policies.

Enable delayed cleanup of virtual server connections

The state of a virtual server depends on the states of the services bound to it, and the state of each service depends on the monitors bound to it. If a server is slow or down, the monitoring probes time out and the service that represents the server is marked as DOWN. A virtual server is marked as DOWN only when all services bound to it are marked as DOWN. You can configure services and virtual servers to either terminate all connections when they go down, or allow the connections to go through. The latter setting is for situations in which a service is marked as DOWN because of a slow server.

When you configure the down state flush option, the NetScaler appliance performs a delayed cleanup of connections to a GSLB service that is down.

To enable delayed cleanup of virtual server connections by using the command line interface

At the command prompt, type the following commands to configure delayed connection cleanup and verify the configuration:

```
1 set gslb service <name> -downStateFlush (ENABLED | DISABLED)
2 show gslb service <name>
```

Example:

```
1 set gslb service Service-GSLB-1 -downStateFlush ENABLED
2 Done
3
4 show gslb service Service-GSLB-1
5 Done
```
To enable delayed cleanup of virtual server connections by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Services** and double-click the service.
2. Click the **Other Settings** section and select the **Down State Flush** option.

Manage local DNS traffic by using DNS policies

You can use DNS policies to implement site affinity by directing traffic from the IP address of a local DNS resolver or network to a predefined target GSLB site. This is configured by creating DNS policies with DNS expressions and binding the policies globally on the NetScaler appliance.

DNS expressions

The NetScaler appliance provides certain predefined DNS expressions that can be used for configuring actions specific to a domain. Such actions can, for example, drop certain requests, select a specific view for a specific domain, or redirect certain requests to a specific location.

These DNS expressions (also called rules) are combined to create DNS policies that are then bound globally on the NetScaler appliance.

Following is the list of predefined DNS qualifiers available on the NetScaler appliance:

- CLIENT.UDP.DNS.DOMAIN.EQ("domainname")
- CLIENT.UDP.DNS.IS_AREC
- CLIENT.UDP.DNS.IS_AAAAREC
- CLIENT.UDP.DNS.IS_SRVREC
- CLIENT.UDP.DNS.IS_MXREC
- CLIENT.UDP.DNS.IS_SOAREC
- CLIENT.UDP.DNS.IS_PTRREC
- CLIENT.UDP.DNS.IS_CNAME
- CLIENT.UDP.DNS.IS_NSREC
- CLIENT.UDP.DNS.IS_ANYREC

The CLIENT.UDP.DNS.DOMAIN DNS expression can be used with string expressions. If you are using domain names as part of the expression, they must end with a period (.). For example, CLIENT.UDP.DNS.DOMAIN.ENDSWITH("abc.com.")

To create an expression by using the configuration utility

1. Click the icon next to the Expression text box. Click Add. (Leave the Flow Type and Protocol drop-down list boxes empty.) Follow these steps to create a rule.
2. In the Qualifier box, select a qualifier (for example, LOCATION).
3. In the Operator box, select an operator (for example, ==).
4. In the Value box, type a value (for example, Asia, Japan....).
5. Click OK. Click Create and click Close. The rule is created.
6. Click OK.

Configure DNS actions

A DNS policy includes the name of a DNS action to be performed when the policy rule evaluates to TRUE. A DNS action can do one of the following:

- Send the client an IP address for which you have configured a DNS view. For more information about DNS views, see Adding DNS Views.
- Send the client the IP address of a GSLB service after referring to a list of preferred locations that overrides static proximity behavior. For more information about preferred locations, see Overriding Static Proximity Behavior by Configuring Preferred Locations.
- Send the client a specific IP address as determined by the evaluation of the DNS query or response (DNS response rewrite).
- Forward a request to the name server without performing a lookup in the appliance’s DNS cache.
- Drop a request.

You cannot create a DNS action for dropping a DNS request or for bypassing the DNS cache on the appliance. If you want to drop a DNS request, use the built-in action, dns_default_act_Drop. If you want to bypass the DNS cache, use the built-in action, dns_default_act_Cachebypass. Both actions are available along with custom actions in the Create DNS Policy and the Configure DNS Policy dialog boxes. These built-in actions cannot be modified or removed.

To configure a DNS action by using the command line interface

At the command prompt, type the following commands to configure a DNS action and verify the configuration:

```
1 add dns action <actionName> <actionType> (<IPAddress <ip_addr | ipv6_addr> ... | -viewName <string> | -preferredLocList <string> ...) [-TTL <secs>]
2 show dns action [<actionName>]
```

Examples

Example 1: Configuring DNS Response Rewrite. The following DNS action sends the client a preconfigured IP address when the policy to which the action is bound evaluates to true:
Example 2: Configuring a DNS-View Based Response. The following DNS action sends the client an IP address for which you have configured a DNS view:

```
1 add dns action send_ip_from_view_internal_ip ViewName -viewName view_internal_ip
2  Done
3
4 show dns action send_ip_from_view_internal_ip
5 1) ActionName: send_ip_from_view_internal_ip ActionType: ViewName
   ViewName: view_internal_ip
6  Done
```

Example 3: Configuring a Response Based on a Preferred Location List. The following DNS action sends the client the IP address that corresponds to the preferred location that it selects from the specified list of locations:

```
1 add dns action send_preferred_location GslbPrefLoc -preferredLocList NA .tx.ns1.*.*.* NA.tx.ns2.*.*.* NA.tx.ns3.*.*.*
2  Done
3
4 show dns action send_preferred_location
5 1) ActionName: send_preferred_location ActionType: GslbPrefLoc
   PreferredLocList: "NA.tx.ns1.*.*.*" "NA.tx.ns2.*.*.*" "NA.tx.ns3.*.*.*"
6  Done
```

To configure a DNS action by using the NetScaler configuration utility

1. Navigate to Traffic Management > DNS > Actions, create or edit a DNS action.
2. In the Create DNS Action or Configure DNS Action dialog box, set the following parameters:
   - Action Name (cannot be changed for an existing DNS action)
   - Type (cannot be changed for an existing DNS action)
To set the Type parameter, do one of the following:

- To create a DNS action that is associated with a DNS view, select View Name. Then, from the View Name list, select the DNS view that you want to use in the action.
- To create a DNS action with a preferred location list, select Preferred Location List. In Preferred Location, enter a location, and then click Add. Add as many DNS locations as you want.
- To configure a DNS action for rewriting a DNS response on the basis of policy evaluation, select Rewrite Response. In IP Address, enter an IP address, and then click Add. Add as many IP addresses as you want.

- TTL (applicable only to the Rewrite Response action type)

**Configure DNS policies**

DNS policies operate on a location database that uses static and custom IP addresses. The attributes of the incoming local DNS request are defined as part of an expression, and the target site is defined as part of a DNS policy. While defining actions and expressions, you can use a pair of single quotation marks (‘’) as a wildcard qualifier to specify more than one location. When a DNS policy is configured and a GSLB request is received, the custom IP address database is first queried for an entry that defines the location attributes for the source:

- When a DNS query comes from an LDNS, the characteristics of the LDNS are evaluated against the configured policies. If they match, an appropriate action (site affinity) is executed. If the LDNS characteristics match more than one site, the request is load balanced between the sites that match the LDNS characteristics.
- If the entry is not found in the custom database, the static IP address database is queried for an entry, and if there is a match, the above policy evaluation is repeated.
- If the entry is not found in either the custom or static databases, the best site is selected and sent in the DNS response on the basis of the configured load balancing method.

The following restrictions apply to DNS policies created on the NetScaler appliance.

- A maximum of 64 policies are supported.
- DNS policies are global to the NetScaler appliance and cannot be applied to a specific virtual server or domain.
- Domain or virtual server specific binding of policy is not supported.

You can use DNS policies to direct clients that match a certain IP address range to a specific site. For example, if you have a GSLB setup with multiple GSLB sites that are separated geographically, you can direct all clients whose IP address is within a specific range to a particular data center.
Both TCP-based and UDP-based DNS traffic can be evaluated. Policy expressions are available for UDP-based DNS traffic on the server and for both UDP-based DNS traffic and TCP-based DNS traffic on the client side. Additionally, you can configure expressions to evaluate queries and responses that involve only the following DNS question types (or QTYPE values):

- A
- AAAA
- NS
- SRV
- PTR
- CNAME
- SOA
- MX
- ANY

The following response codes (RCODE values) are also supported:

- NOERROR - No error
- FORMERR - Format error
- SERVFAIL - Server failure
- NXDOMAIN - Non-existent domain
- NOTIMP - Query type not implemented
- REFUSED - Query refused

You can configure expressions to evaluate DNS traffic. A DNS expression begins with the DNS.REQ or DNS.RES prefixes. Functions are available for evaluating the queried domain, the query type, and the carrier protocol. For more information about DNS expressions, see “Expressions for Evaluating a DNS Message and Identifying Its Carrier Protocol” in “Policy Configuration and Reference”.

To add a DNS policy by using the command line interface

At the command prompt, type the following commands to create a DNS policy and verify the configuration:

```
1  add dns policy <name> <rule> <actionName>
2  show dns policy <name>
```

Example:

```
1  > add dns policy policy-GSLB-1 'CLIENT.UDP.DNS.DOMAIN.EQ("domainname")' my_dns_action
2  Done
3  > show dns policy policy-GSLB-1
4  Name: policy-GSLB-1
```
To remove a configured DNS policy by using the command line interface

At the command prompt, type:

```
rm dns policy <name>
```

To configure a DNS policy by using the NetScaler configuration utility

1. Navigate to Traffic Management > DNS > Policies and create a DNS policy.
2. In the Create DNS Policy or Configure DNS Policy dialog box, set the following parameters:
   - Policy Name (cannot be changed for an existing policy)
   - Action
   - Expression
     To specify an expression, do the following:
     a) Click Add, and then, in the drop-down box that appears, select the expression element with which you want to begin the expression. A second list appears. The list contains a set of expression elements that you can use immediately after the first expression element.
     b) In the second list, select the expression element that you want, and then enter a period.
     c) After each selection, if you enter a period, the next set of valid expression elements appear in a list. Select expression elements and fill in arguments to functions until you have the expression you want.
3. Click Create or OK, and then click Close.

Bind DNS policies

DNS policies are bound globally on the NetScaler appliance and are available for all configured GSLB virtual servers. Even though DNS policies are globally bound, policy execution can be limited to a specific GSLB virtual server by specifying the domain in the expression.

Note: Even though the bind dns global command accepts REQ_OVERRIDE and
RES_OVERRIDE as valid bind points, those bind points are redundant, because DNS policies can be bound only globally. Bind your DNS policies only to the REQ_DEFAULT and RES_DEFAULT bind points.

**To bind a DNS policy globally by using the command line interface**

At the command prompt, type the following commands to bind a DNS policy globally and verify the configuration:

```
1 bind dns global <policyName> <priority> [-gotoPriorityExpression <string>] [-type <type>]
2 show dns global -type <type>
```

**Example:**

```
1 bind dns global policy-GSLB-1 10 -gotoPriorityExpression END
2 Done
3 show dns global -type REQ_DEFAULT
4 1) Policy Name: policy-GSLB-1
5   Priority: 10
6   GotoPriorityExpression: END
7 Done
```

**To bind a DNS policy globally by using the configuration utility**

1. Navigate to Traffic Management > DNS > Policies.
2. In the details pane, click Global Bindings.
3. In the Bind/Unbind DNS Policy(s) to Global dialog box, click Insert Policy.
4. In the Policy Name column, select, from the list, the policy that you want to bind. Alternatively, in the list, click New Policy, and then create a DNS policy by setting parameters in the Create DNS Policy dialog box.
5. To modify a policy that is already bound globally, click the name of the policy, and then click Modify Policy. Then, in the Configure DNS Policy dialog box, modify the policy, and then click OK.
6. To unbind a policy, click the name of the policy, and then click Unbind Policy.
7. To modify the priority assigned to a policy, double-click the priority value, and then enter a new value.
8. To regenerate assigned priorities, click Regenerate Priorities. The priority values are modified to begin at 100, with increments of 10, without affecting the order of evaluation.
9. Click OK.
To view the global bindings of a DNS policy by using the command line interface

At the command prompt, type:

```
show dns global
```

To view the global bindings of a DNS policy by using the configuration utility

1. Navigate to **Traffic Management > DNS > Policies.**
2. In the details pane, click **Global Bindings.** The global bindings of all DNS policies appear in this dialog box.

Adding DNS Views

You can configure DNS views to identify various types of clients and provide an appropriate IP address to a group of clients who query for the same GSLB domain. DNS views are configured by using DNS policies that select the IP addresses sent back to the client.

For example, if you have configured GSLB for your company’s domain and have the server hosted in your company’s network, clients querying the domain from within your company’s network can be provided with the server’s internal IP address instead of the public IP address. Clients that query DNS for the domain from the Internet, on the other hand, can be provided the domain’s public IP address.

To add a DNS view, you assign it a name of up to 31 characters. The leading character must be a number or letter. The following characters are also allowed: @ _ - . (period) : (colon) # and space ( ). After adding the view, you configure a policy to associate it with clients and a part of the network, and you bind the policy globally. To configure and bind a DNS policy, see **Managing Local DNS Traffic by Using DNS Policies.**

To add a DNS view by using the command line interface

At the command prompt, type the following commands to create a DNS view and verify the configuration:

```
1 add dns view <viewName>
2 show dns view <viewName>
```

Example:

```
1 add dns view PrivateSubnet
2 show dns view PrivateSubnet
```
To remove a DNS view by using the command line interface

At the command prompt, type:

```
rm dns view <viewName>
```

To add a DNS view by using the configuration utility

Navigate to Traffic Management > DNS > Views and add a DNS view.

For details on how to create a DNS policy and how to bind DNS policies globally, see Managing Local DNS Traffic by Using DNS Policies.

Configure GSLB for proximity

September 12, 2018

When you configure GSLB for proximity, client requests are forwarded to the closest data center. The main benefit of the proximity-based GSLB method is faster response times resulting from the selection of the closest available data center. Such a deployment is critical for applications that require fast access to large volumes of data.

You can configure GSLB for proximity based on the round trip time (RTT), static proximity, or a combination of the two.

Configure dynamic round trip time (RTT) method

Dynamic round trip time (RTT) is a measure of time or delay in the network between the client’s local DNS server and a data resource. To measure dynamic RTT, the NetScaler appliance probes the client’s local DNS server and gathers RTT metric information. The appliance then uses this metric to make its load balancing decision. Global server load balancing monitors the real-time status of the network and dynamically directs the client request to the data center with the lowest RTT value.

To configure GSLB for proximity with dynamic method, you must first configure the basic GSLB set up and then configure dynamic RTT.

First create two GSLB sites, local and remote. Then, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Then create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server at the local site. Finally, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

For details on how to configure a basic GSLB setup, see Configuring GSLB Entities Individually.
Once you have configured a basic GSLB setup, configure the dynamic RTT method.

For details on how to configure the GSLB virtual server to use the dynamic RTT method for load balancing, see Configuring Dynamic RTT.

**Configure static proximity**

The static proximity method for GSLB uses an IP address-based static proximity database to determine the proximity between the client's local DNS server and the GSLB sites. The NetScaler appliance responds with the IP address of a site that best matches the proximity criteria.

If two or more GSLB sites at different geographic locations serve the same content, the NetScaler appliance maintains a database of IP address ranges and uses the database for decisions about the GSLB sites to which to direct incoming client requests.

To configure GSLB for proximity with static proximity, you must first configure the basic GSLB set up and then configure static proximity.

First create two GSLB sites, local and remote. Then, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Then create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server at the local site. Finally, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

For details on how to configure a basic GSLB setup, see Configuring GSLB Entities Individually.

Once you have configured a basic GSLB setup, configure static proximity.

For details on how to configure the GSLB virtual server to use static proximity for load balancing, see Configuring Static Proximity.

**Configure static proximity and dynamic RTT**

You can configure the GSLB virtual server to use a combination of static proximity and dynamic RTT when you have some clients coming from an internal network like a branch office. You can configure GSLB such that the clients coming from the branch office or any other internal network are directed to a particular GSLB site that is geographically close to the client network. For all other requests, you can use dynamic RTT.

First create two GSLB sites, local and remote. Then, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Then create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server at the local site. Finally, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

For details on how to configure a basic GSLB setup, see Configuring GSLB Entities Individually.
Once you have configured a basic GSLB setup, configure the GSLB virtual server to use static proximity for all traffic originating from an internal network and then use dynamic RTT for all other traffic.

For details on how to configure static proximity, see Configuring Static Proximity and for details on how to configure dynamic RTT, see Configuring Dynamic RTT.

Protect the GSLB setup against failure

September 12, 2018

You can protect your GSLB setup against failure of a GSLB site or a GSLB virtual server by configuring a backup GSLB virtual server, configuring the NetScaler appliance to respond with multiple IP addresses, or configuring a Backup IP address for a GSLB domain. You can also divert excess traffic to a backup virtual server by using spillover.

Configure a backup GSLB virtual server

Configuring a backup entity for a GSLB virtual server ensures that DNS traffic to a site is not interrupted if the GSLB virtual server goes down. The backup entity can be another GSLB virtual server, or it can be a backup IP address. With a backup entity configured, if the primary GSLB virtual server goes down, the backup entity handles DNS requests. To specify what should happen when the primary GSLB virtual server comes back up again, you can configure the backup entity to continue handling traffic until you manually enable the primary virtual server to take over (using the disablePrimaryOnDown option), or you can configure a timeout period after which the primary takes over.

Note: You can configure a single backup entity as a backup for multiple GSLB virtual servers.

If you configure both the timeout and the disablePrimaryOnDown option for the backup entity, the backup session time-out takes precedence over the disablePrimaryOnDown setting.

To configure a backup GSLB virtual server by using the command line interface

At the command prompt, type the following commands to configure a GSLB virtual server as a backup virtual server and verify the configuration:

```bash
1 set gslb vserver <name> -backupVServer <name> [-backupSessionTimeout <timeoutValue>] [-disablePrimaryOnDown (ENABLED | DISABLED)]
2
3 show gslb vserver <name>
```

Example:
To set GSLB virtual server as a backup virtual server by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers, and double-click the GSLB virtual server.
2. Click the Backup Virtual Server section and select the backup virtual server.

Configure a GSLB setup to respond with multiple IP addresses

A typical DNS response contains the IP address of the best performing GSLB service. However, if you enable multiple IP response (MIR), the NetScaler appliance sends the best GSLB service as the first record in the response and adds the remaining active services as additional records. If MIR is disabled (the default), the NetScaler appliance sends the best service as the only record in the response.

To configure a GSLB virtual server for multiple IP responses by using the command line interface

At the command prompt, type the following commands to configure a GSLB virtual server for multiple IP responses and verify the configuration:

```
1. set gslb vserver <name> -MIR (ENABLED | DISABLED)
2. show gslb vserver <name>
```

Example:

```
1. set gslb vserver vserver-GSLB-1 -MIR ENABLED
2. show gslb vserver <vserverName>
```

To set a GSLB virtual server for multiple IP responses by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the GSLB virtual server for which you want to configure a backup virtual server (for example, vserver-GSLB-1).
2. On the Advanced tab, under When this VServer is “UP,” select the Send all “active” service IP in response (MIR) check box, and click OK.
Configuring a GSLB Virtual Server to Respond with an Empty Address Record When DOWN

A DNS response can contain either the IP address of the requested domain or an answer stating that the IP address for the domain is not known by the DNS server, in which case the query is forwarded to another name server. These are the only possible responses to a DNS query.

When a GSLB virtual server is disabled or in a DOWN state, the response to a DNS query for the GSLB domain bound to that virtual server contains the IP addresses of all the services bound to the virtual server. However, you can configure the GSLB virtual server to in this case send an empty down response (EDR). When this option is set, a DNS response from a GSLB virtual server that is in a DOWN state does not contain IP address records, but the response code is successful. This prevents clients from attempting to connect to GSLB sites that are down.

Note: You must configure this setting for each virtual server to which you want it to apply.

To configure a GSLB virtual server for empty down responses by using the command line interface

At the command prompt, type:

```
set gslb vserver <name> -EDR (ENABLED | DISABLED)
```

Example:

```
> set gslb vserver vserver-GSLB-1 -EDR ENABLED
Done
```

To set a GSLB virtual server for empty down responses by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the GSLB virtual server for which you want to configure a backup virtual server (for example, vserver-GSLB-1).
2. On the Advanced tab, under When this VServer is “Down,” select the Do not send any service’s IP address in response (EDR) check box.
3. Click OK.

Configure a backup IP address for a GSLB domain

You can configure a backup site for your GSLB configuration. With this configuration in place, if all of the primary sites go DOWN, the IP address of the backup site is provided in the DNS response.
Typically, if a GSLB virtual server is active, that virtual server sends a DNS response with one of the active site IP addresses as selected by the configured GSLB method. If all the configured primary sites in the GSLB virtual server are inactive (in the DOWN state), the authoritative domain name system (ADNS) server or DNS server sends a DNS response with the backup site's IP address.

Note: When a backup IP address is sent, persistence is not honored.

To set a backup IP address for a domain by using the command line interface

At the command prompt, type the following commands to set a backup IP address and verify the configuration:

```
1  set gslb vserver <name> -domainName <string> -backupIP <IPAddress>
2  show gslb vserver <name>
```

Example:

```
1  set gslb vserver vserver-GSLB-1 -domainName www.abc.com -backupIP 10.102.29.66
2  show gslb vserver vserver-GSLB-1
```

To set a backup IP address for a domain by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the GSLB virtual server to which you want to bind the backup domain (for example, vserver-GSLB-1).
2. Click the Domains section, configure the GSLB domain and specify the IP address of the backup domain in the Backup IP field.

Divert excess traffic to a backup virtual server

Once the number of connections to a primary GSLB virtual server exceeds the configured threshold value, you can use the spillover option to divert new connections to a backup GSLB virtual server. This threshold value can be calculated dynamically or set manually. Once the number of connections to the primary virtual server drops below the threshold, the primary GSLB virtual server resumes serving client requests.

You can configure persistence with spillover. When persistence is configured, new clients are diverted to the backup virtual server if that client is not already connected to a primary virtual server. When persistence is configured, connections that were diverted to the backup virtual server are not moved back to the primary virtual server after the number of connections to the primary virtual server drops.
below the threshold. Instead, the backup virtual server continues to process those connections until they are terminated by the user. Meanwhile, the primary virtual server accepts new clients.

The threshold can be measured either by the number of connections or by the bandwidth.

If the backup virtual server reaches the configured threshold and is unable to take any additional load, the primary virtual server diverts all requests to the designated redirect URL. If a redirect URL is not configured on the primary virtual server, subsequent requests are dropped.

The spillover feature prevents the remote backup GSLB service (backup GSLB site) from getting flooded with client requests when the primary GSLB virtual server fails. This occurs when a monitor is bound to a remote GSLB service, and the service experiences a failure that causes its state to go DOWN. The monitor continues to keep the state of the remote GSLB service UP, however, because of the spillover feature.

As part of the resolution to this problem, two states are maintained for a GSLB service, the primary state and effective state. The primary state is the state of the primary virtual server and the effective state is the cumulative state of the virtual servers (primary and backup chain). The effective state is set to UP if any of the virtual servers in the chain of virtual servers is UP. A flag that indicates that the primary VIP has reached the threshold is also provided. The threshold can be measured by either the number of connections or the bandwidth.

A service is considered for GSLB only if its primary state is UP. Traffic is directed to the backup GSLB service only when all the primary virtual servers are DOWN. Typically, such deployments will have only one backup GSLB service.

Adding primary and effective states to a GSLB service has the following effects:

- When source IP persistence is configured, the local DNS is directed to the previously selected site only if the primary virtual server on the selected site is UP and below threshold. Persistence can be ignored in the round robin mode.
- If cookie-based persistence is configured, client requests are redirected only when the primary virtual server on the selected site is UP.
- If the primary virtual server has reached its saturation and the backup VIP(s) is absent or down, the effective state is set to DOWN.
- If external monitors are bound to an HTTP-HTTPS virtual server, the monitor decides the primary state.
- If there is no backup virtual server to the primary virtual server and the primary virtual server has reached its threshold, the effective state is set to DOWN.

To configure a backup GSLB virtual server by using the command line interface

At the command prompt, type the following commands to configure a backup GSLB virtual server and verify the configuration:
To configure a backup GSLB virtual server by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the virtual server that you want to configure as a backup (for example, Vserver-LB-1).
2. Click the SpillOver section and set the following parameters:
   - Method—soMethod
   - Threshold—soThreshold
   - Persistence Time-out (min) — soPersistenceTimeout
3. Select the Persistence option and click OK.

Configure GSLB for disaster recovery

September 12, 2018

Disaster recovery capability is critical, because downtime is costly. A NetScaler appliance configured for GSLB forwards traffic to the least-loaded or the best-performing data center. This configuration, referred to as an active-active setup, not only improves performance, but also provides immediate disaster recovery by routing traffic to other data centers if a data center that is part of the setup goes down. Alternatively, you can configure an active-standby GSLB setup for disaster recovery only.

Configure GSLB for disaster recovery in an active-standby data center setup

A conventional disaster recovery setup includes an active data center and a standby data center. The standby data center is a remote site. When a failover occurs as a result of a disaster event that causes the primary active data center to be inactive, the standby data center becomes operational.

Configuring disaster recovery in an active-standby data-center setup consists of the following tasks.

- Create the active data center.
- Add a local GSLB site.
- Add a GSLB vserver, which represents the active data center.
- Bind the domain to the GSLB virtual server.
- Add gslb services and bind the services to active GSLB virtual server.

- Create the standby data center.
  - Add a remote gslb site.
  - Add a gslb vserver, which represents standby data center.
  - Add gslb services which represents standby data center and bind the services to the standby gslb vserver.
  - Designate the standby data center by configuring the standby GSLB virtual server as the backup virtual server for the active GSLB virtual server.

Once you have configured the primary data center, replicate the configuration for the backup data center and designate it as the standby GSLB site by designating a GSLB virtual server at that site as the backup virtual server.

For details on how to configure a basic GSLB setup, see Configuring GSLB Entities Individually.

To designate the standby GSLB site by using the command line interface

At both the active site and the remote site, at the command prompt, type:

```
set gslb vserver <name> -backupVserver <string>
```

Example:

```
set gslb vserver vserver-GSLB-1 -backupVServer vserver-GSLB-2
```

To configure the standby site by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the GSLB virtual server for the primary site.
2. Click the Backup Virtual Server section and select a backup virtual server.

By default, once the primary virtual server becomes active, it starts receiving traffic. However, if you want the traffic to be directed to the backup virtual server even after the primary virtual server becomes active, use the ‘disable primary on down’ option.
**Configure for disaster recovery in an active-active data center setup**

An active-active GSLB deployment, in which both GSLB sites are active, removes any risk that may arise in having a standby data center. With such a setup, web or application content can be mirrored in geographically separate locations. This ensures that data is consistently available at each distributed data center.

To configure GSLB for disaster recovery in an active-active data center set up, you must first configure the basic GSLB setup on the first data center and then configure all other data centers.

First create at least two GSLB sites. Then, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Then create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server in the local site. Finally, at the local site, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

Once you have configured the first data center, replicate the configuration for other data centers part of the setup.

For details on how to configure a basic GSLB setup, see [Configuring GSLB Entities Individually](#).

**Configuring for Disaster Recovery with Weighted Round Robin**

When you configure GSLB to use the weighted round robin method, weights are added to the GSLB services and the configured percentage of incoming traffic is sent to each GSLB site. For example, you can configure your GSLB setup to forward 80 percent of the traffic to one site and 20 percent of the traffic to another. After you do this, the NetScaler appliance will send four requests to the first site for each request that it sends to the second.

To set up the weighted round robin method, first create two GSLB sites, local and remote. Next, for the local site create a GSLB virtual server and GSLB services, and bind the services to the virtual server. Configure the GSLB method as round robin. Next, create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server. Finally, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

Each service that represents a physical server in the network has weights associated with it. Therefore the GSLB service is assigned a dynamic weight that is the sum of weights of all services bound to it. Traffic is then split between the GSLB services based on the ratio of the dynamic weight of the particular service to the total weight. You can also configure individual weights for each GSLB service instead of the dynamic weight.

If the services do not have weights associated with them, you can configure the GSLB virtual server to use the number of services bound to it to calculate the weight dynamically.

For details on how to configure a basic GSLB setup, see [Configuring GSLB Entities Individually](#).
Once you configure a basic GSLB setup, you must configure the weighted round robin method such that the traffic is split between the configured GSLB sites according to the weights configured for the individual services.

To configure a virtual server to assign weights to services by using the command line interface

At the command prompt, type one of the following commands, depending upon whether you want to create a new load balancing virtual server or configure an existing one:

1. `add lb vserver <name>@ -weight <WeightValue> <ServiceName>`
2. `set lb vserver <name>@ -weight <WeightValue> <ServiceName>`

Example:

1. `add lb vserver Vserver-LB-1 -weight 4 Service-HTTP-1`
2. `set lb vserver Vserver-LB-1 -weight 4 Service-HTTP-1`

To set dynamic weight by using the command line interface

At the command prompt, type:

1. `set gslb vserver <name> -dynamicWeight DynamicWeightType`

Example:

1. `set gslb vserver Vserver-GSLB-1 -dynamicWeight ServiceWeight`

To add weights to the GSLB services by using the command line interface

At the command prompt, type:

1. `set gslb vserver <name> -serviceName GSLBServiceName -weight WeightValue`

Example:

1. `set gslb vserver Vserver-GSLB-1 -serviceName Service-GSLB-1 -weight 1`
To configure a virtual server to assign weights to services by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers and double-click the virtual server (for example, Vserver-LB-1).
2. Click the Services section and set the weight of a service.

To add weights to the GSLB services by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the virtual server (for example, vserver-GSLB-1)
2. Click the Services section and set the weight of the service in the Weight field.

To set dynamic weight by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the virtual server (for example, vserver-GSLB-1).
2. Click the Method section and, from the Dynamic Weight drop-down list select SERVICEWEIGHT.

Configuring for Disaster Recovery with Data Center Persistence

Data center persistence is required for web applications that require maintaining a connection with the same server instead of having the requests load balanced. For example, in an e-commerce portal, maintaining a connection between the client and the same server is critical. For such applications, HTTP redirect persistence can be configured in an active-active setup.

To configure GSLB for disaster recovery with data center persistence, you must first configure the basic GSLB setup and then configure HTTP redirect persistence.

First create two GSLB sites, local and remote. Next, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Next, create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server at the local site. Next, create a load balancing virtual server with the same virtual server IP address as the GSLB service. Finally, duplicate the previous steps for the remote configuration, or configure the NetScaler appliance to autosynchronize your GSLB configuration.

For details on how to configure a basic GSLB setup, see Configuring GSLB Entities Individually.

Once you have configured a basic GSLB setup, configure HTTP redirect precedence to enable data center persistence.
To configure HTTP redirect by using the command line interface

At the command prompt, type the following commands to configure HTTP redirect and verify the configuration:

1. `set gslb service <serviceName> -sitePersistence <sitePersistence> -sitePrefix <string>
2. `show gslb service <serviceName>

Example:

1. `set gslb service Service-GSLB-1 -sitePersistence HTTPRedirect -sitePrefix vserver-GSLB-1
2. `show gslb service Service-GSLB-1

To configure HTTP redirect by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services and double-click the GSLB service to be configured.
2. Click the Site Persistence section, select the HTTPRedirect option, and in the Site Prefix text box, enter the site prefix (for example, vserver-GSLB-1).

Note

When site persistence is not configured and if a load balancing virtual server that is configured as a local GSLB service is DOWN, the HTTP requests are redirected to other healthy GSLB sites using a 302 redirect.

Override static proximity behavior by configuring preferred locations

September 12, 2018

You might want to direct traffic from a local DNS (LDNS) server or network to a GSLB service other than the GSLB service that the static proximity method selects for that traffic. That is, you have a preferred location for that traffic. To override the static proximity method with preferred locations, you can do the following:

1. Configure a DNS action that consists of a list of preferred locations. For more information about configuring a DNS action, see Configuring a DNS Action.
2. Configure a DNS policy to identify the traffic arriving from the LDNS server or network for which you want to override static proximity, and apply the action in the policy.
3. Bind the policy to the global request bind point.
In the DNS action, you can configure a list of up to 8 preferred locations. The locations must be provided in the dotted qualifier notation, which is the notation in which you add custom locations to the static proximity database. The locations can include wildcards for qualifiers that you want to omit. For information about the dotted qualifier notation for locations, see Adding Custom Entries to a Static Proximity Database. When entering the preferred locations, you must enter them in the descending order of priority.

When a policy evaluates to TRUE, the NetScaler appliance matches the preferred locations, in priority order, with the locations of GSLB services. Matches are of the following two types:

- If all the non-wildcard qualifiers in a preferred location match the corresponding qualifiers in the location of a GSLB service, the match is considered a perfect match. For example, a GSLB service location of .UK.* or Europe.UK.. is a perfect match for the preferred location .UK.*.
- If only a subset of the non-wildcard qualifiers match, the match is considered a partial match. For example, a GSLB service location of Europe.EG is a partial match for the preferred location Europe.UK.

When a DNS policy evaluates to TRUE, the following algorithm is used to select a GSLB service:

1. The appliance evaluates the preferred location that has the highest priority and moves down the priority order until a perfect match is found between a preferred location and the location of a GSLB service.

   If a perfect match is found, the appliance checks whether the corresponding GSLB service is up. If it is up, it returns the IP address of the GSLB service in the DNS response. If multiple perfect matches are found (which can happen when one or more wildcards are used in a preferred location), the appliance checks the state of each of the corresponding GSLB services and load balances the GSLB services that are up.

2. If a perfect match is not found for any of the preferred locations, the appliance returns to the preferred location that has the highest priority and moves down the priority order until a partial match is found between a preferred location and the location of a GSLB service.

   If a partial match is found, the appliance checks whether the corresponding GSLB service is up. If it is up, it returns the IP address of the GSLB service in the DNS response. If multiple partial matches are found, the appliance checks the state of each of the corresponding GSLB services and load balances the GSLB services that are up.

3. If none of the perfect and partial matches are up, the appliance load balances all other available GSLB services.

   In this way, the appliance implements a type of site affinity for traffic that matches the DNS policy.
Example

Consider a GSLB configuration that consists of the following eight GSLB services:

- Asia.IN
- Asia.JPN
- Asia.HK
- Europe.UK
- Europe.RU
- Europe.EG
- Africa.SD
- Africa.ZMB

Further consider the following DNS action and policy configuration:

```
1 > add dns action prefLoc11 GslbPrefLoc -preferredLocList "Asia.HK" "Europe.UK"
2 Done
3 > add dns policy dnsPolPrefLoc "CLIENT.IP.SRC.MATCHES_LOCATION("*.ZMB .*,*")" prefLoc11
4 Done
```

When the appliance receives a request from the location .ZMB.*, the preferred locations are evaluated as follows:

1. The appliance attempts to find a GSLB service whose location is a perfect match for Asia.HK, which is the preferred location that has the highest priority. It finds that the GSLB service at Asia.HK is a perfect match. If the GSLB service is up, it sends the client the IP address of the GSLB service.
2. If the GSLB service at Asia.HK is down, the appliance attempts to find a perfect match for the second preferred location, Europe.UK. It finds that the GSLB service at Europe.UK is a perfect match. If the GSLB service is up, it sends the client the IP address of the service.
3. If the GSLB service at Europe.UK is down, it returns to the preferred location that has the highest priority, Asia.HK, and looks for partial matches. For Asia.HK, it finds that Asia.IN and Asia.JPN are partial matches. If only one of the corresponding GSLB services is up, it sends the client the IP address of the service. If both locations are up, it load balances the two services.
4. If all partial matches for Asia.HK are down, the appliance looks for partial matches for Europe.UK. It finds that Europe.RU and Europe.EG are partial matches for the preferred location. If only one of the corresponding GSLB services is up, it sends the client the IP address of the service. If both locations are up, it load balances the two services.
5. If all partial matches for Europe.UK are down, the appliance load balances all other available GSLB services. In the current example, the appliance load balances Africa.SD and Africa.ZMB because the remaining six GSLB services have been found to be down.
Configure GSLB service selection using content switching

September 12, 2018

In a typical GSLB deployment, you can prioritize the selection of a set of GSLB services bound to a GSLB virtual server, but you cannot do the following:

- Restrict the selection of a GSLB service from a subset of GSLB services bound to a GSLB virtual server for the given domain.
- Apply different load balancing methods on the different subsets of GSLB services in the deployment.
- Apply spillover policies on a subset of GSLB services, and you cannot have a backup for a subset of GSLB services.
- Configure a subset of GSLB services to serve different content. That is, you cannot content switch between servers in different GSLB sites. The GSLB configuration assumes that the servers contain the same content.
- Define a subset GSLB services with different priorities and specify an order in which the services in the subset are applied to a request.

You can now configure a content switching (CS) policy to customize the GSLB deployment. First configure a set of GSLB services and bind it to a GSLB virtual server. Then, configure a CS virtual server of target type GSLB, define a CS policy and action with the GSLB virtual server as target virtual server, and bind the CS policy to CS virtual server.

**Important**

- Only CS policies with DNS based expressions can be bound to a CS virtual server of target type GSLB.
- If a GSLB service is bound to a CS virtual server through a GSLB virtual server, you cannot bind another GSLB virtual server bound with the same GSLB service to the CS virtual server.

**Example**

Consider a GLSB deployment that includes two GSLB sites. At each site, four GSLB services (S-1, S-2, S-3, and S-4) are bound to GSLB virtual server VS-1. You can configure a content switching (CS) virtual server of target type GSLB and define a CS policy and action with VS-1 as the target virtual server, so that requests for content in English are served only by S-1 and S-2, and requests for content in the local language are served only by S-3 and S-4.

You could give S-1 priority by configuring a backup virtual server to VS-1 and binding S-2 to the backup virtual server. Client requests would then be served by S-1 unless the server it represents went down, in which case the requests would be served by S-2. If both S-1 and S-2 were down, clients would receive an empty response.

**To configure GSLB Service Selection using Content Switching:**
1. Configure GSLB. For instructions, see Configuring Global Server Load Balancing.
2. Configure a Content Switching (CS) virtual server of target type GSLB. For more information, see Creating Content Switching Virtual Servers.
3. Configure Content Switching (CS) policies. For more information, see Configuring Content Switching Policies.
4. Configure CS actions that designate a GSLB virtual server as the target virtual server. For more information, see Configuring a Content Switching Action.
5. Bind the CS policies to the CS virtual server. For more information, see Binding Policies to a Content Switching Virtual Server.
6. Bind the domain to the CS virtual server instead of the GSLB virtual server.

Sample Configuration

The following sample configuration sends requests from the client with IP address 5.5.5.5 to SERVICE_GSLB1 and SERVICE_GSLB2. SERVICE_GSLB1 has a higher priority than SERVICE_GSLB2, and SERVICE_GSLB2 serves the client requests only when SERVICE_GSLB1 is down. If both SERVICE_GSLB1 and SERVICE_GSLB2 are down, SERVICE_GSLB3 and service-GSLB4 are not considered, and a blank response is sent to the client.

```
1 add cs vs CSVSERVER_GSLB http - targettype GSLB
2 Done
3 add gslb vs VSERVER_GSLB1 http
4 Done
5 add gslb vs VSERVER_GSLB2 http
6 Done
7 add gslb vs VSERVER_GSLB_BACKUP1 http
8 Done
9 set gslb vs VSERVER_GSLB1 -backupvserver VSERVER_GSLB_BACKUP1
10 Done
11 add gslb service SERVICE_GSLB1 1.1.1.1 HTTP 80 -sitename site1
12 Done
13 add gslb service SERVICE_GSLB2 1.1.1.2 HTTP 80 -sitename site1
14 Done
15 add gslb service SERVICE_GSLB3 1.1.1.3 HTTP 80 -sitename site2
16 Done
17 add gslb service SERVICE_GSLB4 1.1.1.4 HTTP 80 -sitename site2
18 Done
19 bind gslb vs VSERVER_GSLB1 -servicename SERVICE_GSLB1
20 Done
21 bind gslb vs VSERVER_GSLB_BACKUP1 -servicename SERVICE_GSLB2
22 Done
23 bind gslb vs VSERVER_GSLB2 -servicename SERVICE_GSLB3
24 Done
```
Configure GSLB for DNS queries with NAPTR records

September 12, 2018

In a typical Global Server Load Balancing (GSLB) deployment, the NetScaler appliance receives DNS queries for A/AAAA records, selects the most appropriate GSLB service according to the configured load balancing method, and returns the service’s IP address as a reply to the DNS query. You can now configure the appliance to receive DNS queries for NAPTR records and respond with the list of services configured for a domain. The appliance also monitors the health of the services, and in the response it provides a list of only the services that are up.

Example:

In Telco deployments, you can configure a NetScaler appliance to receive DNS queries with NAPTR records from clients such as mobile management entities (MMEs), which play the role of a DNS resolver to discover all the services that are offered by the domain name. The appliance responds to the query with NAPTR records for all the services that are up. The MME can use this NAPTR response to run the S-NAPTR procedure to select the nodes on the basis of the service offered, colocation, topological closeness, and so on.

If multiple nodes qualify for selection, the MME can use the preference field in the NAPTR record from the NetScaler appliance to determine the node.
**NAPTR Record Format**

While responding to a DNS query with NAPTR record, a NetScaler appliance constructs a response NAPTR record for each GSLB service.

The following table lists the files in the NAPTR record:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Domain</td>
<td>The GSLB domain</td>
</tr>
<tr>
<td>TTL</td>
<td>The amount of time for which the NAPTR record can be cached.</td>
</tr>
<tr>
<td>Class</td>
<td>The class of the record. By default, this value is set to IN.</td>
</tr>
<tr>
<td>Type</td>
<td>The DNS record type.</td>
</tr>
<tr>
<td>Order</td>
<td>Specifies the order in which the NAPTR record MUST be processed. You can specify the order in the GSLB service. Otherwise, it is set to 1.</td>
</tr>
<tr>
<td>Preference</td>
<td>Specifies the order in which NAPTR records with equal “order” values SHOULD be processed, low numbers being processed before high numbers. If the order is not specified in the GSLB service, it is set to 1.</td>
</tr>
<tr>
<td>Flags</td>
<td>Controls the aspects of the rewriting and interpretation of the fields in the record. The NetScaler appliance sets this value to A.</td>
</tr>
<tr>
<td>Service</td>
<td>Specifies the available service(s).</td>
</tr>
<tr>
<td>Regular Expression</td>
<td>Regular expressions are not supported, so this value is set to NULL.</td>
</tr>
<tr>
<td>Replacement</td>
<td>The domain name of the node that hosts the services.</td>
</tr>
</tbody>
</table>

**Configuration procedure**

For detailed GSLB configuration instructions, see Configuring Global Server Load Balancing (GSLB). Make sure that you do the following:

- Set the following parameters while adding the GSLB virtual server:
NetScaler 12.0

- serviceType: ANY
- dnsRecordType: NAPTR
- lbMethod: CUSTOMLOAD

Example:

```
add gslb vserver gslb_vs ANY -dnsRecordType NAPTR -lbMethod CUSTOMLOAD
```

- While adding a GSLB site, set the `naptrReplacementSuffix` parameter to the domain name that you want to embed in the NAPTR records.

Example:

```
add gslb site site1 10.102.218.200 -naptrReplacementSuffix example.com
```

- Set the following parameters while adding the GSLB service:
  - naptrreplacement
  - naptrOrder
  - naptrServices
  - naptrDomainTTL
  - naptrPreference

Sample configuration

```
add gslb vserver gslb_vs ANY -dnsRecordType NAPTR -lbMethod CUSTOMLOAD
Done
add gslb site site1 10.102.218.200 -naptrReplacementSuffix example.com
Done
add gslb service sgw1 3.3.3.13 ANY * -siteName site1 -naptrreplacement sgw1.site1 -naptrOrder 2 -naptrServices x-3gpp-sgw:x-s5-gtp -naptrDomainTTL 20 -naptrPreference 200
Done
add gslb service sgw2 3.3.3.11 ANY * -siteName site1 -naptrreplacement sgw2.site1 -naptrOrder 5 -naptrServices x-3gpp-sgw:x-s5-gtp -naptrDomainTTL 20 naptrPreference 100
Done
```
Note

DNS queries with NAPTR records are not supported in parent-child configuration.

Use the EDNS0 client subnet option for GSLB

January 6, 2019

EDNS Client Subnet (ECS) is a DNS header extension that provides the client subnet details. You can use these details to improve the accuracy of NetScaler Global Server Load Balancing (GSLB) by using the client network location rather than the DNS resolver location to determine the topological closeness of the client.
NetScaler 12.0

**Note**

NetScaler supports only EDNS0.

**Important:**

Make sure that the LDNS in your deployment supports EDNS0 Client Subnet so that the incoming DNS queries contains the EDNS0 Client Subnet option and the NetScaler appliance uses the ECS address while processing the DNS query.

In a typical GSLB deployment, when you use proximity-based load balancing methods like static proximity or dynamic round-trip time (RTT), the NetScaler appliance uses the local DNS (LDNS) IP address for determining the topological closeness of the client and performs GSLB accordingly. But when a centralized DNS resolver, such as Google DNS or OpenDNS, is involved in the deployment, the NetScaler appliance sends the DNS request to a datacenter close to the centralized DNS resolver, which might not be close to the client. For example, in a typical NetScaler GSLB deployment using the static proximity load balancing method, an end-user request from Japan is sent to a datacenter in Japan and an end user request from California is sent to a datacenter in California. But if a centralized DNS resolver is involved, the NetScaler appliance might send a request from Japan to a datacenter in California.

You can use the ECS option in deployments that include the NetScaler appliance configured as Authoritative DNS (ADNS) server for a GSLB domain. If you use static proximity as the load balancing method, you can use the IP subnet in the EDNS header instead of the LDNS IP address to determine the geographical proximity of the client. In the case of proxy mode deployment, the NetScaler appliance forwards an ECS-enabled DNS query as-is to the back-end servers, and the appliance does not cache ECS-enabled DNS responses.

**Note**

The ECS option is not applicable for all other deployment modes, such as ADNS mode for non-GSLB domains, resolver mode, and forwarder mode. In all these modes, the ECS option is ignored by the NetScaler appliance. Also, by default, ECS is disabled for GSLB deployment.

**To enable EDNS0 Client Subnet option by using the command line interface:**

At the command prompt, type:

```
1  set gslb vserver <vserver_name> **-ECS ENABLED
2
3  set gslb vserver vserver=GSLB-1 -ECS ENABLED
```
Address validation

You can configure a GSLB virtual server to verify that the address returned by the EDNS0 Client Subnet (ECS) option of the DNS query is not a private or an unroutable IP address. With address validation enabled, the NetScaler appliance ignores the ECS address in the DNS query if it is listed in the following table, and instead uses the LDNS IP address for global server load balancing.

Note

By default, address validation is disabled.

<table>
<thead>
<tr>
<th>Address Type</th>
<th>Address</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPV4</td>
<td>10.0.0.0/8</td>

To enable address validation by using the command line interface

At the command prompt, type:

```
1 set gslb vserver <vserver_name> -ecsAddressValidation ENABLED
2
3 set gslb vserver vserver-GSLB-1 -ecsAddressValidation ENABLED
```

Example of a complete parent-child configuration using the metrics exchange protocol

January 6, 2019

Consider the following parent-child topology in which the GSLB sites are distributed globally.

- Site1 and Site2 are the parent sites.
- Site1_child1 and Site1_child2 are the child sites of Site1.
- Site2_child1 and Site2_child2 are the child sites of Site2.

The following commands illustrate the complete configuration of the parent-child topology.

```

<table>
