 - d) In the **Modify Signature Item** dialog box, **Element** text box, modify the pattern. If you are modifying a transformation pattern, you can modify either or both patterns under Elements, in the From and the To text boxes.
 - e) Click **OK**.
8. To remove a pattern, select the pattern that you want to remove, then click the **Remove** button

below the details pane beneath the **Filtered Results** window. When prompted, confirm your choice by clicking **Close**.

9. To add the patterns category to the cross-site scripting branch:

- a) Select the branch to which you want to add the patterns category.
- b) Click the **Add** button directly below the **Filtered Results** window.

Note: Currently you can add only one category, named patterns, to the cross-site scripting branch, so after you click **Add**, you must accept the default choice, which is patterns.

- c) Click **OK**.

10. To remove a branch, select that branch, and then click the Remove button directly below the **Filtered Results** window. When prompted, confirm your choice by clicking **OK**.

Note: If you remove a default branch, you remove all of the patterns in that branch. Doing so can disable the security checks that use that information.

11. When you are finished modifying the SQL injection, cross-site scripting, and XPath injection patterns, click **OK**, and then click **Close** to return to the **Modify Signatures Object** dialog box.
12. Click **OK** at any point to save your changes, and when you are finished configuring the signatures object, click **Close**.

Protecting JSON applications using signatures

May 2, 2023

JavaScript Object Notation (JSON) is a text-based open standard derived from the JavaScript scripting language. JSON is preferred for human readable representation of simple data structures and associative arrays, called objects. It serves as an alternative to XML and is primarily used to transmit serialized data structures for communicating with web applications. The JSON files are typically saved with a .json extension.

The JSON payload is typically sent with the MIME type specified as **application/json**. The other “standard” content types for JSON are:

- **application/x-javascript**
- **text/javascript**
- **text/x-javascript**
- **text/x-json**

Using the NetScaler Web App Firewall signatures to protect JSON applications

To allow JSON requests, the appliance is preconfigured with the JSON content type as shown in the following show-command output:

```
1 > sh appfw jsonContentType
2 1)      JSONContenttypevalue:  "^application/json$" IsRegex:  REGEX
3 Done
4 <!--NeedCopy-->
```

The NetScaler Web App Firewall processes the post body for the following content-types only:

- **application/x-www-form-urlencoded**
- **multipart/form-data**
- **text/x-gwt-rpc**

The requests that are received with other content-type headers including application/json (or any other allowed content type) are forwarded to the backend after header inspection. The post body in such requests is not inspected for security check violations even when the profile's security checks such as SQL or cross-site scripting are enabled.

In order to protect JSON applications and detect violations, Web App Firewall signatures can be used. All requests that contain the allowed content-type header are processed by the Web App Firewall for signature match. You can add your own customized signature rules to process JSON payload to perform various security check inspections (for example, cross-site scripting, SQL, and Field Consistency), to detect violations in the headers as well as the post body, and take specified actions.

Tip

Unlike the other built-in defaults, the preconfigured JSON content type can be edited or removed by using the CLI or the GUI (GUI). If legitimate requests for JSON applications are getting blocked and triggering content-type violations, check to make sure that the content type value is configured accurately. For additional details regarding how Web App Firewall processes content-type header, see [Content type protection](#)

To add or remove JSON content-type by using the command line interface

At the command prompt, type one of the following commands:

```
add appfw jsonContentType ^application/json$ IsRegEx REGEX
rm appfw JSONContentType "^application/json$"
```

To managing JSON content types by using the GUI

Navigate to **Security > Web App Firewall** and, in the **Settings** section, select **Manage JSON Content Types**.

In the **Configure Web App Firewall JSON Content Type** panel, add, edit, or delete JSON content types to suit the needs of your applications.

Configuring signature protection to detect attacks in JSON payload

In addition to a valid JSON content type, you need to configure signatures to specify the pattern(s) that, when detected in a JSON request, indicate a security breach. The specified actions, such as block and log, are taken when an incoming request triggers a match for all the target patterns in the signature rule.

To add a customized signature rule, Citrix recommends that you use the GUI. Navigate to **System > Security > Web App Firewall > Signatures**. Double click the target signature object to access the **Edit Web App Firewall Signatures** panel. Click on the **Add** button to configure the actions, category, log string, rule patterns and so on. Although Web App Firewall inspects all allowed content-type payload for signature match, you can optimize the processing by specifying the JSON expression in the rule. When you **Add** a new rule pattern, select **Expression** in the drop-down options for **Match** and provide the target match expression from your JSON payload to identify the specific requests that need to be inspected. An expression must begin with a **TEXT.** prefix. You can add other rule patterns to specify additional match patterns to identify the attack.

The following example shows a signature rule. If any cross-site script tag is detected in the POST body of the JSON payload that matches the specified XPATH_JSON expression, a signature match is triggered.

Example of a signature to detect cross-site scripting in JSON payload

```
1 <SignatureRule actions="log,stats" category="JSON" enabled="ON" id="
   1000001" severity="" source="" type="" version="1">
2
3 <PatternList>
4
5 <RequestPatterns>
6
7 <Pattern>
8
9 <Location area="HTTP_POST_BODY"/>
10
11 <Match type="Expression">TEXT.XPATH_JSON(xp%/glossary/title%).
   CONTAINS("example glossary")</Match>
```

```
12
13     </Pattern>
14
15     <Pattern>
16
17         <Location area="HTTP_METHOD"/>
18
19         <Match type="LITERAL">POST</Match>
20
21     </Pattern>
22
23     <Pattern>
24
25         <Location area="HTTP_POST_BODY"/>
26
27         <Match type="CrossSiteScripting"/>
28
29     </Pattern>
30
31 </RequestPatterns>
32
33 </PatternList>
34
35 <LogString>Cross-site scripting violation detected in json payload</
    LogString>
36
37 <Comment/>
38
39 </SignatureRule>
40 <!--NeedCopy-->
```

Example of the payload

The following payload triggers the signature match, because it includes the cross-site scripting tag **<Gotcha!!>**.

```
1 {
2   "glossary": {
3     "title": "example glossary", "GlossDiv": {
4       "title": "S", "GlossList": {
5         "GlossEntry": {
6           "ID": "SGML", "SortAs": "SGML", "GlossTerm": "Standard Generalized
           Markup Language", "Acronym": "SGML", "Abbrev": "ISO 8879:1986", "
           GlossDef": {
7             "para": "A meta-markup language, used to create markup languages **<
           Gotcha!!>** such as DocBook.", "GlossSeeAlso": ["GML", "XML"] }
8         , "GlossSee": "markup" }
9       }
10    }
11  }
12 }
```

```
13
14 <!--NeedCopy-->
```

Example of the log message

```
1 Aug 21 12:21:42 <local0.info> 10.217.31.239 08/21/2015:23:21:42 GMT ns
  0-PPE-1 : APPFW APPFW_SIGNATURE_MATCH 1471 0 : 10.217.253.62 990-
  PPE0 NtJnVMNnvPeQJnaUzXYW/GTvAQsA010 prof1 http://10.217.31.212/FFC/
  login_post.php Signature violation rule ID 1000001: cross-site
  scripting violation detected in json payload <not blocked>
2 <!--NeedCopy-->
```

Note

If you send the same payload after removing the cross-site script tag (<Gotcha!!>), the signature rule match is not triggered.

Highlights

- To protect JSON payload, use Web App Firewall signatures to detect cross-site scripting, SQL and other violations.
- Verify that the JSON content type is configured on the appliance as the allowed content type.
- Make sure that the content type in the payload matches the configured JSON content type.
- Make sure that all the patterns configured in the signature rule match for the signature violation to be triggered.
- When you add a signature rule, it MUST have at least one Rule pattern to match the Expression in the JSON payload. All the PI expressions in signature rules must start with the prefix TEXT. and must be Boolean.

Protect application or JSON content-type with SQL and cross-site scripting encoded payload using policies and signatures

NetScaler Web App Firewall can protect application or JSON content type using policies and signatures.

Inspect application or JSON content type for SQL injection using policies

You must add the following policies and bind it to virtual server globally for supporting SQL injection.

```
add appfw policy sql_i_1 HTTP.REQ.BODY(10000).SET_TEXT_MODE(IGNORECASE)
.SET_TEXT_MODE(URLENCODED).DECODE_USING_TEXT_MODE.REGEX_MATCH(re
#((\\A)|(?<=[^a-zA-Z0-9_]))(select|insert|delete|update|drop|
create|alter|grant|revoke|commit|rollback|shutdown|union|intersect
|minus|case|decode|where|group|begin|join|exists|distinct|add|modify|
constraint|null|like|exec|execute|char|or|and|sp_sdidebug)((Z)|(?=[^a
-zA-Z0-9_]))#)APPFW_BLOCK
```

```
add appfw policy sql_i_2 HTTP.REQ.BODY(10000).SET_TEXT_MODE(IGNORECASE)
.SET_TEXT_MODE(URLENCODED).DECODE_USING_TEXT_MODE.REGEX_MATCH(re
#((\\A)|(?<=[^a-zA-Z0-9_]))(xp_availablemedia|xp_cmdshell|xp_deletemail
|xp_dirtree|xp_dropwebtask|xp_dsninfo|xp_enumdsn|xp_enumerrorlogs|
xp_enumgroups|xp_enumqueuedtasks|xp_eventlog|xp_findnextmsg|xp_fixeddrives

ALL_TRIGGERS|SYS\\.ALL_USERS|SYS\\.ALL_VIEWS|SYS\\.USER_ROLE_PRIVS|
SYS\\.USER_SYS_PRIVS|SYS\\.USER_TAB_PRIVS)((Z)|(?=[^a-zA-Z0-9_]))#)
APPFW_BLOCK
```

Inspect application or JSON content type using signatures

You can add the following signature rules to the signature object in the application firewall profile to support SQL injection for JSON content-type.

Note:

Post body signatures are cpu-intensive.

```

Updating a signature object

May 2, 2023

You must update your signatures objects frequently to ensure that your Web App Firewall is providing protection against current threats. You must regularly update both the default Web App Firewall signatures and any signatures that you import from a supported vulnerability scanning tool.

NetScaler regularly updates the default signatures for the Web App Firewall. You can update the default signatures manually or automatically. In either case, ask your NetScaler representative or NetScaler reseller for the URL to access the updates. You can enable automatic updates of the NetScaler native format signatures in the “Engine Settings” and “Signature Auto Update Settings” dialog boxes.

Most makers of vulnerability scanning tools regularly update the tools. Most websites also change frequently. You must update your tool and rescan your websites regularly, exporting the resulting signatures to a file and importing them into your Web App Firewall configuration.

Tip

When you update the Web App Firewall signatures from the NetScaler command line, you must first update the default signatures, and then issue more update commands to update each custom signatures file that is based on the default signatures. If you do not update the default signatures first, a version mismatch error prevents updating of the custom signatures files.

Note

The following applies to merging a third-party signature object with a user-defined signature object with Native rules and user-added rules:

When a version 0 signatures is merged with a new imported file, the resultant signatures remain as version 0.

This means all native (or built-in) rules in the imported file will be ignored after the merge. This is to ensure that the version 0 signatures are maintained as is after a merge.

To include the native rules in the imported file for merge, you must update the existing signatures from version 0 first before the merge. This means you need to abandon the version 0 nature of the existing signatures.

When there is a NetScaler release upgrade, the file “default_signatures.xml” is added to the new build and the file “updated_signature.xml” is removed from the older build. After the upgrade, if the signature auto update feature is enabled, the appliance updates the existing signature to the latest version of the build and generates the “updated_signature.xml” file.

To update the Web App Firewall signatures from the source by using the command line

At the command prompt, type the following commands:

- `update appfw signatures <name> [-mergedefault]`
- `save ns config`

Example

The following example updates the signatures object named MySignatures from the default signatures object, merging new signatures in the default signatures object with the existing signatures. This command does not overwrite any user-created signatures or signatures imported from another source, such as an approved vulnerability scanning tool.

```
1 update appfw signatures MySignatures -mergedefault
2 save ns config
3 <!--NeedCopy-->
```

Updating a signatures object from a NetScaler format file

NetScaler regularly updates the signatures for the Web App Firewall. You must regularly update the signatures on your Web App Firewall to ensure that your Web App Firewall is using the most current list. Ask your NetScaler representative or NetScaler reseller for the URL to access the updates.

To update a signatures object from a NetScaler format file by using the command line

At the command prompt, type the following commands:

- `update appfw signatures <name> [-mergeDefault]`
- `save ns config`

To update a signatures object from a NetScaler format file by using the GUI

1. Navigate to **Security > Web App Firewall > Signatures**.
2. In the details pane, select the signatures object that you want to update.
3. In the **Action** drop-down list, select **Merge**.
4. In the **Update Signatures Object** dialog box, choose one of the following options.
 - **Import from URL**—Choose this option if you download signature updates from a web URL.
 - **Import from Local File**—Choose this option if you import signature updates from a file on your local hard drive, network hard drive, or other storage device.
5. In the text area, type the URL, or type or browse to the local file.
6. Click **Update**. The update file is imported, and the Update Signatures dialog box changes to a format nearly identical to that of the **Modify Signatures Object** dialog box. The **Update Signatures Object** dialog box displays all branches with new or modified signature rules, SQL injection or cross-site scripting patterns, and XPath injection patterns if there are any.
7. Review and configure the new and modified signatures.
8. When you are finished, click **OK**, and then click **Close**.

Updating a signatures object from a supported vulnerability scanning tool

Note:

Before you update a signatures object from a file, you must create the file by exporting signatures from the vulnerability scanning tool.

To import and update signatures from a vulnerability scanning tool

1. Navigate to **Security > Web App Firewall > Signatures**.
2. In the details pane, select the signatures object that you want to update, and then click **Merge**.
3. In the **Update Signatures Object** dialog box, on the **External Format** tab, Import section, choose one of the following options.
 - **Import from URL**—Choose this option if you download signature updates from a Web URL.
 - **Import from Local File**—Choose this option if you import signature updates from a file on your local or a network hard drive or other storage device.
4. In the text area, type the URL, or browse or type the path to the local file.
5. In the XSLT section, choose one of the following options.
 - **Use Built-in XSLT File**—Choose this option if you want to use a built-in XSLT file.
 - **Use Local XSLT File**—Choose this option to use an XSLT file on your local computer.
 - **Reference XSLT from URL**—Choose this option to import an XSLT file from a web URL.
6. If you chose Use Built-in XSLT File, in the Built-In XSLT drop-down list select the file that you want to use from the following options:
 - **Cenzic.**
 - **Deep_Security_for_Web_Apps.**
 - **Hewlett_Packard_Enterprise_WebInspect.**
 - **IBM-AppScan-Enterprise.**
 - **IBM-AppScan-Standard.**
 - **Qualys.**
 - **Whitehat.**
7. Click **Update**. The update file is imported, and the Update Signatures dialog box changes to a format nearly identical to that of the Modify Signatures Object dialog box, which is described in [Configuring or Modifying a Signatures Object](#). The **Update Signatures Object** dialog box displays all branches with new or modified signature rules, SQL injection or cross-site scripting patterns, and XPath injection patterns if there are any.
8. Review and configure the new and modified signatures.
9. When you are finished, click **OK**, and then click **Close**.

Signature auto update

May 2, 2023

The Signature Auto Update functionality in the Web Application Firewall allows the user to get the latest signatures to protect the web application against new vulnerabilities. The auto update feature provides better protection without the need for ongoing manual intervention to get the latest updates.

The signatures are auto updated on an hourly basis and do not require regular check for the availability of the most recent update. Once you enable Signature Auto Update, then the NetScaler appliance connects to the server hosting the signatures to check if a newer version is available.

Customizable location

The latest Application Firewall signatures are hosted on Amazon which is configured as the default Signature URL to check for the latest update.

However, the user has an option to download these signature mapping files to their internal server. User can then configure a different Signature URL path to download the signature mapping files from a local server. For the auto update feature to work, you might need to configure the DNS server to access the external site.

Update signatures

All the user defined signature objects which are created using the appfw default signature object have a version greater than zero. If you enable Signature Auto Update, then all the signatures are updated automatically.

If the user has imported signatures with the external format such as Cenzic or Qualys, then the signatures are imported with the version as zero. Similarly, if the user has created a signature object using the blank template, then it is created as a zero version signature. These signatures are not automatically updated, because the user might not be interested in the overhead of managing the default signatures that is not used.

However, Web Application Firewall also allows the user the flexibility to manually select these signatures and update them to add the default signature rules to the existing rules. After the signatures are manually updated, the version changes and then the signatures will also get auto updated along with the other signatures.

Configure the signature auto update

To configure the signature auto update feature using the CLI:

At the command prompt, type:

```

1 set appfw settings SignatureAutoUpdate on
2 set appfw settings SignatureUrl https://s3.amazonaws.com/
  NSAppFwSignatures/SignaturesMapping.xml
3 <!--NeedCopy-->
  
```

To configure the signature auto update using the GUI:

1. Navigate to **Security > NetScaler Web App Firewall > Signatures**.
2. Select **Auto Update Settings** from **Action**.
3. Enable the **Signatures Auto Update** option.
4. You can specify a customized path for the signature update URL, if necessary. Click **Reset** to reset to the default `s3.amazonaws.com` server.
5. Click **OK**.

Close

Update signatures manually

To manually update a zero version signature or any other user defined signature, you must first get the latest update for the default signatures and then use this for updating the target user defined signature.

Run the following commands from the CLI to update a signature file:

```
1 update appfw signatures "*Default Signatures"  
2 update appfw signatures cenxic -mergedefault  
3 <!--NeedCopy-->
```

Note:

`Default Signatures` is case sensitive. `Cenxic` in the preceding command is the name of the signature file that is updated.

Import default signatures without internet access

It is recommended to configure a proxy server to point to Amazon (AWS) server to get the latest update. However, if the NetScaler appliance does not have an internet connection to the external sites, then the user can store the updated signature files on a local server. The appliance can then download the signatures from the local server. In this scenario, the user must constantly check the **Amazon site** to get the latest updates. You can download and verify the signature file against the corresponding sha1 file which were created by using the **Citrix public** key to protect against tampering.

To copy the Signatures files to a local server, complete the following procedure:

1. Create a local directory such as `<MySignatures>` on a local server.
2. Open the AWS site.
3. Copy the `SignaturesMapping.xml` file to the `<MySignatures>` folder.

If you open the `SignaturesMapping.xml` file, you can see all the xml files for signatures and their corresponding sha1 files for different supported versions. One such pair is highlighted in the following screenshot:

1. Create a subdirectory `<sigs>` in the `<MySignatures>` folder.
2. Copy all pairs of the `*.xml` files listed in the `<file>` tags and the `*.xml.sha1` files listed in the corresponding `<sha1>` tags of the `SignaturesMapping.xml` file to the `<sigs>` folder. The following are a few sample files that is copied to the `<sigs>` folder:

```
https://s3.amazonaws.com/NSAppFwSignatures/sigs/sig-r10.1b86v3s3.xml  
https://s3.amazonaws.com/NSAppFwSignatures/sigs/sig-r10.1b86v3s3.xml.  
sha1  
https://s3.amazonaws.com/NSAppFwSignatures/sigs/sig-r10.1b0v3s2.xml  
https://s3.amazonaws.com/NSAppFwSignatures/sigs/sig-r10.1b0v3s2.xml.  
sha1
```

Note:

You can give any name to the `<MySignatures>` folder and it can be in any location but the subdirectory `<sigs>` must be a subdirectory in the `<MySignatures>` folder where the mapping file is copied. In addition, ensure that as shown in the SignaturesMapping.xml, the subdirectory name `<sigs>` must have the exact name and is case sensitive. All Signature files and their corresponding sha1 files should be copied under this `<sigs>` directory.

After mirroring the contents from the hosted Amazon web server to the local server, change the path to the new local web server to set it as the SignatureUrl for auto update. For example, run the following command from the command line interface of the appliance:

```
1 set appfw settings SignatureUrl https://myserver.example.net/
   MySignatures/SignaturesMapping.xml
2 <!--NeedCopy-->
```

The update operation can take several minutes, depending on the number of signatures to be updated. Allow sufficient time for the update operation to complete.

If you face an error “Error in accessing URL!” while configuring, follow the steps to resolve it.

1. Add the url `https://myserver.example.net` to `/netscaler/ns_gui/admin_ui/php/application/controllers/common/utils.php` so that Content Security Policy (CSP) security does not block the url access. Please note that these settings do not persists in an upgrade. User has to add it again after the upgrade.

```
1 $configuration_view_connect_src = "connect-src 'self' https://app.pendo
   .io https://s3.amazonaws.comhttps://myserver.example.net;";
2 <!--NeedCopy-->
```

1. User must configure the webserver `https://myserver.example.net` such that it responds to the following CORS headers for `https://myserver.example.net/MySignatures/SignaturesMapping.xml`

```
1 Access-Control-Allow-Methods: GET
2 Access-Control-Allow-Origin: *
3 Access-Control-Max-Age: 3000
4 <!--NeedCopy-->
```

Guidelines to update signatures

Following guidelines are used when updating signatures:

- The signatures are updated when the Signature update URL has a signature object which has the same or newer version.

- Each Signature Rule is associated with a rule ID and version number. For example: `<SignatureRule id="803"version="16"...>`
- Signature Rule from the incoming Signatures file with the same ID and version number as the existing one is ignored even if it has different patterns or log string.
- Signature Rule with a new ID is added. All the actions and enabled flag are used from the new file.

Note:

You must review the updated signatures periodically to enable the newly added rules and change other action settings as per the requirements of the application.

- Rules with the same ID but with a newer version number replace the existing one. All the actions and enabled flag from the existing rule is preserved.

Tip:

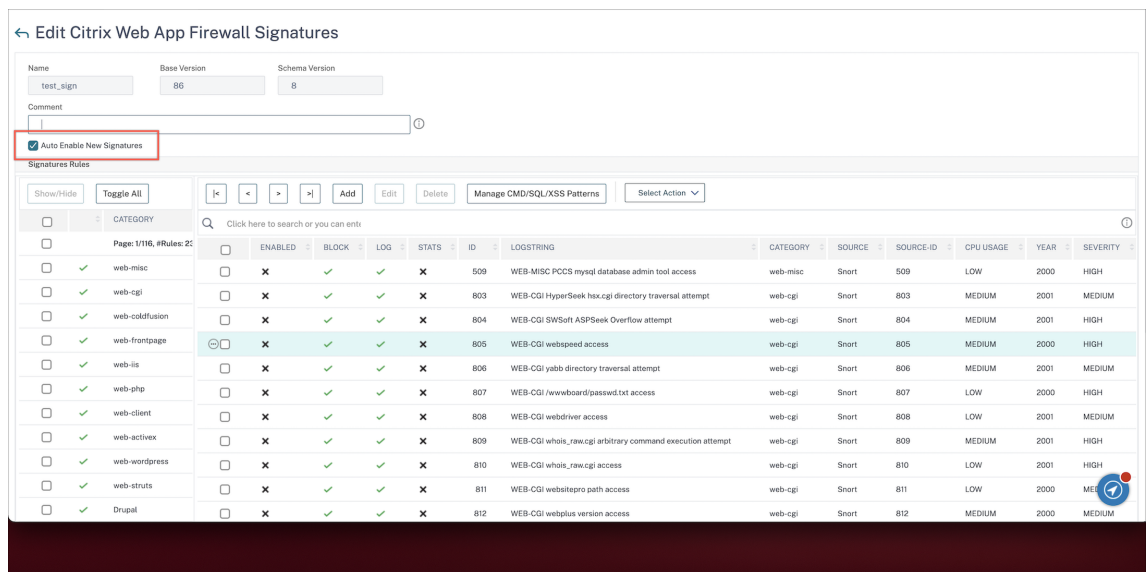

When you update the signatures from the CLI, you must first update the default signatures. You must then add update commands to update each custom signature file that is based on the default signatures. If you do not update the default signatures first, a version mismatch error prevents custom signatures file update.

Auto-enable new signatures

From release 13.1 build 27.x and later, you can select **Auto Enable New Signatures** to allow new WAF signature default rules to be auto-enabled after an update.

Auto-enable new signatures using the GUI

1. Navigate to **Security > NetScaler Web App Firewall > Signatures**.
2. Select a signature and click **Edit**.
3. Select **Auto Enable New Signatures**.

Auto-enable new signatures using the CLI

At the command prompt, type:

```
import appfw signatures <src> <name> [-xslt <string>] [-comment <string>] [-overwrite] [-merge [-preservedefactions]] [-sha1 <string>] [-VendorType Snort] [-autoEnableNewSignatures ( ON | OFF )]
```

Example:

```
import signatures http://www.example.com/ns/signatures.xml my-signature -autoEnableNewSignatures ON
```

Snort rule integration

February 9, 2024

With malicious attacks on web applications, it is important to protect your internal network. Malicious data not only affect your web applications at the interface level but malicious packets also reach the application layer. To overcome such attacks, it is important to configure an intrusion detection and prevention system that examines your internal network.

Snort rules are integrated into the appliance for examine malicious attacks in data packets at the application layer. You can download the snort rules and convert it into WAF signatures rules. The signatures have rule-based configuration that can detect malicious activities such as DOS attacks, buffer overflows, stealth port scans, CGI attacks, SMB probes, and OS Fingerprinting attempts. By integrating Snort rules, you can strengthen your security solution at the interface and at the application level.

Configure snort rules

The configuration begins by first downloading the Snort rules and then importing it into WAF signature rules. Once you have converted the rules into WAF signatures, the rules can be used as WAF security checks. The snort based signature rules examine the incoming data packet to detect if there are malicious attacks on your network.

A new parameter, “VendorType” is added to the import command to convert Snort rules to WAF signatures.

The parameter “VendorType” is set on SNORT only for Snort rules.

Download snort rules by using the command interface

You can download the Snort rules as a text file from the below URL:

<https://www.snort.org/downloads/community/snort3-community-rules.tar.gz>

Import snort rules by using the command interface

After you download, you can import the Snort rules into your appliance.

At the command prompt, type:

```
import appfw signatures <src> <name> [-xslt <string>] [-comment <string>] [-overwrite] [-merge [-preservedefactions]] [-sha1 <string>] [-VendorType Snort]
```

Example:

```
import appfw signatures http://www.example.com/ns/signatures.xml sig-snort -comment "signatures from snort rules" -VendorType snort
```

Arguments:

Src. URL (protocol, host, path, and file name) for the location at which to store the imported signatures object.

Note:

The import fails if the object to be imported is on an HTTPS server that requires client certificate authentication for access. Mandatory argument of maximum length: 2047

Name. Name to assign to the signatures object on the NetScaler. Mandatory argument of maximum length: 31

Comment. Description of how to preserve information about the signatures object. Maximum Length: 255

overwrite. Overwrite any existing signatures object of the same name.

Merge. Merges existing Signature with new signature rules.

Preservedefactions. Preserves def actions of signature rules.

VendorType. Third-party vendor to generate the WAF signatures. Possible values: Snort.

Configure snort rules by using the NetScaler GUI

The GUI configuration for Snort rules is similar to configuring other external web application scanners like Cenzic, Qualys, Whitehat.

Follow the steps below to configure Snort:

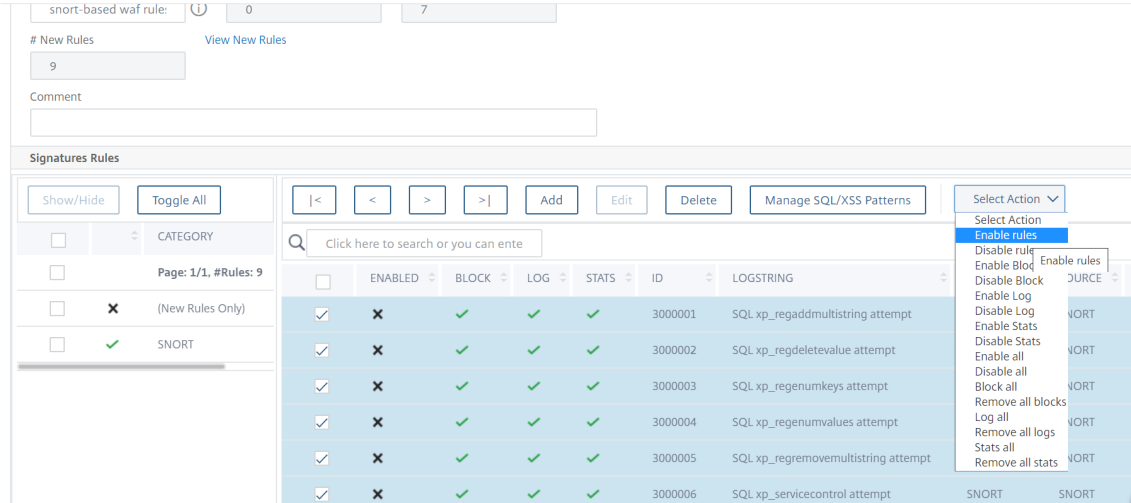

1. Navigate to **Configuration > Security > NetScaler Web App Firewall > Signatures**.
2. In the **Signatures** page, click **Add**.
3. In the **Add Signatures** page, set the following parameters to configure Snort rules.
 - a) File format. Select the file format as external.
 - b) Import from. Select the import option as a snort file or URL to enter the URL.
 - c) Snort V3 Vendor. Select the check box to import Snort rules from a file or from a URL.
4. Click **Open**.

The screenshot shows the 'Add Signatures' configuration window. It features a back arrow icon and the title 'Add Signatures'. The form contains the following fields and options:

- File Format***: Three radio button options: 'Native', 'External' (selected), and 'Blank Signatures'.
- Import From***: Two radio button options: 'File' (selected) and 'URL'.
- Local File***: A text input field with a 'Choose File' dropdown menu and the text 'snort.txt'.
- SNORT V3 Vendor**: A checked checkbox.
- At the bottom, there are two buttons: 'Open' (in a blue box) and 'Close' (in a white box with a blue border).

The appliance imports the Snort rules as snort-based WAF signature rules.

As a best practice, you must use filter actions to enable snort rules that you prefer to import as WAF signature rules on the appliance.

5. To confirm, click **Yes**.
6. The selected rules are enabled on the appliance.
7. Click **OK**.

Exporting a signatures object to a file

May 2, 2023

You export a signatures object to a file so that you can import it to another NetScaler.

To export a signatures object to a file

1. Navigate to **Security > NetScaler Web App Firewall > Signatures**.
2. In the details pane, select the signatures object that you want to configure.
3. In the **Actions** drop-down list, select **Export**.
4. In the **Export Signatures Object** dialog box, **Local File** text box, type the path and name of the file to which you want to export the signatures object, or use the **Browse** dialog to designate a path and name.
5. Click **OK**.

Edit signatures to add or modify rules

May 2, 2023

You can edit the user-defined signatures to add or modify a rule. A local signature rule has the same attributes as a default signature rule from Citrix, and it functions in the same way. You enable or disable it, and configure the signature actions for it, just as you do for a default signature.

Add a local rule if you need to protect your websites and services from a known attack that the existing signatures do not match. For example, you might discover a new type of attack and determine its characteristics by examining the logs on your web server, or you might obtain third-party information about a new type of attack.

At the heart of a signature rule are the rule *patterns*, which collectively describe the characteristics of the attack that the rule is designed to match. Each pattern can consist of a simple string, a PCRE-format regular expression, or the built-in SQL injection or cross-site scripting patterns.

You might want to modify a signature rule by adding a new pattern or modifying an existing pattern to match an attack. For example, you might find out about changes to an attack, or you might determine a better pattern by examining the logs on your web server, or from third-party information.

Add or modify a local signature rule

1. Navigate to **Security > NetScaler Web App Firewall > Signatures**.
2. In the details pane, select the user-defined signatures that you want to edit, and then click **Edit**.
3. In the **Signature Rules** section, click **Add**. The **Signature Rule** pane appears.
4. Configure the actions for a signature by selecting the appropriate check boxes.
 - **Enabled**. Enables the new signature rule. If you do not select this, this new signature rule is added to your configuration, but is inactive.
 - **Block**. Blocks connections that violate this signature rule.
 - **Log**. Logs violations of this signature rule to the NetScaler log.
 - **Stat**. Includes violations of this signature rule in the statistics.
 - **Remove**. Strips information that matches the signature rule from the response. (Applies only to response rules.)
 - **X-Out**. Masks information that matches the signature rule with the letter X. (Applies only to response rules.)
 - **Allow Duplicates**. Allows duplicates of this signature rule in this signatures object.
5. Choose a category for the new signature rule from the **Category** drop-down list.

If you want to create a category, click **Add**. For more information, see [Add a signature rule category](#).

6. In the **LogString** text box, type a brief description of the signature rule to be used in the logs.
7. In the **Comment** text box, type a comment. (Optional)
8. Click **More** to modify the advanced options.
 - a) To strip HTML comments before applying this signature rule, in the Strip Comments drop-down list choose All or Exclude Script Tag.
 - b) To set CSRF Referrer Header checking, in the CSRF Referrer Header checking radio button array, select either the If Present or Always radio button.
 - c) To manually modify the Rule ID assigned to this local signature rule, modify the number in the Rule ID text box. The ID must be a positive integer between 1000000 and 1999999 that has not already been assigned to a local signature rule.
 - d) To assign a version number to the new signature rule, modify the number in the Version Number text box.
 - e) To assign a Source ID, modify the string in the Source ID text box.
 - f) To specify the source, choose Local or Snort from the Source drop-down list, or click the Add icon to the right of the list and add a new source.
 - g) To assign a harm score to violations of this local signature rule, type a number between 1 and 10 in the Harm Score text box.
 - h) To assign a severity rating to this local signature rule, in the Severity drop-down list choose High, Medium, or Low, or click the Add icon to the right of the list and add a new severity rating.
 - i) To assign a violation type to this local signature rule, in the Type drop-down list choose Vulnerable or Warning, or click the Add icon to the right of the list and add a new violation type.
9. In **Rule Patterns**, click **Add** to add a pattern. You can also edit the existing patterns to do so click **Edit**.

For more information about adding or editing patterns, see [Signature Rule Patterns](#).

10. Click **OK**.

Add a signature rule category

Putting signature rules into a category enables you to configure the actions for a group of signatures instead of for each individual signature. You might want to do so for the following reasons:

- **Ease of selection.** For example, assume that all of the signature rules in a particular group protect against attacks on a specific type of web server software or technology. If your protected

websites use that software or technology, you want to enable them all. If they do not, you do not want to enable any of them.

- **Ease of initial configuration.** It is easiest to set defaults for a group of signatures as a category, instead of one-by-one. You can then make any changes to the individual signatures as needed.
- **Ease of ongoing configuration.** It is easier to configure signatures if you can display only those that meet specific criteria, such as belonging to a specific category.

Add a signature rule category

November 3, 2023

Adding signature rules to a category enables you to configure the actions for a group of signatures instead of for each individual signature. You might want to do so for the following reasons:

- **Ease of selection.** For example, assume that all of signature rules in a particular group protect against attacks on a specific type of web server software or technology. If your protected websites use that software or technology, you want to enable them all. If they do not, you do not want to enable any of them.
- **Ease of initial configuration.** It is easiest to set defaults for a group of signatures as a category, instead of one-by-one. You can then make any changes to individual signatures as needed.
- **Ease of ongoing configuration.** It is easier to configure signatures if you can display only those that meet specific criteria, such as belonging to a specific category.

1. Navigate to **Security > Web App Firewall > Signatures**.
2. In the details pane, select that signatures object that you want to configure, and then click **Open**.
3. In the **Modify Signatures Object** dialog box, in the middle of the screen, beneath the **Filtered Results** window, click **Add**.
4. In the **Add Local Signature Rule** dialog box, click the icon to the right of the Category drop-down list.
5. In the **Add Signature Rule Category** dialog box, **New Category** text box, type a name for your new signature category. The name can consist of from one to 64 characters.
6. Click **OK**.

Add signature rule patterns

May 2, 2023

You can add a pattern or modify an existing pattern to specify a string or expression that characterizes an attack if the signature matches. To detect the patterns an attack exhibits, you can examine the logs on your web server. You can use a tool to observe connection data in real time, or obtain the string or expression from a third-party report about the attack.

Important

A new pattern that you add to a signature rule is in an AND relationship with the existing patterns. Do not add a pattern to an existing signature rule if you do not want a potential attack to have to match all patterns to match the signature.

Each pattern can consist of a simple string, a PCRE-format regular expression, or the built-in SQL injection or cross-site scripting pattern. Before you attempt to add a pattern that is based on a regular expression, you must make sure that you understand PCRE-format regular expressions. PCRE expressions are complex and powerful. If you do not understand how they work, you can unintentionally create a pattern that matches something that you did not want (a *false positive*) or that fails to match something that you did want (a *false negative*).

Custom signature pattern for non-default content types

The NetScaler Web App Firewall (WAF) now supports new location to inspect canonicalized content. By default, WAF does not block encoded payload with non-default content types. When these content types are whitelisted, and no configured action is applied, the SQL and cross-site scripting protection check do not filter SQL or cross-site scripting attacks in the encoded payloads. To resolve the issue, a user can create a custom signature rule with this new location (HTTP_CANON_POST_BODY) that examines the encoded payloads for non-default content-types and if there is any SQL or cross-site scripting attack, it blocks the traffic after canonicalization of the post body.

Note:

That support is applicable only for HTTP requests.

If you are not already familiar with PCRE-format regular expressions, you can use the following resources to learn the basics, or for help with some specific issue:

- “Mastering Regular Expressions,” Third Edition. Copyright (c) 2006 by Jeffrey Friedl. O’Reilly Media, ISBN: 9780596528126.
- “Regular Expressions Cookbook”. Copyright (c) 2009 by Jan Goyvaerts and Steven Levithan. O’Reilly Media, ISBN: 9780596520687
- [PCRE Man page/Specification](#)
- [PCRE Man Page/Specification](#)
- [Wikipedia PCRE entry](#)

- [PCRE Mailing List](#)

If you need to encode non-ASCII characters in a PCRE-format regular expression, the NetScaler platform supports the encoding of hexadecimal UTF-8 codes. For more information, see [PCRE Character Encoding Format](#).

Configure a signature rule pattern

When you are editing a signature, you can add or edit the rule pattern. To add or modify the signature rules, see [Edit signatures to add or modify rules](#).

- **Type** - Select the type of connection that the pattern is intended to match.
 - **Request** - It matches the request elements or features such as injected SQL code, attacks on web forms, cross-site scripts, or inappropriate URLs.
 - **Response** - It matches the response elements or features such as credit card numbers or safe objects.
- **Location** - Select an **Area** to examine with this pattern. The area describes what elements of the HTTP request or response to examine for this pattern. Based on the selected pattern type, the options appear in the **Area** list. depend upon the chosen pattern type.

For the **Request** pattern type, items relevant to HTTP requests appear.

- **HTTP_ANY**. All parts of the HTTP connection.
- **HTTP_COOKIE**. All cookies in the HTTP request headers after any cookie transformations are performed.

Note

Does not search HTTP response “Set-Cookie:”headers.

- **HTTP_FORM_FIELD**. Form fields and their contents, after URL decoding, percent decoding, and removal of excess whitespace. You can use the `<Location>` tag to further restrict the list of form field names to be searched.
- **HTTP_HEADER**. The value portions of the HTTP header after any cross-site scripting or URL decoding transformations.
- **HTTP_METHOD**. The HTTP request method.
- **HTTP_URL**. The value portion of the URL in the HTTP headers, excluding any query or fragment ports, after conversion to the UTF-* character set, URL decoding, stripping of whitespace, and conversion of relative URLs to absolute. Does not include HTML entity decoding.

- **HTTP_ORIGIN_URL.** The origin URL of a web form.
- **HTTP_POST_BODY.** The HTTP post body and the web form data that it contains.
- **HTTP_RAW_COOKIE.** All HTTP request cookie, including the “Cookie:”name portion.
Note: Does not search HTTP response “Set-Cookie:”headers.
- **HTTP_RAW_HEADER.** The entire HTTP header, with individual headers separated by line-feed characters (\n) or carriage return/line-feed strings (\r\n).

For the **Response** type, items relevant to HTTP responses appear.

- **HTTP_RAW_RESP_HEADER.** The entire response header, including the name and value parts of the response header after URL transformation has been done, and the complete response status. As with HTTP_RAW_HEADER, individual headers are separated by line-feed characters (\n) or carriage return/line-feed strings (\r\n).
- **HTTP_RAW_SET_COOKIE.** The entire Set-Cookie header after any URL transformations have been performed

Note

URL transformation can change both the domain and path parts of the Set-Cookie header.

- **HTTP_RAW_URL.** The entire request URL before any URL transformations is performed, including any query or fragment parts.
- **HTTP_RESP_HEADER.** The value part of the complete response headers after any URL transformations have been performed.
- **HTTP_RESP_BODY.** The HTTP response body
- **HTTP_SET_COOKIE.** All “Set-Cookie”headers in the HTTP response headers.
- **HTTP_STATUS_CODE.** The HTTP status code.
- **HTTP_STATUS_MESSAGE.** The HTTP status message.

When you select an option from the **Area** list, it dynamically changes options for the selected area.

- **Any.** Checks field names or URLs.
- **Literal.** Checks field names or URLs that contain a literal string. After you select Literal, a text box is displayed. Type the literal string that you want in the text box.
- **PCRE.** Checks field names or URLs that match a PCRE-format regular expression. After you select this choice, the regular expression window is displayed. Type the regular expression in the window. You can use the **Regex Tokens** to insert common regular expression elements at the cursor, or you can click Regex Editor to display the Regular Expression Editor

dialog box, which provides more assistance in constructing the regular expression that you want.

- **Expression.** Checks field names or URLs that match a NetScaler default expression.
- **Pattern** - A pattern is a literal string or PCRE-format regular expression that defines the pattern that you want to match. Select the **Match** type from the list.
 - **Literal.** A literal string.
 - **PCRE.** A PCRE-format regular expression.

Note

When you choose PCRE, the regular expression tools beneath the Pattern window are enabled. These tools are not useful for most other types of patterns.

- **Expression.** An expression in the NetScaler default expressions language is the same expression language for creating Web App Firewall policies on the NetScaler appliance. Although the NetScaler expressions language was originally developed for policy rules, it is a highly flexible general purpose language that can also be used to define a signature pattern.

When you choose Expression, the NetScaler Expression Editor appears beneath the Pattern window. For more information about the Expression Editor and instructions on how to use it, see [To add a firewall rule \(expression\) by using the Add Expression dialog box](#)

- **SQL Injection.** Directs the Web App Firewall to look for injected SQL in the specified location.
- **CrossSiteScripting.** Directs the Web App Firewall to look for cross-site scripts in the specified location.
- **CommandInjection.** Directs the NetScaler Web App Firewall to look for any injected malicious commands in the specified location.
- **SQLInjectionGrammar.** Directs the NetScaler Web App Firewall to look for injected SQL grammar in the specified location. Especially when commonly used words such as `Select` and `From` are used in an HTTP request.
- **CommandInjectionGrammar.** Directs the NetScaler Web App Firewall to look for injected malicious command grammar in the specified location. Especially, when a commonly used word such as “Exit” is used in an HTTP request.

If you want to configure more settings, specify the following:

- **Offset.** The number of characters to skip over before starting to match on this pattern. You use this field to start examining a string at some point other than the first character.

- **Depth.** How many characters from the starting point to examine for matches. You use this field to limit searches of a large string to a specific number of characters.
- **Min-Length.** The string to be searched must be at least the specified number of bytes in length. Shorter strings are not matched.
- **Max-Length.** The string to be searched must be no longer than the specified number of bytes in length. Longer strings are not matched.
- **Search method.** A check box labeled `fastmatch`. You can enable `fastmatch` only for a literal pattern, to improve performance.

Note

Until you click **OK** in the **Signature Rule Pattern** pane, your changes are not saved. Do not close either of these dialog boxes without clicking **OK** unless you want to discard your changes.

Import and merge rules

November 3, 2023

When using the signature editor to perform an import and merge operation from the GUI, you can now see the new, updated, duplicate, and invalid rules.

The signature editor displays the following four new rows:

1. New Rules
2. Updated Rules
3. Duplicate Rules
4. Invalid Rules

The output of the New Rules Only and Updated Rules Only filters also appears in the Category filter pane of the Edit window in signature editor.

You will need to import the files from GUI to see the corresponding links for New, duplicate, invalid and updated rules.

Procedure to import signature rules:

1. In the NetScaler web GUI, go to **Configuration > Security > NetScaler Web App Firewall Signatures**. In the Signatures window, click **Add**. Then select **File Format > Native, Import From > URL** and in the URL field, add the above link. If you are unable to access the URL, you can download the [XML data](#).
2. After you click **Open**, the signature file will open and you can see links for new rule and invalid rules.

3. If you import a `rd` party signature rule, you can see 90 new rules and 9 duplicate rules in the imported .xml file. If you are unable to access the URL, you can download the [XML data](#).

Signature updates in high availability deployment and build upgrades

September 21, 2020

The signature update occurs on the primary node. While the signatures are updated on the primary node, in parallel the updated files are simultaneously synchronized with the secondary node.

The Default signature is always updated first and then the rest of the user-defined signatures are updated.

Connecting to Amazon AWS

The default route NSIP is used to connect to the Amazon AWS. If there is a specific use case scenario where SNIP is used, and if there are multiple SNIPs, the first one to receive the ARP response from the hosting site will hold the route.

Signature updates during version upgrades

In case of an upgrade, if the NS has an older base version for the signatures, *Default signature is automatically updated if a newer signature version is available.

If the schema has changed, the schema version of all the signature objects gets updated when the version is upgraded.

However, for the base version of the user-defined signatures, the behavior is different in release 10.5 versus release 11.0.

In release 10.5, only the default signature was updated and the base version of the rest of the signatures remained unchanged after the build upgrade.

In release 11.0, this behavior has changed. When the appliance is upgraded to install a new build, not only the *Default signature object but all the other user-defined signatures that currently exist in the appliance are also updated and will have the same version after the build upgrade.

In both 10.5 and 11.0 release builds, if auto-update is configured, the *Default Signatures as well as all non-zero version signatures get auto-updated to the latest released signature version and will have the same base version.

Overview of security checks

September 28, 2023

The Web App Firewall advanced protections (security checks) are a set of filters designed to catch complex or unknown attacks on your protected websites and web services. The security checks use heuristics, positive security, and other techniques to detect attacks that may not be detected by signatures alone. You configure the security checks by creating and configuring a Web App Firewall profile, which is a collection of user-defined settings that tell the Web App Firewall which security checks to use and how to handle a request or response that fails a security check. A profile is associated with a signatures object and with a policy to create a security configuration.

The Web App Firewall provides twenty security checks, which differ widely in the types of attacks that they target and how complex they are to configure. The security checks are organized into the following categories:

- **Common security checks.** Checks that apply to any aspect of web security that either does not involve content or is equally applicable to all types of content.
- **HTML security checks.** Checks that examine HTML requests and responses. These checks apply to HTML-based websites and to the HTML portions of Web 2.0 sites, which contain mixed HTML and XML content.
- **XML security checks.** Checks that examine XML requests and responses. These checks apply to XML-based web services and to the XML portions of Web 2.0 sites.

The security checks protect against a wide range of types of attack, including attacks on operation system and web server software vulnerabilities, SQL database vulnerabilities, errors in the design and coding of websites and web services, and failures to secure sites that host or can access sensitive information.

All security checks have a set of configuration options, the check actions, which control how the Web App Firewall handles a connection that matches a check. Three check actions are available for all security checks. They are:

- **Block.** Block connections that match the signature. Disabled by default.
- **Log.** Log connections that match the signature, for later analysis. Enabled by default.
- **Stats.** Maintain statistics, for each signature, that show how many connections it matched and provide certain other information about the types of connections that were blocked. Disabled by default.

A fourth check action, **Learn**, is available for more than half of the check actions. It observes traffic to a protected website or web service and uses connections that repeatedly violate the security check to generate recommended exceptions (relaxations) to the check, or new rules for the check. In addition

to the check actions, certain security checks have parameters that control the rules that the check uses to determine which connections violate that check, or that configure the Web App Firewall's response to connections that violate the check. These parameters are different for each check, and they are described in the documentation for each check.

To configure security checks, you can use the Web App Firewall wizard, as described in [The Web App Firewall Wizard](#), or you can configure the security checks manually, as described in [Manual Configuration By Using the GUI](#). Some tasks, such as manually entering relaxations or rules or reviewing learned data, can be done only by using the GUI, not the command line. Using the wizard is usually best configuration method, but in some cases manual configuration might be easier if you are thoroughly familiar with it and simply want to adjust the configuration for a single security check.

Regardless of which method you use to configure the security checks, each security check requires that certain tasks be performed. Many checks require that you specify exceptions (relaxations) to prevent blocking of legitimate traffic before you enable blocking for that security check. You can do this manually, by observing the log entries after a certain amount of traffic has been filtered and then creating the necessary exceptions. However, it is usually much easier to enable the learning feature and let it observe the traffic and recommend the necessary exceptions.

Web App Firewall uses packet engines (PE) during processing the transactions. Each packet engine has a limit of 100K sessions which is sufficient for most deployment scenarios. However, when Web App Firewall is processing heavy traffic and the session timeout is configured at a higher value, the sessions might get accumulated. If the number of alive Web App Firewall sessions exceed the 100K per PE limit, the Web App Firewall security check violations might not be sent to the Security Insight appliance. Lowering the session timeout to a smaller value, or using sessionless mode for the security checks with sessionless URL closure or sessionless field consistency might help in preventing the sessions getting accumulated. If this is not a viable option in scenarios where transactions might require longer sessions, upgrading to a higher-end platform with more packet engine is recommended.

Support for cached AppFirewall is added, and the max session setting through the CLI per core is set to 50K sessions.

Request and response security checks

The following are the list of security checks:

Request checks

The following are the request security checks:

- Start URL
- Deny URL

- Cookie Consistency
- Cookie Hijacking
- Buffer Overflow
- Post Body Limit
- Content-type
- Infer Content Type XML Payload
- File Upload Types
- Form Field Consistency
- Field Formats
- CSRF Form Tagging
- HTML Cross-Site Scripting
- HTML SQL Injection
- HTML Command Injection
- Block Keyword - XML
- XML Format
- XML Denial of Service
- XML Cross-Site Scripting
- XML SQL Injection
- XML Attachement
- XML Message Validation
- JSON Denial of Service
- JSON Cross-Site Scripting
- JSON SQL Injection
- JSON Command Injection
- Block Keyword - JSON

Response checks

The following are the response security checks:

- Credit Card
- Safe Object
- XML SOAP Fault Filtering
- Some of Web Service Interoperability

Top level protections

May 2, 2023

Four of the Web App Firewall protections are especially effective against common types of Web attacks, and are therefore more commonly used than any of the others. They are:

- **HTML Cross-Site Scripting.** Examines requests and responses for scripts that attempt to access or modify content on a different website than the one on which the script is located. When this check finds such a script, it either renders the script harmless before forwarding the request or response to its destination, or it blocks the connection.
- **HTML SQL Injection.** Examines requests that contain form field data for attempts to inject SQL commands into an SQL database. When this check detects injected SQL code, it either blocks the request or renders the injected SQL code harmless before forwarding the request to the Web server.

Note: If both of the following conditions apply to your configuration, you must make certain that your Web App Firewall is correctly configured:

- If you enable the HTML Cross-Site Scripting check or the HTML SQL Injection check (or both), and
- Your protected websites accept file uploads or contain Web forms that can contain large POST body data.

For more information about configuring the Web App Firewall to handle this case, see [Configuring the Application Firewall](#).

- **Buffer Overflow.** Examines requests to detect attempts to cause a buffer overflow on the Web server.
- **Cookie Consistency.** Examines cookies returned with user requests to verify that they match the cookies your Web server set for that user. If a modified cookie is found, it is stripped from the request before the request is forwarded to the Web server.

The Buffer Overflow check is simple; you can usually enable blocking for it immediately. The other three top-level checks are considerably more complex and require configuration before you can safely use them to block traffic. NetScaler strongly recommends that, rather than attempting to configure these checks manually, you enable the learning feature and allow it to generate the necessary exceptions.

HTML cross-site scripting check

May 9, 2023

The HTML Cross-Site Scripting (cross-site scripting) check examines both the headers and the POST bodies of user requests for possible cross-site scripting attacks. If it finds a cross-site script, it either

modifies (*transforms*) the request to render the attack harmless, or blocks the request.

Note:

The HTML Cross-Site Scripting (cross-site scripting) check works only for content type, content length, and so forth. Also ensure to have the 'checkRequestHeaders' option enabled in your Web Application Firewall profile.

You can prevent misuse of the scripts on your protected websites by using the HTML Cross-Site Scripting scripts that violate the *same origin rule*, which states that scripts must not access or modify content on any server but the server on which they are located. Any script that violates the same origin rule is called a cross-site script, and the practice of using scripts to access or modify content on another server is called cross-site scripting. The reason cross-site scripting is a security issue is that a web server that allows cross-site scripting can be attacked with a script that is not on that web server, but on a different web server, such as one owned and controlled by the attacker.

Unfortunately, many companies have a large installed base of JavaScript-enhanced web content that violates the same origin rule. If you enable the HTML Cross-Site Scripting check on such a site, you have to generate the appropriate exceptions so that the check does not block legitimate activity.

The Web App Firewall offers various action options for implementing HTML Cross-Site Scripting protection. In addition to the **Block**, **Log**, **Stats** and **Learn** actions, you also have the option to **Transform cross-site scripts** to render an attack harmless by the entity encoding the script tags in the submitted request. You can configure Check complete URLs for cross-site scripting parameter to specify if you want to inspect not just the query parameters but the entire URL to detect cross-site scripting attack. You can configure the **InspectQueryContentTypes** parameter to inspect the request query portion for the cross-site scripting attack for the specific content-types.

You can deploy relaxations to avoid false positives. The Web App Firewall learning engine can provide recommendations for configuring relaxation rules.

To configure an optimized HTML Cross-Site Scripting protection for your application, configure one of the actions:

- **Block**—If you enable block, the block action is triggered if the cross-site scripting tags are detected in the request.
- **Log**—If you enable the log feature, the HTML Cross-Site Scripting check generates log messages indicating the actions that it takes. If block is disabled, a separate log message is generated for each header or form field in which the cross-site scripting violation was detected. However, only one message is generated when the request is blocked. Similarly, 1 log message per request is generated for the transform operation, even when cross-site scripting tags are transformed in multiple fields. You can monitor the logs to determine whether responses to legitimate requests are getting blocked. A large increase in the number of log messages can indicate attempts to launch an attack.

- **Stats**—If enabled, the stats feature gathers statistics about violations and logs. An unexpected surge in the stats counter might indicate that your application is under attack. If legitimate requests are getting blocked, you might have to revisit the configuration to see if you must configure the new relaxation rules or modify the existing ones.
- **Learn**—If you are not sure which relaxation rules might be ideally suited for your application, you can use the learn feature to generate HTML Cross-Site Scripting rule recommendations based on the learned data. The Web App Firewall learning engine monitors the traffic and provides learning recommendations based on the observed values. To get optimal benefit without compromising performance, you might want to enable the learn option for a short time to get a representative sample of the rules, and then deploy the rules and disable learning.
- **Transform cross-site scripts**—If enabled, the Web App Firewall makes the following changes to requests that match the HTML Cross-Site Scripting check:
 - Left angle bracket (<) to HTML character entity equivalent (<)
 - Right angle bracket (>) to HTML character entity equivalent (>)

This ensures that browsers do not interpret unsafe html tags, such as `<script>`, and thereby run malicious code. If you enable both request-header checking and transformation, any special characters found in request headers are also modified. If the scripts on your protected website contain cross-site scripting features, but your website does not rely upon those scripts to operate correctly, you can safely disable blocking and enable transformation. This configuration ensures that no legitimate web traffic is blocked, while stopping any potential cross-site scripting attacks.

- **Check complete URLs for cross-site scripting.** If checking of complete URLs is enabled, the Web App Firewall examines entire URLs for HTML cross-site scripting attacks instead of checking just the query portions of URLs.
- **Check Request headers.** If Request header checking is enabled, the Web App Firewall examines the headers of requests for HTML cross-site scripting attacks, instead of just URLs. If you use the GUI, you can enable this parameter in the Settings tab of the Web App Firewall profile.
- **InspectQueryContentTypes.** If Request query inspection is configured, the App Firewall examines the query of requests for cross-site scripting attacks for the specific content-types. If you use the GUI, you can configure this parameter in the Settings tab of the App Firewall profile.

Important:

As part of the streaming changes, the Web App Firewall processing of the cross-site scripting tags has changed. This change is applicable to 11.0 builds onwards. This change is also pertinent for the enhancement builds of 10.5.e that support request side streaming. In earlier releases, the presence of either open bracket (<), or close bracket (>), or both open and close brackets (<>) was flagged as cross-site scripting Violation. The behavior has changed in the builds that include support for request side streaming. Only the close bracket character (>) is no longer considered as an attack. Requests are blocked even when an open bracket character (<) is present, and is

considered as an attack. The Cross-site scripting attack gets flagged.

Cross-site scripting Fine grained Relaxations

The Web App Firewall gives you an option to exempt a specific form field, header, or Cookie from the cross-site scripting inspection check. You can completely bypass the inspection for one or more of these fields by configuring the relaxation rules.

The Web App Firewall allows you to implement tighter security by fine-tuning the relaxation rules. An application might require the flexibility to allow specific patterns, but configuring a relaxation rule to bypass the security inspection might make the application vulnerable to attacks, because the target field is exempted from inspection for any cross-site scripting attack patterns. Cross-site scripting fine grained relaxation provides the option to allow specific attributes, tags, and patterns. The rest of the attributes, tags, and patterns are blocked. For example, the Web App Firewall currently has a default set of more than 125 denied patterns. Because hackers can use these patterns in Cross-site script attacks, the Web App Firewall flags them as potential threats. You can relax one or more patterns that are considered safe for the specific location. The rest of the potentially dangerous cross-site scripting patterns are still checked for the target location and continue to trigger the security check violations. You now have much tighter control.

The commands used in relaxations have optional parameters for **Value Type** and **Value Expression**. The value type can be left blank or you have an option to select **Tag** or **Attribute** or **Pattern**. If you leave the value type blank, the configured field of the specified URL is exempted from the Cross-Site Scripting check inspection. If you select a value type, you must provide a value expression. You can specify whether the value expression is a regular expression or a literal string. When the input is matched against the allowed and denied list, only the specified expressions configured in the relaxation rules are exempted.

The Web App Firewall has the following cross-site scripting built-in lists:

1. **cross-site scripting Allowed Attributes:** There are 52 defaults allowed attributes, such as, **abbr, accesskey, align, alt, axis, bgcolor, border, cell padding, cell spacing, char, charoff, charset** and so forth
2. **cross-site scripting Allowed Tags:** There are 47 defaults allowed tags, such as, **address, basefont, bgsound, big, blockquote, bg, br, caption, center, cite, dd, del** and so forth
3. **cross-site scripting Denied Patterns:** There are 129 defaults denied patterns, such as, **FSCommand, javascript:, onAbort, onActivate** and so forth

Warning

Web App Firewall action URLs are regular expressions. When configuring HTML cross-site scripting relaxation rules, you can specify **Name**, and **Value Expression** to be literal or RegEx. Regular

expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the rule that you want to add as an exception, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (.) metacharacter or the wildcard combination, can have results that you do not want, such as blocking access to web content that you did not intend to block or allowing an attack that the HTML Cross-Site Scripting check would otherwise have blocked.

Points to Consider:

- Value expression is an optional argument. A field name might not have any value expression.
- A field name can be bound to multiple value expressions.
- Value expressions must be assigned a value type. The cross-site scripting value type can be: 1) Tag, 2) Attribute, or 3) Pattern.
- You can have multiple relaxation rules per field name/URL combination
- The form field names and the action URLs are not case sensitive.

Using the Command Line to Configure the HTML Cross-Site Scripting check

To configure HTML Cross-Site Scripting check actions and other parameters by using the command line

If you use the command-line interface, you can enter the following commands to configure the HTML Cross-Site Scripting Check:

- `set appfw profile` topic.
- `<name> -crossSiteScriptingAction ([[block] [learn] [log] [stats]] | [**none**])`
- `[set appfw profile` topic.
- `<name> **-crossSiteScriptingTransformUnsafeHTML** (ON | OFF)`
- `set appfw profile` topic.
- `<name> -crossSiteScriptingCheckCompleteURLs (ON | OFF)`
- `set appfw profile` topic.
- `' - checkRequestHeaders (ON | OFF)`
- `<name> - CheckRequestQueryNonHtml \ (ON | OFF)`

To configure an HTML Cross-Site Scripting check relaxation rule by using the command line

Use the `bind` or `unbind` command to add or delete binding, as follows:

- `bind appfw profile <name> -crossSiteScripting <String> \[isRegex \ (REGEX | NOTREGEX)] <formActionURL> \[-location <location>] \[-valueType \ (Tag|Attribute|Pattern)\[<valueExpression>] \[-isValueRegex \ (REGEX | NOTREGEX)]]`

- `unbind appfw profile <name> -crossSiteScripting <String> <formActionURL> \[-location <location>] \[-valueType \((Tag |Attribute|Pattern) \[<valueExpression>])]`

Using the GUI to configure the HTML cross-site scripting check

In the GUI, you can configure the HTML Cross-Site Scripting check in the pane for the profile associated with your application.

To configure or modify the HTML Cross-Site Scripting check by using the GUI

1. Navigate to **Application Firewall > Profiles**, highlight the target profile, and click **Edit**.
2. In the **Advanced Settings** pane, click **Security Checks**.

The security check table displays the currently configured action settings for all the security checks. You have 2 options for configuration:

- a. If you want to enable or disable **Block**, **Log**, **Stats**, and **Learn** actions for the HTML Cross-Site Scripting, you can select or clear check boxes in the table, click **OK**, and then click **Save and Close** to close the **Security Check** pane.
- b. If you want to configure more options for this security check, double-click **HTML Cross-Site Scripting**, or select the row and click **Action Settings**, to display the following options:

Transform cross-site scripts—Transform unsafe script tags.

Check complete URLs for Cross-site scripting—Instead of checking just the query part of the URL, check the complete URL for cross-site script violations.

After changing any of the above settings, click **OK** to save the changes and return to the Security Checks table. You can proceed to configure other security checks if needed. Click **OK** to save all the changes you have made in the **Security Checks** section, and then click **Save and Close** to close the **Security Check** pane.

To enable or disable the **Check request Header** setting, in the **Advanced Settings** pane, click **Profile Settings**. In **Common Settings**, Select or clear the **Check Request Headers** check box. Click **OK**. You can either use the **X** icon at the top right hand side of the **Profile Settings** pane to close this section or, if you have finished configuring this profile, you can click **Done** to return to the **Application Firewall > Profile**.

To enable or disable the **Check request Query Non HTML** setting, in the **Advanced Settings** pane, click **Profile Settings**. In **Common Settings**, Select or clear the **Check request Query Non HTML** check box. Click **OK**. You can either use the **X** icon at the top right hand side of the **Profile Settings** pane to close this section or, if you have finished configuring this profile, you can click **Done** to return to the **App Firewall > Profile**.

To configure an HTML Cross-Site Scripting relaxation rule by using the GUI

1. Navigate to **Application Firewall > Profiles**, highlight the target profile, and click **Edit**.
2. In the **Advanced Settings** pane, click **Relaxation Rules**.
3. In the Relaxation Rules table, double-click the **HTML Cross-Site Scripting** entry, or select it and click **Edit**.
4. In the **HTML Cross-Site Scripting Relaxation Rules** dialogue box, perform **Add**, **Edit**, **Delete**, **Enable**, or **Disable** operations for relaxation rules.

Note

When you add a new rule, the **Value Expression** field is not displayed unless you select **Tag** or **Attribute** or **Pattern** option in the **Value Type** Field.

To manage HTML Cross-Site Scripting relaxation rules by using the visualizer

For a consolidated view of all the relaxation rules, you can highlight the **HTML Cross-Site Scripting** row in the Relaxation Rules table, and click **Visualizer**. The visualizer for deployed relaxations offers you the option to **Add** a new rule or **Edit** an existing one. You can also **Enable** or **Disable** a group of rules by selecting a node and clicking the corresponding buttons in the relaxation visualizer.

To view or customize the Cross-Site Scripting patterns by using the GUI

You can use the GUI to view or customize the default list of cross-site scripting allowed attributes or allowed tags. You can also view or customize the default list of cross-site scripting denied Patterns.

The default lists are specified in **Application Firewall > Signatures > Default Signatures**. If you do not bind any signature object to your profile, the default cross-site scripting allowed and denied list specified in the Default Signatures object will be used by the profile for the Cross-Site Scripting security check processing. The Tags, Attributes, and Patterns, specified in the default signatures object, are read-only. You cannot edit or modify them. If you want to modify or change these, make a copy of the Default Signatures object to create a User-Defined signature object. Make changes in the allowed or denied lists in the new User-defined signature object and use this signature object in your profile that is processing the traffic for which you want to use these customized allowed and denied lists.

1. To view default cross-site scripting patterns:
 - a. Navigate to **Application Firewall > Signatures**, select **Default Signatures**, and click **Edit**. Then click **Manage SQL/cross-site scripting Patterns**.

The **Manage SQL/cross-site scripting Paths** table shows the following three rows pertaining to cross-site scripting:

`xss/allowed/attribute`

`xss/allowed/tag`

`xss/denied/pattern`

b. Select a row and click **Manage Elements** to display the corresponding cross-site scripting Elements (Tag, Attribute, Pattern) used by the Web App Firewall **Cross-Site Scripting** check.

1. **To customize cross-site scripting Elements:** You can edit the User-Defined signature object to customize the allowed Tag, allowed Attributes, and denied Patterns. You can add new entries or remove the existing ones.

a. Navigate to **Application Firewall > Signatures**, highlight the target User-defined signature, and click **Edit**. Click **Manage SQL/cross-site scripting Patterns** to display the **Manage SQL/cross-site scripting paths** table.

b. Select the target cross-site scripting row.

i. Click **Manage Elements**, to **Add**, **Edit** or **Remove** the corresponding cross-site scripting element.

ii. Click **Remove** to remove the selected row.

Warning:

You must be careful before you remove or modify any default cross-site scripting element, or delete the cross-site scripting path to remove the entire row. The signature rules and the Cross-Site Scripting security check rely on these elements for detecting attacks to protect your applications. Customizing the cross-site scripting Elements can make your application vulnerable to Cross-Site Scripting attacks if the required pattern is removed during editing.

Learn HTML Cross-Site Scripting (cross-site scripting) violations

With learning enabled, the NetScaler Web App Firewall learning engine monitors the traffic and learns the cross-site scripting URL violations. You can periodically inspect cross-site scripting URL rules and deploy it for false positive scenarios.

Note:

In a cluster configuration, all nodes must be of the same version to deploy the cross-site scripting URL rules.

As part of the learning configuration, the Web App Firewall offers fine grained HTML Cross-Site Scripting learning. The learning engine makes recommendations regarding the observed Value Type (Tag, Attribute, Pattern) and the corresponding Value expression observed in the input fields. In addition to checking the blocked requests to determine whether the current rule is too restrictive and needs to be relaxed, you can review the rules generated by the learning engine to determine which value type and value expressions are triggering violations and need to be addressed in the relaxation rules.

Note:

The Web App Firewall's learning engine can distinguish only the first 128 bytes of the name. If a form has multiple fields with names that match for the first 128 bytes, the learning engine might not be able to distinguish between them. Similarly, the deployed relaxation rule might inadvertently relax all such fields from HTML Cross-Site Scripting inspection.

Tip:

Cross-site scripting tags which are longer than 12 characters are not learned or logged correctly. If you need a larger tag length for learning, you can add a large non-appearing tag in the **AS_cross-site scripting_ALLOWED_TAGS_LIST** for length 'x'.

The HTML Cross-Site Scripting learning process reduces false positives in cross-site scripting attacks. With learning enabled, you can learn all violations in a request and potentially apply relaxation to multiple tags, attributes, or patterns without the need of repetition.

For example, if there are 15 custom tags in a payload each resulting in a violation, you can apply the fine grain relaxation for all tags that are flagged as a violation, instead of repeating the process to apply relaxation for one tag at a time.

Scenario 1: Learning enabled, and block enabled:

In this scenario, the NetScaler appliance learns all the violations in custom tags/attributes/patterns, and the request is blocked and each violation is logged. The behavior is consistent for violations identified in form field, header, or cookie.

Scenario 2: Learning enabled and block disabled:

In this scenario, the NetScaler appliance learns the violations in custom tags/attributes/patterns and each of the violations is logged. The request is not blocked. The behavior is consistent for violations identified in form field, header, or cookie.

To view or use learned data by using the command line interface

At the command prompt, type one of the following commands:

- `show appfw learningdata <profilename> crossSiteScripting`
- `rm appfw learningdata <profilename> -crossSiteScripting <string> <formActionURL> \[<location>] \[<valueType> <valueExpression>]`
- `export appfw learningdata <profilename> **crossSiteScripting*`

Configure cross-site scripting fine grain relaxation to bypass custom tags

You can configure cross-site scripting relaxation in the web app firewall profile to bypass custom tags/attributes/patterns not present in the allow list.

At the command prompt, type:

```
bind appfw profile p1 -crossSiteScripting <string> <formActionURL> -
valueType <valueType> <value expression>
```

Example:

```
bind appfw profile profile1 -crossSiteScripting formfield1 http://
1.1.1.1 -valueType Tag tag1
```

To view or use learned data by using the GUI

1. Navigate to **Application Firewall > Profiles**, highlight the target profile, and click **Edit**.
2. In the **Advanced Settings** pane, click **Learned Rules**. You can select the **HTML Cross-Site Scripting** entry in the Learned Rules table and double-click it to access the learned rules. The table displays the **Field Name**, **Action URL**, **Value Type**, **Value**, and **Hits** columns. You can deploy the learned rules or edit a rule before deploying it as a relaxation rule. To discard a rule, you can select it and click the **Skip** button. You can edit only one rule at a time, but you can select multiple rules to deploy or skip.

You also have the option to show a summarized view of the learned relaxations by selecting the **HTML Cross-Site Scripting** entry in the Learned Rules table and clicking **Visualizer** to get a consolidated view of all the learned violations. The visualizer makes it easy to manage the learned rules. It presents a comprehensive view of the data on one screen and facilitates taking action on a group of rules with one click. The biggest advantage of the visualizer is that it recommends regular expressions to consolidate multiple rules. You can select a subset of these rules, based on the delimiter and Action URL. You can display 25, 50, or 75 rules in the visualizer, by selecting the number from a drop-down list. The visualizer for learned rules offers the option to edit the rules and deploy them as relaxations. Or you can skip the rules to ignore them.

Using the log feature with the HTML Cross-Site Scripting check

When the log action is enabled, the HTML Cross-Site Scripting security check violations are logged in the audit log as **APPFW_cross-site scripting** violations. The Web App Firewall supports both Native and CEF log formats. You can also send the logs to a remote syslog server.

To access the log messages by using the command line

Switch to the shell and tail the ns.logs in the `/var/log/` folder to access the log messages pertaining to the HTML Cross-Site Scripting violations:

```
Shell
tail -f /var/log/ns.log | grep APPFW\\_cross-site scripting
```

Example of a Cross-Site Scripting security check violation log message in CEF log format:

```

1 Jul 11 00:45:51 <local0.info> 10.217.31.98 CEF:0|Citrix|NetScaler|NS11

```

Access the log messages by using the GUI

The GUI includes a useful tool (Syslog Viewer) for analyzing the log messages. You have multiple options for accessing the Syslog Viewer:

- Navigate to the **Application Firewall > Profiles**, select the target profile, and click **Security Checks**. Highlight the **HTML Cross-Site Scripting** row and click **Logs**. When you access the logs directly from the HTML Cross-Site Scripting check of the profile, the GUI filters out the log messages and displays only the logs pertaining to these security check violations.
- You can also access the Syslog Viewer by navigating to **NetScaler > System > Auditing**. In the **Audit Messages** section, click the **Syslog messages** link to display the Syslog Viewer, which displays all log messages, including other security check violation logs. This is useful for debugging when multiple security check violations might be triggered during request processing.
- Navigate to **Application Firewall > policies > Auditing**. In the Audit Messages section, click the **Syslog messages** link to display the Syslog Viewer, which displays all log messages, including other security check violation logs.

The HTML based Syslog Viewer provides various filter options for selecting only the log messages that are of interest to you. To select log messages for the **HTML Cross-Site Scripting** check, filter by selecting **APPFW** in the drop-down list options for **Module**. The **Event Type** list offers a rich set of options to further refine your selection. For example, if you select the **APPFW_cross-site scripting** check box and click the **Apply** button, only log messages pertaining to the **HTML Cross-Site Scripting security** check violations appear in the Syslog Viewer.

If you place the cursor in the row for a specific log message, multiple options, such as **Module**, **Event Type**, **Event ID**, **Client IP** and so forth appear below the log message. You can select any of these options to highlight the corresponding information in the log message.

Click to Deploy functionality is available only in the GUI. You can use the Syslog Viewer to not only view the logs but also to deploy the HTML Cross-Site Scripting relaxation rules based on the log messages for the Web App Firewall security check violations. The log messages must be in CEF log format for this operation. Click to deploy functionality is available only for log messages that are generated by the block (or not block) action. You cannot deploy a relaxation rule for a log message about the transform operation.

To deploy a relaxation rule from the Syslog Viewer, select the log message. A check box appears in the upper right corner of the **Syslog Viewer** box of the selected row. Select the check box, and then select an option from the **Action** list to deploy the relaxation rule. **Edit & Deploy**, **Deploy**, and **Deploy All** are available as **Action** options.

The HTML Cross-Site Scripting rules that are deployed by using the **Click to Deploy** option do not include the fine grain relaxation recommendations.

Configure click to deploy feature by using the GUI

1. In the Syslog Viewer, select **APPFW** in the **Module** options.
2. Select the **APP_cross-site scripting** as the **Event Type** to filter corresponding log messages.
3. Select the check box to identify the rule to deploy.
4. Use the **Action** drop-down list of options to deploy the relaxation rule.
5. Verify that the rule appears in the corresponding relaxation rule section.

Statistics for the HTML Cross-Site Scripting violations

When the stats action is enabled, the counter for the HTML Cross-Site Scripting check is incremented when the Web App Firewall takes any action for this security check. The statistics are collected for Rate and Total count for Traffic, Violations, and Logs. The size of an increment of the log counter can vary depending on the configured settings. For example, if the block action is enabled, the request for a page that contains 3 HTML Cross-Site Scripting violations increments the stats counter by one, because the page is blocked when the first violation is detected. However, if the block is disabled, processing the same request increments the statistics counter for violations and the logs by three, because each violation generates a separate log message.

To display HTML Cross-Site Scripting check statistics by using the command line

At the command prompt, type:

```
> sh appfw stats
```

To display stats for a specific profile, use the following command:

```
> \*\*stat appfw profile\*\* <profile name>
```

Display HTML Cross-Site Scripting statistics by using the GUI

1. Navigate to **Security > Application Firewall > Profiles > Statistics**.
2. In the right pane, access the **Statistics** Link.
3. Use the scroll bar to view the statistics about HTML Cross-Site Scripting violations and logs. The statistics table provides real-time data and is updated every 7 seconds.

Highlights

- **Built-in Support for HTML Cross-Site Scripting attack Protection**—The NetScaler Web App Firewall protects against Cross-Site Scripting attacks by monitoring a combination of allowed attributes and tags, and denied patterns in the received payload. All the built-in default allowed tags, allowed attributes and denied patterns used by the cross-site scripting check are specified in the `/netscaler/default_custom_settings.xml` file.
- **Customization**—You can change the default list of tags, attributes, and patterns to customize the Cross-Site Scripting security check inspection for the specific needs of your application. Make a copy of the default signature object, modify existing entries, or add new ones. Bind this signature object to your profile to make use of the customized configuration.
- **Hybrid Security Model**—Both signatures and deep security protections use the SQL/cross-site scripting patterns specified in the signature object that is bound to the profile. If no signature object is bound to the profile, the SQL/cross-site scripting patterns present in the default signature object are used.
- **Transform**—Note the following about the transform operation:

The transform operation works independently of the other Cross-Site Scripting action settings. If transform is enabled and block, log, stats, and learn are all disabled, cross-site scripting tags are transformed.

If the block action is enabled, it takes precedence over the transform action.

- **Fine Grained Relaxation and Learning**. Fine-tune the relaxation rule to relax a subset of cross-site scripting elements from security check inspection but detect the rest. The learning engine recommends a specific value type and value expressions based on the observed data.
- **Click to Deploy**—Select one, or multiple cross-site scripting violation log messages in the syslog viewer and deploy them as relaxation rules.
- **Charset**—The default charset for the profile must be set based on the need of the application. By default, the profile charset is set to English US (ISO-8859-1). If a request is received without

the specified charset, the Web App Firewall processes the request as if it is ISO-8859-1. The open bracket character (<) or the close bracket character (>) will not get interpreted as cross-site scripting tags if these characters are encoded in other charsets. For example, if a request contains a UTF-8 character string “%uff1cscript%uff1e” but the charset is not specified on the request page, the cross-site scripting violation might not get triggered unless the default charset for the profile is specified as Unicode.

HTML SQL injection check

February 9, 2024

Many web applications have web forms that use SQL to communicate with relational database servers. Malicious code or a hacker can use an insecure web form to send SQL commands to the web server. The Web App Firewall HTML SQL Injection check provides special defenses against injection of unauthorized SQL code that might break security. If the Web App Firewall detects unauthorized SQL code in a user request, it either transforms the request, to render the SQL code inactive, or blocks the request. The Web App Firewall examines the request payload for injected SQL code in three locations: 1) POST body, 2) headers, and 3) cookies. To examine a query portion in requests for injected SQL code, please configure an application firewall profile setting ‘InspectQueryContentTypes’ for the specific content-types.

A default set of keywords and special characters provides known keywords and special characters that are commonly used to launch SQL attacks. You can add new patterns, and you can edit the default set to customize the SQL check inspection. The Web App Firewall offers various action options for implementing SQL Injection protection. In addition to the **Block, Log, Stats** and **Learn** actions, the Web App Firewall profile also offers the option to **transform SQL special characters** to render an attack harmless.

In addition to actions, there are several parameters that can be configured for SQL injection processing. You can check for **SQL wildcard characters**. You can change the SQL Injection type and select one of the 4 options (**SQLKeyword, SQLSplChar, SQLSplCharANDKeyword, SQLSplCharORKeyword**) to indicate how to evaluate the SQL keywords and SQL special characters when processing the payload. The **SQL Comments Handling parameter** gives you an option to specify the type of comments that need to be inspected or exempted during SQL Injection detection.

You can deploy relaxations to avoid false positives. The Web App Firewall learning engine can provide recommendations for configuring relaxation rules.

The following options are available for configuring an optimized SQL Injection protection for your application:

Block—The block action is triggered only if the input matches the SQL injection type specification. For example, if **SQLSplCharANDKeyword** is configured as the SQL injection type, a request is not blocked if it contains no key words, even if SQL special characters are detected in the input. Such a request is blocked if the SQL injection type is set to either **SQLSplChar**, or **SQLSplCharORKeyword**.

Log—If you enable the log feature, the SQL Injection check generates log messages indicating the actions that it takes. If the block action is disabled, a separate log message is generated for each input field in which the SQL violation was detected. However, only one message is generated when the request is blocked. Similarly, one log message per request is generated for the transform operation, even when SQL special characters are transformed in multiple fields. You can monitor the logs to determine whether responses to legitimate requests are getting blocked. A large increase in the number of log messages can indicate attempts to launch an attack.

Stats—If enabled, the stats feature gathers statistics about violations and logs. An unexpected surge in the stats counter might indicate that your application is under attack. If legitimate requests are getting blocked, you might have to revisit the configuration to see if you need to configure new relaxation rules or modify the existing ones.

Learn—If you are not sure which SQL relaxation rules might be ideally suited for your application, you can use the learn feature to generate recommendations based on the learned data. The Web App Firewall learning engine monitors the traffic and provides SQL learning recommendations based on the observed values. To get optimal benefit without compromising performance, you might want to enable the learn option for a short time to get a representative sample of the rules, and then deploy the rules and disable learning.

Transform SQL special characters—The Web App Firewall considers three characters, Single straight quote (‘), Backslash (\), and Semicolon (;) as special characters for SQL security check processing. The SQL Transformation feature modifies the SQL Injection code in an HTML request to ensure that the request is rendered harmless. The modified HTML request is then sent to the server. All default transformation rules are specified in the /netscaler/default_custom_settings.xml file.

The transform operation renders the SQL code inactive by making the following changes to the request:

- Single straight quote (‘) to double straight quote (“).
- Backslash (\) to double backslash (\\).
- Semicolon (;) is dropped completely.

These three characters (special strings) are necessary to issue commands to an SQL server. Unless an SQL command is prefaced with a special string, most SQL servers ignore that command. Therefore, the changes that the Web App Firewall performs when transformation is enabled prevent an attacker from injecting active SQL. After these changes are made, the request can safely be forwarded to your protected website. When web forms on your protected website can legitimately contain SQL special strings, but the web forms do not rely on the special strings to operate correctly, you can disable block-

ing and enable transformation to prevent blocking of legitimate web form data without reducing the protection that the Web App Firewall provides to your protected websites.

The transform operation works independently of the **SQL Injection Type** setting. If transform is enabled and the SQL Injection type is specified as the SQL keyword, SQL special characters are transformed even if the request does not contain any keywords.

Tip

You normally enable either transformation or blocking, but not both. If the block action is enabled, it takes precedence over the transform action. If you have blocking enabled, enabling transformation is redundant.

Check for SQL Wildcard Characters—Wild card characters can be used to broaden the selections of a SQL (SQL-SELECT) statement. These wild card operators can be used with **LIKE** and **NOT LIKE** operators to compare a value to similar values. The percent (%), and underscore (_) characters are frequently used as wild cards. The percent sign is analogous to the asterisk (*) wildcard character used with MS-DOS and to match zero, one, or multiple characters in a field. The underscore is similar to the MS-DOS question mark (?) wildcard character. It matches a single number or character in an expression.

For example, you can use the following query to do a string search to find all customers whose names contain the D character.

SELECT * from customer WHERE name like “%D%”:

The following example combines the operators to find any salary values that have 0 in the second and third place.

SELECT * from customer WHERE salary like ‘_00%’:

Different DBMS vendors have extended the wildcard characters by adding extra operators. The NetScaler Web App Firewall can protect against attacks that are launched by injecting these wildcard characters. The 5 default Wildcard characters are percent (%), underscore (_), caret (^), opening bracket ([), and closing bracket (]). This protection applies to both HTML and XML profiles.

The default wildcard chars are a list of literals specified in the ***Default Signatures**:

- `<wildchar type="LITERAL">%</wildchar>`
- `<wildchar type="LITERAL">_</wildchar>`
- `<wildchar type="LITERAL">^</wildchar>`
- `<wildchar type="LITERAL">[</wildchar>`
- `<wildchar type="LITERAL">]</wildchar>`

Wildcard characters in an attack can be PCRE, like [^A-F]. The Web App Firewall also supports PCRE wildcards, but the literal wildcard chars above are sufficient to block most attacks.

Note:

The SQL wildcard character check is different from the SQL special character check. This option must be used with caution to avoid false positives.

Check Request Containing SQL Injection Type—The Web App Firewall provides 4 options to implement the desired level of strictness for SQL Injection inspection, based on the individual need of the application. The request is checked against the injection type specification for detecting SQL violations. The 4 SQL injection type options are:

- **SQL Special Character and Keyword**—Both an SQL keyword and an SQL special character must be present in the input to trigger SQL violation. This least restrictive setting is also the default setting.
- **SQL Special Character**—At least one of the special characters must be present in the input to trigger SQL violation.
- **SQL key word**—At least one of the specified SQL keywords must be present in the input to trigger an SQL violation. Do not select this option without due consideration. To avoid false positives, make sure that none of the keywords are expected in the inputs.
- **SQL Special Character or Keyword**—Either the key word or the special character string must be present in the input to trigger the security check violation.

Tip:

If you configure the Web App Firewall to check for inputs that contain an SQL special character, the Web App Firewall skips web form fields that do not contain any special characters. Since most SQL servers do not process SQL commands that are not preceded by a special character, enabling this option can significantly reduce the load on the Web App Firewall and speed up processing without placing your protected websites at risk.

SQL comments handling—By default, the Web App Firewall checks all SQL comments for injected SQL commands. Many SQL servers ignore anything in a comment, however, even if preceded by an SQL special character. For faster processing, if your SQL server ignores comments, you can configure the Web App Firewall to skip comments when examining requests for injected SQL. The SQL comments handling options are:

- **ANSI**—Skip ANSI-format SQL comments, which are normally used by UNIX-based SQL databases. For example:
 - `--` (Two Hyphens) - This is a comment that begins with two hyphens and ends with end of line.
 - `{ }` - Braces (Braces enclose the comment. The `{` precedes the comment, and the `}` follows it. Braces can delimit single- or multiple-line comments, but comments cannot be nested)

- `/**/`: C style comments (Does not allow nested comments). Please note `/*!` <comment that begin with slash followed by asterisk and exclamation mark is not a comment > `*/`
 - MySQL Server supports some variants of C-style comments. These enable you to write code that includes MySQL extensions, but is still portable, by using comments of the following form: `/*! MySQL-specific code */`
 - `.` #: MySQL comments: This is a comment that begins with # character.
- **Nested**—Skip nested SQL comments, which are normally used by Microsoft SQL Server. For example; `--`(Two Hyphens), and `/**/` (Allows nested comments)
 - **ANSI/Nested**—Skip comments that adhere to both the ANSI and nested SQL comment standards. Comments that match only the ANSI standard, or only the nested standard, are still checked for injected SQL.
 - **Check all Comments**—Check the entire request for injected SQL without skipping anything. This is the default setting.

Tip

Usually, you must not choose the Nested or the ANSI/Nested option unless your back-end database runs on Microsoft SQL Server. Most other types of SQL server software do not recognize nested comments. If nested comments appear in a request directed to another type of SQL server, they might indicate an attempt to breach security on that server.

Check Request headers—Enable this option if, in addition to examining the input in the form fields, you want to examine the request headers for HTML SQL Injection attacks. If you use the GUI, you can enable this parameter in the **Advanced Settings -> Profile Settings** pane of the Web App Firewall profile.

Note:

If you enable the Check Request header flag, you might have to configure a relaxation rule for the **User-Agent** header. Presence of the SQL keyword **like** and SQL special character semi-colon (`;`) might trigger false positive and block requests that contain this header.

Warning

If you enable both request header checking and transformation, any SQL special characters found in the headers are also transformed. The Accept, Accept-Charset, Accept-Encoding, Accept-Language, Expect, and User-Agent headers normally contain semicolons (`;`). Enabling both Request header checking and transformation simultaneously might cause errors.

InspectQueryContentTypes—Configure this option if you want to examine the request query portion for SQL Injection attacks for the specific content-types. If you use the GUI, you can configure this parameter in the **Advanced Settings -> Profile Settings** pane of the App Firewall profile.

SQL Fine grained Relaxations

The Web App Firewall gives you an option to exempt a specific form field, header, or Cookie from the SQL Injection inspection check. You can completely bypass the inspection for one or more of these fields by configuring the relaxation rules for the SQL Injection check.

The Web App Firewall allows you to implement tighter security by fine-tuning the relaxation rules. An application might require the flexibility to allow specific patterns, but configuring a relaxation rule to bypass the security inspection might make the application vulnerable to attacks, because the target field is exempted from inspection for any SQL attack patterns. SQL fine grained relaxation provides the option to allow specific patterns and block the rest. For example, the Web App Firewall currently has a default set of more than 100 SQL keywords. Because hackers can use these keywords in SQL Injection attacks, the Web App Firewall flags them as potential threats. You can relax one or more keywords that are considered safe for the specific location. The rest of the potentially dangerous SQL keywords are still checked for the target location and continue to trigger the security check violations. You now have much tighter control.

The commands used in relaxations have optional parameters for **Value Type** and **Value Expression**. You can specify whether the value expression is a regular expression or a literal string. The value type can be left blank or you have an option to select **Keyword** or **SpecialString** or **WildChar**.

Warning:

Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the URL that you want to add as an exception, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (*) metacharacter or wildcard combination, can have results that you do not want, such as blocking access to web content that you did not intend to block or allowing an attack that the HTML SQL Injection check would otherwise have blocked.

Points to Consider:

- Value expression is an optional argument. A field name might not have any value expression.
- A field name can be bound to multiple value expressions.
- Value expressions must be assigned a value type. The SQL value type can be: 1) Keyword, 2) SpecialString, or 3) WildChar.
- You can have multiple relaxation rules per field name/URL combination.

Using the Command Line to Configure the SQL Injection Check

To configure SQL Injection actions and other parameters by using the command line:

In the command line interface, you can use either the **set appfw profile** command or the **add appfw profile** command to configure the SQL Injection protections. You can enable the block, learn, log,

stats actions and specify whether you want to transform the special characters used in SQL Injection attack strings to disable the attack. Select the type of SQL attack pattern (key words, wildcard characters, special strings) you want to detect in the payloads, and indicate whether you want the Web App Firewall to also inspect the request Headers for SQL Injection violations. Use the **unset appfw profile** command to revert the configured settings back to their defaults. Each of the following commands sets only one parameter, but you can include multiple parameters in a single command:

- **set application firewall profile** “Parameter descriptions provided at the bottom of the page.”
`<name> -SQLInjectionAction ([block] [learn] [log] [stats]) | [none])`
- **set application firewall profile** “Parameter descriptions provided at the bottom of the page.”
`<name> -SQLInjectionTransformSpecialChars (**ON** | OFF)`
- **set application firewall profile** “Parameter descriptions provided at the bottom of the page.”
`<name> -**SQLInjectionCheckSQLWildChars** (**ON** | **OFF**)`
- **set application firewall profile** “Parameter descriptions provided at the bottom of the page.”
`**<name> -**SQLInjectionType** ([**SQLKeyword**] | [**SQLSplChar**] | [**SQLSplCharANDKeyword**] | [**SQLSplCharORKeyword**])`
- **set application firewall profile** “Parameter descriptions provided at the bottom of the page.”
`<name> -**SQLInjectionParseComments** ([**checkall**] | [**ansi|nested**] | [**ansinested**])`
- **set application firewall profile** “Parameter descriptions provided at the bottom of the page.”
`<name> -CheckRequestHeaders (ON | OFF)` Parameter descriptions provided at the bottom of the page.
- `<name> - CheckRequestQueryNonHtml (ON | OFF)` Parameter descriptions provided at the bottom of the page.

To configure a SQL Injection relaxation rule by using the command interface

Use the bind or unbind command to add or delete binding, as follows:

- `bind appfw profile <name> -SQLInjection <String> [isRegex(REGEX|NOTREGEX)] <formActionURL> [-location <location>] [-valueType (Keyword|SpecialString|Wildchar)[<valueExpression>] [-isValueRegex (REGEX | NOTREGEX)]]`
- `unbind appfw profile <name> -SQLInjection <String> <formActionURL> [-location <location>] [-valueTyp (Keyword|SpecialString|Wildchar)[<valueExpression>]]`

Note:

You can find the list of SQL keywords from the default signature file contents by viewing the view signature object, which has list of SQL key words and SQL special characters.

Using the GUI to Configure the SQL Injection Security Check

In the GUI, you can configure the SQL Injection security check in the pane for the profile associated with your application.

To configure or modify the SQL Injection check by using the GUI

1. Navigate to **Application Firewall > Profiles**, highlight the target profile, and click **Edit**.
2. In the **Advanced Settings** pane, click **Security Checks**.

The security check table displays the currently configured action settings for all the security checks. You have 2 options for configuration:

- a. If you want to enable or disable Block, Log, Stats, and Learn actions for HTML SQL Injection, you can select or clear check boxes in the table, click **OK**, and then click **Save and Close** to close the **Security Check** pane.
- b. If you want to configure more options for this security check, double click HTML SQL Injection, or select the row and click **Action Settings**, to display the following options:

Transform SQL Special character—Transform any SQL Special characters in the request.

Check for SQL Wildcard Characters—Consider SQL Wildcard characters in the payload to be attack patterns.

Check Request Containing—Type of SQL injection (SQLKeyword, SQLSplChar, SQLSplCharANDKeyword, or SQLSplCharORKeyword) to check.

SQL Comments Handling—Type of comments (Check All Comments, ANSI, Nested, or ANSI/Nested) to check.

After changing any of the above settings, click **OK** to save the changes and return to the Security Checks table. You can proceed to configure other security checks if needed. Click **OK** to save all the changes you have made in the Security Checks section, and then click **Save and Close** to close the Security Check pane.

To configure an SQL Injection relaxation rule by using the GUI

- Navigate to **Application Firewall > Profiles**, highlight the target profile, and click **Edit**.
- In the **Advanced Settings** pane, click **Relaxation Rules**.
- In the Relaxation Rules table, double-click the **HTML SQL Injection** entry, or select it and click **Edit**.
- In the **HTML SQL Injection Relaxation Rules** dialogue box, perform **Add**, **Edit**, **Delete**, **Enable**, or **Disable** operations for relaxation rules.

Note

When you add a new rule, the **Value Expression** field is not displayed unless you select **Keyword** or **SpecialString** or **WildChar** option in the **Value Type** Field.

To manage SQL injection relaxation rules by using the visualizer

For a consolidated view of all the relaxation rules, you can highlight the **HTML SQL Injection** row and click **Visualizer**. The visualizer for deployed relaxations offers you the option to **Add** a new rule or **Edit** an existing one. You can also **Enable** or **Disable** a group of rules by selecting a node and clicking the corresponding buttons in the relaxation visualizer.

View or customize injection patterns by using the GUI

You can use the GUI to view or customize the injection patterns.

The default SQL patterns are specified in the default signatures file. If you do not bind any signature object to your profile, the default Injection patterns specified in the default signatures object will be used by the profile for the command injection security check processing. The rules and patterns, specified in the default signatures object, are read-only. You cannot edit or modify them. If you want to modify or change these patterns, make a copy of the default sSignatures object to create a User-Defined signature object. Make changes in the command injection patterns in the new User-defined signature object and use this signature object in your profile that is processing the traffic for which you want to use these customized patterns.

For more information, see [Signatures](#)

To view the default injection patterns by using the GUI:

1. Navigate to **Application Firewall > Signatures**, select ***Default Signatures**, and click **Edit**.
2. Click **Manage CMD/SQL/XSS patterns**. The **Manage SQL/cross-site scripting paths** table shows patterns pertaining to CMD/SQL/XS injection:

| CMD/SQL/XSS Paths (read-only) | | |
|--|---|--------|
| <input type="button" value="Manage Elements"/> | | |
| <input type="checkbox"/> | PATHS | #ITEMS |
| <input type="checkbox"/> | commandinjection/keyword | 286 |
| <input type="checkbox"/> | commandinjection/specialstring | 12 |
| <input type="checkbox"/> | injection (delimiter=not_alphanum, type=SQL)/keyword | 134 |
| <input type="checkbox"/> | injection (delimiter=not_alphanum, type=SQL)/specialstring | 3 |
| <input type="checkbox"/> | injection (delimiter=not_alphanum, type=SQL)/transformrules/transform | 5 |
| <input type="checkbox"/> | injection (delimiter=not_alphanum, type=SQL)/wildchar | 5 |
| <input type="checkbox"/> | xss/allowed/attribute | 52 |
| <input type="checkbox"/> | xss/allowed/tag | 47 |
| <input type="checkbox"/> | xss/denied/pattern | 179 |

1. Select a row and click **Manage Elements** to display the corresponding injection patterns (keywords, special strings, transformation rules or the wildcard characters) used by the Web App Firewall command injection check.

Using the Learn Feature with the SQL Injection Check

When the learn action is enabled, the Web App Firewall learning engine monitors the traffic and learns the triggered violations. You can periodically inspect these learned rules. After due consideration, you can deploy the learned rule as an SQL Injection relaxation rule.

SQL Injection Learning enhancement—An Web App Firewall learning enhancement was introduced in release 11.0 of the NetScaler software. To deploy fine grained SQL Injection relaxation, the Web App Firewall offers fine grained SQL Injection learning. The learning engine makes recommendations regarding the observed Value Type (keyword, SpecialString, Wildchar) and the corresponding Value expression observed in the input fields. In addition to checking the blocked requests to determine whether the current rule is too restrictive and needs to be relaxed, you can review the rules generated by the learning engine to determine which value type and value expressions are triggering violations and need to be addressed in the relaxation rules.

Important

The Web App Firewall’s learning engine can distinguish only the first 128 bytes of the name. If a form has multiple fields with names that match for the first 128 bytes, the learning engine might

not be able to distinguish between them. Similarly, the deployed relaxation rule might inadvertently relax all such fields from SQL Injection inspection.

Note To bypass the SQL check in the User-Agent header, use the following relaxation rule:

```
bind appfw profile your_profile_name -SQLInjection User-Agent ".*\n"-location HEADER
```

To view or use learned data by using the command line interface

At the command prompt, type one of the following commands:

- `show appfw learningdata <profilename> SQLInjection`
- `rm appfw learningdata <profilename> -SQLInjection <string> <formActionURL> [<location>] [<valueType> <valueExpression>]`
- `export appfw learningdata <profilename> SQLInjection`

To view or use learned data by using the GUI

1. Navigate to **Application Firewall > Profiles**, highlight the target profile, and click **Edit**.
2. In the **Advanced Settings** pane, click **Learned Rules**. You can select the **HTML SQL Injection** entry in the Learned Rules table and double-click it to access the learned rules. You can deploy the learned rules or edit a rule before deploying it as a relaxation rule. To discard a rule, you can select it and click the **Skip** button. You can edit only one rule at a time, but you can select multiple rules to deploy or skip.

You also have the option to show a summarized view of the learned relaxations by selecting the **HTML SQL Injection** entry in the Learned Rules table and clicking **Visualizer** to get a consolidated view of all the learned violations. The visualizer makes it easy to manage the learned rules. It presents a comprehensive view of the data on one screen and facilitates taking action on a group of rules with one click. The biggest advantage of the visualizer is that it recommends regular expressions to consolidate multiple rules. You can select a subset of these rules, based on the delimiter and Action URL. You can display 25, 50, or 75 rules in the visualizer, by selecting the number from a drop-down list. The visualizer for learned rules offers the option to edit the rules and deploy them as relaxations. Or you can skip the rules to ignore them.

Using the Log Feature with the SQL Injection Check

When the log action is enabled, the HTML SQL Injection security check violations are logged in the audit log as **APPFW_SQL** violations. The Web App Firewall supports both Native and CEF log formats. You can also send the logs to a remote syslog server.

To access the log messages by using the command line

Switch to the shell and tail the ns.logs in the **/var/log/** folder to access the log messages pertaining to the SQL Injection violations:

```
> Shell
```

```
# tail -f /var/log/ns.log | grep APPFW_SQL
```

Example of an HTML SQL Injection log message when the request is transformed

```

Note

As part of the streaming changes in 10.5.e build (enhancement builds) and 11.0 build onwards, we now process the input data in blocks. RegEx pattern matching is now restricted to 4K for contiguous character string matching. With this change, the SQL violation log messages might include different information compared to the earlier builds. The keyword and special character in the input can be separated by many bytes. We now keep track of the SQL keywords and special strings when processing the data, instead of buffering the entire input value. In addition to the field name, the log message now includes the SQL keyword, or the SQL special character, or both the SQL keyword and the SQL special character, as determined by the configured setting. The rest of the input is no longer included in the log message, as shown in the following example:

Example:

In 10.5, when the Web App Firewall detects the SQL violation, the entire input string might be included in the log message, as shown below:

```
SQL Keyword check failed for field text=\"select a name from
```

```
testbed1;(;)\".*<blocked>
```

In the enhancement builds of 10.5.e that support request side streaming and 11.0 build onwards, we log only the field name, keyword, and special character (if applicable) in the log message, as shown below:

```
SQL Keyword check failed for field **text="select(;"<blocked>
```

This change is applicable to requests that contain application/x-www-form-urlencoded, or multipart/form-data, or text/x-gwt-rpc content-types. Log messages generated during processing of **JSON** or **XML** payloads are not affected by this change.

To access the log messages by using the GUI

The GUI includes a useful tool (**Syslog Viewer**) for analyzing the log messages. You have multiple options for accessing the Syslog Viewer:

- Navigate to the **Application Firewall > Profiles**, select the target profile, and click **Security Checks**. Highlight the **HTML SQL Injection** row and click **Logs**. When you access the logs directly from the HTML SQL Injection check of the profile, the GUI filters out the log messages and displays only the logs pertaining to these security check violations.
- You can also access the Syslog Viewer by navigating to **NetScaler > System > Auditing**. In the Audit Messages section, click the **Syslog messages** link to display the Syslog Viewer, which displays all log messages, including other security check violation logs. This is useful for debugging when multiple security check violations might be triggered during request processing.
- Navigate to **Application Firewall > policies > Auditing**. In the Audit Messages section, click the **Syslog messages** link to display the Syslog Viewer, which displays all log messages, including other security check violation logs.

The HTML based Syslog Viewer provides various filter options for selecting only the log messages that are of interest to you. To select log messages for the **HTML SQL Injection** check, filter by selecting **APPFW** in the drop-down list options for **Module**. The **Event Type** list offers a rich set of options to further refine your selection. For example, if you select the **APPFW_SQL** check box and click the **Apply** button, only log messages pertaining to the **SQL Injection** security check violations appear in the Syslog Viewer.

If you place the cursor in the row for a specific log message, multiple options, such as **Module**, **Event Type**, **Event ID**, **Client IP** and so forth. appear below the log message. You can select any of these options to highlight the corresponding information in the log message.

Click to Deploy functionality is available only in the GUI. You can use the Syslog Viewer to not only view the logs but also to deploy HTML SQL Injection relaxation rules based on the log messages for the Web App Firewall security check violations. The log messages must be in CEF log format for this operation. Click to deploy functionality is available only for log messages that are generated by the

block (or not block) action. You cannot deploy a relaxation rule for a log message about the transform operation.

To deploy a relaxation rule from the Syslog Viewer, select the log message. A check box appears in the upper right corner of the **Syslog Viewer** box of the selected row. Select the check box, and then select an option from the Action list to deploy the relaxation rule. **Edit & Deploy**, **Deploy**, and **Deploy All** are available as **Action** options.

The SQL Injection rules that are deployed by using the Click to Deploy option do not include the fine grain relaxation recommendations.

To use Click to Deploy functionality in the GUI:

1. In the Syslog Viewer, select **Application Firewall** in the **Module** options.
2. Select the **APP_SQL** as the **Event Type** to filter corresponding log messages.
3. Select the check box to identify the rule to deploy.
4. Use the **Action** drop-down list of options to deploy the relaxation rule.
5. Verify that the rule appears in the corresponding relaxation rule section.

Statistics for the SQL Injection violations

When the stats action is enabled, the counter for the SQL Injection check is incremented when the Web App Firewall takes any action for this security check. The statistics are collected for Rate and Total count for Traffic, Violations, and Logs. The size of an increment of the log counter can vary depending on the configured settings. For example, if the block action is enabled, the request for a page that contains 3 SQL Injection violations increments the stats counter by one, because the page is blocked as soon as the first violation is detected. However, if the block is disabled, processing the same request increments the statistics counter for violations and the logs by three, because each violation generates a separate log message.

To display SQL Injection check statistics by using the command line:

At the command prompt, type:

```
sh appfw stats
```

To display stats for a specific profile, use the following command:

```
> stat appfw profile <profile name>
```

To display HTML SQL Injection statistics by using the GUI

1. Navigate to **System > Security > Application Firewall**.
2. In the right pane, access the **Statistics** Link.
3. Use the scroll bar to view the statistics about HTML SQL Injection violations and logs. The statistics table provides real-time data and is updated every 7 seconds.

Highlights

Note the following points about the SQL Injection check:

- **Built-in Support for SQL Injection Protection**—The NetScaler Web App Firewall protects against SQL Injection by monitoring a combination of SQL keywords and special characters in the form parameters. All SQL keywords, special characters, wildcard characters, and default transformation rules are specified in the `/netscaler/default_custom_settings.xml` file.
- **Customization**—You can change the default key words, special characters, wildcard characters, and transformation rules to customize the SQL security check inspection for the specific needs of your application. Make a copy of the default signature object, modify existing entries, or add new ones. Bind this signature object to your profile to make use of the customized configuration.
- **Hybrid Security Model**—Both signatures and deep security protections use the SQL/cross-site scripting patterns specified in the signature object that is bound to the profile. If no signature object is bound to the profile, the SQL/cross-site scripting patterns present in the default signature object are used.
- **Transform**—Note the following about the transform operation:
 - The transform operation works independently of the other SQL Injection action settings. If transform is enabled and the block, log, stats, and learn are all disabled, SQL special characters are transformed.
 - When SQL Transformation is enabled, user requests are sent to the back end servers after the SQL special characters are transformed in non-block mode. If the block action is enabled, it takes precedence over the transform action. If the injection type is specified as SQL special character and the block is enabled, the request is blocked despite the transform action.
- **Fine Grained Relaxation and Learning**—Fine-tune the relaxation rule to relax a subset of SQL elements from security check inspection but detect the rest. The learning engine recommends a specific value type and value expressions based on the observed data.
- **Click to Deploy**—Select one, or multiple SQL violation log messages in the syslog viewer and deploy them as relaxation rules.

SQL grammar-based protection for HTML and JSON payload

February 9, 2024

NetScaler Web App Firewall uses a pattern match approach for detecting SQL injection attacks in [HTTP](#) and [JSON](#) payloads. The approach uses a set of pre-defined key-words and (or) special char-

acters to detect an attack and flag it as a violation. Although this approach is effective, it can result in many false positives resulting in adding one or more relaxation rules. Especially when commonly used words such as “Select” and “From” are used in an HTTP or JSON request. We can reduce false positives by implementing the SQL grammar protection check for [HTML](#) and [JSON](#) payload.

In the existing pattern match approach, an SQL injection attack is identified if a pre-defined keyword and or a special character is present in an HTTP request. In this case, the statement need not be a valid SQL statement. But in the grammar-based approach, an SQL injection attack is detected only if a keyword or a special character is present in a SQL statement or is part of a SQL statement thereby reducing false positive scenarios.

SQL grammar-based protection usage scenario

Consider a statement, “Select my tickets and let’s meet at union station” present in an HTTP request. Although, the statement is not a valid SQL statement, the existing pattern match approach detects the request as an SQL injection attack because the statement uses keywords such as “Select”, “and” and “Union”. But, in the case of the SQL grammar approach, the statement is not detected as a violation attack because the keywords are not present in a valid SQL statement or not part of a valid SQL statement.

The grammar-based approach can also be configured for detecting SQL injection attacks in [JSON](#) payloads. For adding a relaxation rule, you can reuse the existing relaxation rules. Fine grained relaxation rules are also applicable for SQL grammar, for rules with “valueType” “keyword”. In [JSON](#) SQL grammar, the existing URL-based method can be reused.

Configure SQL grammar-based protection for HTML using the CLI

To implement SQL grammar based detection, you must configure the “SQLInjectionGrammar” parameter in the Web App Firewall profile. By default, the parameter is disabled. All existing SQL Injection actions are supported except learning. Any new profile created after an upgrade supports SQL injection grammar and it continues to have default type as “special character or keyword” and it must be explicitly enabled.

At the command prompt, type:

```
1 add appfw profile <profile-name> - SQLInjectionAction <action-name> -  
  SQLInjectionGrammar ON/OFF  
2 <!--NeedCopy-->
```

Example:

```
add appfw profile profile1 -SQLInjectionAction Block -SQLInjectionGrammar  
ON
```

Configure SQL pattern-match protection and grammar-based protection for HTML using the CLI

If you have enabled both grammar-based and pattern-match approaches, then the appliance performs grammar-based detection first and if there is SQL injection detection with the action type set to block, the request is blocked (without verifying detection using pattern-match).

At the command prompt, type:

```
1 add appfw profile <profile-name> - SQLInjectionAction <action-name> -
  SQLInjectionGrammar ON - SQLInjectionType <Any action other than '
  None ' : SQLSplCharANDKeyword/ SQLSplCharORKeyword/ SQLSplChar/
  SQLKeyword>
2 <!--NeedCopy-->
```

Example:

```
add appfw profile p1 -SQLInjectionAction block - SQLInjectionGrammar
ON -SQLInjectionType SQLSplChar
```

Configure SQL Injection check only with grammar-based protection for HTML using the CLI

At the command prompt, type:

```
1 add appfw profile <profile-name> - SQLInjectionAction <action-name> -
  SQLInjectionGrammar ON - SQLInjectionType None
2 <!--NeedCopy-->
```

Example:

```
add appfw profile p1 -SQLInjectionAction block - SQLInjectionGrammar
ON -SQLInjectionType None
```

Bind relaxation rules for SQL grammar-based protection for HTML using the CLI

If your application requires you to bypass the SQL injection check for a specific “ELEMENT” or “ATTRIBUTE” in the payload, you must configure a relaxation rule.

Note:

Relaxation rules with valueType “keyword” are evaluated only when the appliance performs detection using SQL grammar.

The SQL command Injection inspection relaxation rules have the following syntax. At the command prompt, type:

```

1 bind appfw profile <name> -SQLInjection <String> [isRegex(REGEX|
  NOTREGE)] <formActionURL> [-location <location>] [-valueType (Keywor
  |SpecialString|Wildchar) [<valueExpression>][-isValueRegex (REGEX |
  NOTREGEX) ]]
2 <!--NeedCopy-->

```

Example:

```

bind appfw profile p1 -sqlinjection abc http://10.10.10.10/
bind appfw profile p1 -sqlinjection 'abc[0-9]+'http://10.10.10.10/ -
isregex regEX
bind appfw profile p1 -sqlinjection 'name'http://10.10.10.10/ -valueType
Keyword 'selec[a-z]+' -isvalueRegex regEX

```

Configure SQL grammar based protection for HTML using the GUI

Complete the GUI procedure to configure grammar based HTML SQL Injection detection.

1. On the navigation pane, navigate to **Security > Profiles**.
2. In the **Profiles** page, click **Add**.
3. In the **NetScaler Web App Firewall Profile** page, click **Security Checks** under **Advanced Settings**.
4. In the **Security Checks** section, go to **HTML SQL Injection** settings.
5. Click the executable icon near the check box.
6. Click **Action Settings** to access the **HMTL SQL Injection Settings** page.
7. Select the **Check using SQL Grammar** check box.
8. Click **OK**.

Configure SQL grammar-based protection for JSON payload using the CLI

To implement SQL grammar-based detection for the JSON payload, you must configure the “JSON-SQLInjectionGrammar”parameter in the Web App Firewall profile. By default, the parameter is disabled. All existing SQL Injection actions are supported except learning. Any new profile created after an upgrade supports SQL injection grammar and it continues to have default type as “special character or keyword”and you must explicitly enable it.

At the command prompt, type:

```

1 add appfw profile <profile-name> -type JSON -JSONSQLInjectionAction <
  action-name> -JSONSQLInjectionGrammar ON/OFF
2 <!--NeedCopy-->

```

Example:

```
add appfw profile profile1 -type JSON -JSONSQLInjectionAction Block -
JSONSQLInjectionGrammar ON
```

Configure SQL pattern match protection and grammar-based protection for JSON payload using the CLI

If you have enabled both grammar-based and pattern-match checks, then the appliance performs grammar-based detection first and if there is SQL injection detection with the action type set to block, the request is blocked (without verifying detection using pattern-match).

Note:

Relaxation rules with valueType “keyword” are evaluated only when the appliance performs detection using SQL grammar.

At the command prompt, type:

```
1 add appfw profile <profile-name> -type JSON -JSONSQLInjectionAction <
  action-name> -JSONSQLInjectionGrammar ON -JSONSQLInjectionType <Any
  action other than 'None': SQLSplCharANDKeyword/
  SQLSplCharORKeyword/ SQLSplChar/ SQLKeyword>
2 <!--NeedCopy-->
```

Example:

```
add appfw profile p1 -type JSON -JSONSQLInjectionAction block -
JSONSQLInjectionGrammar ON -JSONSQLInjectionType SQLSplChar
```

Configure SQL Injection check only grammar-based protection for JSON payload using the CLI

At the command prompt, type:

```
1 add appfw profile <profile-name> -type JSON -JSONSQLInjectionAction <
  action-name> -JSONSQLInjectionGrammar ON -JSONSQLInjectionType None
  \
2 <!--NeedCopy-->
```

Example:

```
add appfw profile p1 -type JSON -JSONSQLInjectionAction block -
JSONSQLInjectionGrammar ON -JSONSQLInjectionType None
```

Bind url-based relaxation rules for JSON SQL grammar-based protection for JSON payload using the CLI

If your application requires you to bypass the **JSON** command injection inspection for a specific “ELEMENT” or “ATTRIBUTE” in the payload, you can configure a relaxation rule.

The **JSON** command Injection inspection relaxation rules have the following syntax. At the command prompt, type:

```
1 bind appfw profile <profile name> -JSONCMDURL <expression> -comment <
  string> -isAutoDeployed ( AUTODEPLOYED | NOTAUTODEPLOYED ) -state (
  ENABLED | DISABLED )
2 <!--NeedCopy-->
```

Example:

```
bind appfw profile p1 -sqlinjection abc http://10.10.10.10/
bind appfw profile p1 -sqlinjection 'abc[0-9]+'http://10.10.10.10/ -
isregex regEX
bind appfw profile p1 -sqlinjection 'name'http://10.10.10.10/ -valueType
Keyword 'selec[a-z]+' -isvalueRegex regEX
```

Configure SQL grammar based protection for JSON payload using the GUI

Complete the GUI procedure to configure grammar based JSON SQL Injection detection.

1. On the navigation pane, navigate to **Security > Profiles**.
2. In the **Profiles** page, click **Add**.
3. In the **NetScaler Web App Firewall Profile** page, click **Security Checks** under **Advanced Settings**.
4. In the **Security Checks** section, go to **JSON SQL Injection** settings.
5. Click the executable icon near the check box.
6. Click **Action Settings** to access the **JSON SQL Injection Settings** page.
7. Select the **Check using SQL Grammar** check box.
8. Click **OK**.

Command injection grammar-based protection for HTML payload

February 9, 2024

NetScaler Web App Firewall uses a pattern match approach for detecting command injection attacks in HTML payloads. The approach uses a set of pre-defined keywords and (or) special characters to

detect an attack and flag it as a violation. Although this approach is effective, it can result in many false positives that lead to adding one or more relaxation rules. Especially, when a commonly used word such as “Exit” is used in an HTTP request. We can reduce false positives by implementing the command injection grammar-based protection check for the HTML payload.

In the pattern-match approach, a command injection attack is identified if a pre-defined keyword and (or) a special character is present in an HTTP request. In this case, the statement need not be a valid command injection statement. But in the grammar-based approach, a command injection attack is detected only if a keyword or a special character is present in a command injection statement. Therefore, false-positive scenarios are reduced.

Command injection grammar-based protection usage scenario

Consider a statement, “Rush towards the exit!” present in an HTTP request. Although the statement is not a valid command injection statement, the pattern-match approach detects the request as a command injection attack due to the keyword “exit”. But in the command injection grammar-based approach, the statement is not detected as a violation attack because the keywords are not present in a valid command injection statement.

Configure command injection grammar-based protection parameter using the CLI

To implement command injection grammar-based detection, you must configure the “CMDInjectionGrammar” parameter in the Web App Firewall profile. By default, the parameter is disabled. All existing command injection actions are supported except learning. Any new profile created after an upgrade supports command injection grammar. The new profile continues to have the default type as “special character or keyword” and command injection grammar must be explicitly enabled.

At the command prompt, type:

```
1 add appfw profile <profile-name> - CMDInjectionAction <action-name> -  
  CMDInjectionGrammar ON/OFF  
2 <!--NeedCopy-->
```

Example:

```
1 add appfw profile profile1 - CMDInjectionAction Block -  
  CMDInjectionGrammar ON  
2 <!--NeedCopy-->
```

Configure command injection pattern-match protection and grammar-based protection using the CLI

If you have enabled both grammar-based and pattern-match approaches, then the appliance performs grammar-based detection first. If there is a command injection detected with the action type set to “block”, the request is blocked (without verifying detection using pattern-match).

At the command prompt, type:

```
1 add appfw profile <profile-name> - CMDInjectionAction <action-name> -  
  CMDInjectionGrammar ON - CMDInjectionType <Any action other than ‘  
  None ’ : CMDSplCharANDKeyword/ CMDSplCharORKeyword/ CMDSplChar/  
  CMDKeyword>  
2 <!--NeedCopy-->
```

Example:

```
1 add appfw profile p1 - CMDInjectionAction block - CMDInjectionGrammar  
  ON - CMDInjectionType CMDSplChar  
2 <!--NeedCopy-->
```

Configure command injection check only with grammar-based protection using the CLI

At the command prompt, type:

```
1 add appfw profile <profile-name> - CMDInjectionAction <action-name> -  
  CMDInjectionGrammar ON - CMDInjectionType None  
2 <!--NeedCopy-->
```

Example:

```
1 add appfw profile p1 - CMDInjectionAction block - CMDInjectionGrammar  
  ON - CMDInjectionType None  
2 <!--NeedCopy-->
```

Bind relaxation rules for command injection grammar-based protection using the CLI

If your application requires you to bypass the command injection check for a specific “ELEMENT” or “ATTRIBUTE” in the HTML payload, you must configure a relaxation rule.

Note:

Relaxation rules with the valueType as “keyword” are evaluated only when the appliance performs detection using command injection grammar.

The command injection inspection relaxation rules have the following syntax. At the command prompt, type:

```
1 bind appfw profile <name> -CMDInjection <String> [isRegex(REGEX |
   NOTREGE)] <formActionURL> [-location <location>] [-valueType (Keyword
   |SpecialString|Wildchar) [<valueExpression>][-isValueRegex (REGEX |
   NOTREGEX) ]]
2 <!--NeedCopy-->
```

Example:

```
1 bind appfw profile p1 -cmdinjection abc http://10.10.10.10/
2
3 bind appfw profile p1 -cmdinjection 'abc[0-9]+' http://10.10.10.10/ -
   isregex regEX
4
5 bind appfw profile p1 -cmdinjection 'name' http://10.10.10.10/ -
   valueType Keyword 'exi[a-z]+' -isvalueRegex regEX
6 <!--NeedCopy-->
```

Configure command injection grammar-based protection using the GUI

Complete the following steps to configure grammar-based HTML command injection detection.

1. Navigate to **Security > NetScaler Web App Firewall Profile > Profiles**.
2. Select a profile and click **Edit**.
3. Go to the **Advanced Settings** section and click **Security Checks**.
4. Select the **HTML Command Injection** check box and click **Action Settings**.
5. Select the **Check using CMD Grammar** check box.
6. Select **None** from **Check Request Containing**.
7. Click **OK**.

Relaxation and deny rules for handling HTML SQL injection attacks

October 12, 2023

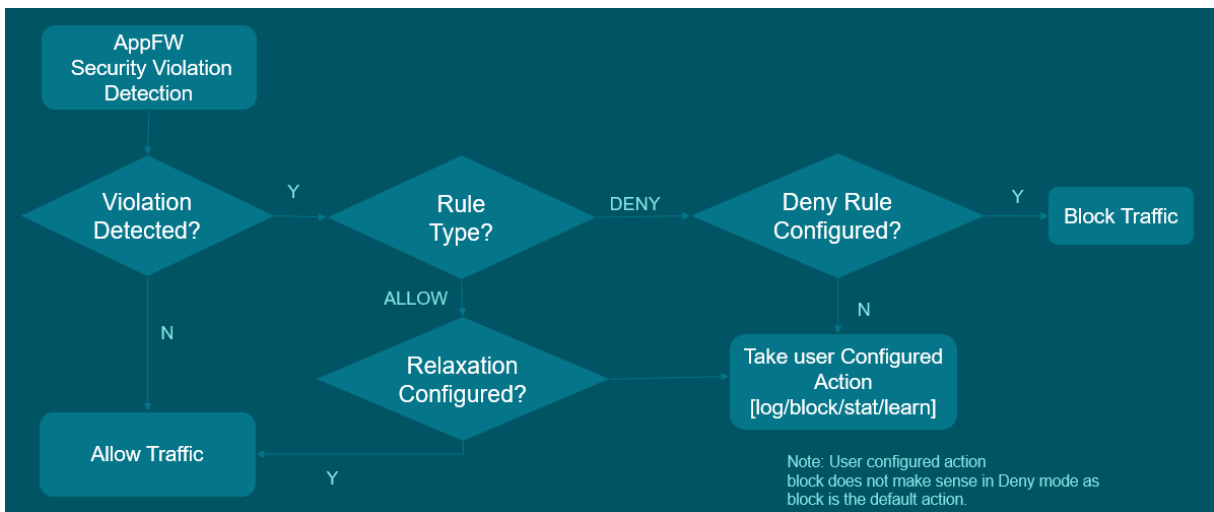

When there is an incoming traffic, the violation detection logic checks for traffic violations. If no HTML SQL injection attacks are detected, the traffic is allowed to pass. But if a violation is detected, the relaxation (allow) and deny rules define how to handle the violations. If the security check is configured in the allow mode (default mode), the detected violation is blocked unless the user has explicitly configured a relaxation or allow rule.

In addition to allow mode, the security check can also be configured in deny mode and use deny rules for handling violations. If the security check is configured in this mode, the detected violations are blocked if a user has explicitly configured a deny rule. If there are no deny rules configured, then the user configured action is applied.

Note:

By default, the URL is a regular expression.

The following illustration explains how to allow and deny modes of operation work:

1. When a violation is detected, the relaxation (allow) and deny rules define how to handle the violations.
2. If the security check is configured in deny mode (if configured in allow mode, jump to step 5), the violation is blocked unless you have explicitly configured a deny rule.
3. If the violation matches a deny rule, the appliance blocks the traffic.
4. If the traffic violation does not match a rule, the appliance applies a user-defined action (block, reset, or drop).
5. If the security check is configured in allow mode, the Web App Firewall module checks if there are any allow rule configured.
6. If the violation matches an allow rule, the appliance allows the traffic to bypass otherwise, it is blocked.

Configure security check-in relaxation and enforcement mode using CLI

At the command prompt, type:

```

1 set appfw profile <name> - SQLInjectionAction [block stats learn] -
   SQLInjectionRuleType [ALLOW DENY]
2 <!--NeedCopy-->
  
```

Example:

```
set appfw profile prof1 sqlInjectionAction block -sqlInjectionRuleType
ALLOW DENY
```

Configure security check-in relaxation and enforcement mode using GUI

1. Navigate to **Security > NetScaler Web App Firewall** and **Profiles**.
2. On the **Profiles** page, select a profile and click **Edit**.
3. On the **NetScaler Web App Firewall Profile** page, go to the **Advanced Settings** section and click **Security Checks**.
4. In the **Security Checks** section, select **HTML SQL Injection Settings** and click **Action Settings**.
5. On the **HTML Command Injection Settings** page, select that actions to be performed as part of HTML command injection security check and update the parameters.
6. Click **OK**.

Bind relaxation and enforcement rules to Web Application Firewall profile using CLI

At the command prompt, type:

```
1 bind appfw profile <name> -SQLInjection <string> <formActionURL>
2 <!--NeedCopy-->
```

Example:

```
bind appfw profile p1 -SQLInjection field_f1 "/login.php"-RuleType
ALLOW
```

```
bind appfw profile p2 -SQLInjection field_f1 "/login.php"-RuleType
ALLOW
```

Bind relaxation and enforcement rules to Web Application Firewall profile using GUI

1. Navigate to **Security > NetScaler Web App Firewall** and **Profiles**.
2. On the **Profiles** page, select a profile and click **Edit**.
3. On the **NetScaler Web App Firewall Profile** page, go to **Advanced Settings** section and click **Relaxation Rules**.
4. In the **Relaxation Rule** section, select **HTML SQL Injection Settings** and click **Edit**.
5. On the **HTML SQL Injection Relaxation Rules** page, click **Add**.
6. Specify the required details.
7. Click **Create**.

The screenshot shows the configuration form for an HTML SQL Injection Relaxation Rule. The form is titled "HTML SQL Injection Relaxation Rule" and includes the following fields and options:

- Enabled:** A checked checkbox.
- Is Name Regex:** An unchecked checkbox.
- Name*:** A text input field containing "SQLInjectionRelaxRule".
- RegEx Editor:** A link to edit the regular expression.
- URL*:** A text input field containing "www.example.com".
- RegEx Editor:** A link to edit the URL.
- Location:** A dropdown menu set to "FORMFIELD".
- Value Type:** A dropdown menu.
- Comments:** A text area.
- Resource Id:** A text input field containing "2eaf9ba435877ac830eb9e82ab843ec69bcee45186bff95".

At the bottom of the form are two buttons: "Create" and "Close".

HTML command injection protection check

February 9, 2024

The **HTML** command injection check examines if the incoming traffic has unauthorized commands that break the system security or modify the system. If the traffic has any malicious commands when detected, the appliance blocks the request or performs the configured action.

The NetScaler Web App Firewall profile is now enhanced with a new security check for command injection attacks. When the command injection security check examines the traffic and detects any malicious commands, the appliance blocks the request or performs the configured action.

In a command injection attack, the attacker aims to run unauthorized commands on the NetScaler operation system. To achieve this, the attacker injects operating system commands using a vulnerable application. A NetScaler appliance is vulnerable to injection attacks if the application passes any unsafe data (forms, cookies, or header) to the system shell.

How command injection protection works

1. For an incoming request, WAF examines the traffic for keywords or special characters. If the incoming request has no patterns that match any of the denied keywords or special characters, the request is allowed. Otherwise, the request is blocked, dropped, or redirected based on the configured action.
2. If you prefer to exempt a keyword or a special character from the list, you can apply a relaxation rule to bypass the security check under specific conditions.
3. You can enable logging to generate log messages. You can monitor the logs to determine whether responses to legitimate requests are getting blocked. A large increase in the number of log messages can indicate attempts to launch an attack.
4. You can also enable the statistics feature to gather statistical data about violations and logs. An unexpected surge in the stats counter might indicate that your application is under attack. If legitimate requests are getting blocked, you might have to revisit the configuration to see if you must configure the new relaxation rule or modify the existing one.

Keywords and special characters denied for command injection check

To detect and block command injection attacks, the appliance has a set of patterns (keywords and special characters) defined in the default signature file. Following is a list of keywords blocked during command injection detection.

```
1      <commandinjection>
2      <keyword type="LITERAL" builtin="ON">7z</keyword>
3      <keyword type="LITERAL" builtin="ON">7za</keyword>
4      <keyword type="LITERAL" builtin="ON">7zr</keyword>
5      ...
6 </commandinjection>
7 <!--NeedCopy-->
```

Special characters defined in the signature file are:

```
| ; & $ > < '\ ! >> #
```

Configuring command injection check by using the CLI

In the command line interface, you can use either the set the profile command or the add the profile command to configure the command injection settings. You can enable the block, log, and stats actions. You must also set the key words and string characters that you want to detect in the payloads.

At the command prompt, type:

```
set appfw profile <profile-name> -cmdInjectionAction <action-name> -  
CMDInjectionType <CMDInjectionType>]
```

Note:

By default, the command injection action is set as “None.” Also, the default command injection type is set as `CmdSplCharANDKeyWord`.

Example:

```
set appfw profile profile1 -cmdInjectionAction block -CMDInjectionType  
CmdSplChar
```

Where, the available command injection actions are:

- None - Disable command injection protection.
- Log - Log command injection violations for the security check.
- Block - blocks traffic that violates the command injection security check.
- Stats - Generates statistics for command injection security violations.

Where, the available command injection types are:

- `Cmd SplChar`. Checks special characters
- `CmdKeyWord`. Checks command injection Keywords
- `CmdSplCharANDKeyWord`. Checks special characters and command injection. Keywords and blocks only if both are present.
- `CmdSplCharORKeyWord`. Checks special characters and command injection Keywords and blocks if either of them is found.

Configuring relaxation rules for command injection protection check

If your application requires you to bypass the command injection inspection for a specific ELEMENT or ATTRIBUTE in the payload, you can configure a relaxation rule.

The command Injection inspection relaxation rules have the following syntax:

```
bind appfw profile <profile name> -cmdInjection <string> <URL> -  
isregex <REGEX/NOTREGEX>
```

Example for relaxation rule for Regex in header

```
bind appfw profile sample -CMDInjection hdr "http://10.10.10.10/"-  
location header -valueType Keyword '[a-z]+grep'-isvalueRegex REGEX
```

As a result, the injection exempts the command injection check allows header `hdr` containing variants of “grep.”

Example for relaxation rule with valueType as regex in cookie

```
bind appfw profile sample -CMDInjection ck_login "http://10.10.10.10/  
"-location cookie -valueType Keyword 'pkg[a-z]+'-isvalueRegex REGEX
```

Configuring command injection check by using NetScaler GUI

Complete the following steps to configure the command injection check.

1. Navigate to **Security > NetScaler Web App Firewall and Profiles**.
2. On the **Profiles** page, select a profile and click **Edit**.
3. On the **NetScaler Web App Firewall Profile** page, go to the **Advanced Settings** section and click **Security Checks**.
4. In the **Security Checks** section, select **HTML Command Injection** and click **Action** settings.
5. In the **HTML Command Injection Settings** page, set the following parameters:
 - a) Actions. Select one or more actions to perform for command injection security check.
 - b) Check Request Containing. Select a command injection pattern to check if the incoming request has the pattern.
6. Click **OK**.

View or customize command injection patterns by using the GUI

You can use the GUI to view or customize the **HTML** command injection patterns.

The default command injection patterns are specified in default signatures file. If you do not bind any signature object to your profile, the default HTML command injection patterns specified in the default signatures object will be used by the profile for the command injection security check processing. The rules and patterns, specified in the default signatures object, are read-only. You cannot edit or modify them. If you want to modify or change these patterns, make a copy of the default sSignatures object to create a User-Defined signature object. Make changes in the command injection patterns in the new User-defined signature object and use this signature object in your profile that is processing the traffic for which you want to use these customized patterns.

For more information, see [Signatures](#)

To view the default command injection patterns by using the GUI:

1. Navigate to **Application Firewall > Signatures**, select ***Default Signatures**, and click **Edit**.
2. Click **Manage CMD/SQL/XSS patterns**. The **CMD/SQL/XSS Paths (read-only)** table shows patterns pertaining to [CMD/SQL/XSS](#) injection:

| CMD/SQL/XSS Paths (read-only) | | #ITEMS |
|-------------------------------|---|--------|
| <input type="checkbox"/> | PATHS | |
| <input type="checkbox"/> | commandinjection/keyword | 286 |
| <input type="checkbox"/> | commandinjection/specialstring | 12 |
| <input type="checkbox"/> | injection (delimiter=not_alphanum, type=SQL)/keyword | 134 |
| <input type="checkbox"/> | injection (delimiter=not_alphanum, type=SQL)/specialstring | 3 |
| <input type="checkbox"/> | injection (delimiter=not_alphanum, type=SQL)/transformrules/transform | 5 |
| <input type="checkbox"/> | injection (delimiter=not_alphanum, type=SQL)/wildchar | 5 |
| <input type="checkbox"/> | xss/allowed/attribute | 52 |
| <input type="checkbox"/> | xss/allowed/tag | 47 |
| <input type="checkbox"/> | xss/denied/pattern | 179 |

OK

1. Select a row and click **Manage Elements** to display the corresponding command injection patterns (keywords, special strings, transformation rules, or wildcard characters) used by the Web App Firewall command injection check.

To customize a command injection pattern by using the GUI

You can edit the user-defined signature object to customize the **CMD** key words, special strings, and wildcard characters. You can add new entries or remove the existing ones. You can modify the transformation rules for the command injection special strings.

1. **Navigate to Application Firewall > Signatures**, highlight the target User-defined signature, and click **Add**. Click **Manage CMD/SQL/XSS patterns**.
2. In the **Manage CMD/SQL/XSS paths** page, select the target CMD injection row.
3. Click **Manage Elements**, **Add**, or **Remove** a command injection element.

Warning:

You must be careful before you remove or modify any default command injection element, or delete the CMD path to remove the entire row. The signature rules and the command injection security check rely on these elements for detecting command injection attacks to protect your applications. Customizing the SQL patterns can make your application vulnerable to command injection attacks if the required pattern is removed during editing.

Viewing command injection traffic and violation statistics

The **NetScaler Web App Firewall Statistics** page shows security traffic and security violation details in a tabular or graphical format.

To view security statistics by using the command interface.

At the command prompt, type:

```
stat appfw profile profile1
```

| Appfw profile Traffic Statistics | Rate (/s) | Total |
|----------------------------------|-----------|-------|
| Requests | 0 | 0 |
| Request Bytes | 0 | 0 |
| Responses | 0 | 0 |
| Response Bytes | 0 | 0 |

Server Error Response**Statistics Rate (/s) > Total**

| | | |
|-------------------------------|---|---|
| HTTP Client Errors (4xx Resp) | 0 | 0 |
| HTTP Server Errors (5xx Resp) | 0 | 0 |

Viewing HTML command injection statistics by using the NetScaler GUI

Complete the following steps to view the command injection statistics:

1. Navigate to **Security > NetScaler Web App Firewall > Profiles**.
2. In the details pane, select a Web App Firewall profile and click **Statistics**.
3. The **NetScaler Web App Firewall Statistics** page displays the HTML command injection traffic and violation details.
4. You can select **Tabular View** or switch to **Graphical View** to display the data in a tabular or graphical format.

Custom keyword support for HTML payload

February 9, 2024

Starting from NetScaler release 13.1 build 27.xx, you can add keywords of your choice and check if these configured keywords are present in the HTML payload.

SQL injection and command injection have a predefined set of keywords or patterns that they look for in the incoming requests. These predefined sets of keywords might not cover all the keywords as per your requirement and might lead to an increase in the number of false positives. With this feature, you can add keywords that are not covered in the SQL injection and command injection checks and therefore reduce the false positives.

After adding the keywords, you can configure the NetScaler appliance to check if the added keywords are detected in the incoming requests. You can then configure the NetScaler appliance to do one of the following actions:

- **None** –No action is taken. This action is the default.
- **Log** - Log all requests that match the URL and have the configured keywords.
- **Block** –Block all requests that match the URL and have the configured keywords.
- **Stats** –Increment the log counter for each request that matches the URL and has the configured keywords.

Add custom keywords using the CLI

Adding a custom keyword using the CLI involves the following steps:

1. Configure a web application firewall profile and define an action when the custom keyword is detected in the incoming request.

```
1 set appfw profile <profile-name> -blockKeywordAction (block | log
   | stats | none)
2 <!--NeedCopy-->
```

By default, the `-blockKeywordAction` is set to `none`.

Example:

```
1 set appfw profile test_profile -blockKeywordAction none
2 <!--NeedCopy-->
```

2. Bind the web application firewall profile with your custom keywords.

```
1 bind appfw profile <profile_name> -blockKeyword <keyword_name> -
   BlockKeywordType <literal|PCRE > -fieldName <field_name> -
   formURL <URL> -isFieldNameRegex <REGEX|NOTREGEX> -state <enable
   /disable> -comment <text>
2 <!--NeedCopy-->
```

Example:

To add **blockword** as the custom keyword and bind it to **test_profile**, run the following command:

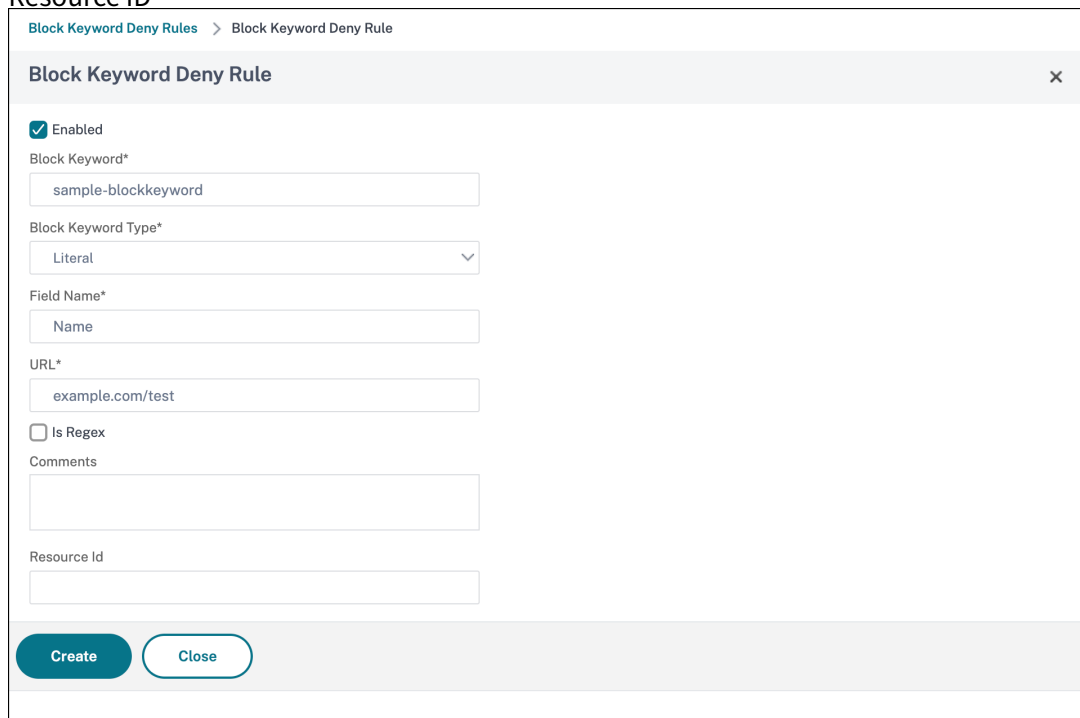

```
1 bind appfw profile test_profile -blockKeyword "blockword"
   BlockKeywordType literal -fieldName "firstname" -formURL "/"
   signup.php" -state enable
2 <!--NeedCopy-->
```

Note:

You can enter an URL or an FQDN in the URL parameter. The FQDN supports both HTTP and HTTPS protocol.

Add custom keywords using the GUI

1. Navigate to **Security > NetScaler Web App Firewall Profile > Profiles**.
2. Select a profile and click **Edit**.
3. Go to the **Advanced Settings** section and click **Deny Rules**.
4. Select **Block Keyword** and click **Edit**.
5. Click **Add** and set the following parameters:
 - Enable
 - Block Keyword
 - Block Keyword Type
 - Field Name
 - URL
 - Is Regex
 - Comments
 - Resource ID

The screenshot shows a configuration dialog for a 'Block Keyword Deny Rule'. The dialog has a title bar with 'Block Keyword Deny Rules' and 'Block Keyword Deny Rule'. The main content area includes the following fields and controls:

- Enabled
- Block Keyword*:
- Block Keyword Type*: ▼
- Field Name*:
- URL*:
- Is Regex
- Comments:
- Resource Id:

At the bottom of the dialog, there are two buttons: **Create** (in a dark blue rounded rectangle) and **Close** (in a light blue rounded rectangle).

6. Click **Create**. The custom keyword that you added is listed in the **Block Keyword Deny Rules** page.
7. Go to the **Advanced Settings** section and click **Security Checks**.
8. Select **Block Keyword** and click **Action Settings**.
9. Select the required actions and click **OK**.

View custom keyword statistics using the CLI

To view the custom keyword statistics, type the following command at the command prompt:

```
1 stat appfw profile <profile name>
2 <!--NeedCopy-->
```

Example

```
1 stat appfw profile test_profile
2 <!--NeedCopy-->
```

View custom keyword statistics the GUI

1. Navigate to **Security > NetScaler Web App Firewall > Profiles**.
2. In the details pane, select a **Web App Firewall profile** and click **Statistics**. The **NetScaler Web App Firewall Statistics** page displays the custom keyword traffic and violation details.
3. You can select **Tabular View** or switch to **Graphical View** to display the data in a tabular or graphical format.

XML external entities (XXE) Attack Protection

February 9, 2024

The XML external entities (XXE) attack protection examines if an incoming payload has any unauthorized XML input regarding entities outside the trusted domain where the web application resides. The XXE attack occurs if you have a weak XML parser that parses an XML payload with input containing references to external entities.

In a NetScaler appliance, if the XML parser is improperly configured, the impact of exploiting the vulnerability can be dangerous. It allows an attacker to read sensitive data on the web server. Perform the denial of service attack and so forth. Therefore, it is important protect the appliance from XXE attacks. Web Application Firewall is able to protect the appliance from XXE attacks as long as the content-type is identified as XML. To prevent a malicious user from bypassing this protection mechanism, WAF blocks an incoming request if the “inferred” content-type in the HTTP headers does not match with the content-type of the body. This mechanism prevents the XXE attack protection bypass when a whitelisted default or non-default content-type is used.

Some of the potential XXE threats that affect a NetScaler appliance are:

- Confidential data leaks

- Denial-of-service (DOS) attacks
- server side forgery requests
- Port scanning

Configure XML external entities (XXE) injection protection

To configure XML external entities (XXE) check by using the command interface:

In the command line interface, you can add or modify the application firewall profile command to configure the **XXE** settings. You can enable the block, log, and stats actions.

At the command prompt, type:

```
set appfw profile <name> [-inferContentTypeXmlPayloadAction <inferContentTypeX  
<block | log | stats | none>]
```

Note:

By default, the XXE action is set as “none.”

Example:

```
set appfw profile profile1 -inferContentTypeXmlPayloadAction Block
```

Where, action types are:

Block: The request is blocked without any exception to the urls in the request.

Log: If a mismatch between content-type in an HTTP request header and payload occurs, information about the violating request must be contained in the log message.

Stats: If a mismatch in the content-types is detected, the corresponding statistics for this violation type is incremented.

None: No action is taken if mismatch in content-types is detected. None cannot be combined with any other action type. Default action is set to None.

Configure XXE injection check by using NetScaler GUI

Complete the following steps to configure the XXE injection check.

1. Navigate to **Security > NetScaler Web App Firewall > Profiles**.
2. On the **Profiles** page, select a profile and click **Edit**.
3. On the **NetScaler Web App Firewall Profile** page, go to the **Advanced Settings** section and click **Security Checks**.

4. In the **Security Checks** section, select **Infer Content Type XML Payload** and click **Action** settings.
5. In the Infer Content Type XML Payload Settings page, set the following parameters:
 - a) Actions. Select one or more actions to perform for XXE injection security check.
6. Click **OK**.

Viewing XXE injection traffic and violation statistics

The NetScaler Web App Firewall Statistics page shows security traffic and security violation details in a tabular or graphical format.

To view security statistics by using the command interface.

At the command prompt, type:

```
stat appfw profile profile1
```

Viewing XXE injection statistics by using the NetScaler GUI

Complete the following steps to view the XXE injection statistics:

1. Navigate to **Security > NetScaler Web App Firewall > Profiles**.
2. In the details pane, select a Web App Firewall profile and click **Statistics**.
3. The **NetScaler Web App Firewall Statistics** page displays the XXE command injection traffic and violation details.
4. You can select **Tabular View** or switch to **Graphical View** to display the data in a tabular or graphical format.

Buffer overflow check

May 2, 2023

The Buffer Overflow check detects attempts to cause a buffer overflow on the web server. If the Web App Firewall detects that the URL, cookies, or header are longer than the configured length, it blocks the request because it can cause a buffer overflow.

The Buffer Overflow check prevents attacks against insecure operating-system or web-server software that can crash or behave unpredictably when it receives a data string that is larger than it can handle.

Proper programming techniques prevent buffer overflows by checking incoming data and either rejecting or truncating overlong strings. Many programs, however, do not check all incoming data and are therefore vulnerable to buffer overflows. This issue especially affects older versions of web-server software and operating systems, many of which are still in use.

The Buffer Overflow security check allows you to configure the **Block**, **Log**, and **Stats** actions. In addition, you can also configure the following parameters:

- **Maximum URL Length.** The maximum length the Web App Firewall allows in a requested URL. Requests with longer URLs are blocked. **Possible Values:** 0–65535. **Default:** 1024
- **Maximum Cookie Length.** The maximum length the Web App Firewall allows for all cookies in a request. Requests with longer cookies trigger the violations. **Possible Values:** 0–65535. **Default:** 4096
- **Maximum Header Length.** The maximum length the Web App Firewall allows for HTTP headers. Requests with longer headers are blocked. **Possible Values:** 0–65535. **Default:** 4096
- **Query string length.** Maximum length allowed for query string in an incoming request. Requests with longer queries are blocked. **Possible Values:** 0–65535. **Default:** 1024
- **Total request length.** Maximum request length allowed for an incoming request. Requests with longer length are blocked. **Possible Values:** 0–65535. **Default:** 24820

Using the command line to configure the Buffer Overflow security check

To configure Buffer Overflow security check actions and other parameters by using the command line

At the command prompt, type:

```
add appfw profile <name> -bufferOverflowMaxURLLength <positive_integer>
> -bufferOverflowMaxHeaderLength <positive_integer> - bufferOverflowMaxCookieLength
<positive_integer> -bufferOverflowMaxQueryLength <positive_integer>
-bufferOverflowMaxTotalHeaderLength <positive_integer>
```

Example:

```
add appfw profile profile1 -bufferOverflowMaxURLLength 7000 -bufferOverflowMaxHeaderLength
7250 - bufferOverflowMaxCookieLength 7100 -bufferOverflowMaxQueryLength
7300 -bufferOverflowMaxTotalHeaderLength 7300
```

Configure buffer overflow security check by using the NetScaler GUI

1. Navigate to **Security > Web App Firewall** and **Profiles**.
2. On the **Profiles** page, select a profile and click **Edit**.

3. On the **NetScaler Web App Firewall Profile** page, go to **Advanced Settings** section and click **Security Checks**.
4. In **Security Checks** section, select **Buffer Overflow** and click **Action Settings**.
5. In the **Buffer Overflow Settings** page, set the following parameters.
 - a. Actions. Select one or more actions to perform for command injection security check.
 - b. Maximum URL Length. Maximum length, in characters, for URLs on your protected websites. Requests with longer URLs are blocked.
 - c. Maximum Cookie Length. Maximum length, in characters, for cookies sent to your protected websites. Requests with longer cookies are blocked.
 - d. Maximum Header Length. Maximum length, in characters, for HTTP headers in requests sent to your protected websites. Requests with longer headers are blocked.
 - e. Maximum Query Length. Maximum length, in bytes, for query string sent to your protected websites. Requests with longer query strings are blocked.
 - f. Maximum Total Header Length. Maximum length, in bytes, for the total HTTP header length in requests sent to your protected websites. The minimum value of this and maxHeaderLen in httpProfile will be used. Requests with longer length are blocked.
6. Click **OK** and **Close**.

Close

Using the Log Feature with the Buffer Overflow Security Check

When the log action is enabled, the Buffer Overflow security check violations are logged in the audit log as **APPFW_BUFFEROVERFLOW_URL**, **APPFW_BUFFEROVERFLOW_COOKIE**, and **APPFW_BUFFEROVERFLOW_HDR** violations. The Web App Firewall supports both Native and CEF log formats. You can also send the logs to a remote syslog server.

If you use the GUI to review the logs, you can use the click-to-deploy feature to apply relaxations indicated by the logs.

To access the log messages by using the command line

Switch to the shell and tail the ns.logs in the **/var/log/** folder to access the log messages pertaining to the Buffer overflow violations:

```
1 > **Shell**
2 > **tail -f /var/log/ns.log | grep APPFW_BUFFEROVERFLOW**
3 <!--NeedCopy-->
```

Example of a CEF log message showing `bufferOverflowMaxCookieLength` violation in non-block mode

```
1 Oct 22 17:35:20 <local0.info> 10.217.31.98 CEF:0|Citrix|NetScaler|NS11

2 <!--NeedCopy-->
```

Example of a Native Format Log message showing `bufferOverflowMaxHeaderLength` violation in block mode

```
1 Oct 22 18:44:00 <local0.info> 10.217.31.98 10/22/2015:18:44:00 GMT ns
  0-PPE-2 : default APPFW **APPFW_BUFFEROVERFLOW_HDR** 155 0 :
  10.217.253.62 374-PPE2 khhBEeY4DB8V2D3H2sMLkXmfWnA0002 owa_profile
  **Header(User-Agent) lenth(82) is greater than maximum allowed(10)
  ** : http://aaron.stratum8.net/ **<blocked>**
2 <!--NeedCopy-->
```

To access the log messages by using the GUI

The GUI includes a useful tool (**Syslog Viewer**) for analyzing the log messages. You have multiple options for accessing the Syslog Viewer:

- Navigate to the **Application Firewall > Profiles**, select the target profile, and click **Security Checks**. Highlight the **Buffer Overflow** row and click **Logs**. When you access the logs directly from the Buffer Overflow Security Check of the profile, the GUI filters out the log messages and displays only the logs pertaining to these security check violations.
- You can also access the Syslog Viewer by navigating to **NetScaler > System > Auditing**. In the Audit Messages section, click the **Syslog messages** link to display the Syslog Viewer, which displays all log messages, including other security check violation logs. This is useful for debugging when multiple security check violations might be triggered during request processing.
- Navigate to **Application Firewall > policies > Auditing**. In the **Audit Messages** section, click the **Syslog messages** link to display the Syslog Viewer, which displays all log messages, including other security check violation logs.

The XML based Syslog Viewer provides various filter options for selecting only the log messages that are of interest to you. To select log messages for the **Buffer Overflow** check, filter by selecting **APPFW** in the drop-down list options for **Module**. The **Event Type** list offers three options, **APPFW_BUFFEROVERFLOW_URL**, **APPFW_BUFFEROVERFLOW_COOKIE**, and **APPFW_BUFFEROVERFLOW_HDR**, to view all the log messages pertaining to buffer overflow security check. You can select one or more options to further refine your selection. For example, if you select the **APPFW_BUFFEROVERFLOW_COOKIE** check box and click the **Apply** button, only log messages pertaining to the **Buffer Overflow security** check violations for the Cookie header appear in the Syslog Viewer. If you place the cursor in the row for a specific log message, multiple options, such as **Module**, **Event Type**, **Event ID**, and **Client IP**, appear below the log message. You can select any of these options to highlight the corresponding information in the log message.

Click-to-Deploy: The GUI provides click-to-deploy functionality, which is currently supported only for the buffer overflow log messages pertaining to the **URL Length** violations. You can use the Syslog Viewer to not only view the triggered violations, but also run informed decisions based on the observed lengths of the blocked messages. If the current value is too restrictive and is triggering false positives, you can select a message and deploy it to replace the current value with the URL length value seen in the message. The log messages must be in CEF log format for this operation. If the relaxation can be deployed for a log message, a check box appears at the right edge of the **Syslog Viewer** box in the row. Select the check box, and then select an option from the **Action** list to deploy the relaxation. **Edit & Deploy**, **Deploy**, and **Deploy All** are available as **Action** options. You can use the **APPFW_BUFFEROVERFLOW_URL** filter to isolate all the log messages pertaining to the configured URL length violations.

If you select an individual log message, all three action options **Edit & Deploy**, **Deploy**, and **Deploy All**

are available. If you select **Edit & Deploy**, the **Buffer Overflow settings** dialogue is displayed. The new URL length that was observed in the request is inserted into the **Maximum URL length input** field. If you click **Close** without any edits, the current configured values remain unchanged. If you click the **OK** button, the new value of the Maximum URL length replaces the previous value.

Note

The **block**, **log** and **stats** action check boxes are unchecked in the displayed **Buffer Overflow settings** dialogue, and need to be reconfigured if you select the **Edit & Deploy** option. Make sure to enable these check boxes before clicking **OK**, otherwise the new URL length gets configured but the actions are set to **none**.

If you select the check boxes for multiple log messages, you can use the **Deploy** or **Deploy All** option. If the deployed log messages have different URL lengths, the configured value gets replaced by the highest URL Length value observed in the selected messages. Deploying the rule results only in changing the **bufferOverflowMaxURLLength** value. Configured actions are retained and remain unchanged.

To use Click-to-Deploy functionality in the GUI

1. In the Syslog Viewer, select **APPFW** in the **Module** options.
2. Enable the **APPFW_BUFFEROVERFLOW_URL** check box as the **Event Type** to filter corresponding log messages.
3. Enable the check box to select the rule.
4. Use the **Action** drop-down list of options to deploy the relaxation.
5. Navigate to **Application Firewall > Profiles**, select the target profile, and click **Security Checks** to access the **Buffer Overflow** settings pane to verify that the **Maximum URL Length** value is updated.

Statistics for the Buffer Overflow violations

When the stats action is enabled, the counter for the Buffer Overflow Security Check is incremented when the Web App Firewall takes any action for this security check. The statistics are collected for Rate and Total count for Traffic, Violations, and Logs. The size of an increment of the log counter can vary depending on the configured settings. For example, if the block action is enabled, a request for a page that contains three Buffer Overflow violations increments the stats counter by one, because the page is blocked when the first violation is detected. However, if block is disabled, processing the same request increments the stat counter for violations because each violation generates a separate log message.

To display Buffer Overflow Security Check statistics by using the command line

At the command prompt, type:

```
> sh appfw stats
```

To display stats for a specific profile, use the following command:

```
> stat appfw profile <profile name>
```

To display Buffer Overflow statistics by using the GUI

1. Navigate to **System > Security > Application Firewall**.
2. In the right pane, access the **Statistics** Link.
3. Use the scroll bar to view the statistics about Buffer Overflow violations and logs. The statistics table provides real-time data and is updated every 7 seconds.

Highlights

- The buffer overflow security check allows you to configure limits to enforce the maximum length of allowed URLs, Cookies, and Headers.
- **Block, Log** and **Stats** actions enable you to monitor the traffic and configure optimal protection for your application.
- Syslog viewer enables you to filter and view all the log messages pertaining to buffer overflow violations.
- **Click-to-Deploy** functionality is supported for the **bufferOverflowMaxURLLength** violations. You can select and deploy an individual rule, or you can select multiple log messages to tweak and relax the current configured value of the maximum allowed length of the URL. The highest value of the URL from the selected group is set as the new value, to allow all these requests that are currently flagged as violations.
- The Web App Firewall now evaluates individual cookies when inspecting the incoming request. If length of any one cookie received in the Cookie header exceeds the configured **BufferOverflowMaxCookieLength**, the Buffer Overflow violation is triggered.

Important

In release 10.5.e (in a few interim enhancements builds prior to 59.13xx.e build) and in the 11.0 release (in builds prior to 65.x), Web App Firewall processing of the Cookie header was changed. In those releases, every cookie is evaluated individually, and if the length of any one cookie received in the Cookie header exceeds the configured **BufferOverflowMaxCookieLength**, the Buffer Overflow violation is triggered. As a result of this change, requests that were blocked in 10.5 and earlier release builds might be allowed, because the length of the entire cookie header is not calculated for determining the cookie length. ** In some situations, the total cookie size forwarded to the server might be larger than the accepted value, and the server might respond with “400 Bad Request”.

This change has been reverted. The behavior in the 10.5.e ->59.13xx.e and subsequent 10.5.e enhancement builds in addition to 11.0 release 65.x and subsequent builds is now similar to that of the non-enhancement builds of release 10.5. The entire raw Cookie header is now considered when calculating the length of the cookie. Surrounding spaces and the semicolon (;) characters separating the name-value pairs are also included in determining the cookie length.

Web App Firewall support for Google web toolkit

May 2, 2023

Note: This feature is available in NetScaler release 10.5.e.

Web servers following Google Web Toolkit (GWT) Remote Procedure Call (RPC) mechanisms can be secured by the NetScaler Web App Firewall without a need for any specific configuration to enable the GWT support.

What is GWT

The GWT is used for building and optimizing complex high-performance web applications by people who do not have expertise in XMLHttpRequest, and JavaScript. This open source, free development toolkit is used extensively for developing small and large scale applications and is quite frequently used for displaying browser based data such as search results for flights, hotels, and so on. The GWT provides a core set of Java APIs and widgets for writing optimized JavaScript scripts that can run on most browsers and mobile devices. The GWT RPC framework makes it easy for the client and server components of the web application to exchange Java objects over HTTP. GWT RPC services are not the same as web services based on SOAP or REST. They are simply a lightweight method for transferring data between the server and the GWT application on the client. GWT handles serialization of the Java objects exchanging the arguments in the method calls and the return value.

For popular websites that use GWT, see

<https://www.quora.com/What-web-applications-use-Google-Web-Toolkit-%28GWT%29>

How a GWT request works

The GWT RPC request is pipe delimited and has variable number of arguments. It is carried as a payload of HTTP POST and has the following values:

1. Content-type = text/x-gwt-rpc. Charset can be any value.
2. Method = POST.

Both GET and POST HTTP requests are considered valid GWT requests if content-type is “text/x-gwt-rpc”. Query strings are now supported as part of GWT requests. Configure the “InspectQueryContentTypes” parameter of the App Firewall profile to “OTHER” to examine the request query portion for content-type “text/x-gwt-rpc”.

The following example shows a valid payload for a GWT request:

```
1 5|0|8|http://localhost:8080/test/|16878339F02B83818D264AE430C20468| com
   .test.client.TestService|testMethod|java.lang.String|java.lang.
   Integer| myInput1|java.lang.Integer/3438268394|1|2|3|4|2|5|6|7|8|1|
2 <!--NeedCopy-->
```

The request can be divided into three parts:

a) Header: 5|0|8|

The first 3 digits 5|0|8| in the above request, represent “version, subversion, and size of table”, respectively. These must be positive integers.

b) String Table:

```
http://localhost:8080/test/|16878339F02B83818D264AE430C20468| com.
test.client.TestService|testMethod|java.lang.String|java.lang.Integer
|myInput1| java.lang.Integer/3438268394|
```

The members of the above pipe delimited string table contain the user-provided inputs. These inputs are parsed for the Web App Firewall checks and are identified as follows:

- 1st: `http://localhost:8080/test/`
This is the Request URL.
- 2nd: `16878339F02B83818D264AE430C20468`
Unique HEX identifier. A request is considered malformed if this string has non-hex characters.
- 3rd: `com.test.client.TestService`
Service Class name
- 4th: `testMethod`
Service method name
- 5th onwards: `java.lang.String|java.lang.Integer|myInput1|java.lang.Integer/3438268394`
Data-types and data. Non-primitive data-types are specified as
`<container>.<sub-cntnr>.name/<integer><identifier>`

c) Payload: 1|2|3|4|2|5|6|7|8|1|

The payload consists of references to the elements in the string table. These integer values cannot be larger than the number of elements in the string table.

Web App Firewall protection for GWT applications

The Web App Firewall understands and interprets GWT RPC requests, inspects the payload for security check violations, and takes specified actions.

The Web App Firewall headers and cookies checks for GWT requests are similar to those for other request formats. After appropriate URL decoding and charset conversion, all the parameters in the string table are inspected. The GWT request body does not contain field names, just the field values. The input values can be validated against the specified format by using the Web App Firewall Field Format check, which can also be used to control the length of the input. The **Cross-site Scripting** and **SQL Injection** attacks in the inputs can be easily detected and thwarted by the Web App Firewall.

Learning and relaxation rules: Learning and deployment of relaxation rules are supported for GWT requests. Web App Firewall rules are in the form of <actionURL> <fieldName> mapping. The GWT request format does not have the field names and thus requires special handling. The Web App Firewall inserts dummy field names in the learned rules that can be deployed as relaxation rules. The `-isRegex` flag works as it does for non-GWT rules.

- Action URL:

Multiple services responding to an RPC can be configured on the same web server. The HTTP request has the URL of the web server, not of the actual service handling the RPC. Therefore, relaxation is not applied on the basis of the HTTP request URL, because that would relax all the services on that URL for the target field. For GWT requests, the Web App Firewall uses the URL of the actual service found in the GWT payload, in the fourth field in the string table.

- Field name:

Since the GWT request body contains only field values, the Web App Firewall inserts dummy field names such as 1, 2, and so on when recommending learned rules.

Example of a GWT learned rule

```
1  POST /abcd/def/gh HTTP/1.1
2  Content-type: text/x-gwt-rpc
3  Host: 10.217.222.75
4  Content-length: 157
5
6  5|0|8|http://localhost:8080/acdtest/|16878339
   F02Baf83818D264AE430C20468|
7  com.test.client.TestService|testMethod|java.lang.String%3b|java.
   lang.Integer|onblur|
8
9  The learn data will be as follows:
```

```

10 > sh learningdata pr1 crossSiteScripting
11 Profile: pr1      SecurityCheck: crossSiteScripting
12 1) Url:      http://localhost:8080/acdtest/ >> From GWT Payload.
13   Field:    10
14   Hits:     1
15   Done
16 <!--NeedCopy-->

```

Example of a GWT relaxation rule

```

bind appfw profile pr1 -crossSiteScripting 1 abcd -isregex
NOTREGEX

```

Log Messages: The Web App Firewall generates log messages for the security check violations that are detected in the GWT requests. A log message generated by a malformed GWT request contains the string “GWT” for easy identification.

Example of a Log message for malformed GWT request:

```

Dec 5 21:48:02 <local0.notice> 10.217.31.247 12/05/2014:21:48:02 GMT
ns 0-PPE-0 : APPFW Message 696 0 : "GWT RPC request with malformed
payload. <blocked>"

```

Difference in processing of GWT vs non-GWT requests:

The same payload can trigger different Web App Firewall security check violations for different Content-types. Consider the following example:

```

5|0|8|http://localhost:8080/acdtest/|16878339F02Baf83818D264AE430C20468
|com.test.client.TestService|testMethod|java.lang.String%3b|java.lang
.Integer|select|

```

Content-type: application/x-www-form-urlencoded:

A request sent with this content type results in a SQL violation if the SQL Injection Type is configured to use any of the four available options: SQLSplCharANDKeyword, SQLSplCharORKeyword, SQLKeyword, or SQLSplChar. The Web App Firewall considers ‘&’ to be the field separator and ‘=’ to be the name-value separator when processing the above payload. Since neither of these characters appears anywhere in the post body, the entire content is treated as a single field name. The field name in this request contains both an SQL special character (;) and an SQL Keyword (select). Therefore violations are caught for all four SQL Injection type options.

Content-type: text/x-gwt-rpc:

A request sent with this content type triggers an SQL violation only if the SQL injection type is set to one of the following three options: SQLSplCharORKeyword, SQLKeyword, or SQLSplChar. No violation is triggered if the SQL injection type is set to SQLSplCharANDKeyword, which is the default option. The Web App Firewall considers the vertical bar | to be the field separator for the above payload in the GWT

request. Therefore, the post body is divided into various form-field values, and form-field names are added (in accordance with the convention described earlier). Because of this splitting, the SQL special character and SQL keyword become parts of separate form fields.

Form field 8: `java.lang.String%3b -\> %3b is the (;)char`

Form Field 10: `select`

As a result, when SQL Injection Type is set to **SQLSplChar**, field 8 indicates the SQL violation. For **SQLKeyword**, field 10 indicates the violation. Either of these two fields can indicate a violation if the SQL Inject type is configured with the **SQLSplCharORKeyword** option, which looks for the presence of either a keyword or a special character. No violation is caught for the default **SQLSplCharAND-Keyword** option, because there is no single field that has a value that contains both **SQLSplChar** and **SQLKeyword** together.

Tips:

- No special Web App Firewall configuration is needed to enable GWT support.
- The Content-type must be text/x-gwt-rpc.
- Learning and deploying of the relaxation rules for all the pertinent Web App Firewall security checks applied to GWT payload works the same as it does for the other supported content-types.
- Only POST requests are considered valid for GWT. All other request methods are blocked if the content-type is text/x-gwt-rpc.
- GWT requests are subject to the configured POST body limit of the profile.
- The sessionless setting for the security checks is not applicable and will be ignored.
- CEF log format is supported for the GWT log messages.

Cookie Protection

May 2, 2023

Cookie is a small packet data sent from a web server to a client browser. Cookies carry sensitive data such as passwords, user authentication details, and credentials over an HTTP connection and stored in a web browser. Hence it is highly important to protect cookies from attackers who steal information.

Cookie consistency check: Examines cookies returned with user requests to verify that they match the cookies your Web server set for that user. If a modified cookie is found, it is stripped from the request before the request is forwarded to the Web server. For more information, see [Cookie consistency check](#) topic.

Cookie hijacking protection: Hijacking refers to a situation where an attacker gains an unauthorized access to cookies. To protect cookie from authorized access, the NetScaler Web App Firewall (WAF)

challenges the TLS connection from the client along with WAF cookie consistency validation. For every new client request, the appliance validates the TLS connection and also verifies the consistency of application and session cookie in the request. For more information, see [Cookie hijacking protection](#) topic.

SameSite cookie attribute: The `SameSite` attribute in the Set-Cookie HTTP response allows you to declare if your cookie must be restricted to a first-party or same-site context. The cookie setting mitigates attacks and provides a secured web communication. For more information, see [SameSite cookie attribute](#) topic.

Cookie consistency check

January 24, 2023

The Cookie Consistency check examines cookies returned by users to verify that they match the cookies that your website set for that user. If a modified cookie is found, it is stripped from the request before the request is forwarded to the web server. You can also configure the Cookie Consistency check to transform all of the server cookies that it processes, by encrypting the cookies, proxying the cookies, or adding flags to the cookies. This check applies to requests and responses.

An attacker would normally modify a cookie to gain access to sensitive private information by posing as a previously authenticated user, or to cause a buffer overflow. The Buffer Overflow check protects against attempts to cause a buffer overflow by using a long cookie. The Cookie Consistency check focuses on the first scenario.

If you use the wizard or GUI, in the Modify Cookie Consistency Check dialog box, on the General tab you can enable or disable the following actions:

- Block
- Log
- Learn
- Statistics
- Transform. If enabled, the Transform action modifies all cookies as specified in the following settings:
 - **Encrypt Server Cookies.** Encrypt cookies set by your web server, except for any listed in the Cookie Consistency check relaxation list, before forwarding the response to the client. Encrypted cookies are decrypted when the client sends a subsequent request, and the decrypted cookies are reinserted into the request before it is forwarded to the protected web server. Specify one of the following types of encryption:

- * **None.** Do not encrypt or decrypt cookies. The default.
- * **Decrypt only.** Decrypt encrypted cookies only. Do not encrypt cookies.
- * **Encrypt session only.** Encrypt session cookies only. Do not encrypt persistent cookies. Decrypt any encrypted cookies.
- * **Encrypt all.** Encrypt both session and persistent cookies. Decrypt any encrypted cookies.

Note: When encrypting cookies, the Web App Firewall adds the

HttpOnly flag to the cookie. This flag prevents scripts from accessing and parsing the cookie. The flag therefore prevents a script-based virus or trojan from accessing a decrypted cookie and using that information to breach security. This is done regardless of the Flags to Add in Cookies parameter settings, which are handled independently of the Encrypt Server Cookies parameter settings.

- **Proxy Server Cookies.** Proxy all non-persistent (session) cookies set by your web server, except for any listed in the Cookie Consistency check relaxation list. Cookies are proxied by using the existing Web App Firewall session cookie. The Web App Firewall strips session cookies set by the protected web server and saves them locally before forwarding the response to the client. When the client sends a subsequent request, the Web App Firewall reinserts the session cookies into the request before forwarding it to the protected web server. Specify one of the following settings:

- **None.** Do not proxy cookies. The default.
- **Session only.** Proxy session cookies only. Do not proxy persistent cookies

Note: If you disable cookie proxying after having enabled it (set this value to None after it was set to Session only), cookie proxying is maintained for sessions that were established before you disabled it. You can therefore safely disable this feature while the Web App Firewall is processing user sessions.

- **Flags to Add in Cookies.** Add flags to cookies during transformation. Specify one of the following settings:

- **None.** Do not add flags to cookies. The default.
- **HTTP only.** Add the HttpOnly flag to all cookies. Browsers that support the HttpOnly flag do not allow scripts to access cookies that have this flag set.
- **Secure.** Add the Secure flag to cookies that are to be sent only over an SSL connection. Browsers that support the Secure flag do not send the flagged cookies over an insecure connection.
- **All.** Add the HttpOnly flag to all cookies, and the Secure flag to cookies that are to be sent only over an SSL connection.

If you use the command-line interface, you can enter the following commands to configure the Cookie Consistency Check:

- `set appfw profile <name> -cookieConsistencyAction [**block**] [**learn**] [**log**] [**stats**] [**none**]`
- `set appfw profile <name> -cookieTransforms ([**ON**] | [**OFF**])`
- `set appfw profile <name> -cookieEncryption ([**none**] | [**decryptOnly**] | [**encryptSession**] | [**encryptAll**])`
- `set appfw profile <name> -cookieProxying ([**none**] | [**sessionOnly**])`
- `set appfw profile <name> -addCookieFlags ([**none**] | [**httpOnly**] | [**secure**] | [**all**])`

To specify relaxations for the Cookie Consistency check, you must use the GUI. On the Checks tab of the Modify Cookie Consistency Check dialog box, click Add to open the Add Cookie Consistency Check Relaxation dialog box, or select an existing relaxation and click Open to open the Modify Cookie Consistency Check Relaxation dialog box. Either dialog box provides the same options for configuring a relaxation.

Following are examples of Cookie Consistency check relaxations:

- **Logon Fields.** The following expression exempts all cookie names beginning with the string `logon_` followed by a string of letters or numbers that is at least two characters long and no more than fifteen characters long:

```
1  ^logon_[0-9A-Za-z]{
2  2,15 }
3  $
4  <!--NeedCopy-->
```

- **Logon Fields (special characters).** The following expression exempts all cookie names beginning with the string `türkçe-logon_` followed by a string of letters or numbers that is at least two characters long and no more than fifteen characters long:

```
1  ^txC3xBCrkrxC3xA7e-logon_[0-9A-Za-z]{
2  2,15 }
3  $
4  <!--NeedCopy-->
```

- **Arbitrary strings.** Allow cookies that contain the string `sc-item_`, followed by the ID of an item that the user has added to his shopping cart (`[0-9A-Za-z]+`), a second underscore (`_`), and finally the number of these items he wants (`[1-9][0-9]?`), to be user-modifiable:

```
1  ^sc-item_[0-9A-Za-z]+_[1-9][0-9]?$
2  <!--NeedCopy-->
```

Caution: Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the URL you want to add as an exception, and nothing else. Careless use of wildcards,

and especially of the dot-asterisk (.*) metacharacter/wildcard combination, can have results you do not want or expect, such as blocking access to web content that you did not intend to block or allowing an attack that the Cookie Consistency check would otherwise have blocked.

Cookie hijacking protection

February 9, 2024

Cookie hijacking protection mitigates cookie stealing attacks from hackers. In the security attack, an attacker takes over a user session to gain unauthorized access to a web application. When a user browses a website, for example banking application, the website establishes a session with the browser. During the session, the application saves the user details such as login credentials, page visits in a cookie file. The cookie file is then sent to the client browser in the response. The browser stores the cookies to maintain active sessions. The attacker can steal these cookies either manually from the cookie store of the browser or through some rouge browser extension. The attacker then use these cookies to gain access into the user's web application sessions.

To mitigate cookie attacks, the NetScaler Web App Firewall (WAF) challenges the TLS connection from the client along with WAF cookie consistency validation. For every new client request, the appliance validates the TLS connection and also verifies the consistency of application and session cookie in the request. If an attacker tries to mix and match application cookies and session cookies stolen from the victim, the cookie consistency validation fails, and the configured cookie hijack action is applied. For more information about cookie consistency, see [Cookie Consistency Check](#).

Note:

The Cookie hijacking feature supports logging and SNMP traps. For more information about logging, see ADM topic and for more information about SNMP configuration see SNMP topic.

Limitations

- JavaScript must be enabled in the client browser.
- Cookie Hijacking protection is not supported on TLS version 1.3.
- Limited support for the Internet Explorer (IE) browser because the browser does not reuse the SSL connections. Results in multiple redirects sent for a request eventually leading to a “MAX REDIRECTS EXCEEDED” error in the IE browser.

How cookie hijacking protection works

The following scenarios explain how cookie hijacking protection works in a NetScaler appliance.

Scenario 1: User accessing the first webpage without session cookie

1. The user attempts to authenticate into a web application and begins to access the first webpage without any ADC session cookie in the request.
2. When the request is received, the appliance creates an Application Firewall session with a session cookie ID.
3. This initiates a TLS connection for the session. Since the JavaScript is not sent and ran on the client browser, the appliance marks the TLS connection as validated and no challenge is required.

Note:

Even if an attacker tries to send all the app cookie IDs from a victim without sending the session cookie, the appliance detects the issue and strips off all the app cookies in the request before forwarding the request to the back-end server. The back end server considers this request without no app cookie and takes necessary as per its configuration.

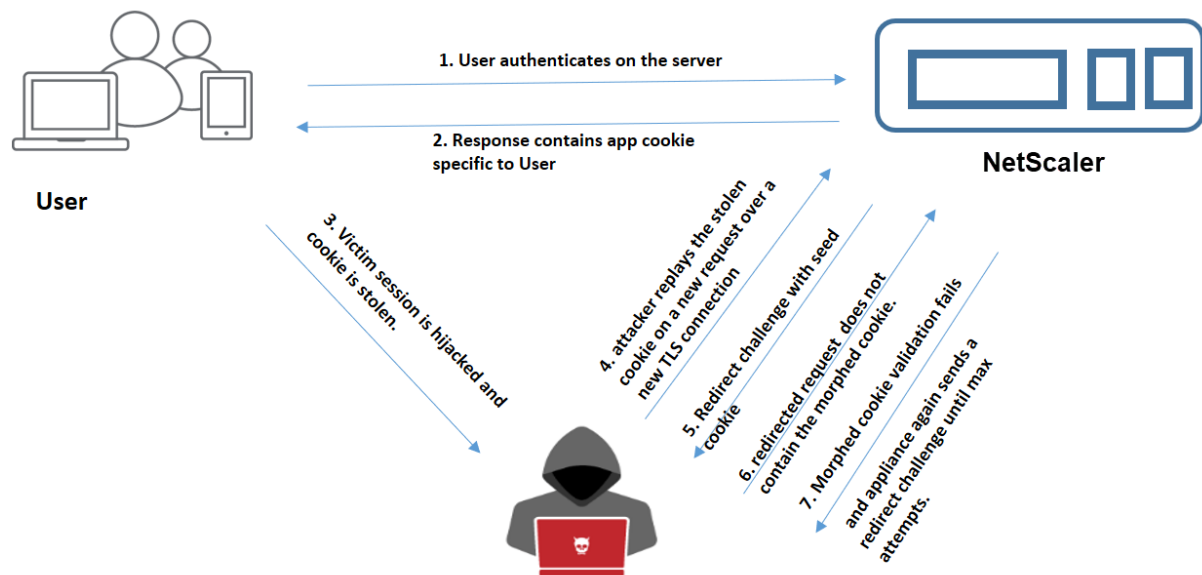

4. When the back-end server sends a response, the appliance receives the response and forwards it with a JavaScript session token and seed cookie. The appliance then marks the TLS connection as verified.
5. When the client browser receives the response, the browser runs the JavaScript and generates a morphed cookie ID using the session token and seed cookie.
6. When a user sends a subsequent request over the TLS connection, the appliance bypasses the morphed cookie validation. This is because the TLS connection is already validated.

Scenario 2: User accessing successive webpages over new TLS connection with session cookie

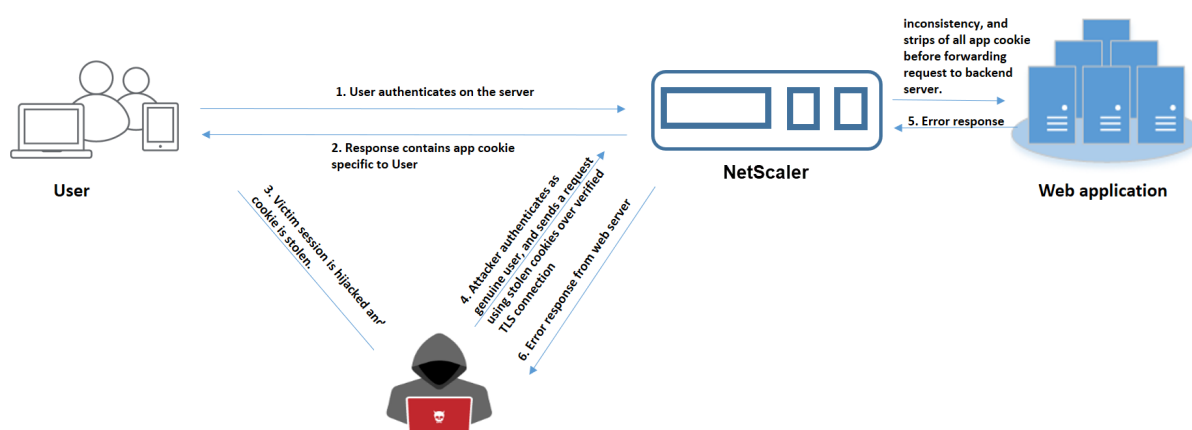

1. When a user sends an HTTP request for successive pages over a new TLS connection, the browser sends session cookie ID and morphed cookie ID.
2. Since this is a new TLS connection, the appliance detects the TLS connection and challenges the client with redirect response with seed cookie.
3. The client upon receiving the response from the ADC, calculates the morphed cookie using the session's token and new seed cookie.
4. The client then sends this newly calculated morphed cookie along with a session ID.
5. If the morphed cookie calculated within the ADC appliance and the one sent over the request matches, then the TLS connection is marked as verified.
6. If the calculated morphed cookie differs from the one present in the client request, then validation fails. After which, the appliance sends the challenge back to the client, to send a proper morphed cookie.

Scenario 3: Attacker impersonating as a non-authenticated user

1. When a user authenticates into the web application, the attacker uses different techniques to steal the cookies and replay them.
2. Since this is a new TLS connection from the attacker, the ADC sends a redirect challenge along with a new seed cookie.
3. Since the attacker does not have JavaScript running, the response from the attacker for the redirected request does not contain the morphed cookie.
4. This results in morphed cookie validation failure at the ADC appliance side. The appliance again sends a redirect challenge to the client.
5. If the number of morphed cookie validation attempts exceeds the threshold limit, the appliance flags the status as cookie hijacking.
6. If the attacker tries to mix and match application cookies and session cookies stolen from the victim, the cookie consistency check fails, and the appliance applies the configured cookie hijack action.

Scenario 4: Attacker impersonating as an authenticated user

1. Attackers can also attempt to authenticate into a web application as a genuine user and replay the victim's cookies to gain access to the web session.
2. The ADC appliance detects such impersonated attackers also. Although a verified TLS connection is used by the attacker in replaying a victim's cookie, the ADC appliance still verifies if the session cookie and application cookie in the request are consistent. The appliance verifies the consistency of an application cookie using the session cookie in the request. Since the request contains an attacker's session cookie and a victim's app cookie, the cookie consistency validation fails.
3. As a result, the appliance applies the configured cookie hijack action. If the configured action is set as "block," then the appliance strips off all the application cookies and sends the request to the back-end Server.
4. The back-end server receives a request with no application cookie and so it responds an error response to the attacker, such as "User not logged in".

Configure cookie hijacking by using the CLI

You can select a specific application firewall profile and set one or more actions that prevent cookie hijacking.

At the command prompt, type:

```
set appfw profile <name> [-cookieHijackingAction <action-name> <block  
| log | stats | none>]
```

Note:

By default, the action is set to “none.”

Example:

```
set appfw profile profile1 - cookieHijackingAction Block
```

Where, action types are:

Block: Block connections that violate this security check.

Log: Log violations of this security check.

Stats: Generate statistics for this security check.

None: Disable all actions for this security check.

Configure cookie hijacking by using the NetScaler GUI

1. Navigate to **Security > NetScaler Web App Firewall > Profiles**.
2. On the **Profiles** page, select a profile and click **Edit**.
3. On the **NetScaler Web App Firewall Profile** page, go to **Advanced Settings** section and click **Security Checks**.
4. In the **Security Checks** section, select **Cookie Hijacking** and then click **Action** settings.
5. In the **Cookie Hijacking Settings** page, select one or more actions to prevent cookie hijacking.
6. Click **OK**.

Add a relaxation rule for cookie consistency validation by using the NetScaler GUI

To handle false positives in cookie consistency validation, you can add a relaxation rule for cookies that can be exempted from cookie validation.

1. Navigate to **Security > NetScaler Web App Firewall > Profiles**.
2. On the **Profiles** page, select a profile and click **Edit**.
3. On the **NetScaler Web App Firewall Profile** page, go to **Advanced Settings** section and click **Relaxation rules**.

4. In the **Relaxation Rules** section, select **Cookie Consistency** and click **Action**.
5. In the **Cookie Consistency Relaxation Rule** page, set the following parameters.
 - a) Enabled. Select if you want to enable the relaxation rule.
 - b) Is Cookie Name Regex. Select if the cookie name is a regular expression.
 - c) Cookie Name. Enter the name of the cookie that can be exempted from cookie validation.
 - d) Regex Editor. Click this option to provide the regular expression details.
 - e) Comments. A brief description about the cookie.
6. Click **Create** and **Close**.

View cookie hijacking traffic and violation statistics by using the CLI

View security traffic and security violation details in a tabular or graphical format.

To view security statistics:

At the command prompt, type:

```
stat appfw profile profile1
```

| Appfw profile Traffic Statistics | Rate (/s) | Total |
|----------------------------------|-----------|-------|
| Requests | 0 | 0 |
| Request Bytes | 0 | 0 |

SameSite cookie attribute

May 2, 2023

For secure web communication, Google has mandated the usage of the [SameSite](#) cookie attribute. By complying with Google Chrome’s new [SameSite](#) policy, the NetScaler appliance can manage third-party cookies with the [SameSite](#) attribute set in the `set-cookie` header. The cookie setting mitigates attacks and provides a secured web communication.

Until February 2020, the [SameSite](#) attribute was not explicitly set in the cookie. The browser took the default value as “None.” However, with certain browser upgrade, such as Google Chrome 80, there is a change in the default cross-domain behavior in cookies.

Setting cookie attribute value

The [SameSite](#) attribute is set to one of the following values and for the Google Chrome browser, the default value is set as “Lax.”

None. Indicates the browser to use the cookie for requests in the cross-site context only on secure connections.

Lax. Indicates the browser to use the cookie for requests in the same-site context. In the cross-site context, only safe HTTP methods like GET request can use the cookie.

Strict. Use the cookie only when the user is requesting for the domain explicitly.

Note:

If set-cookies (including firewall session cookies) have the `SameSite` attribute and if the `addcookiesamesite` attribute flag is enabled in the Web Application Firewall profile, then the `SameSite` attribute is overwritten according to the value configured in the profile.

Configure the SameSite attribute in the Web App Firewall profile by using the CLI

To configure the `SameSite` attribute, you must complete the following steps:

1. Enable the `SameSite` cookie attribute.
2. Set the cookie attribute for the appfw session cookies.

Enable the ‘Samesite’ cookie attribute

At the command prompt, type:

```
set appfw profile <profile-name> -insertCookieSameSiteAttribute \ ( ON  
| OFF)
```

Example:

```
set appfw profile p1 -insertCookieSameSiteAttribute ON
```

Set same site cookie attribute value for Web Application Firewall session cookies

At the command prompt, type:

```
set appfw profile <profile-name> - cookieSameSiteAttribute \ ( LAX |  
NONE | STRICT )
```

Example:

```
set appfw profile p1 - cookieSameSiteAttribute LAX
```

Where attribute types are,

None. Cookie attribute SameSite is set to “none” and marked secure for all WAF and application cookies.

Lax. Cookie attribute SameSite is set to “Lax” for all WAF and application cookies.

Strict. Cookie attribute SameSite is set to “Lax” for all WAF and application cookies.

Configure the SameSite cookie attribute in the Web App Firewall profile by using the GUI

1. Navigate to **Security > NetScaler Web App Firewall > Profiles**.
2. In the details pane, select a profile and click **Edit**.
3. In the **NetScaler Web App Firewall Profile** page, click **Profile Settings** under **Advanced Settings**.
4. In **Profile Settings** section set the following parameters:
 - a. Insert the cookie `Samesite` attribute. Select the check box to enable the cookie `Samesite` attribute.
 - b. Cookie Samesite Attribute. Select an option from the drop-down list to set the `Samesite` cookie value.
5. Click **OK** and **Done**.

The screenshot displays the 'Profile Settings' configuration page for a NetScaler Web App Firewall profile. The 'Name' field is set to 'test' and the 'Profile Type' is 'HTML'. Under the 'Inspected Content Types' section, three content types are checked: 'application/x-www-form-urlencoded', 'multipart/form-data', and 'text/x-gwt-rpc'. In the 'Common Settings' section, the 'Signature Post Body Limit (Bytes)' is set to 2048. The 'Bound Signatures' dropdown is empty. The 'Cookie Samesite Attribute' dropdown is set to 'Lax' and is highlighted with a red box. The 'Insert Cookie Samesite Attribute' checkbox is checked and also highlighted with a red box. Other settings include 'Multiple Header Actions' with 'Block' and 'Log' checked, and 'Inspect Query Content Types' with 'HTML', 'XML', and 'JSON' listed.

Data leak prevention checks

September 21, 2020

The data-leak-prevention checks filter responses to prevent leaks of sensitive information, such as credit card numbers and social security numbers, to unauthorized recipients.

Credit card check

May 2, 2023

If you have an application that accepts credit cards, or your websites have access to database servers that store credit card numbers, you must use Data Leak Prevention (DLP) measures and configure protection for each type of credit card that you accept.

The NetScaler Web App Firewall Credit Card check prevents attackers from exploiting Data Leak Prevention flaws to obtain credit card numbers of your customers. By following simple configuration steps, you can enforce protection of one or more of the following credit cards: 1) Visa, 2) Master Card, 3) Discover, 4) American Express (Amex), 5) JCB, and 6) Diners Club.

The Credit Card security check examines server responses to identify instances of the target credit card numbers, and applies a specified action when such a number is found. The action can be to transform the response by X'ing out all but the last group of digits in the credit card number, or to block the response if it contains more than a specified number of credit card numbers. If you specify both, the block action takes precedence. The Maximum credit cards allowed per page setting determines when the block action is invoked. The default setting, 0 (no credit card numbers allowed on the page), is the safest, but you can allow up to 255. Depending on where the violation is detected in the response and the block action gets triggered, you might get fewer than the maximum allowed number of credit cards in the response.

To avoid false positives, you can apply relaxations to exempt specific numbers from the Credit Card check. For example, a social security number, purchase order number, or Google account number might be similar to a credit card number. You can specify individual numbers or use a regular expression to indicate the string of digits to be bypassed when processing the response URL for credit card inspection.

If you're not sure which credit card numbers to exempt, you can use the learn feature to generate recommendations based on the learned data. To get optimal benefit without compromising performance, you might want to enable this option for a short time to get a representative sample of the rules, and then deploy the relaxations and disable learning.

If you enable the log feature, the Credit Card check generates log messages indicating the actions that it takes. You can monitor the logs to determine whether responses to legitimate requests are getting blocked. A large increase in the number of log messages can indicate thwarted attempts to gain access. By default, the `doSecureCreditCardLogging` parameter is ON, so the credit card number is not included in the log message generated by the safe commerce (Credit Card) violation.

The stats feature gathers statistics about violations and logs. An unexpected surge in the stats counter might indicate that your application is under attack.

To configure the Credit Card security check for protecting your application, configure the profile that governs inspecting the traffic to and from this application.

Note:

A website that does not access a SQL database usually does not have access to sensitive private information such as credit card numbers.

Using the command line to configure the credit card check

In the command line interface, you can use either the `set appfw profile` command or the `add appfw profile` command to activate credit-card checking and specify which actions to perform. You can use the `unset appfw profile` command to revert back to the default settings. To specify relaxations, use the `bind appfw` command to bind credit card numbers to the profile.

To configure a credit card check by using the command line

Use either the `set appfw profile` command or the `add appfw profile` command, as follows:

- `set appfw profile <name> -creditCardAction (([block][learn] [log][stats]) | [none])`
- `set appfw profile <name> -creditCard (VISA | MASTERCARD | DISCOVER | AMEX | JCB | DINERSCLUB)`
- `set appfw profile <name> -creditCardMaxAllowed <integer>`
- `set appfw profile <name> -creditCardXOut ([ON] | [OFF])<name> -doSecureCreditCardLogging ([ON] | [OFF])`
- To configure a Credit Card relaxation rule by using the command line

Use the `bind` command to bind the credit card number to the profile. To remove a credit card number from a profile, use the `unbind` command, with the same arguments that you used for the `bind` command. You can use the `show` command to display the credit card numbers bound to a profile.

- To bind a credit card number a profile

```
bind appfw profile <profile-name> -creditCardNumber <any number/regex> "<url>"
```

Example: `bind appfw profile test_profile -creditCardNumber 378282246310005 http://www.example.com/credit_card_test.html`

- To unbind a credit card number from a profile

```
unbind appfw profile <profile-name> -creditCardNumber <credit  
card number / regex> <url>
```

- To show the list of credit card numbers bound to a profile.

```
show appfw profile <profile>
```

Using the GUI to configure the credit card check

In the GUI, you configure the credit card security check in the pane for the profile associated with your application.

To add or modify the Credit Card security check by using the GUI

1. Navigate to **Web App Firewall > Profiles**, highlight the target profile, and click **Edit**.
2. In the **Advanced Settings** pane, click **Security Checks**.

The security check table displays the currently configured action settings for all the security checks. You have 2 options for configuration:

- a) If you just want to enable or disable Block, Log, Stats, and Learn actions for Credit Card, you can select or clear check boxes in the table, click **OK**, and then click **Save** and **Close** to close the **Security Check** pane.
 - b) If you want to configure additional options for this security check, double click Credit Card, or select the row and click **Action Settings** to display additional options as follows:
 - Out—Mask any credit card number detected in a response by replacing each digit, except the digits in the final group, with the letter “X.
 - Maximum credit cards allowed per page—Specify the number of credit cards that can be forwarded to the client without triggering a block action.
 - Protected Credit Cards. Select or clear a check box to enable or disable protection for each type of credit card.
 - You can also edit the Block, Log, Stats and Learn actions in the Credit Card Settings pane.After making any of the above changes, click OK to save the changes and return to the Security Checks table. You can proceed to configure other security checks if needed. Click OK to save all the changes you have made in the Security Checks section and then click Save and Close to close the Security Check pane.
3. In the **Advanced Settings** pane, click **Profile settings**. To enable or disable secure logging of credit card Numbers, select or clear the **Secure Credit Card Logging** check box. (By default, it is selected).

Click **OK** to save the changes.

- To configure a Credit Card relaxation rule by using the GUI
 1. Navigate to **Web App Firewall > Profiles**, highlight the target profile, and click **Edit**.
 2. In the **Advanced Settings** pane, click **Relaxation Rules**. The Relaxation Rules table has a Credit Card entry. You can double click, or select this row and click **Edit** to access the **Credit Card Relaxation Rules** dialogue. You can perform Add, Edit, Delete, Enable, or Disable operations for relaxation rules.

Using the learn feature with the credit card check

When the learn action is enabled, the Web App Firewall learning engine monitors the traffic and learns the triggered violations. You can periodically inspect these learned rules. After due consideration, if you want to exempt a specific string of digits from the Credit Card security check, you can by deploy the learned rule as a relaxation rule.

- To view or use learned data by using the command line interface

```
show appfw learningdata <profilename> creditCardNumber
rm appfw learningdata <profilename> -creditcardNumber <credit
card number> "<url>"
export appfw learningdata <profilename> creditCardNumber
```

- To view or use learned data by using the GUI
 1. Navigate to **Web App Firewall > Profiles**, highlight the target profile, and click **Edit**.
 2. In the **Advanced Settings** pane, click **Learned Rules**. You can select the Credit Card entry in the Learned Rules table and double-click it to access the learned rules. You can deploy the learned rules or edit a rule before deploying it as a relaxation rule. To discard a rule, you can select it and click the **Skip** button. You can edit only one rule at a time, but you can select multiple rules to deploy or skip.

You also have the option to show a summarized view of the learned relaxations by selecting the Credit Card entry in the Learned Rules table and clicking Visualizer to get a consolidated view of all the learned violations. The visualizer makes it very easy to manage the learned rules. It presents a comprehensive view of the data on one screen and facilitates taking action on a group of rules with one click. The biggest advantage of the visualizer is that it recommends regular expressions to consolidate multiple rules. You can select a subset of these rules, based on the delimiter and Action URL. You can display 25, 50, or 75 rules in the visualizer, by selecting the number from a drop-down list. The visualizer for learned rules offers the option to edit the rules and deploy them as relaxations. Or you can skip the rules to ignore them.

Using the log feature with the credit card check

When the log action is enabled, the Credit Card security check violations are logged in the audit log as APPFW_SAFECOMMERCE or APPFW_SAFECOMMERCE_XFORM violations. The Web App Firewall supports both Native and CEF log formats. You can also send the logs to a remote syslog server.

The default setting for doSecureCreditCardLogging is ON. If you change it to OFF, both credit card number and type are included in the log message.

Depending on the settings configured for the Credit Card checks, the application-firewall generated log messages might include the following information:

- Response was blocked or not blocked.
- Credit card numbers were transformed (X'd out). A separate log message is generated for each transformed credit card number, so multiple log messages might be generated during processing of a single response.
- Response contained the maximum number of potential credit card numbers.
- Credit card numbers and their corresponding types.
- To access the log messages by using the command line

Switch to the shell and tail the ns.logs in the /var/log/ folder to access the log messages pertaining to the Credit Card violations:

- Shell

```
tail -f /var/log/ns.log
```

```
grep SAFECOMMERCE
```

-

- To access the log messages by using the GUI
 1. The GUI includes a very useful tool (Syslog Viewer) for analyzing the log messages. You have a couple of options for accessing the Syslog Viewer: Navigate to the **target profile > Security Checks**. Highlight the Credit Card row and click Logs. When you access the logs directly from the Credit Card security check of the profile, it filters out the log messages and displays only the logs pertaining to these security check violations.
 2. You can also access the Syslog Viewer by navigating to **NetScaler > System > Auditing**. In the Audit Messages section, click the **Syslog messages** link to display the Syslog Viewer, which displays all log messages, including other security check violation logs. This is useful for debugging when multiple security check violations might be triggered during request processing.

The HTML based Syslog Viewer provides various filter options for selecting only the log messages that are of interest to you. To access Credit Card security check violation log messages, filter by selecting APPFW in the dropdown options for Module. The Event Type displays a rich set of options to further refine your selection. For example, if you select the APPFW_SAFECOMMERCE and APPFW_SAFECOMMERCE_XFORM check boxes and click the Apply button, only log messages pertaining to the Credit Card security check violations appear in the Syslog Viewer.

If you place the cursor in the row for a specific log message, multiple options, such as Module and EventType, appear below the log message. You can select any of these options to highlight the corresponding information in the logs.

Example of a Native format log message when the response is not blocked

```

1 May 29 01:26:31 <local0.info> 10.217.31.98 05/29/2015:01:26:31 GMT ns

Statistics for the credit card violations

When the stats action is enabled, the corresponding counter for the Credit Card check is incremented when the Web App Firewall takes any action for this security check. The statistics are collected for Rate and Total count for Traffic, Violations, and Logs. The increment of the log counter can vary depending on the configured settings. For example, if the block action is enabled and the Max Allowed credit card setting is 0, the request for a page that contains 20 credit card numbers increments the stats counter by one when the page is blocked as soon as the first credit card number is detected. However, if block is disabled and transform is enabled, processing the same request increments the statistics counter for logs by 20, because each credit card transformation generates a separate log message.

- To display Credit Card statistics by using command line

At the command prompt, type:

```
sh appfw stats
```

To display stats for a specific profile, use the following command:

```
stat appfw profile <profile name>
```

To display Credit Card statistics by using GUI

1. Navigate to **System > Security > Web App Firewall**.
2. In the right pane, access the **Statistics** Link.
3. Use the scroll bar to view the statistics about Credit Card violations and logs. The statistics table provides real-time data and is updated every 7 seconds.

Highlights

Note the following points about the Credit Card security check:

- The Web App Firewall enables you to protect credit card information and detect any attempts to access this sensitive data.
- To use the Credit Card protection check, you must specify at least one type of credit card and an action. The check is then applied to HTML, XML, and Web 2.0 profiles.

You can pipe the output of `sh appfw profile` command and `grep` for CreditCard to see all the Credit Card specific configuration. For example, `sh appfw profile my_profile`

`grep CreditCard` displays the configured settings of various parameters as well as the relaxation rules pertaining to the Credit Card check for the Web App Firewall profile named `my_profile`.

- You can exclude specific numbers from Credit Card inspection without bypassing the security check inspection for the rest of the credit card numbers.
- Relaxation is available for all Web App Firewall protected credit card patterns. In the GUI, you can use the visualizer to specify Add, Edit, Delete, Enable, or Disable operations on relaxation rules.
- The Web App Firewall learning engine can monitor the outgoing traffic to recommend rules based on observed violations. Visualizer support is also available for managing the learned credit card rules in the GUI. You can edit and deploy the learned rules, or skip them after careful inspection.
- The setting for number of allowed credit cards applies to each response. It does not pertain to the cumulative total of credit card numbers observed during the entire user session.
- The number of X'd out digits depends on the length of the credit card numbers. Ten digits are X'd out for credit cards that have 13 through 15 digits. Twelve digits are X'd out for credit cards that have 16 digits. If your application does not require sending the entire credit card number in the response, Citrix recommends that you enable this action to mask the digits in the credit card numbers.
- The X-out operation transforms all the credit cards and works independently of the configured settings for the maximum number of allowed credit cards. For example, if there are 4 credit cards in the response and the `creditCardMaxAllowed` parameter is set to 10, all 4 credit cards are X'd-out, but they are not blocked. If the credit card numbers are spread out in the document, a partial response with X'd-out numbers might be sent to the client before the response is blocked.
- Do not disable the `doSecureCreditCardLogging` parameter before due consideration. When this parameter is turned off, the credit card numbers are displayed and are accessible in the log messages. These numbers are not masked in the logs, even if the X-out action is enabled. If you are sending logs to a remote syslog server, and the logs are compromised, the credit card numbers can be exposed.
- When the response page is blocked because of a Credit Card violation, the Web App Firewall does not redirect to the error page.

Safe object check

May 2, 2023

The Safe Object check provides user-configurable protection for sensitive business information, such as customer numbers, order numbers, and country-specific or region-specific telephone numbers or

postal codes. A user-defined regular expression or custom plug-in tells the Web App Firewall the format of this information and defines the rules to be used to protect it. If a string in a user request matches a safe object definition, the Web App Firewall either blocks the response, masks the protected information, or removes the protected information from the response before sending it to the user, depending on how you configured that particular safe object rule.

The Safe Object check prevents attackers from exploiting a security flaw in your web server software or on your website to obtain sensitive private information, such as company credit card numbers or social security numbers. If your websites do not have access to these types of information, you do not need to configure this check. If you have a shopping cart or other application that can access such information, or your websites have access to database servers that contain such information, you must configure protection for each type of sensitive private information that you handle and store.

Note:

A website that does not access an SQL database usually does not have access to sensitive private information.

The safe object check is unlike that for any other check. Each safe object expression that you create is the equivalent of a separate security check, similar to the credit card check, for that type of information.

Configure the safe object check using the GUI

Note

You must configure the safe object check only using the GUI. The command-line interface is not supported.

To add a safe object security check using the GUI:

1. Navigate to **Security > NetScaler Web App Firewall > Profiles**.
2. Select the required profile and click **Edit**.
3. In the **Advanced Settings** pane, click **Relaxation Rules**.
4. Select **Safe Object** and click **Edit**.
5. Click **Add** and configure the following:
 - **Safe Object Name.** A name for your new safe object. The name can begin with a letter, number, or the underscore symbol. The name can consist of one to 255 letters, numbers, and the hyphen (-), period (.) pound (#), space (), at sign (@), equals (=), colon (:), and underscore (_) symbols.

- **Actions.** Enable or disable the **Block**, **Log**, and **Statistics** actions, and the following actions:
 - **X-Out.** Mask any information that matches the safe object expression with the letter “X”.
 - **Remove.** Remove any information that matches the safe object expression.
- **Regular Expression.** Enter a PCRE-compatible regular expression that defines the safe object. You can create the regular expression in one of following ways:
 - By typing the regular expression directly into the text box
 - By using the **Regex Tokens** menu to enter regular expression elements and symbols directly into the text box
 - By opening the Regular Expressions Editor and using it to construct the expression. The regular expression must consist of ASCII characters only. Do not cut and paste characters that are not part of the basic 128-character ASCII set. If you want to include non-ASCII characters, you must manually type those characters in PCRE hexadecimal character encoding format.

Note:

Do not use start anchors (^) at the beginning of Safe Object expressions, or end anchors (\$) at the end of Safe Object expressions. These PCRE entities are not supported in Safe Object expressions, and if used, causes your expression not to match what it was intended to match.

- **Maximum Match Length.** Enter a positive integer that represents the maximum length of the string that you want to match. For example, if you want to match U.S. social security numbers, enter the number 11 in this field. That allows your regular expression to match a string with nine numerals and two hyphens. If you want to match California driver’s license numbers, enter the number eight (8).

Caution:

If you do not maximum match length, the Web App Firewall uses the default value of one (1) when filtering for strings that match your safe object expressions. As a result, most safe object expressions fail to match their target strings.

You can modify an existing express by selecting the required expression, clicking **Open** and then configuring the expression in the **Modify Safe Object** dialog box.

Following are examples of Safe Object check regular expressions:

- Look for strings that appear to be U.S. social security numbers (SSN). The SSN consists of the following characters in the mentioned order:

- Three numerals (the first of which must not be zero)
- A hyphen
- Two more numerals
- A second hyphen
- A string of four more numerals

```

1  [1-9][0-9]{
2  3,3 }
3  -[0-9]{
4  2,2 }
5  -[0-9]{
6  4,4 }
7
8  <!--NeedCopy-->
```

- Look for strings that appear to be California driver's license IDs, which start with a letter and are followed by a string of exactly seven numerals:

```

1  [A-Za-z][0-9]{
2  7,7 }
3
4  <!--NeedCopy-->
```

- Look for strings that appear to be customer IDs. The customer IDs consist of the following in the mentioned order:
 - A string of five hexadecimal characters (all the numerals and the letters A through F)
 - A hyphen
 - A three-letter code
 - A second hyphen
 - A string of 10 numerals

```

1  [0-9A-Fa-f]{
2  5,5 }
3  -[A-Za-z]{
4  3,3 }
5  -[0-9]{
6  10,10 }
7
8  <!--NeedCopy-->
```

Caution:

Regular expressions are powerful. If you are less familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that the regular expression defines exactly the type of string you want to add as a safe object definition. Careless use of wildcards, and especially of the dot-asterisk (.*?) metacharacter/wildcard combination, can have results you

did not want or expect, such as blocking access to web content that you did not intend to block.

Advanced form protection checks

November 11, 2021

The advanced Form Protection checks examine web form data to prevent attackers from compromising your system by modifying the web forms on your websites or sending unexpected types and quantities of data to your website in a form.

Note:

SQL, cross-site scripting, FFC, and FieldFormat protection checks are applied if the **Exclude Upload Files From Security Checks** is unset.

A file upload is also a form element that has control-name **name** field that is submitted as part of form submission.

Refer to this page, for more information: [Forms](#)

Note

Form protections will close nested forms when any form based checks are enabled. This is to ensure [HTML Standard](#) is followed.

Field formats check

May 2, 2023

The Field Formats check verifies the data that users send to your websites in web forms. It examines both the length and type of data to ensure that it is appropriate for the form field in which it appears. If the Web App Firewall detects inappropriate web form data in a user request, it blocks the request.

By preventing an attacker from sending inappropriate web form data to your website, the Field Formats check prevents certain types of attacks on your website and database servers. For example, if a particular field expects the user to enter a phone number, the Field Formats check examines the user-submitted input to ensure that the data matches the format of a phone number. If a particular field expects a first name, the Field Formats check ensures that the data in that field is of a type and length appropriate for a first name. It does the same thing for each form field that you configure it to protect.

This check applies to HTML requests only. It does not apply to XML requests. You can configure Field Format Checks in HTML profiles or Web 2.0 profiles to inspect HTML payload for protecting your applications. The Web App Firewall also supports Field Format Check protection for Google Web Toolkit (GWT) applications.

The Field Formats check requires that you enable one or more actions. The Web App Firewall examines the submitted inputs and applies the specified actions.

Note

Field format rules are tightening rules. Adding them to relaxation list from learned data acts as a blocking rule.

To relax field format rules, please remove particular “fieldname” from the fieldformat relaxations list.

You have the option to set the default field formats to specify Field Type and the minimum and maximum length of data expected in each form field on each web form that you want to protect. You can deploy relaxation rules to configure a Field Format for an individual field of a specific form. Multiple rules can be added to specify the field name, the action URL, and Field Formats. Specify Field Formats to accept different types of inputs in different form fields. The learning feature can provide recommendations for the relaxation rules.

Field Format Actions—You can enable Block, Log, Stats, and Learn actions. At least one of these actions must be enabled to engage the Field Format Check protection.

- **Block.** If you enable block, the block action is triggered if the input does not conform to the specified Field Format. If a rule was configured for the target field, the input is checked against the specified rule. Otherwise, it is checked against the default field format specification. Any mismatch in the Field Type or min/max length specification results in blocking the request.
- **Log.** If you enable the log feature, the Field Format check generates log messages indicating the actions that it takes. You can monitor the logs to determine whether responses to legitimate requests are getting blocked. A large increase in the number of log messages can indicate malicious attempts to launch an attack.
- **Stats.** If enabled, the stats feature gathers statistics about violations and logs. An unexpected surge in the stats counter might indicate that your application is under attack, or you might have to revisit the configuration to see if the specified field format is too restrictive.
- **Learn.** If you are not sure which Field Types or minimum and maximum length values might be ideally suited for your application, you can use the learn feature to generate recommendations based on the learned data. The Web App Firewall learning engine monitors the traffic and provides field format recommendations based on the observed values. To get optimal benefit without compromising performance, you might want to enable the learn option for a short time to get a representative sample of the rules, and then deploy the rules and disable learning.

Note: The Web App Firewall’s learning engine can distinguish only the first 128 bytes of the

name. If a form has multiple fields with names that match for the first 128 bytes, the learning engine might not be able to distinguish between them. Similarly, the deployed relaxation rule might inadvertently relax all such fields.

Default Field Format—In addition to configuring the actions, you can configure the default Field Format to specify the type of data expected in all the form fields for your application. A Field Type can be selected as the Field Format type. Minimum length and Maximum length parameters can be used to specify the length of the allowed inputs. As an alternative to Field Types, you can use Character Maps to specify what's allowed in a field (except in cluster deployments).

- **Field Type**—Field Types are named expressions to which you assign assigned priority values. Field Type expressions specify the allowed inputs and are matched against the submitted data to determine whether the received values are consistent with the allowed values. The Field Types are checked in the order of their priority numbers. A lower number indicates a higher priority. The Web App Firewall gives you the option to add your own Field Types and assign them the priorities you want. The priority value can range from 0 through 64000. The following built-in Field Types are provided to help simplify the configuration process:

```

1  > sh appfw fieldtype
2  1)      Name:  integer           Regex:  "[+-]?[0-9]+$"
3          Priority:  30           Comment: Integer
4          Builtin:  IMMUTABLE
5  2)      Name:  alpha            Regex:  "[a-zA-Z]+$"
6          Priority:  40           Comment: "Alpha
7          characters"
8          Builtin:  IMMUTABLE
9  3)      Name:  alphanumeric     Regex:  "[a-zA-Z0-9]+$"
10         Priority:  50           Comment: "Alpha-numeric
11         characters"
12         Builtin:  IMMUTABLE
13  4)      Name:  nohtml           Regex:  "[^&<>]*$"
14         Priority:  60           Comment: "Not HTML"
15         Builtin:  IMMUTABLE
16  5)      Name:  any              Regex:  ".*$"
17         Priority:  70           Comment: Anything
18         Builtin:  IMMUTABLE
19  Done
20  >
21  <!--NeedCopy-->

```

Note: The built-in Field Types are IMMUTABLE. They cannot be modified or removed. Any Field Types that you add are MODIFIABLE. You can edit them or remove them.

Configuring a Field Type as a default Field Format might be useful when you have a PCRE expression that can identify the valid inputs in all or most of the form fields for your application and exclude the invalid inputs. For example, if all the inputs in your application forms are expected to contain only numbers and letters, you might want to use the built-in Field Type alphanumeric as

the default Field Type. Any non-alphanumeric character such as a backslash () or semicolon ; in the input will trigger a violation. You can also add your own customized Field Types and use them to configure default Field Formats. For example, if you want to make the lowercase “x”, “y”, and “z” the only allowed alpha characters, you can configure a customized Field Type with regular expression “^[x-z]+\$”. You can assign it a higher priority (lower priority number) than the built-in Field Types and use it as the default Field Type.

- **Minimum Length**—The default minimum data length assigned to form fields in web forms that do not have an explicit setting. This parameter is set to 0 by default, which allows the user to leave the field blank. Any higher setting forces users to fill in the field.

Caution: If the minimum length value is 0 but the Field Type is integer, alpha, or alphanum, a request is blocked if any input field is left empty, despite the minimum length setting. That is because the regEx for these Field Types contains a + character, which means one or more characters. Distinguishing an integer from an alpha character requires at least one character.

- **Maximum Length**—The default maximum data length assigned to form fields in web forms that do not have an explicit setting. This parameter is set to 65535 by default.

Note: Characters vs bytes. The minimum and the maximum lengths for the field formats represent the number of bytes, not the number of characters. Languages that have greater than one-byte character representation can cause the limit to be exceeded with fewer characters than the number configured for the maximum value. For example, with double-byte character representation, the maximum value of 9 allows no more than 4 characters.

Tip: The GUI allows you to cut and paste UTF-8 characters directly into the GUI without having to convert them to hex.

- **Character Maps:** In addition to recommending the Field Types, the Web App Firewall learning engine offers you an additional option, Use Character Maps, to deploy the Format Check rules. A Character Map is a set of all the characters allowed in a particular form field. You can fine tune the Field format specification to allow or disallow specific characters by using Character Maps. A separate Character Map is generated for each form field. The alpha and numeric characters are treated differently in Character Maps. If any alpha character is seen in the input, all alpha characters [A-Za-z] will be allowed by the recommended PCRE expression in the Character Map. Similarly, if any digit is included, all digits [0-9] will be allowed. Non-printable characters are specified by using the x construct. Only single Byte characters with values between 0-255 are considered for Character Map recommendations.

A Character Map can be more specific than the corresponding Field Type recommendation. In some situations, Character Maps might be a better option, because they give you tighter control over the set of characters allowed as inputs. The deployed character maps are displayed as strings that start with prefix “CM” followed by digits. The priority for the Character Maps starts at

10000. As with user-added Field Types, you can add, edit or remove a Character Map. Character Maps that are currently used in deployed rules cannot be modified or removed.

Note: Character Maps are not supported in cluster deployments.

Note

When you add a field formats rule with any built-in Field Type and use character map instead of Field Type and save it, the changes do not get saved and rule still shows with Field Type.

When the character map matches one of the built-in type, the field type is reused instead of creating a new character map.

Using the command line to configure the field format check

In the command line interface, you can use the `add appfw fieldtype` command to add a new Field Type. You can use either the `set appfw profile` command or the `add appfw profile` command to configure the Field Format check and specify which actions to perform. You can use the `unset appfw profile` command to revert the configured settings back to their defaults. To specify a Field Format rule, use the `bind appfw` command to bind a Field Type to a form Field and the action URL, along with the minimum and maximum length specifications.

To add, remove or view a Field Type by using the command line:

Use the `add` command to add a Field Type. You must specify the Name, Regular expression and Priority when adding a new Field Type. You also have the option to add a Comment. You can use the `show` command to display the configured Field Types. You can also delete a Field Type by using the `remove` command, which requires only the Name of the Field Type.

```
add [appfw] fieldType <name> <regex> <priority> [-comment <string>]
```

where:

<regex> is a regular expression

<priority> is a positive_integer

Example:

```
1 add fieldtype "Cust_Zipcode" "[0-9]{
2   5 }
3   [-][0-9]{
4   4 }
5   $" 4
6
7 - show [appfw] fieldType [<name>]
8
9   Example: sh fieldtype
10
```

```

11     sh appfw fieldType
12
13     sh appfw fieldType cust_zipcode
14
15 - `rm [appfw] fieldType <name>`
16
17     Example: rm fieldType cust_ziPcode
18
19     `rm appfw fieldType cust_ziPcode`
20 <!--NeedCopy-->

```

Note: As shown above, use of “appfw” in the command is optional. For example, “Add Field-Type” or “Add appfw fieldType” are both valid options. The names of the Field Types are case insensitive due to normalization. As shown in the above examples, Cust_Zipcode, cust_zipcode, and cUsT_ziPcode refer to the same Field Type.

To configure a Field Format check by using the command line

Use either the set appfw profile command or the add appfw profile command, as follows:

- `set appfw profile <name> -fieldFormatAction ([[block] [learn] [log] [stats]])| [none])`
- `set appfw profile <name> -defaultFieldFormatType <string>`
- `set appfw profile <name> -defaultFieldFormatMinLength <integer>`
- `set appfw profile <name> -defaultFieldFormatMaxLength <integer>`

To configure a Field Format relaxation rule by using the command line

```

1 bind appfw profile <name> (-fieldFormat <string> <formActionURL> <
  fieldType>
2 [-fieldFormatMinLength <positive_integer>] [-fieldFormatMaxLength <
  positive_integer>]
3 [-isRegex ( REGEX | NOTREGEX )])
4 <!--NeedCopy-->

```

Example:

```

1 bind appfw profile pr_ffc -fieldFormat "login_name" ".*\/login.php"
  integer -fieldformatMinLength 3 -FieldformatMaxlength 6
2 <!--NeedCopy-->

```

Using the GUI to configure the field formats security check

In the GUI, you can manage the Field Types. You can also configure the Field Formats security check in the pane for the profile associated with your application.

To add, modify or remove a Field Type using the GUI

1. Navigate to Application Firewall node. In the Settings, click **Manage Field Types** to display the Configure Application Firewall Field Type dialogue box.
2. Click **Add** to add a new Field Type. Follow the instructions in this pane and click Create. You can also edit or delete any user-added Field Type if it is currently not being used by a deployed rule.

To add or modify the Field Formats security check by using the GUI

1. Navigate to **Application Firewall > Profiles**, highlight the target profile, and click **Edit**.
2. In the **Advanced Settings** pane, click **Security Checks**.

The security check table displays the currently configured action settings for all the security checks. You have 2 options for configuration:

- a) If you just want to enable or disable **Block, Log, Stats, and Learn** actions for Field Formats, you can select or clear check boxes in the table, click **OK**, and then click **Save and Close** to close the Security Check pane.
- b) If you want to configure additional options for this security check, double click Field Formats, or select the row and click Action Settings, to display the following options for **Default Field Format**:

- **Field Type**—Select the Field Type that you want to configure as the default Field Type. You can select the built-in and user-defined Field Types. The deployed Character Maps are also included in the list and can be selected.
- **Minimum Length**—Specify the minimum number of characters that must be in each field. Possible values: 0-65535.
- **Maximum Length**—Specify the maximum number of characters that must be in each field. Possible values: 1-65535.

You can also edit the **Block, Log, Stats** and **Learn** actions in the Field Formats Settings pane.

After making any of the above changes, click **OK** to save the changes and return to the Security Checks table. You can proceed to configure other security checks if needed. Click **OK** to save all the changes you have made in the Security Checks section, and then click **Save and Close** to close the Security Check pane.

To configure a Field Formats relaxation rule by using the GUI

1. Navigate to **Application Firewall > Profiles**, highlight the target profile, and click **Edit**.
2. In the **Advanced Settings** pane, click **Relaxation Rules**. The Relaxation Rules table has a Field Formats entry. You can double click, or select this row and click the Edit button, to access the Field Formats Relaxation Rules dialogue. You can perform **Add, Edit, Delete, Enable, or Disable** operations for relaxation rules.

For a consolidated view of all the relaxation rules, you can highlight the Field Formats row and click Visualizer. The visualizer for deployed relaxations offers you the option to Add a new rule or Edit an existing one. You can also Enable or Disable a group of rules by selecting a node and clicking the corresponding buttons in the relaxation visualizer.

Using the learn feature with the Field Formats Check

When the learn action is enabled, the Web App Firewall learning engine monitors the traffic and learns the triggered violations. You can periodically inspect these learned rules. After due consideration, you can deploy the learned rule as a Field Format relaxation rule.

Field formats learning enhancement—An Web App Firewall learning enhancement was introduced in release 11.0. In the previous releases, once the learned field format recommendation is deployed, the Web App Firewall learning engine stops monitoring the valid requests for the purpose of recommending new rules on the basis of the new data points. This limits the configured security protection, because the learning database does not include any representations of the new data seen in the valid requests processed by the security check.

Violations are no longer coupled with learning. The learning engine learns and makes recommendations for the field formats regardless of the violations. In addition to checking the blocked requests to determine whether the current field format is too restrictive and needs to be relaxed, the learning engine also monitors the allowed requests to determine whether the current field format is too permissive, and allows elevating the security by deploying a more restrictive rule.

Following is a summary of the Field Formats learning behavior:

No Field format is bound—The behavior remains unchanged in this scenario. All learn data is sent to the aslearn engine. The learning engine suggests a field format rule based on the data set.

Field format is bound: In the previous releases, observed data is sent to the aslearn engine only in the case of a violation. The learning engine suggests a field format rule based on the data set. In the 11.0 release, all data is sent to aslearn engine even if no violation is triggered. The learning engine suggests a field format rule based on the entire data set of all received inputs.

Use Case for learning enhancement:

If the initial field format learned rules are based on a small sample of data, a few non typical values might result in a recommendation that is too lenient for the target field. The ongoing learning allows the Web App Firewall to observe data points from every request to collect a representative sample for the learned recommendations. This is helpful in further tightening the security to deploy the optimal input format with an adequate range value.

HOW FIELD FORMAT RULES ARE SUGGESTED

The field format learning makes use of the priority of the Field Types as well as the configured settings of the following learning thresholds:

- **FieldFormatMinThreshold**—Minimum number of times a specific form field must be observed before a learned relaxation is generated. Default: 1.
- **FieldFormatPercentThreshold**—Percentage of times a form field matched a particular Field Type, before a learned relaxation is generated. Default: 0.

The field format rule recommendations are based on the following criteria:

- **Field Type recommendations**—The Field Type recommendations are determined by the assigned priorities of the existing Field Types and the specified Field Format thresholds. The priorities determine the order in which the Field Types are matched against the inputs. A lower number specifies a higher priority. For example, Field Type integer has the higher priority (30) and is therefore evaluated before Field Type alphanumeric (50). The thresholds determine the number of inputs evaluated to collect a representative sample for the data point. Assigning the right priority to the configured Field Types, and configuring an appropriate **learningsetting** value for the **fieldFormatPercentThreshold** and **fieldFormatMinThreshold** parameters, is essential for getting the correct Field Format recommendation. The Field Type with the highest priority, based on the configured thresholds, is matched first against the inputs. If there is a match, this Field Type is suggested without considering the other Field Types. For example, three default Field Types, integer, alphanumeric, and any will match if all the inputs contain only numbers. However, integer will be recommended since it has the highest priority.
- **Minimum and Maximum length recommendations**—Calculations for the minimum and max-

imum lengths for the Field Format are done independently of the determination for the Field Type. The field format length calculations are based on the average length of all the observed inputs. Half of this calculated average is suggested as the min value, and twice the value of this average is suggested as the max value. The range for the Minimum Length is 0-65535 and the range for the Maximum Length is 1-65535. The configured value for the minimum length cannot exceed the maximum length.

- **Handling of space character**—The Field Format check counts every space character when checking for the Field Formats length. Leading or trailing spaces are not stripped, and multiple consecutive spaces in the middle of the input string are no longer consolidated to a single space during input processing.

Example to illustrate the Field Format recommendations:

```

1 Total requests: 100
2 Number of Req with Field Type:
3 Int : 22          (22 int values) - 22%
4 Alpha : 44       (44 alpha values) - 44%
5 Alphanum: 14     (14 + 44 + 22 = 80 alphanum values) = 80%
6 noHTML: 10      (80 + 10 = 90 noHTML values) = 90%
7 any : 10        (90 + 10 = 100 any values) = 100%
8
9 % threshold                Suggested Field Type
10 0-22                      int
11 23-44                     alpha
12 45-80                     alphanum
13 81-90                     noHTML
14 91-100                   any
15 <!--NeedCopy-->

```

To view or use learned data by using the command line interface

```

1 show appfw learningdata <profilename> FieldFormat
2 rm appfw learningdata <profilename> -fieldFormat <string> <
  formActionURL>
3 export appfw learningdata <profilename> FieldFormat
4 <!--NeedCopy-->

```

To view or use learned data by using the GUI

1. Navigate to **Application Firewall > Profiles**, highlight the target profile, and click **Edit**.
2. In the **Advanced Settings** pane, click **Learned Rules**. You can select the Field Formats entry in the Learned Rules table and double-click it to access the learned rules. You can deploy the learned rules or edit a rule before deploying it as a relaxation rule. To discard a rule, you can select it and click the **Skip** button. You can edit only one rule at a time, but you can select multiple rules to deploy or skip.

You also have the option to show a summarized view of the learned relaxations by selecting the Field Formats entry in the Learned Rules table and clicking Visualizer to get a consolidated

view of all the learned violations. The visualizer makes it very easy to manage the learned rules. It presents a comprehensive view of the data on one screen and facilitates taking action on a group of rules with one click. The biggest advantage of the visualizer is that it recommends regular expressions to consolidate multiple rules. You can select a subset of these rules, based on the delimiter and Action URL. You can display 25, 50, or 75 rules in the visualizer, by selecting the number from a drop-down list. The visualizer for learned rules offers the option to edit the rules and deploy them as relaxations. Or you can skip the rules to ignore them.

Using the log feature with the field formats check

When the log action is enabled, the Field Formats security check violations are logged in the audit log as APPFW_FIELDFORMAT violations. The Web App Firewall supports both Native and CEF log formats. You can also send the logs to a remote syslog server.

To access the log messages by using the command line

Switch to the shell and tail the ns.logs in the /var/log/ folder to access the log messages pertaining to the Field Formats violations:

- `Shell`
- `tail -f /var/log/ns.log | grep APPFW_FIELDFORMAT`

To access the log messages by using the GUI

The GUI includes a very useful tool (Syslog Viewer) for analyzing the log messages. You have multiple options for accessing the Syslog Viewer:

- Navigate to the **Application Firewall > Profiles**, select the target profile, and click **Security Checks**. Highlight the Field Formats row and click **Logs**. When you access the logs directly from the **Field Formats security** check of the profile, it filters out the log messages and displays only the logs pertaining to these security check violations.
- You can also access the Syslog Viewer by navigating to **NetScaler > System > Auditing**. In the **Audit Messages** section, click the **Syslog messages** link to display the **Syslog Viewer**, which displays all log messages, including other security check violation logs. This is useful for debugging when multiple security check violations might be triggered during request processing.
- Navigate to **Application Firewall > policies > Auditing**. In the **Audit Messages** section, click the Syslog messages link to display the Syslog Viewer, which displays all log messages, including other security check violation logs.

The HTML based Syslog Viewer provides various filter options for selecting only the log messages that are of interest to you. To access Field Formats security check violation log messages, filter by selecting APPFW in the dropdown options for Module. The Event Type displays a rich set of options to further refine your selection. For example, if you select the **APPFW_FIELDFORMAT**

check box and click the **Apply** button, only log messages pertaining to the Field Formats security check violations appear in the Syslog Viewer.

If you place the cursor in the row for a specific log message, multiple options, such as Module and EventType, appear below the log message. You can select any of these options to highlight the corresponding information in the logs.

Example of a Native format log message when the request is not blocked

```

```

Statistics for the field formats violations

When the stats action is enabled, the corresponding counter for the Field Formats check is incremented when the Web App Firewall takes any action for this security check. The statistics are collected for Rate and Total count for Traffic, Violations, and Logs. The increment of the log counter can vary depending on the configured settings. For example, if the block action is enabled, the request for a page that contains 3 Field Format violations increments the stats counter by one, because the page is blocked as soon as the first Field Formats violation is detected. However, if block is disabled, processing the same request increments the statistics counter for violations and the logs by 3, because each Field Formats violation generates a separate log message.

To display Field Formats statistics by using command line

At the command prompt, type:

```
sh appfw stats
```

To display stats for a specific profile, use the following command:

```
stat appfw profile <profile name>
```

To display Field Formats statistics by using GUI

1. Navigate to **System > Security > Application Firewall**.
2. In the right pane, access the Statistics Link.
3. Use the scroll bar to view the statistics about Field Formats violations and logs. The statistics table provides real-time data and is updated every 7 seconds.

Deployment Tip

- Enable Field format actions log, learn and stats.
- After running a representative sample of the traffic to your application, review the learned recommendations.
- If a Field Type is recommended by most of the learned rules, configure that Field Type as the Default Field Type. For minimum and maximum lengths, use the widest range suggested by these rules.
- Deploy rules for other fields for which different Field Types or different minimum/maximum lengths are better suited.
- Enable blocking and disable learning.
- Monitor stats and logs. If a significant number of violations are still being triggered, you might want to review the log messages to confirm that the violations represent malicious requests that must have been blocked. If valid requests are being flagged as violations, you can either edit the configured Field Format rule to further relax it or enable learning again to get recommendations based on the new data points.

Note: You can fine tune your configuration by getting new learning recommendations.

Highlights

Note the following points about the Field Format security check:

- **Protection**—By configuring optimal field format rules, you can protect against many attacks. For example, if you specify that a field can only have integers, hackers will not be able to launch SQL Injection or cross-site scripting attacks by using this field, because the inputs required to launch such attacks will not meet the configured field format requirement.
- **Performance**—You can limit the minimum and the maximum allowed length for the inputs in the field format rules. This can prevent a malicious user from entering excessively large input strings in an attempt to add processing overhead to the server, or worse, cause the server to dump core because of stack overflow. By limiting the input size, you can shorten the time required for processing legitimate requests.
- **Configuring Field Formats**—You must enable one of the actions (block, log, stats, learn) to engage the field Format protection. You can also specify the Field format rules to identify the allowed inputs in your form fields.

- **Selecting Character Maps vs. Field Types**—Both Character Maps and Field Types use regular expressions. However, a Character Map provides a more specific expression by narrowing down the list of allowed characters. For example, for an input such as janedoe@citrix.com, the learning engine might recommend the Field Type nohtml but the Character Map [.@-Za-z] might be more specific, because it narrows down the allowed set of non-alpha characters. The Character Map option allows, in addition to alpha characters, only two non-alpha characters: period (.) and at (@).
- **Ongoing Learning**—The Web App Firewall monitors and takes into account all the incoming data (violations as well as allowed inputs) to build a learning table for recommending rules. The rules are revised and updated as new incoming data arrives. New field format rules are suggested for a field even if it already has a bound field format rule. If the configured Field Formats are too restrictive and are blocking the valid requests, you can deploy a more relaxed Field Format. Similarly, if the current Field Formats are too generic, you can further refine and tighten the security by deploying a more restrictive Field Format.
- **Overwriting Rules**—If a rule has already been deployed for a field/URL combination, the GUI allows the user to update the field format. A dialog box asks for confirmation to replace the existing rule. If you are using the command line interface, you have to explicitly unbind the previous binding and then bind the new rule.
- **Multiple match**—If multiple field formats match a given field name and its action URL, the Web App Firewall arbitrarily selects one of them to apply.
- **Buffer boundary**—If a field value extends across multiple streaming buffers, and the format for these two parts of the field value is different, a field format corresponding to “any” is sent to the learn database.
- **Field Format vs. Field Consistency Check**—Both the Field Format check and the Field Consistency check are form-based protection checks. The Field Formats check provides a different type of protection than does the Form Field Consistency check. The Form Field Consistency check verifies that the structure of the web forms returned by users is intact, that data format restrictions configured in the HTML are respected, and that data in hidden fields has not been modified. It can do this without any specific knowledge about your web forms other than what it derives from the web form itself. The Field Formats check verifies that the data in each form field matches the specific formatting restrictions that you configured manually, or that the learning feature generated and you approved. In other words, the Form Field Consistency check enforces general web form security, while the Field Formats check enforces the specific rules for the allowed inputs for your web forms.

Form field consistency check

December 4, 2020

The Form Field Consistency check examines the web forms returned by users of your website, and verifies that web forms were not modified inappropriately by the client. This check applies only to HTML requests that contain a web form, with or without data. It does not apply to XML requests.

The Form Field Consistency check prevents clients from making unauthorized changes to the structure of the web forms on your website when they fill out and submit a form. It also ensures that the data a user submits meets the HTML restrictions for length and type, and that data in hidden fields is not modified. This prevents an attacker from tampering with a web form and using the modified form to gain unauthorized access to website, redirect the output of a contact form that uses an insecure script and thereby send unsolicited bulk email, or exploit a vulnerability in your web server software to gain control of the web server or the underlying operating system. Web forms are a weak link on many websites and attract a wide range of attacks.

The Form Field Consistency check verifies all of the following:

- If a field is sent to the user, the check ensures that it is returned by the user.
- The check enforces HTML field lengths and types.

Note:

- The Form Field Consistency check enforces HTML restrictions on data type and length but does not otherwise validate the data in web forms. You can use the Field Formats check to set up rules that validate data returned in specific form fields on your web forms.
- The Form Field Consistency protection inserts a hidden field “as_fid” in the response forms which are sent to the client. The same hidden field will be stripped by ADC when the client submits the form. If there is any client-side javascript doing checksum computation on the form fields and verifying the same checksum at the backend may cause application breakage. In this scenario, it is recommended to relax the application firewall form field consistency hidden field “as_fid” from client-side javascript checksum computation.

- If your web server does not send a field to the user, the check does not allow the user to add that field and return data in it.
- If a field is a read-only or hidden field, the check verifies that the data has not changed.
- If a field is a list box or radio button field, the check verifies that the data in the response corresponds to one of the values in that field.

If a web form returned by a user violates one or more of the Form Field consistency checks, and you have not configured the Web App Firewall to allow that web form to violate the Form Field Consistency checks, the request is blocked.

If you use the wizard or the GUI, in the Modify Form Field Consistency Check dialog box, on the General tab you can enable or disable the Block, Log, Learn, and Statistics actions.

You also configure Sessionless Field Consistency in the General tab. If Sessionless Field Consistency is enabled, the Web App Firewall checks only the web form structure, dispensing with those parts of the Form Field Consistency check that depend upon maintaining session information. This can speed the Form Field Consistency check with little security penalty for websites that use many forms. To use Sessionless Field Consistency on all web forms, select On. To use it only for forms submitted with the HTTP POST method, select postOnly

If you use the command-line interface, you can enter the following command to configure the Form Field Consistency Check:

- `set appfw profile <name> -fieldConsistencyAction [**block**] [**learn**] [**log**] [**stats**] [**none**]`

To specify relaxations for the Form Field Consistency check, you must use the GUI. On the Checks tab of the Modify Form Field Consistency Check dialog box, click Add to open the Add Form Field Consistency Check Relaxation dialog box, or select an existing relaxation and click Open to open the Modify Form Field Consistency Check Relaxation dialog box. Either dialog box provides the same options for configuring a relaxation, as described in [Manual Configuration By Using the GUI](#).

Following are examples of Form Field Consistency check relaxations:

Form Field Names:

- Choose form fields with the name UserType:

```
1 ^UserType$
2 <!--NeedCopy-->
```

- Choose form fields with names that begin with UserType_ and are followed by a string that begins with a letter or number and consists of from one to twenty-one letters, numbers, or the apostrophe or hyphen symbol:

```
1 ^UserType_[0-9A-Za-z][0-9A-Za-z' -]{
2 0,20 }
3 $
4 <!--NeedCopy-->
```

- Choose form fields with names that begin with Turkish-UserType_ and are otherwise the same as the previous expression, except that they can contain Turkish special characters throughout:

```
1 ^T\xC3\xBCrk\xC3\xA7e-UserType_([0-9A-Za-z]|\x[0-9A-Fa-f][0-9A-
2 Fa-f])+$
3 <!--NeedCopy-->
```

Note:

See [PCRE Character Encoding Format](#) for a complete description of supported special characters and how to encode them properly.

- Choose form field names that begin with a letter or number, consist of a combination of letters and/or numbers only, and that contain the string Num anywhere in the string:

```
1  ^[0-9A-Za-z]*Num[0-9A-Za-z]*$
2  <!--NeedCopy-->
```

Form Field Action URLs:

- Choose URLs beginning with `http://www.example.com/search.pl?` and containing any string after the query except for a new query:

```
1  ^http://www[.]example[.]com/search[.]pl?[^?]*$
2  <!--NeedCopy-->
```

- Choose URLs that begin with `http://www.example-español.com` and have paths and filenames that consist of upper-case and lower-case letters, numbers, non-ASCII special characters, and selected symbols in the path. The ñ character and any other special characters are represented as encoded UTF-8 strings containing the hexadecimal code assigned to each special character in the UTF-8 charset:

```
1  ^http://www[.]example-espa\xC3\xB1o\x1[.]com/((([0-9A-Za-z]|\x[0-9A-
   -Fa-f][0-9A-Fa-f])
2  ([0-9A-Za-z_-]|\x[0-9A-Fa-f][0-9A-Fa-f])*\/)*([0-9A-Za-z]|\x[0-9
   A-Fa-f][0-9A-Fa-f])
3  ([0-9A-Za-z_-]|\x[0-9A-Fa-f][0-9A-Fa-f])*[.](asp|htp|php|s?html
   ?)$
4  <!--NeedCopy-->
```

- Choose all URLs that contain the string `/search.cgi?`:

```
1  ^[^\<>]*/search[.]cgi\?[^\<>]*$
2  <!--NeedCopy-->
```

Caution:

Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the URL you want to add as an exception, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (.) metacharacter/wildcard combination, can have results you do not want or expect, such as blocking access to web content that you did not intend to block or allowing an attack that the Cookie Consistency check would otherwise have blocked.

CSRF form tagging check

May 2, 2023

The Cross Site Request Forgery (CSRF) Form Tagging check tags each web form sent by a protected website to users with a unique and unpredictable FormID, and then examines the web forms returned by users to ensure that the supplied FormID is correct. This check protects against cross-site request forgery attacks. This check applies only to HTML requests that contain a web form, with or without data. It does not apply to XML requests.

The CSRF Form Tagging check prevents attackers from using their own web forms to send high volume form responses with data to your protected websites. This check requires relatively little CPU processing capacity compared to certain other security checks that analyze web forms in depth. It is therefore able to handle high volume attacks without seriously degrading the performance of the protected website or the Web App Firewall itself.

Before you enable the CSRF Form Tagging check, you must be aware of the following:

- You need to enable form tagging. The CSRF check depends on form tagging and does not work without it.
- You must disable the NetScaler Integrated Caching feature for all web pages containing forms that are protected by that profile. The Integrated Caching feature and CSRF form tagging are not compatible.
- You must consider enabling Referrer checking. Referrer checking is part of the Start URL check, but it prevents cross-site request forgeries, not Start URL violations. Referrer checking also puts less load on the CPU than does the CSRF Form Tagging check. If a request violates Referrer checking, it is immediately blocked, so the CSRF Form Tagging check is not invoked.
- The CSRF Form Tagging check does not work with web forms that use different domains in the form-origin URL and form-action URL. For example, CSRF Form Tagging cannot protect a web form with a form-origin URL of <http://www.example.com> and a form action URL of <http://www.example.org/form.pl>, because example.com and example.org are different domains.

If you use the wizard or the GUI, in the Modify CSRF Form Tagging Check dialog box, on the General tab you can enable or disable the Block, Log, Learn and Statistics actions.

If you use the command-line interface, you can enter the following command to configure the CSRF Form Tagging Check:

- `set appfw profile <name> -CSRFtagAction [**block**] [**log**] [**learn**] [**stats**] [**none**]`

To specify relaxations for the CSRF Form Tagging check, you must use the GUI. On the Checks tab of

the Modify CSRF Form Tagging Check dialog box, click Add to open the Add CSRF Form Tagging Check Relaxation dialog box, or select an existing relaxation and click Open to open the Modify CSRF Form Tagging Check Relaxation dialog box. Either dialog box provides the same options for configuring a relaxation.

An alert is generated when you set the NetScaler Web App Firewall session limit to a value of 0 or lower, because such a setting affects advanced protection check functionality that requires a properly functioning Web App Firewall session.

Following are examples of CSRF Form Tagging check relaxations:

Note: The following expressions are URL expressions that can be used in both the Form Origin URL and Form Action URL roles.

- Choose URLs beginning with `http://www.example.com/search.pl?` and containing any string after the query, except for a new query:

```
1 ^http://www[.]example[.]com/search[.]pl?[^\?]*$
2 <!--NeedCopy-->
```

- Choose URLs that begin with `http://www.example-español.com` and have paths and filenames that consist of upper-case and lower-case letters, numbers, non-ASCII special characters, and selected symbols in the path. The ñ character and any other special characters are represented as encoded UTF-8 strings containing the hexadecimal code assigned to each special character in the UTF-8 charset:

```
1 ^http://www[.]example-espaxC3xB1o1[.]com/(([0-9A-Za-z]|\x[0-9A-
   Fa-f][0-9A-Fa-f])
2 ([0-9A-Za-z_-]|\x[0-9A-Fa-f][0-9A-Fa-f])*/)*([0-9A-Za-z]|\x[0-9A-Fa-f
   ][0-9A-Fa-f])([0-9A-Za-z_-]|\x[0-9A-Fa-f][0-9A-Fa-f])*[.](asp|http|
   php|s?html?)$
3 <!--NeedCopy-->
```

- Choose all URLs that contain the string `/search.cgi?`:

```
1 ^[\?<>]*/search[.]cgi\?[\?<>]*$
2 <!--NeedCopy-->
```

Important

Regular expressions are powerful. If you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the URL that you want to add as an exception, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (.) metacharacter/wildcard combination, can have results you do not want, such as blocking access to web content that you did not intend to block or allowing an attack that the check would otherwise have blocked.

Tip

When enableValidate referrer header is enabled under the Start URL Action, ensure that the Referrer Header URL is added to StartURL as well.

Note

When NetScaler reaches the appfw_session_limit and CSRF checks are enabled, the web application freezes.

To prevent web application freeze, decrease the session timeout and increase the session limit by using the following commands:

```
From CLI: > set appfw settings -sessiontimeout 300
```

```
From shell: root@ns# nsapimgr_wr.sh -s appfw_session_limit=200000
```

Logging and generating SNMP alarms when appfw_session_limit is reached assists you in troubleshooting and debugging issues.

Managing CSRF form tagging check relaxations

May 2, 2023

You configure an exception (or relaxation) to the CSRF Form Tagging security check in the Add Cross-Site Request Forgery Tagging Check Relaxation dialog box or the Modify Cross-Site Request Forgery Tagging Check Relaxation dialog box.

To configure a CSRF form tagging check relaxation by using the GUI

1. Navigate to **Security > NetScaler Web App Firewall > Profiles**.
2. In the **Profiles** pane, select the profile you want to configure, and then click **Open**.
3. In the **Configure Web App Firewall Profile** dialog box, click the **Security Checks** tab. The **Security Checks** tab contains the list of Web App Firewall security checks.
4. To add or modify a CSRF relaxation, do one of the following:
 - To add a new relaxation, click **Add**.
 - To modify an existing relaxation, select the relaxation that you want to modify, and then click **Open**.

The **Add Cross-Site Request Forgery Tagging Check Relaxation** or **Modify Cross-Site Request Forgery Tagging Check Relaxation** dialog box is displayed. Except for the title, these dialog boxes are identical.

5. Fill in the dialog box as described below.
 - **Enabled check box**—Select to place this relaxation or rule in active use; clear to deactivate it.
 - **Form Origin URL**—In the text area, enter a PCRE-format regular expression that defines the URL that hosts the form.
 - **Form Action URL**—In the text area, enter a PCRE-format regular expression that defines the URL to which data entered into the form is delivered.
 - **Comments**—In the text area, type a comment. Optional.

Note:

For any element that requires a regular expression, you can type the regular expression, use the **Regex Tokens** menu to insert regular expression elements and symbols directly into the text box, or click **Regex Editor** to open the **Add Regular Expression** dialog box, and use it to construct the expression.

6. Click **OK**. The **Add Cross-Site Request Forgery Tagging Check Relaxation** or **Modify Cross-Site Request Forgery Tagging Check Relaxation** dialog box closes and you return to the **Modify Cross-Site Request Forgery Tagging Check** dialog box.
7. To remove a relaxation or rule, select it, and then click **Remove**.
8. To enable a relaxation or rule, select it, and then click **Enable**.
9. To disable a relaxation or rule, select it, and then click **Disable**.
10. To configure the settings and relationships of all existing relaxations in an integrated interactive graphic display, click **Visualizer**, and use the display tools.
11. To review and configure learned rules for the CSRF check, click **Learning** and perform the steps in [To configure and use the Learning feature](#).
12. Click **OK**.

URL protection checks

December 4, 2020

The URL Protection checks examine request URLs to prevent attackers from aggressively attempting to access multiple URLs (forceful browsing) or using a URL to trigger a known security vulnerability in web server software or website scripts.

Start URL check

December 4, 2020

The Start URL check examines the URLs in incoming requests and blocks the connection attempt if the URL does not meet the specified criteria. To meet the criteria, the URL must match an entry in the Start URL list, unless the Enforce URL Closure parameter is enabled. If you enable this parameter, a user who clicks a link on your website is connected to the target of that link.

The primary purpose of the Start URL check is to prevent repeated attempts to access random URLs on a website, (forceful browsing) through bookmarks, external links, or jumping to pages by manually typing in the URLs to skip the pages required to reach that part of the website. Forceful browsing can be used to trigger a buffer overflow, find content that users were not intended to access directly, or find a back door into secure areas of your Web server. The Web App Firewall enforces a website's given traversal or logic path by allowing access to only the URL's that are configured as start URLs.

If you use the wizard or the GUI, in the Modify Start URL Check dialog box, on the General tab you can enable or disable Block, Log, Statistics, Learn actions, and the following parameters:

- **Enforce URL Closure.** Allow users to access any web page on your website by clicking a hyperlink on any other page on your website. Users can navigate to any page on your website that can be reached from the home page or any designated start page by clicking hyperlinks.
Note: The URL closure feature allows any query string to be appended to and sent with the action URL of a web form submitted by using the HTTP GET method. If your protected websites use forms to access an SQL database, make sure that you have the SQL injection check enabled and properly configured.
- **Sessionless URL Closure.** From the client's point of view, this type of URL closure functions in exactly the same way as standard, session-aware URL Closure, but uses a token embedded in the URL instead of a cookie to track the user's activity, which consumes considerably fewer resources. When sessionless URL closure is enabled, the Web App Firewall appends a "as_url_id" tag to all the URL's that are in URL closure.
Note: When enabling sessionless (Sessionless URL Closure), you must also enable regular URL closure (Enforce URL Closure) or sessionless URL closure does not work.
- **Validate Referrer Header.** Verify that the Referrer header in a request that contains web form data from your protected website instead of another website. This action verifies that your website, not an outside attacker, is the source of the web form. Doing so protects against cross-site request forgeries (CSRF) without requiring form tagging, which is more CPU-intensive than header checks. The Web App Firewall can handle the HTTP Referrer header in one of the following four ways, depending on which option you select in the drop-down list:
 - **Off**—Do not validate the Referrer header.

- **If-Present**—Validate the Referer header if a Referer header exists. If an invalid Referer header is found, the request generates a referer-header violation. If no Referer header exists, the request does not generate a referer-header violation. This option enables the Web App Firewall to perform Referer header validation on requests that contain a Referer header, but not block requests from users whose browsers do not set the Referer header or who use web proxies or filters that remove that header.
- **Always Except Start URLs**—Always validate the Referer header. If there is no Referer header and the requested URL is not exempted by the startURL relaxation rule, the request generates a referer-header violation. If the Referer header is present but it is invalid, the request generates a referer-header violation.
- **Always Except First Request**—Always validate the referer header. If there is no referer header, only the URL that is accessed first is allowed. All other URL's are blocked without a valid referer header. If the Referer header is present but it is invalid, the request generates a referer-header violation.

One Start URL setting, **Exempt Closure URLs from Security Checks**, is not configured in the Modify Start URL Check dialog box, but is configured in the Settings tab of the Profile. If enabled, this setting directs the Web App Firewall not to run further form based checks (such as Cross-Site Scripting and SQL Injection inspection) on URLs that meet the URL Closure criteria.

Note

Although the referer header check and Start URL security check share the same action settings, it is possible to violate the referer header check without violating the Start URL check. The difference is visible in the logs, which log referer header check violations separately from Start URL check violations.

The Referer header settings (OFF, if-Present, AlwaysExceptStartURLs, and AlwaysExceptFirstRequest) are arranged in order of least restrictive to most restrictive and work as follows:

OFF:

- Referer Header Not checked.

If-Present:

- Request has no referer header -> Request is allowed.
- Request has referer header and the referer URL is in URL closure -> Request is allowed.
- Request has referer header and the referer URL is **not** in URL closure -> Request is blocked.

AlwaysExceptStartURLs:

- Request has no referer header and the request URL is a start URL -> Request is allowed.
- Request has no referer header and the request URL is not a start URL ->Request is blocked.
- Request has referer header and the referer URL is in URL closure -> Request is allowed.

- Request has referer header and the referer URL is **not** in URL closure -> Request is blocked.

AlwaysExceptFirstRequest:

- Request has no referer header and is the first request URL of the session -> Request is allowed.
- Request has no referer header and is **not** the first request URL of the session -> Request is blocked.
- Request has referer header and is either the first request URL of the session or is in URL closure -> Request is allowed.
- Request has referer header and is neither the first request URL of the session nor is in URL closure -> Request is blocked.

If you use the command-line interface, you can enter the following commands to configure the Start URL Check:

- `set appfw profile <name> -startURLAction [block] [learn] [log] [stats] [none]`
- `set appfw profile <name> -startURLClosure ([ON] | [OFF])`
- `set appfw profile <name> -sessionlessURLClosure ([ON] | [OFF])`
- `set appfw profile <name> -exemptClosureURLsFromSecurityChecks ([ON] | [OFF])`
- `set appfw profile <name> -RefererHeaderCheck ([OFF] | [if-present] | [AlwaysExceptStartURLs] | [AlwaysExceptFirstRequest])`

To specify relaxations for the Start URL check, you must use the GUI. On the Checks tab of the Modify Start URL Check dialog box, click Add to open the Add Start URL Check Relaxation dialog box, or select an existing relaxation and click Open to open the Modify Start URL Check Relaxation dialog box. Either dialog box provides the same options for configuring a relaxation.

Following are examples of Start URL check relaxations:

- Allow users to access the home page at `www.example.com`:

```
1 ^http://www[.]example[.]com$
2 <!--NeedCopy-->
```

- Allow users to access all static HTML (.htm and .html), server-parsed HTML (.htp and .shtml), PHP (.php), and Microsoft ASP (.asp) format web pages at `www.example.com`:

```
1 ^http://www[.]example[.]com/([0-9A-Za-z][0-9A-Za-z_-]*/)*
2 [0-9A-Za-z][0-9A-Za-z_.-]*[.](asp|http|php|s?html?)$
3 <!--NeedCopy-->
```

- Allow users to access web pages with pathnames or file names that contain non-ASCII characters at `www.example-español.com`:

```

1 ^http://www[.]example-espaxC3xB1o1[.]com/(([0-9A-Za-z]|x[0-9A-Fa-
  f][0-9A-Fa-f])([0-9A-Za-z_-]|x[0-9A-Fa-f][0-9A-Fa-f])*/)*
2 ([0-9A-Za-z]|x[0-9A-Fa-f][0-9A-Fa-f])([0-9A-Za-z_-]|x[0-9A-Fa-
  f][0-9A-Fa-f])*[.](asp|htp|php|s?html?)$
3 <!--NeedCopy-->

```

Note: In the above expression, each character class has been grouped with the string `x[0-9A-Fa-f][0-9A-Fa-f]`, which matches all properly-constructed character encoding strings but does not allow stray backslash characters that are not associated with a UTF-8 character encoding string. The double backslash (`\\`) is an escaped backslash, which tells the Web App Firewall to interpret it as a literal backslash. If you included only one backslash, the Web App Firewall would instead interpret the following left square bracket (`[`) as a literal character instead of the opening of a character class, which would break the expression.

- Allow users to access all GIF (.png), JPEG (.jpg and .jpeg), and PNG (.png) format graphics at `www.example.com`:

```

1 ^http://www[.]example[.]com/([0-9A-Za-z][0-9A-Za-z_-]*/)*
2 [0-9A-Za-z][0-9A-Za-z_.-]*[.](gif|jpe?g|png)$
3 <!--NeedCopy-->

```

- Allow users to access CGI (.cgi) and PERL (.pl) scripts, but only in the CGI-BIN directory:

```

1 ^http://www[.]example[.]com/CGI-BIN/[0-9A-Za-z][0-9A-Za-z_
  .-]*[.](cgi|pl)$
2 <!--NeedCopy-->

```

- Allow users to access Microsoft Office and other document files in the docsarchive directory:

```

1 ^http://www[.]example[.]com/docsarchive/[0-9A-Za-z][0-9A-Za-z_
  .-]*[.](doc|xls|pdf|ppt)$
2 <!--NeedCopy-->

```

Note

By default, all Web App Firewall URLs are considered to be regular expressions.

Caution: Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions that you write. Make sure that they define exactly the URL you want to add as an exception, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (`.*`) metacharacter/wildcard combination, can have results you do not want, such as blocking access to web content that you did not intend to block or allowing an attack that the Start URL check would otherwise have blocked.

Tip

You can add the *-and-* to the allowed list of SQL keywords for URL naming scheme. For example, example <https://FQDN/bread-and-butter>.

Deny URL check

February 9, 2024

The Deny URL check examines and blocks connections to URLs that are commonly accessed by hackers and malicious code. This check contains a list of URLs that are common targets of hackers or malicious code and that rarely if ever appear in legitimate requests. You can also add URLs or URL patterns to the list. The Deny URL check prevents attacks against various security weaknesses known to exist in web server software or on many websites.

The Deny URL check takes priority over the Start URL check, and thus denies malicious connection attempts even when a Start URL relaxation would normally allow a request to proceed.

In the Modify Deny URL Check dialog box, on the General tab you can enable or disable the Block, Log, and Statistics actions.

If you use the command-line interface, you can enter the following command to configure the Deny URL Check:

```
1 set appfw profile <name> -denyURLAction [**block**] [**log**] [**stats**] [**none**]
2 <!--NeedCopy-->
```

You can create and configure your own deny URLs only in the NetScaler GUI.

1. Navigate to **Security > NetScaler Web App Firewall > Profiles**.
2. Select a profile for which you want to add a deny URL and click **Edit**.
3. In the **NetScaler Web App Firewall Profile** page, select **Relaxation Rules** from the **Advanced Settings** section.
4. Select **Deny URL** and click **Edit**.
5. In the **Deny URL Rules** page, click **Add**.
6. Specify the following details and click **Create**.
 - **Deny URL** - A regular expression to define a deny URL.
 - **Comments** - Description for the expression.
 - **Resource ID** - Unique ID to identify the deny URL rule.

Deny URL Rule

Enabled

Deny URL*

`^http://images[.]example[.]com$`

[RegEx Editor](#)

Comments

Do not allow users to access the image server at images.example.com directly.

Resource Id

0001

7. Click **Close**.

8. In the **NetScaler Web App Firewall Profile** page, click **Done**.

Following are examples of Deny URL expressions:

- Do not allow users to access the image server at images.example.com directly:

```

1 ^http://images[.]example[.]com$
2 <!--NeedCopy-->
    
```

- Do not allow users to access CGI (.cgi) or PERL (.pl) scripts directly:

```

1 ^http://www[.]example[.]com/([0-9A-Za-z][0-9A-Za-z_-]*/)*
2 [0-9A-Za-z][0-9A-Za-z_.-]*[.](cgi|pl)$
3 <!--NeedCopy-->
    
```

- Here is the same deny URL, modified to support non-ASCII characters:

```

1 ^http://www[.]example[.]com/((([0-9A-Za-z]|x[0-9A-Fa-f][0-9A-Fa-f
2 ([0-9A-Za-z_-]|x[0-9A-Fa-f][0-9A-Fa-f)]*/)*([0-9A-Za-z]|x[0-9A-Fa
3 ([0-9A-Za-z_-]|x[0-9A-Fa-f][0-9A-Fa-f)]*.[.](cgi|pl)$
4 <!--NeedCopy-->
    
```

Caution:

Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define

exactly the URL or pattern that you want to block, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (.) metacharacter/wildcard combination, can have results that you do not want, such as blocking access to web content that you did not intend to block.

XML protection checks

December 4, 2020

The XML Protection checks examine requests for XML-based attacks of all types.

Caution:

The XML security checks apply only to content that is sent with an HTTP content-type header of text/xml. If the content-type header is missing, or is set to a different value, all XML security checks are bypassed. If you plan to protect XML or Web 2.0 web applications, the webmasters of each web server that hosts those applications must ensure that the proper HTTP content-type header is sent.

XML format check

September 21, 2020

The XML Format check examines the XML format of incoming requests and blocks those requests that are not well formed or that do not meet the criteria in the XML specification for properly-formed XML documents. Some of those criteria are:

- An XML document must contain only properly-encoded Unicode characters that match the Unicode specification.
- No special XML syntax characters—such as <, > and &—can be included in the document except when used in XML markup.
- All begin, end, and empty-element tags must be correctly nested, with none missing or overlapping.
- XML element tags are case-sensitive. All beginning and end tags must match exactly.
- A single root element must contain all the other elements in the XML document.

A document that does not meet the criteria for well-formed XML does not meet the definition of an XML document. Strictly speaking, it is not XML. However, not all XML applications and web services enforce the XML well-formed standard, and not all handle poorly-formed or invalid XML correctly. Inappropriate handling of a poorly-formed XML document can cause security breaches. The purpose

of the XML Format check is to prevent a malicious user from using a poorly-formed XML request to breach security on your XML application or web service.

If you use the wizard or the GUI, in the Modify XML Format Check dialog box, on the General tab you can enable or disable the Block, Log, and Statistics actions.

If you use the command-line interface, you can enter the following command to configure the XML Format Check:

- `set appfw profile <name> -xmlFormatAction [**block**] [**log**] [**stats**] [**none**]`

You cannot configure exceptions to the XML Format check. You can only enable or disable it.

XML Denial-of-Service check

September 24, 2020

The XML Denial of Service (XML DoS or XDoS) check examines incoming XML requests to determine whether they match the characteristics of a denial-of-service (DoS) attack. If there is a match, blocks those requests. The purpose of the XML DoS check is to prevent an attacker from using XML requests to launch a denial-of-service attack on your web server or website.

If you use the wizard or the GUI, in the Modify XML Denial-of-Service Check dialog box, on the **General** tab you can enable or disable the Block, Log, Statistics, and Learn actions:

If you use the command-line interface, you can enter the following command to configure the XML Denial-of-Service check:

- `set appfw profile <name> -xmlDoSAction [**block**] [**log**] [**learn**] [**stats**] [**none**]`

To configure individual XML Denial-of-Service rules, you must use the GUI. On the **Checks** tab of the **Modify XML Denial-of-Service Check** dialog box, select a rule and click **Open** to open the **Modify XML Denial-of-Service** dialog box for that rule. The individual dialog boxes differ for the different rules but are simple. Some only allow you to enable or disable the rule; others allow you to modify a number by typing a new value in a text box.

Note:

The expected behavior of Learning engine for denial-of-service attack is based on the configured action. If the action is set as “Block”, the engine learns the configured bind value +1 and the XML

parsing stops when there is a violation. If the configured action is not set as “Block”, the engine learns the actual incoming violation length value.

The individual XML Denial-of-Service rules are:

- **Maximum Element Depth.** Restrict the maximum number of nested levels in each individual element to 256. If this rule is enabled, and the Web App Firewall detects an XML request with an element that has more than the maximum number of allowed levels, it blocks the request. You can modify the maximum number of levels to any value from one (1) to 65,535.
- **Maximum Element Name Length.** Restrict the maximum length of each element name to 128 characters. This includes the name within the expanded namespace, which includes the XML path and element name in the following format:

```
1 {  
2 http://prefix.example.com/path/ }  
3 target_page.xml  
4 <!--NeedCopy-->
```

The user can modify the maximum name length to any value between one (1) character and 65,535.

- **Maximum # Elements.** Restrict the maximum number of any one type of element per XML document to 65,535. You can modify the maximum number of elements to any value between one (1) and 65,535.
- **Maximum # Element Children.** Restrict the maximum number of children (including other elements, character information, and comments) each individual element is allowed to have to 65,535. You can modify the maximum number of element children to any value between one (1) and 65,535.
- **Maximum # Attributes.** Restrict the maximum number of attributes each individual element is allowed to have to 256. You can modify the maximum number of attributes to any value between one (1) and 256.
- **Maximum Attribute Name Length.** Restrict the maximum length of each attribute name to 128 characters. You can modify the maximum attribute name length to any value between one (1) and 2,048.
- **Maximum Attribute Value Length.** restrict the maximum length of each attribute value to 2048 characters. You can modify the maximum attribute name length to any value between one (1) and 2,048.
- **Maximum Character Data Length.** Restrict the maximum character data length for each element to 65,535. You can modify the length to any value between one (1) and 65,535.
- **Maximum File Size.** Restrict the size of each file to 20 MB. You can modify the maximum file size to any value.

- **Minimum File Size.** Require that each file is least 9 bytes in length. You can modify the minimum file size to any positive integer representing various bytes.
- **Maximum # Entity Expansions.** Limit the number of entity expansions allowed to the specified number. Default: 1024.
- **Maximum Entity Expansion Depth.** Restrict the maximum number of nested entity expansions to no more than the specified number. Default: 32.
- **Maximum # Namespaces.** Limit the number of namespace declarations in an XML document to no more than the specified number. Default: 16.
- **Maximum Namespace URI Length.** Limit the URL length of each namespace declaration to no more than the specified number of characters. Default: 256.
- **Block Processing Instructions.** Block any special processing instructions included in the request. This rule has no user-modifiable values.
- **Block DTD.** Block any document type definitions (DTD) included with the request. This rule has no user-modifiable values.
- **Block External Entities.** Block all references to external entities in the request. This rule has no user-modifiable values.
- **SOAP Array Check.** Enable or disable the following SOAP array checks:
 - **Maximum SOAP Array Size.** The maximum total size of all SOAP arrays in an XML request before the connection is blocked. You can modify this value. Default: 20000000.
 - **Maximum SOAP Array Rank.** The maximum rank or dimensions of any single SOAP array in an XML request before the connection is blocked. You can modify this value. Default: 16.

XML cross-site scripting check

May 2, 2023

The XML Cross-Site Scripting check examines the user requests for possible cross-site scripting attacks in the XML payload. If it finds a possible cross-site scripting attack, it blocks the request.

To prevent misuse of the scripts on your protected web services to breach security on your web services, the XML Cross-Site Scripting check blocks scripts that violate the same origin rule, which states that scripts must not access or modify content on any server but the server on which they are located. Any script that violates the same origin rule is called a cross-site script, and the practice of using scripts to access or modify content on another server is called cross-site scripting. The reason

cross-site scripting is a security issue is that a web server that allows cross-site scripting can be attacked with a script that is not on that web server, but on a different web server, such as one owned and controlled by the attacker.

The Web App Firewall offers various action options for implementing XML Cross-Site Scripting protection. You have the option to configure **Block**, **Log**, and **Stats** actions.

The Web App Firewall XML cross-site scripting check is performed on the payload of the incoming requests and attack strings are identified even if they are spread over multiple lines. The check looks for cross-site scripting attack strings in the **element** and the **attribute** values. You can apply relaxations to bypass security check inspection under specified conditions. The logs and statistics can help you identify needed relaxations.

The CDATA section of the XML payload might be an attractive area of focus for the hackers because the scripts are not executable outside the CDATA section. A CDATA section is used for content that is to be treated entirely as character data. HTML mark up tag delimiters `<`, `>`, and `/>` will not cause the parser to interpret the code as HTML elements. The following example shows a CDATA Section with cross-site scripting attack string:

```
1      <![CDATA[  
2      <script language="Javascript" type="text/javascript">alert ("Got  
3          you")</script>  
4      ]]>  
5  <!--NeedCopy-->
```

Action Options

An action is applied when the XML Cross-Site Scripting check detects an cross-site scripting attack in the request. The following options are available for optimizing XML Cross-Site Scripting protection for your application:

- **Block**—Block action is triggered if the cross-site scripting tags are detected in the request.
- **Log**—Generate log messages indicating the actions taken by the XML Cross-Site Scripting check. If block is disabled, a separate log message is generated for each location (ELEMENT, ATTRIBUTE) in which the cross-site scripting violation is detected. However, only one message is generated when the request is blocked. You can monitor the logs to determine whether responses to legitimate requests are getting blocked. A large increase in the number of log messages can indicate attempts to launch an attack.
- **Stats**—Gather statistics about violations and logs. An unexpected surge in the stats counter might indicate that your application is under attack. If legitimate requests are getting blocked, you might have to revisit the configuration to see if you need to configure new relaxation rules or modify the existing ones.

Relaxation Rules

If your application requires you to bypass the Cross-Site Scripting check for a specific ELEMENT or ATTRIBUTE in the XML payload, you can configure a relaxation rule. The XML Cross-Site Scripting check relaxation rules have the following parameters:

- **Name**—You can use literal strings or regular expressions to configure the name of the ELEMENT or the Attribute. The following expression exempts all ELEMENTS beginning with the string `name_` followed by a string of uppercase or lowercase letters, or numbers, that is at least two and no more than fifteen characters long:

```
^name_[0-9A-Za-z]{ 2,15 } $
```

Note

The names are case sensitive. Duplicate entries are not allowed, but you can use capitalization of the names and differences in location to create similar entries. For example, each of the following relaxation rules is unique:

1. XMLcross-site scripting: ABC IsRegex: NOTREGEX
Location: ATTRIBUTE State: ENABLED
2. XMLcross-site scripting: ABC IsRegex: NOTREGEX
Location: ELEMENT State: ENABLED
3. XMLcross-site scripting: abc IsRegex: NOTREGEX
Location: ELEMENT State: ENABLED
4. XMLcross-site scripting: abc IsRegex: NOTREGEX
Location: ATTRIBUTE State: ENABLED

- **Location**—You can specify the Location of the Cross-site Scripting Check exception in your XML payload. The option ELEMENT is selected by default. You can change it to ATTRIBUTE.
- **Comment**—This is an optional field. You can use up to a 255 character string to describe the purpose of this relaxation Rule.

Warning

Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the name that you want to add as an exception, and nothing else. Careless use of Regular Expressions can have results that you do not want, such as blocking access to web content that you did not intend to block or allowing an attack that the XML Cross-Site Scripting check would otherwise have blocked.

Using the Command Line to Configure the XML Cross-Site Scripting check

To configure XML Cross-Site Scripting check actions and other parameters by using the command line

If you use the command-line interface, you can enter the following commands to configure the XML Cross-Site Scripting Check:

```
> set appfw profile <name> -XMLcross-site scriptingAction ([[block] [log] [stats]] | [none])
```

To configure a XML Cross-Site Scripting check relaxation rule by using the command line

You can add relaxation rules to bypass inspection of cross-site scripting script attack inspection in a specific location. Use the bind or unbind command to add or delete the relaxation rule binding, as follows:

```
> bind appfw profile <name> -XMLcross-site scripting <string> [isRegex (REGEX | NOTREGEX)] [-location ( ELEMENT | ATTRIBUTE )] -comment <string> [-state ( ENABLED | DISABLED )]
> unbind appfw profile <name> -XMLcross-site scripting <String>
```

Example:

```
> bind appfw profile test_pr -XMLcross-site scripting ABC
```

After executing the above command, the following relaxation rule is configured. The rule is enabled, the name is treated as a literal (NOTREGEX), and ELEMENT is selected as the default location:

```
1 1)      XMLcross-site scripting:  ABC                IsRegex:  NOTREGEX
2
3      Location:  ELEMENT                State:  ENABLED
4
5 `> unbind appfw profile test_pr -XMLcross-site scripting abc`
6
7 ERROR: No such XMLcross-site scripting check
8
9 `> unbind appfw profile test_pr -XMLcross-site scripting ABC`
10
11 Done
12 <!--NeedCopy-->
```

Using the GUI to configure the XML Cross-Site scripting check

In the GUI, you can configure the XML Cross-Site scripting check in the pane for the profile associated with your application.

To configure or modify the XML Cross-Site Scripting check by using the GUI

1. Navigate to **Web App Firewall > Profiles**, highlight the target profile, and click **Edit**.
2. In the Advanced Settings pane, click **Security Checks**.

The security check table displays the currently configured action settings for all the security checks. You have 2 options for configuration:

- a) If you just want to enable or disable **Block**, **Log**, and **Stats** actions for the **XML Cross-Site Scripting check**, you can select or clear check boxes in the table, click **OK**, and then click Save and Close to close the Security Check pane.
- b) You can double click **XML Cross-Site Scripting**, or select the row and click **Action Settings**, to display the action options. After changing any of the action settings, click **OK** to save the changes and return to the Security Checks table.

You can proceed to configure other security checks if needed. Click **OK** to save all the changes you have made in the Security Checks section, and then click **Save and Close** to close the Security Check pane.

To configure a XML Cross-Site Scripting relaxation rule by using the GUI

1. Navigate to **Web App Firewall > Profiles**, highlight the target profile, and click **Edit**.
2. In the **Advanced Settings** pane, click **Relaxation Rules**.
3. In the Relaxation Rules table, double-click the **XML Cross-Site Scripting** entry, or select it and click **Edit**.
4. In the **XML Cross-Site Scripting Relaxation Rules** dialogue box, perform **Add**, **Edit**, **Delete**, **Enable**, or **Disable** operations for relaxation rules.

To manage XML Cross-Site Scripting relaxation rules by using the visualizer

For a consolidated view of all the relaxation rules, you can highlight the **XML Cross-Site Scripting** row in the Relaxation Rules table, and click **Visualizer**. The visualizer for deployed relaxations offers you the option to **Add** a new rule or **Edit** an existing one. You can also **Enable** or **Disable** a group of rules by selecting a node and clicking the corresponding buttons in the relaxation visualizer.

To view or customize the Cross-Site Scripting patterns by using the GUI

You can use the GUI to view or customize the default list of cross-site scripting allowed attributes or allowed tags. You can also view or customize the default list of cross-site scripting denied Patterns.

The default lists are specified in **Web App Firewall > Signatures > Default Signatures**. If you do not bind any signature object to your profile, the default cross-site scripting Allowed and Denied list specified in the Default Signatures object will be used by the profile for the Cross-Site Scripting security check processing. The Tags, Attributes, and Patterns, specified in the default signatures object, are read-only. You cannot edit or modify them. If you want to modify or change these, make a copy of the Default Signatures object to create a User-Defined signature object. Make changes in the Allowed or Denied lists in the new user-defined signature object and use this signature object in the profile that is processing the traffic for which you want to use these customized allowed and denied lists.

For more information about signatures, see <http://support.citrix.com/proddocs/topic/ns-security-10-map/appfw-signatures-con.html>.

To view default cross-site scripting patterns:

1. Navigate to **Web App Firewall > Signatures**, select ***Default Signatures**, and click **Edit**. Then click **Manage SQL/cross-site scripting Patterns**.

The **Manage SQL/cross-site scripting Paths** table shows following three rows pertaining to cross-site scripting :

| | |
|---|-----------------------|
| 1 | xss/allowed/attribute |
| 2 | |
| 3 | xss/allowed/tag |
| 4 | |
| 5 | xss/denied/pattern |
| 6 | <!--NeedCopy--> |

Select a row and click **Manage Elements** to display the corresponding cross-site scripting Elements (Tag, Attribute, Pattern) used by the Web App Firewall **Cross-Site Scripting** check.

To customize cross-site scripting Elements: You can edit the user-defined signature object to customize the allowed Tag, allowed Attributes and denied Patterns. You can add new entries or remove the existing ones.

1. **Navigate to Web App Firewall > Signatures**, highlight the target user-defined signature, and click **Edit**. Click **Manage SQL/cross-site scripting Patterns** to display the **Manage SQL/cross-site scripting paths** table.
2. Select the target cross-site scripting row.
 - a) Click **Manage Elements**, to **Add**, **Edit** or **Remove** the corresponding cross-site scripting element.
 - b) Click **Remove** to remove the selected row.

Warning

Be very careful when you remove or modify any default cross-site scripting element, or delete the cross-site scripting path to remove the entire row. The signatures, HTML Cross-Site Scripting security check, and XML Cross-Site Scripting security check rely on these Elements for detecting attacks to protect your applications. Customizing the cross-site scripting Elements can make your application vulnerable to Cross-Site Scripting attacks if the required pattern is removed during editing.

Using the log feature with the XML cross-site scripting check

When the log action is enabled, the XML Cross-Site Scripting security check violations are logged in the audit log as **APPFW_XML_cross-site scripting** violations. The Web App Firewall supports both

Native and CEF log formats. You can also send the logs to a remote syslog server.

To access the log messages by using the command line

Switch to the shell and tail the ns.logs in the /var/log/ folder to access the log messages pertaining to the XML Cross-Site Scripting violations:

```
1 > **Shell**
2
3 > **tail -f /var/log/ns.log | grep APPFW_XML_cross-site scripting**
4 <!--NeedCopy-->
```

Example of a XML Cross-Site Scripting security check violation log message in Native log format showing <blocked> action

```
1 Oct 7 01:44:34 <local0.warn> 10.217.31.98 10/07/2015:01:44:34 GMT ns
  0-PPE-1 : default APPFW APPFW_XML_cross-site scripting 1154 0 :
  10.217.253.69 3466-PPE1 - owa_profile http://10.217.31.101/FFC/login
  .html Cross-site script check failed for field script="Bad tag:
  script" <**blocked**>
2 <!--NeedCopy-->
```

Example of a XML Cross-Site Scripting security check violation log message in CEF log format showing <not blocked> action

```
1 Oct 7 01:46:52 <local0.warn> 10.217.31.98 CEF:0|Citrix|NetScaler|NS11
  .0|APPFW|APPFW_XML_cross-site scripting|4|src=10.217.30.17
  geolocation=Unknown spt=33141 method=GET request=http://
  10.217.31.101/FFC/login.html msg=Cross-site script check failed for
  field script="Bad tag: script" cn1=1607 cn2=3538 cs1=owa_profile cs2
  =PPE0 cs4=ERROR cs5=2015 act=**not blocked**
2 <!--NeedCopy-->
```

To access the log messages by using the GUI

The GUI includes a useful tool (**Syslog Viewer**) for analyzing the log messages. You have multiple options for accessing the Syslog Viewer:

- Navigate to the **Web App Firewall > Profiles**, select the target profile, and click **Security Checks**. Highlight the **XML Cross-Site Scripting** row and click **Logs**. When you access the logs directly from the XML Cross-Site Scripting check of the profile, the GUI filters out the log messages and displays only the logs pertaining to these security check violations.
- You can also access the Syslog Viewer by navigating to **NetScaler > System > Auditing**. In the Audit Messages section, click the Syslog messages link to display the Syslog Viewer, which displays all log messages, including other security check violation logs. This is useful for debugging when multiple security check violations might be triggered during request processing.
- Navigate to **Web App Firewall > policies > Auditing**. In the **Audit Messages** section, click the **Syslog messages** link to display the Syslog Viewer, which displays all log messages, including

other security check violation logs.

The XML based Syslog Viewer provides various filter options for selecting only the log messages that are of interest to you. To select log messages for the **XML Cross-Site Scripting** check, filter by selecting **APPFW** in the dropdown options for **Module**. The **Event Type** list offers a rich set of options to further refine your selection. For example, if you select the **APPFW_XML_cross-site scripting** check box and click the **Apply** button, only log messages pertaining to the XML Cross-Site Scripting security check violations appear in the Syslog Viewer.

If you place the cursor in the row for a specific log message, multiple options, such as **Module**, **Event Type**, **Event ID**, **Client IP** and so forth. appear below the log message. You can select any of these options to highlight the corresponding information in the log message.

Statistics for the XML cross-site scripting violations

When the stats action is enabled, the counter for the XML Cross-Site Scripting check is incremented when the Web App Firewall takes any action for this security check. The statistics are collected for Rate and Total count for Traffic, Violations, and Logs. The size of an increment of the log counter can vary depending on the configured settings. For example, if the block action is enabled, a request for a page that contains three XML Cross-Site Scripting violations increments the stats counter by one, because the page is blocked as soon as the first violation is detected. However, if block is disabled, processing the same request increments the statistics counter for violations and the logs by three, because each violation generates a separate log message.

To display XML Cross-Site Scripting check statistics by using the command line

At the command prompt, type:

```
> **sh appfw stats**
```

To display stats for a specific profile, use the following command:

```
> **stat appfw profile** <profile name>
```

To display XML Cross-Site Scripting statistics by using the GUI

1. Navigate to **System > Security > Web App Firewall**.
2. In the right pane, access the **Statistics** Link.
3. Use the scroll bar to view the statistics about XML Cross-Site Scripting violations and logs. The statistics table provides real-time data and is updated every 7 seconds.

XML SQL injection check

May 2, 2023

The XML SQL injection check examines the user requests for possible XML SQL Injection attacks. If it finds injected SQL in XML payloads, it blocks the requests.

A XML SQL attack can inject source code into a web application such that it can be interpreted and run as a valid SQL query to perform a database operation with malicious intent. For example, XML SQL attacks can be launched to gain unauthorized access to the contents of a database or to manipulate the stored data. XML SQL Injection attacks are not only common, but can also be very harmful and costly.

Compartmentalizing the privileges of the database users can assist in protecting the database to some extent. All database users must be given only the required privileges to complete their intended tasks, so that they cannot run SQL queries to perform other tasks. For example, a read-only user must not be allowed to write or manipulate data tables. The Web App Firewall XML SQL Injection check inspects all XML requests to provide special defenses against injection of unauthorized SQL code that might break security. If the Web App Firewall detects unauthorized SQL code in any XML request of any user, it can block the request.

The NetScaler Web App Firewall inspects the presence of SQL keywords and special characters to identify the XML SQL Injection attack. A default set of keywords and special characters provides known keywords and special characters that are commonly used to launch XML SQL attacks. The Web App Firewall considers three characters, single straight quote ('), backslash (\), and semicolon (;) as special characters for SQL security check processing. You can add new patterns, and you can edit the default set to customize the XML SQL check inspection.

The Web App Firewall offers various action options for implementing XML SQL Injection protection. You can **Block** the request, **Log** a message in the ns.log file with details regarding the observed violations, and collect **Stats** to keep track of the number of observed attacks.

In addition to actions, there are several parameters that can be configured for XML SQL injection processing. You can check for **SQL wildcard characters**. You can change the XML SQL Injection type and select one of the 4 options (**SQLKeyword**, **SQLSplChar**, **SQLSplCharANDKeyword**, **SQL-SplCharORKeyword**) to indicate how to evaluate the SQL keywords and SQL special characters when processing the XML payload. The XML **SQL Comments Handling** parameter gives you an option to specify the type of comments that need to be inspected or exempted during XML SQL Injection detection.

You can deploy relaxations to avoid false positives. The Web App Firewall XML SQL check is performed on the payload of the incoming requests, and attack strings are identified even if they are spread over multiple lines. The check looks for SQL Injection strings in the **element** and the **attribute** values. You

can apply relaxations to bypass security check inspection under specified conditions. The logs and statistics can help you identify needed relaxations.

Action options

An action is applied when the XML SQL Injection check detects an SQL Injection attack string in the request. The following actions are available for configuring an optimized XML SQL Injection protection for your application:

Block—If you enable block, the block action is triggered only if the input matches the XML SQL injection type specification. For example, if **SQLSplCharANDKeyword** is configured as the XML SQL injection type, a request is not blocked if it does not contain any key words, even if SQL special characters are detected in the payload. Such a request is blocked if the XML SQL injection type is set to either **SQLSplChar**, or **SQLSplCharORKeyword**.

Log—If you enable the log feature, the XML SQL Injection check generates log messages indicating the actions that it takes. If block is disabled, a separate log message is generated for each location (**ELEMENT, ATTRIBUTE**) in which the XML SQL violation was detected. However, only one message is generated when the request is blocked. You can monitor the logs to determine whether responses to legitimate requests are getting blocked. A large increase in the number of log messages can indicate attempts to launch an attack.

Stats—If enabled, the stats feature gathers statistics about violations and logs. An unexpected surge in the stats counter might indicate that your application is under attack. If legitimate requests are getting blocked, you might have to revisit the configuration to see if you need to configure new relaxation rules or modify the existing ones.

XML SQL parameters

In addition to the block, log and stats actions, you can configure the following parameters for XML SQL Injection check:

Check for XML SQL wildcard Characters—Wild card characters can be used to broaden the selections of a structured query language (SQL-SELECT) statement. These wild card operators can be used in conjunction with **LIKE** and **NOT LIKE** operators to compare a value to similar values. The percent (%), and underscore (_) characters are frequently used as wild cards. The percent sign is analogous to the asterisk (*) wildcard character used with MS-DOS and to match zero, one, or multiple characters in a field. The underscore is similar to the MS-DOS question mark (?) wildcard character. It matches a single number or character in an expression.

For example, you can use the following query to do a string search to find all customers whose names contain the D character.

```
SELECT * from customer WHERE name like "%D%"
```

The following example combines the operators to find any salary values that have 0 as the second and third character.

```
SELECT * from customer WHERE salary like '_00%
```

Different DBMS vendors have extended the wildcard characters by adding extra operators. The NetScaler Web App Firewall can protect against attacks that are launched by injecting these wildcard characters. The 5 default Wildcard characters are percent (%), underscore (_), caret (^), opening square bracket ([), and closing square bracket (]). This protection applies to both HTML and XML profiles.

The default wildcard chars are a list of literals specified in the ***Default Signatures:**

```
1 - <wildchar type= " LITERAL " >%</wildchar>
2 - <wildchar type= " LITERAL " >_</wildchar>
3 - <wildchar type= " LITERAL " >^</wildchar>
4 - <wildchar type= " LITERAL " >[</wildchar>
5 - <wildchar type= " LITERAL " >]</wildchar>
6 <!--NeedCopy-->
```

Wildcard characters in an attack can be PCRE, like [^A-F]. The Web App Firewall also supports PCRE wildcards, but the literal wildcard chars above are sufficient to block most attacks.

Note

The XML SQL **wildcard character** check is different from the XML SQL **special character** check. This option must be used with caution to avoid false positives.

Check Request Containing SQL Injection Type—The Web App Firewall provides 4 options to implement the desired level of strictness for SQL Injection inspection, based on the individual need of the application. The request is checked against the injection type specification for detecting SQL violations. The 4 SQL injection type options are:

- **SQL Special Character and Keyword**—Both an SQL keyword and an SQL special character must be present in the inspected location to trigger SQL violation. This least restrictive setting is also the default setting.
- **SQL Special Character**—At least one of the special characters must be present in the processed payload string to trigger SQL violation.
- **SQL keyword**—At least one of the specified SQL keywords must be present in the processed payload string to trigger an SQL violation. Do not select this option without due consideration. To avoid false positives, make sure that none of the keywords are expected in the inputs.
- **SQL Special Character or Keyword**—Either the keyword or the special character string must be present in the payload to trigger the security check violation.

Tip

If you select the SQL Special Character option, the Web App Firewall skips strings that do not contain any special characters. Since most SQL servers do not process SQL commands that are not preceded by a special character, enabling this option can significantly reduce the load on the Web App Firewall and speed up processing without placing your protected websites at risk.

SQL comments handling—By default, the Web App Firewall parses and checks all comments in XML data for injected SQL commands. Many SQL servers ignore anything in a comment, even if preceded by an SQL special character. For faster processing, if your XML SQL server ignores comments, you can configure the Web App Firewall to skip comments when examining requests for injected SQL. The XML SQL comments handling options are:

- **ANSI**—Skip ANSI-format SQL comments, which are normally used by UNIX-based SQL databases.
- **Nested**—Skip nested SQL comments, which are normally used by Microsoft SQL Server.
- **ANSI/Nested**—Skip comments that adhere to both the ANSI and nested SQL comment standards. Comments that match only the ANSI standard, or only the nested standard, are still checked for injected SQL.
- **Check all Comments**—Check the entire request for injected SQL, without skipping anything. This is the default setting.

Tip

In most cases, you must not choose the Nested or the ANSI/Nested option unless your back-end database runs on Microsoft SQL Server. Most other types of SQL server software do not recognize nested comments. If nested comments appear in a request directed to another type of SQL server, they might indicate an attempt to breach security on that server.

Relaxation rules

If your application requires you to bypass the XML SQL Injection inspection for a specific ELEMENT or ATTRIBUTE in the XML payload, you can configure a relaxation rule. The XML SQL Injection inspection relaxation rules have the following parameters:

- **Name:** You can use literal strings or regular expressions to configure the name of the **ELEMENT** or the **ATTRIBUTE**. The following expression exempts all **ELEMENTS** beginning with the string **PurchaseOrder_** followed by a string of numbers that is at least two and no more than ten characters long:

Comment: “Exempt XML SQL Check for Purchase Order Elements”

```

1   XMLSQLInjection:  "PurchaseOrder_[0-9A-Za-z]{
2   2,10 }
3   "
4
5   IsRegex:  REGEX           Location:  ELEMENT
6
7   State:  ENABLED
8 <!--NeedCopy-->

```

Note: The names are case sensitive. Duplicate entries are not allowed, but you can use capitalization of the names and differences in location to create similar entries. For example, each of the following relaxation rules is unique:

```

1 1)   XMLSQLInjection:  XYZ           IsRegex:  NOTREGEX
2
3      Location:  ELEMENT           State:  ENABLED
4
5 2)   XMLSQLInjection:  xyz           IsRegex:  NOTREGEX
6
7      Location:  ELEMENT           State:  ENABLED
8
9 3)   XMLSQLInjection:  xyz           IsRegex:  NOTREGEX
10
11     Location:  ATTRIBUTE          State:  ENABLED
12
13 4)   XMLSQLInjection:  XYZ           IsRegex:  NOTREGEX
14
15     Location:  ATTRIBUTE          State:  ENABLED
16 <!--NeedCopy-->

```

- **Location:** You can specify the Location of the XML SQL Inspection exception in your XML payload. The option **ELEMENT** is selected by default. You can change it to **ATTRIBUTE**.
- **Comment:** This is an optional field. You can use up to a 255 character string to describe the purpose of this relaxation Rule.

Warning

Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the name that you want to add as an exception, and nothing else. Careless use of Regular Expressions can have results that you do not want, such as blocking access to web content that you did not intend to block or allowing an attack that the XML SQL Injection inspection would otherwise have blocked.

Using the command line to configure the XML SQL Injection Check

To configure XML SQL Injection actions and other parameters by using the command line:

In the command line interface, you can use either the **set appfw profile** command or the **add appfw profile** command to configure the XML SQL Injection protections. You can enable the block, log, and stats action(s). Select the type of SQL attack pattern (key words, wildcard characters, special strings) you want to detect in the payloads. Use the **unset appfw profile** command to revert the configured settings back to their defaults. Each of the following commands sets only one parameter, but you can include multiple parameters in a single command:

- `set appfw profile <name> **-XMLSQLInjectionAction** ([[block] [log] [stats]])| [none])`
- `set appfw profile <name> -XMLSQLInjectionCheckSQLWildChars (ON | OFF)`
- `set appfw profile <name> -XMLSQLInjectionType ([SQLKeyword] | [SQLSplChar] | [SQLSplCharANDKeyword] | [SQLSplCharORKeyword])`
- `set appfw profile <name> -XMLSQLInjectionParseComments ([checkall] | [ansi|nested] | [ansinested])`

To configure a SQL Injection relaxation rule by using the command line

Use the bind or unbind command to add or delete relaxation rules, as follows:

```
1 - bind appfw profile <name> -XMLSQLInjection <string> [isRegex (REGEX
  | NOTREGEX)] [-location ( ELEMENT | ATTRIBUTE )] -comment <string>
  [-state ( ENABLED | DISABLED )]
2 - unbind appfw profile <name> -XMLSQLInjection <String>
3 <!--NeedCopy-->
```

Example:

```
1 > bind appfw profile test_profile -XMLSQLInjection "PurchaseOrder_[0-9A
  -Za-z]{
2 2,15 }
3 " -isregex REGEX -location ATTRIBUTE
4
5 > unbind appfw profile test_profile -XMLSQLInjection "PurchaseOrder_
  [0-9A-Za-z]{
6 2,15 }
7 " -location ATTRIBUTE
8 <!--NeedCopy-->
```

Using the GUI to configure the XMLSQL injection security check

In the GUI, you can configure the XML SQL Injection security check in the pane for the profile associated with your application.

To configure or modify the XML SQL Injection check by using the GUI

1. Navigate to **Web App Firewall > Profiles**, highlight the target profile, and click **Edit**.

2. In the Advanced Settings pane, click **Security Checks**.

The security check table displays the currently configured action settings for all the security checks. You have 2 options for configuration:

- a. If you just want to enable or disable Block, Log, and Stats actions for XML SQL Injection, you can select or clear check boxes in the table, click OK, and then click Save and Close to close the Security Check pane.
- b. If you want to configure additional options for this security check, double click XML SQL Injection, or select the row and click **Action Settings**, to display the following options:

Check for SQL Wildcard Characters—Consider SQL Wildcard characters in the payload to be attack patterns.

Check Request Containing—Type of SQL injection (SQLKeyword, SQLSplChar, SQLSplCharANDKeyword, or SQLSplCharORKeyword) to check.

SQL Comments Handling—Type of comments (Check All Comments, ANSI, Nested, or ANSI/Nested) to check.

After changing any of the above settings, click **OK** to save the changes and return to the Security Checks table. You can proceed to configure other security checks if needed. Click **OK** to save all the changes you have made in the Security Checks section, and then click **Save** and **Close** to close the Security Check pane.

To configure a XML SQL Injection relaxation rule by using the GUI

1. Navigate to **Web App Firewall > Profiles**, highlight the target profile, and click **Edit**.
2. In the **Advanced Settings** pane, click **Relaxation Rules**.
3. In the Relaxation Rules table, double-click the **XML SQL Injection** entry, or select it and click **Edit**.
4. In the **XML SQL Injection Relaxation Rules** dialogue box, perform **Add**, **Edit**, **Delete**, **Enable**, or **Disable** operations for relaxation rules.

To manage XML SQL Injection relaxation rules by using the visualizer

For a consolidated view of all the relaxation rules, you can highlight the **XML SQL Injection** row in the Relaxation Rules table, and click **Visualizer**. The visualizer for deployed relaxations offers you the option to **Add** a new rule or **Edit** an existing one. You can also **Enable** or **Disable** a group of rules by selecting a node and clicking the corresponding buttons in the relaxation visualizer.

To view or customize the SQL Injection patterns by using the GUI:

You can use the GUI to view or customize the SQL patterns.

The default SQL patterns are specified in **Web App Firewall > Signatures > *Default Signatures**. If you do not bind any signature object to your profile, the default SQL patterns specified in the Default

Signatures object will be used by the profile for XML SQL Injection security check processing. The rules and patterns in the Default Signatures object are read-only. You cannot edit or modify them. If you want to modify or change these patterns, create a user-defined signature object by making a copy of the Default Signatures object and changing the SQL patterns. Use the user-defined signature object in the profile that processes the traffic for which you want to use these customized SQL patterns.

For more information, see [Signatures](#).

To view default SQL patterns:

a. Navigate to **Web App Firewall > Signatures**, select ***Default Signatures**, and click **Edit**. Then click **Manage SQL/cross-site scripting Patterns**.

The Manage SQL/cross-site scripting Paths table shows following four rows pertaining to SQL Injection:

```

1 Injection (not_alphanum, SQL)/ Keyword
2
3 Injection (not_alphanum, SQL)/ specialstring
4
5 Injection (not_alphanum, SQL)/ transformrules/transform
6
7 Injection (not_alphanum, SQL)/ wildchar
8 <!--NeedCopy-->

```

b. Select a row and click **Manage Elements** to display the corresponding SQL patterns (keywords, special strings, transformation rules or the wildcard characters) used by the Web App Firewall SQL injection check.

To customize SQL Patterns: You can edit a user-defined signature object to customize the SQL key words, special strings, and wildcard characters. You can add new entries or remove the existing ones. You can modify the transformation rules for the SQL special strings.

a. Navigate to **Web App Firewall > Signatures**, highlight the target user-defined signature, and click **Edit**. Click **Manage SQL/cross-site scripting Patterns** to display the **Manage SQL/cross-site scripting paths** table.

b. Select the target SQL row.

i. Click **Manage Elements**, to **Add**, **Edit** or **Remove** the corresponding SQL element.

ii. Click **Remove** to remove the selected row.

Warning

You must be very careful when removing or modifying any default SQL element, or deleting the SQL path to remove the entire row. The signature rules as well as the XML SQL Injection security check rely on these elements for detecting SQL Injection attacks to protect your applications. Customizing the SQL patterns can make your application vulnerable to XML SQL attacks if the

required pattern is removed during editing.

Using the log feature with the XML SQL injection check

When the log action is enabled, the **XML SQL Injection** security check violations are logged in the audit log as **APPFW_XML_SQL** violations. The Web App Firewall supports both Native and CEF log formats. You can also send the logs to a remote syslog server.

To access the log messages by using the command line:

Switch to the shell and tail the ns.logs in the /var/log/ folder to access the log messages pertaining to the XML Cross-Site Scripting violations:

```
1 > Shell
2
3 > tail -f /var/log/ns.log | grep APPFW_XML_SQL
4 <!--NeedCopy-->
```

To access the log messages by using the GUI

The GUI includes a useful tool (Syslog Viewer) for analyzing the log messages. You have multiple options for accessing the Syslog Viewer:

- Navigate to **Web App Firewall > Profiles**, select the target profile, and click **Security Checks**. Highlight the **XML SQL Injection** row and click **Logs**. When you access the logs directly from the XML SQL Injection check of the profile, the GUI filters out the log messages and displays only the logs pertaining to these security check violations.
- You can also access the Syslog Viewer by navigating to **System > Auditing**. In the Audit Messages section, click the **Syslog messages** link to display the Syslog Viewer, which displays all log messages, including other security check violation logs. This is useful for debugging when multiple security check violations might be triggered during request processing.
- Navigate to **Web App Firewall > Policies > Auditing**. In the Audit Messages section, click the **Syslog messages** link to display the **Syslog Viewer**, which displays all log messages, including other security check violation logs.

The XML based Syslog Viewer provides various filter options for selecting only the log messages that are of interest to you. To select log messages for the **XML SQL Injection** check, filter by selecting **APPFW** in the dropdown options for **Module**. The **Event Type** list offers a rich set of options to further refine your selection. For example, if you select the **APPFW_XML_SQL** check box and click the **Apply** button, only log messages pertaining to the **XML SQL Injection** security check violations appear in the Syslog Viewer.

If you place the cursor in the row for a specific log message, multiple options, such as **Module**, **Event Type**, **Event ID**, and **Client IP** appear below the log message. You can select any of these options to

highlight the corresponding information in the log message.

Statistics for the XML SQL injection violations

When the stats action is enabled, the counter for the **XML SQL Injection** check is incremented when the Web App Firewall takes any action for this security check. The statistics are collected for Rate and Total count for Traffic, Violations, and Logs. The size of an increment of the log counter can vary depending on the configured settings. For example, if the block action is enabled, a request for a page that contains three **XML SQL Injection** violations increments the stats counter by one, because the page is blocked as soon as the first violation is detected. However, if block is disabled, processing the same request increments the statistics counter for violations and the logs by three, because each violation generates a separate log message.

To display XML SQL Injection check statistics by using the command line

At the command prompt, type:

```
> sh appfw stats
```

To display stats for a specific profile, use the following command:

```
> stat appfw profile <profile name>
```

To display XML SQL Injection statistics by using the GUI

1. Navigate to **System > Security > Web App Firewall**.
2. In the right pane, access the **Statistics** Link.
3. Use the scroll bar to view the statistics about **XML SQL Injection** violations and logs. The statistics table provides real-time data and is updated every 7 seconds.

XML attachment check

September 21, 2020

The XML Attachment check examines incoming requests for malicious attachments, and it blocks those requests that contain attachments that might breach applications security. The purpose of the XML Attachment check is to prevent an attacker from using an XML attachment to breach security on your server.

If you use the wizard or the GUI, in the Modify XML Attachment Check dialog box, on the General tab you can enable or disable the Block, Learn, Log, Statistics, and Learn actions:

If you use the command-line interface, you can enter the following command to configure the XML Attachment Check:

- `set appfw profile <name> -xmlAttachmentAction [block] [learn] [log] [stats] [none]`

You must configure the other XML Attachment check settings in the GUI. In the [Modify XML Attachment](#) Check dialog box, on the Checks tab, you can configure the following settings:

- **Maximum Attachment Size.** Allow attachments that are no larger than the maximum attachment size you specify. To enable this option, first select the Enabled check box, and then type the maximum attachment size in bytes in the [Size](#) text box.
- **Attachment Content Type.** Allow attachments of the specified content type. To enable this option, first select the Enabled check box, and then enter a regular expression that matches the Content-Type attribute of the attachments that you want to allow.
 - You can type the URL expression directly in the text window. If you do so, you can use the [Regex Tokens](#) menu to enter a number of useful regular expressions at the cursor instead of typing them manually.
 - You can click [Regex Editor](#) to open the [Add Regular Expression](#) dialog box and use it to construct the URL expression.

Web services interoperability check

December 4, 2020

The Web Services Interoperability (WS-I) check examines both requests and responses for adherence to the WS-I standard, and blocks those requests and responses that do not adhere to this standard. The purpose of the WS-I check is to block requests that might not interact with other XML appropriately. An attacker can use inconsistencies in interoperability to launch an attack on your XML application.

If you use the wizard or the GUI, in the [Modify Web Services Interoperability Check](#) dialog box, on the General tab you can enable or disable the Block, Log, Statistics, and Learn actions.

If you use the command-line interface, you can enter the following command to configure the Web Services Interoperability check:

- `set appfw profile <name> -xmlWSIAction [block]][log] [learn] [stats] [none]`

To configure individual Web Services Interoperability rules, you must use the GUI. On the Checks tab of the [Modify Web Services Interoperability Check](#) dialog box, select a rule and click [Enable](#) or [Disable](#) to enable or disable the rule. You can also click [Open](#) to open the [Web Services Interoperability Detail](#)

message box for that rule. The message box displays read-only information about the rule. You cannot modify or make other configuration changes to any of these rules.

The WS-I check uses the rules listed in WS-I Basic Profile 1.0. WS-I delivers best practices for developing interoperable Web Services solutions. WS-I checks are performed only on SOAP Messages.

Description of each WSI standard rule is provided below:

| Rule | Description |
|--------|---|
| BP1201 | Message body should be a soap:envelope with namespace. |
| R1000 | When an ENVELOPE is a Fault, the soap:Fault element MUST NOT have element children other than faultcode, faultstring, faultactor and detail. |
| R1001 | When an ENVELOPE is a Fault, the element children of the soap:Fault element MUST be unqualified. |
| R1003 | A RECEIVER MUST accept fault messages that have any number of qualified or unqualified attributes, including zero, appearing on the detail element. The namespace of qualified attributes can be anything other than the namespace of the qualified document element Envelope. |
| R1004 | When an ENVELOPE contains a faultcode element, the content of that element must be either one of the fault codes defined in SOAP 1.1 (supplying additional information if necessary in the detail element), or a QName whose namespace is controlled by the fault's specifying authority (in that order of preference). |
| R1005 | An ENVELOPE MUST NOT contain soap:encodingStyle attribute on any of the elements whose namespace is the same as the namespace of the qualified document element Envelope. |
| R1006 | An ENVELOPE MUST NOT contain soap:encodingStyle attributes on any element that is a child of soap:Body. |

| Rule | Description |
|-------|---|
| R1007 | An ENVELOPE described in an rpc-literal binding MUST NOT contain soap:encodingStyle attribute on any element that is a grandchild of soap:Body. |
| R1011 | An ENVELOPE MUST NOT have any element children of soap:Envelope following the soap:Body element. |
| R1012 | A MESSAGE MUST be serialized as either UTF-8 or UTF-16. |
| R1013 | An ENVELOPE containing a soap:mustUnderstand attribute MUST only use the lexical forms 0 and 1. |
| R1014 | The children of the soap:Body element in an ENVELOPE MUST be namespace qualified. |
| R1015 | A RECEIVER MUST generate a fault if they encounter an envelope whose document element is not soap:Envelope. |
| R1031 | When an ENVELOPE contains a faultcode element the content of that element must NOT use of the SOAP 1.1 dot notation to refine the meaning of the fault. |
| R1032 | The soap:Envelope, soap:Header, and soap:Body elements in an ENVELOPE MUST NOT have attributes in the same namespace as that of the qualified document element Envelope |
| R1033 | An ENVELOPE SHOULD NOT contain the namespace declaration: <code>xmlns:xml=http://www.w3.org/XML/1998/namespace</code> . |
| R1109 | The value of the SOAPAction HTTP header field in a HTTP request MESSAGE MUST be a quoted string. |
| R1111 | An INSTANCE SHOULD use a 200 OK HTTP status code on a response message that contains an envelope that is not a fault. |
| R1126 | An INSTANCE MUST return a 500 Internal Server Error HTTP status code if the response envelope is a Fault. |

| Rule | Description |
|-------|--|
| R1132 | A HTTP request MESSAGE MUST use the HTTP POST method. |
| R1140 | A MESSAGE SHOULD be sent using HTTP/1.1. |
| R1141 | A MESSAGE MUST be sent using either HTTP/1.1 or HTTP/1.0. |
| R2113 | An ENVELOPE MUST NOT include the soapenc:arrayType attribute. |
| R2211 | An ENVELOPE described with an rpc-literal binding MUST NOT have the xsi:nil attribute with a value of 1 or true on the part accessors. |
| R2714 | For one-way operations, an INSTANCE MUST NOT return a HTTP response that contains an envelope. Specifically, the HTTP response entity-body must be empty. |
| R2729 | An ENVELOPE described with an rpc-literal binding that is a response MUST have a wrapper element whose name is the corresponding wsdl:operation name suffixed with the stringResponse. |
| R2735 | An ENVELOPE described with an rpc-literal binding MUST place the part accessor elements for parameters and return value in no namespace. |
| R2738 | An ENVELOPE MUST include all soapbind:headers specified on a wsdl:input or wsdl:output of a wsdl:operation of a wsdl:binding that describes it. |
| R2740 | A wsdl:binding in a DESCRIPTION SHOULD contain a soapbind:fault describing each known fault. |
| R2744 | A HTTP request MESSAGE MUST contain a SOAPAction HTTP header field with a quoted value equal to the value of the soapAction attribute of soapbind:operation, if present in the corresponding WSDL description. |

XML message validation check

September 21, 2020

The XML Message Validation check examines requests that contain XML messages to ensure that they are valid. If a request contains an invalid XML message, the Web App Firewall blocks the request. The purpose of the XML Validation check is to prevent an attacker from using specially constructed invalid XML messages to breach the security of your application.

If you use the wizard or the GUI, in the Modify XML Message Validation Check dialog box, on the General tab you can enable or disable the Block, Log, and Statistics actions.

If you use the command-line interface, you can enter the following command to configure the XML Message Validation Check:

- `set appfw profile <name> -xmlValidationAction [**block**] [**log**] [**stats**] [**none**]`

You must use the GUI to configure the other XML Validation check settings. In the Modify XML Message Validation Check dialog box, on the Checks tab, you can configure the following settings:

- **XML Message Validation.** Use one of the following options to validate the XML message:
 - **SOAP Envelope.** Validate only the SOAP envelope of XML messages.
 - **WSDL.** Validate XML messages by using an XML SOAP WSDL. If you choose WSDL validation, in the WSDL Object drop-down list you must choose a WSDL. If you want to validate against a WSDL that has not already been imported to the Web App Firewall, you can click the Import button to open the Manage WSDL Imports dialog box and import your WSDL. See [WSDL](#) for more information.
 - * If you want to validate the entire URL, leave the Absolute radio button in the End Point Check button array selected. If you want to validate only the portion of the URL after the host, select the Relative radio button.
 - * If you want the Web App Firewall to enforce the WSDL strictly, and not allow any additional XML headers not defined in the WSDL, you must clear the Allow additional headers not defined in the WSDL check box.

Caution: If you uncheck the Allow Additional Headers not defined in the WSDL check box, and your WSDL does not define all XML headers that your protected XML application or Web 2.0 application expects or that a client sends, you may block legitimate access to your protected service.
 - **XML Schema.** Validate XML messages by using an XML schema. If you choose XML schema validation, in the XML Schema Object drop-down list you must choose an XML schema. If

you want to validate against an XML schema that has not already been imported to the Web App Firewall, you can click the Import button to open the Manage XML Schema Imports dialog box and import your WSDL. See [WSDL](#) for more information.

- **Response Validation.** By default, the Web App Firewall does not attempt to validate responses. If you want to validate responses from your protected application or Web 2.0 site, select the Validate Response check box. When you do, the Reuse the XML Schema specified in request validation check box and the XML Schema Object drop-down list are activated.
 - Check the Reuse XML Schema check box to use the schema you specified for request validation to do response validation as well.
Note: If you check this check box, the XML Schema Object drop-down list is grayed out.
 - If you want to use a different XML schema for response validation, use the XML Schema Object drop-down list to select or upload that XML schema.

XML SOAP fault filtering check

September 21, 2020

The XML SOAP fault filtering check examines responses from your protected web services and filters out XML SOAP faults. This prevents leaking of sensitive information to attackers.

If you use the wizard or the GUI, in the Modify XML SOAP Fault Filtering Check dialog box, on the **General** tab you can enable or disable the Block, Log, and Statistics actions, and the Remove action, which removes SOAP faults before forwarding the response to the user.

If you use the command-line interface, you can enter the following command to configure the XML SOAP Fault Filtering Check:

```
set appfw profile <name> -XMLSOAPFaultAction [block] [log] [stats] [none]
```

You cannot configure exceptions to the XML SOAP Fault Filtering check. You can only enable or disable it.

JSON Protection Checks

May 2, 2023

NetScaler Web App Firewall protects your JSON applications from content-level DoS, SQL, or cross-site scripting attacks. When a JSON request has a DoS, SQL, or cross-site scripting attack, you must protect your application by configuring limits on JSON structures such as arrays and strings.

Note:

The JSON security checks apply only to content that is sent with a JSON content-type header. If the content-type header is missing, or is set to a different value, all JSON security checks are bypassed. If you want to protect your JSON applications, the webmasters of each web server that hosts those applications must ensure a proper JSON content-type header is sent.

The learning feature is not support for JSON SQL, cross-site scripting, DOS content types.

JSON Denial-of-Service protection check

February 9, 2024

The JSON denial-of-service (DoS) check examines an incoming JSON request and validates if there is any data that matches the characteristics of a DoS attack. If the request had JSON violations, the appliance blocks the request, logs the data, sends an SNMP alert, and also displays a JSON error page. The purpose of the JSON DoS check is to prevent an attacker from sending JSON request to launch DoS attacks on your JSON applications or website.

When a client sends a request to a NetScaler appliance, the JSON parser parses the request payload and if a violation is observed, the appliance enforces constraints on the JSON structure. The constraint enforces a size limit on the JSON request. As a result, if any JSON violation was observed, the appliance applies an action and responds with the JSON error page.

JSON DoS rules

When the appliance receives a JSON request, The JSON DOS protection enforces size limit on the following DoS parameters in the request payload.

1. **maximum depth:** Maximum nesting (depth) of JSON document. This check protects against documents that have excessive depth of hierarchy.
2. **maximum document length:** Maximum document length of JSON document.
3. **maximum array length:** Maximum array length in the any of JSON object. This check protects against arrays having large lengths.
4. **maximum string length:** Maximum string length in the JSON. This check protects against strings that have large length.

5. maximum object key count: Maximum key count in the any of JSON object. This check protects against objects that have large number of keys.
6. maximum object key length: Maximum key length in the any of JSON object. This check protects against objects that have large keys.

Following is a list of JSON DoS rules validated during JSON parsing.

1. JSONMaxContainerDepth. This check can be enabled by configuring the JSONMaxContainerDepth check and by default the option is OFF.
2. JSONMaxContainerDepth. This check can be enabled/disabled by configurable option JSONMaxContainerDepthCheck and default value can be changed by option JSONMaxContainerDepth. However, you can vary the maximum levels to a value ranging from 1 to 127. Default value: 5, Minimum value: 1, Maximum value: 127
3. JSONMaxDocumentLength. This check can be enabled by configuring the JSONMaxDocumentLength check and the default option is OFF.
4. JSONMaxDocumentLength. This check can be enabled by configuring the JSONMaxDocumentLength check and the default length is set to 20000000 bytes. Minimum value: 1, Maximum value: 2147483647
5. JSONMaxObjectKeyCount. The rule validates if the JSON maximum object key count check is turned on or off. Possible values: ON, OFF, Default value: OFF
6. JSONMaxObjectKeyCount. This check can be enabled by configuring the JSONMaxObjectKeyCount check. The check protects against objects that have large number of keys and the default value is set to 1000 bytes. Minimum value: 0, Maximum value: 2147483647
7. JSONMaxObjectKeyLength. This check can be enabled by configuring the JSONMaxObjectKeyLength check. The rule validates if the JSON maximum object key length check is turned on or off. By default it is turned OFF.
8. JSONMaxObjectKeyLength. The check protects against objects that have large key length. Default value: 128. Minimum value: 1, Maximum value: 2147483647
9. JSONMaxArrayLength. The rule validates if the JSON maximum array length check is ON or OFF. By default it is turned off.
10. JSONMaxArrayLength. The check protects against arrays that has large lengths. By default, the value is set to 10000. Minimum value: 1, Maximum value: 2147483647
11. JSONMaxStringLength. This check can be enabled by configuring the JSONMaxStringLength check. The check validates if the JSON maximum string length is ON or OFF. By default it is turned off.
12. JSONMaxStringLength. The check protects against strings that has large length. By default, it is set to 1000000. Minimum value: 1, Maximum value: 2147483647

Configure JSON DoS protection check

For configure JSON DoS protection, you must complete the following steps:

1. Add application firewall profile for JSON.
2. Set application firewall profile for JSON DoS settings.
3. Configure JSON DoS variables by binding the application firewall profile.

Add application firewall profile for JSON DoS protection

You must first create a profile that specifies how the application firewall must protect your JSON web content from JSON DoS attack.

At the command prompt, type:

```
add appfw profile <name> -type (HTML | XML | JSON)
```

Note:

When you set the profile type as JSON, other checks such as HTML or XML will not applicable.

Example `add appfw profile profile1 -type JSON`

Set application firewall profile for JSON DoS protection

You must configure the profile for one or more JSON DoS actions and JSON DoS error object to be set on the application firewall profile.

At the command prompt, type:

```
set appfw profile <name> -JSONDoSAction [block] | [log] | [stats] | [none]
```

Block - Block connections that violate this security check.

Log - Log violations of this security check.

Stats - Generate statistics for this security check.

None - Disable all actions for this security check.

Note:

To enable one or more actions, type “set appfw profile -JSONDoSAction” followed by the actions to be enabled.

Example `set appfw profile profile1 -JSONDoSAction block log stat`

Configure DoS variables by binding application firewall profile

To provide JSON DoS protection, you must bind the application firewall profile with JSON DoS settings.

At the command prompt, type:

```
bind appfw profile <name> -JSONDoSURL <expression> [-JSONMaxContainerDepthCheck
( ON | OFF )[-JSONMaxContainerDepth <positive_integer>]] [-JSONMaxDocumentLength
( ON | OFF )[-JSONMaxDocumentLength <positive_integer>]] [-JSONMaxObjectKeyCount
( ON | OFF )[-JSONMaxObjectKeyCount <positive_integer>]] [-JSONMaxObjectKeyLength
( ON | OFF )[-JSONMaxObjectKeyLength <positive_integer>]] [-JSONMaxArrayLength
( ON | OFF )[-JSONMaxArrayLength <positive_integer>]] [-JSONMaxStringLengthCheck
( ON | OFF )[-JSONMaxStringLength <positive_integer>]]
```

Example `bind appfw profile profile1 -JSONDoSURL “.*” -JSONMaxContainerDepthCheck ON`

Note:

The JSON DoS checks will be applicable only if the profile type is selected as JSON. Also, the SQL, cross-site scripting, Field format and Form field signatures are applied on Query parameters in cases of JSON profile.

Import JSON errorpage

If an incoming request had a DoS attack and when you block the request, the appliance displays an error message. For doing this, you must import the JSON error page.

At the command prompt, type:

```
import appfw jsonerrorpage <src> <name> [-comment <string>] [-overwrite
]
```

Where,

src. URL (protocol, host, path, and name) for the location at which to store the imported JSON error object.

Note:

The import fails if the object to be imported is on an HTTPS server that requires client certificate authentication for access. This is a mandatory argument. Maximum Length: 2047.

Name. Name to assign to the JSON error object on the NetScaler. This is a mandatory argument. Maximum Length: 31

Comment. Any comments to preserve information about the JSON error object. Maximum Length: 255

Overwrite. Overwrite any existing JSON error object of the same name.

Sample configuration

```

1 Add appfw prof profjson - type JSON
2 Bind appfw prof profjson - JSONDoSURL “.*” -
  JSONMaxDocumentLengthCheck ON -JSONMaxDocumentLength 30 -
  JSONMaxContainerDepthCheck ON -JSONMaxContainerDepth 3
  JSONMaxObjectKeyCountCheck ON -JSONMaxObjectKeyCount 4 -
  JSONMaxObjectKeyLengthCheck ON -JSONMaxObjectKeyLength 10 -
  JSONMaxArrayLengthCheck ON -JSONMaxArrayLength 5 -
  JSONMaxStringLengthCheck ON -JSONMaxStringLength 30
3 <!--NeedCopy-->

```

Sample Payloads, Log Messages and Counters:

JSONMaxDocumentLength Violation JSONMaxDocumentLength: 30

Payload: {"a": "A", "b": "B", "c": "C", "d": "D", "e": "E"}

Log Message:

```

Configure JSON DoS protection by using GUI

Follow the procedure below to set the JSON DoS protection settings.

1. On the navigation pane, navigate to **Security > Profiles**.
2. In the **Profiles** page, click **Add**.
3. In the **NetScaler Web App Firewall Profile** page, click **Security Checks under Advanced Settings**.
4. In the **Security Checks** section, go to **JSON Denial of Service** settings.
5. Click the executable icon near the checkbox.
6. Click **Action Settings** to access the **JSON Denial of Service Settings** page.
7. Select the JSON DoS action.
8. Click **OK**.
9. In the **NetScaler Web App Firewall Profile** page, click **Relaxation Rules under Advanced Settings**.
10. In **Relaxation Rules** section, select **JSON Denial of Service** settings and click **Edit**.
11. In the **Application Firewall JSON Denial of Service Check** set the JSON DoS validation values.
12. Click **OK**.

| Application Firewall JSON Denial of Service Check | | |
|---|--|-------------|
| Check Name | Enabled | Check Value |
| Max Array Length | <input checked="" type="checkbox"/> jsonmaxarraylengthcheckjsonmaxarraylengthcheck | 10000 |
| Max Container Depth | <input checked="" type="checkbox"/> jsonmaxcontainerdepthcheckjsonmaxcontainerdepthcheck | 5 |
| Max Document Length | <input checked="" type="checkbox"/> jsonmaxdocumentlengthcheckjsonmaxdocumentlengthcheck | 20000000 |
| Max Object Key Count | <input checked="" type="checkbox"/> jsonmaxobjectkeycountcheckjsonmaxobjectkeycountcheck | 10000 |
| Max Object Key Length | <input checked="" type="checkbox"/> jsonmaxobjectkeylengthcheckjsonmaxobjectkeylengthcheck | 128 |
| Max String Length | <input checked="" type="checkbox"/> jsonmaxstringlengthcheckjsonmaxstringlengthcheck | 1000000 |

13. In the **NetScaler Web App Firewall Profile** page, click **Profile Settings** under **Advanced Settings**.
14. In the **Profile Settings** section, go to **JSON Error Settings** sub section to set **JSON DoS error** page.

Profile Settings

Redirect URL

Verbose Log Level

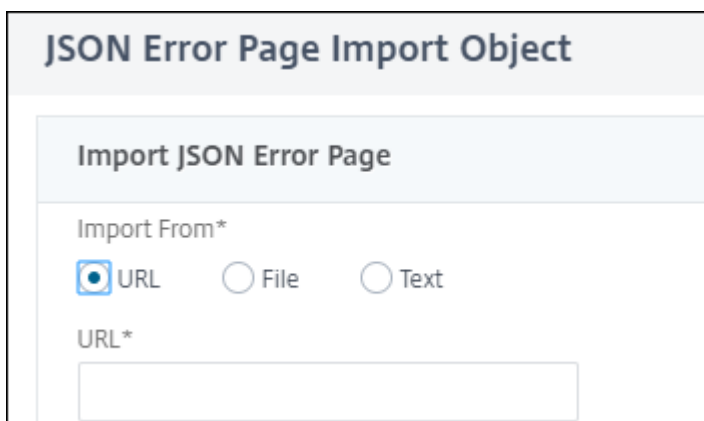

Content Type

Inspected Content Types

application/x-www-form-urlencoded
 multipart/form-data
 text/x-gwt-rpc

JSON Settings

15. In the **JSON Error Page Import Object** page, set the following parameters:
 - a) Import from. Import the error page as text, file or URL.
 - b) URL. URL to redirect the user to the error page.
 - 1 File. Select a file to be imported as JSON DoS error file.
 - c) Text. Enter the JSON file contents.
 - d) Click Continue.
 - e) File. Enter the file name.
 - f) File Content. Add the error file content.
 - g) Click **OK**.

The screenshot shows a dialog box titled "JSON Error Page Import Object". Inside the dialog, there is a section titled "Import JSON Error Page". Below this section, there is a label "Import From*" followed by three radio buttons: "URL" (which is selected), "File", and "Text". Below the radio buttons, there is a text input field labeled "URL*" with a small asterisk indicating it is required.

16. Click **OK**.
17. Click **Done**.

JSON SQL Injection protection check

February 9, 2024

An incoming JSON request can have SQL injection in the form of partial SQL query strings or unauthorized commands in the code. This leads to stealing of data from the JSON database of your web servers. On receiving such request, the appliance blocks such request to protect your data.

Consider a scenario, where a client sends a JSON SQL request to a NetScaler appliance, the JSON parser parses the request payload and if an SQL Injection is observed, the appliance enforces constraints on the JSON SQL content. The constraint enforces a size limit on the JSON SQL request. As a result, if any JSON SQL Injection is observed, the appliance applies an action and responds with the JSON SQL error page.

Configure JSON SQL Injection protection

For configure JSON SQL protection, you must complete the following steps:

1. Add application firewall profile as JSON.
2. Set application firewall profile for JSON SQL Injection settings
3. Configure JSON SQL action by binding the application firewall profile.

Add application firewall profile of type JSON

You must first create a profile that specifies how the application firewall must protect your JSON web content from JSON SQL Injection attack.

At the command prompt, type:

```
add appfw profile <name> -type (HTML | XML | JSON)
```

Note:

When you set the profile type as JSON, other checks such as HTML or XML will not be applicable.

Example

```
add appfw profile profile1 -type JSON
```

Configure JSON SQL Injection action

You must configure one or more JSON SQL Injection actions to protect your application from JSON SQL injection attacks.

At the command prompt, type:

```
set appfw profile <name> - JSONSQLInjectionAction [block] [log] [stats] [none]
```

SQL Injection actions are:

Block - Block connections that violate this security check.

Log - Log violations of this security check.

Stats - Generate statistics for this security check.

None - Disable all actions for this security check.

Configure JSON SQL Injection type

To configure the JSON SQL Injection type on an application firewall profile, at the command prompt, type:

```
set appfw profile <name> - JSONSQLInjectionType <JSONSQLInjectionType>
```

Example

```
set appfw profile profile1 -JSONSQLInjectionType SQLKeyword
```

Where the available SQL Injection types are:

Available SQL injection types.

SQLSplChar. Checks for SQL Special Characters,

SQLKeyword. Checks for SQL Keywords.

SQLSplCharANDKeyword. Checks for both and blocks if found.

SQLSplCharORKeyword. . Blocks if SQL special character or spl keyword is found.

Possible values: SQLSplChar, SQLKeyword, SQLSplCharORKeyword, SQLSplCharANDKeyword.

Note:

To enable one or more actions, type “set appfw profile - JSONSQLInjectionAction” followed by the actions to be enabled.

Example

```
set appfw profile profile1 -JSONSQLInjectionAction block log stat
```

The following example shows a sample payload, its corresponding log message and statistics counters:

```

SQL Injection rule 

Create

Configure fine grain relaxation for JSON SQL injection protection

The Web App Firewall gives you an option to relax a specific JSON key or value from the JSON based SQL Injection inspection check. You can configure multiple options to relax JSON payloads using fine

grain relaxation rules.

Previously, the only way to configure relaxations for JSON protection checks is to specify the entire URL and that would bypass the verification of the entire URL.

The JSON based SQL security protection provides relaxation for the following:

- Key names
- Key values

JSON based SQL protection check enables you to configure relaxations that allow specific patterns and block the rest. For example, the Web App Firewall currently has a default set of more than 100 SQL keywords. Because hackers can use these keywords in SQL Injection attacks, the Web App Firewall flags all as potential threats. If you want to relax one or more keywords that are considered safe for the specific location, you can configure a relaxation rule that can bypass the security check and block the rest. The commands used in relaxations have optional parameters for Value Type and Value Expression. You can specify whether the value expression is a regular expression or a literal string. The value type can be left blank, or you have an option to select Keyword or Special String.

Note:

Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the URL that you want to add as an exception, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (.) metacharacter or wildcard combination, can have results that you do not want, such as blocking access to web content that you did not intend to block or allowing an attack that the JSON SQL Injection check would otherwise have blocked.

Points to Consider

- Value expression is an optional argument. A field name might not have any value expression.
- A key name can be bound to multiple value expressions.
- Value expressions must be assigned a value type. The value type can be: 1) Keyword, 2) Special-String.
- You can have multiple relaxation rules per key name or URL combination.

Configure JSON fine grain relaxation for command injection attacks using command interface

To configure JSON file grain relaxation rule, you must bind the fine grain relaxation entities to the Web App Firewall profile.

At the command prompt, type:

```
1 bind appfw profile <profile name> -jsoncmdURL <URL> -key <key name> -  
  isregex <REGEX/NOTREGEX> -valueType <keyword/SpecialString> <value  
  Expression> -isvalueRegex <REGEX/NOTREGEX>  
2 <!--NeedCopy-->
```

Example:

```
1 bind appfw profile appprofile1 -jsonsqlurl www.example.com -key  
  stn_name -isRegex NOTREGEX -valueType Keyword "union" -  
  isvalueRegex NOTREGEX  
2 <!--NeedCopy-->
```

To configure fine grain relaxation rule for JSON-based command injection attacks by using the GUI

1. Navigate to **Application Firewall > Profiles**, select a profile, and click **Edit**.
2. In the **Advanced Settings** pane, click **Relaxation Rules**.
3. In the **Relaxation Rules** section, select a **JSON SQL Injection** record and click **Edit**.
4. In the **JSON SQL Injection Relaxation Rule** slider, click **Add**.
5. In the **JSON SQL Injection Relaxation Rule** page, set the following parameters.
 - a) Enabled
 - b) Is Name Regex
 - c) Key Name
 - d) URL
 - e) Value Type
 - f) Comments
 - g) Resource ID
6. Click **Create**.

JSON Cross-Site Scripting protection check

February 9, 2024

If an incoming JSON payload has a malicious cross-site scripting data, WAF blocks the request. The following procedures explain how you can configure this through CLI and GUI interfaces.

Configure JSON Cross-Site Scripting protection

For configure JSON cross-site scripting protection, you must complete the following steps:

1. Add application firewall profile as JSON.
2. Configure JSON cross-site scripting action to block cross-site scripting malicious payload

Add application firewall profile of type JSON

You must first create a profile that specifies how the application firewall must protect your JSON web content from JSON cross-site scripting attack.

At the command prompt, type:

```
add appfw profile <name> -type (HTML | XML | JSON)
```

Note:

When you set the profile type as JSON, other checks such as HTML or XML will not applicable.

Example

```
add appfw profile profile1 -type JSON
```

Sample output for JSON cross-site scripting violation

```

1 JSONcross-site scriptingAction: block log stats
2 Payload: {
3   "username": "<a href=\"jAvAsCrIpT:alert(1)\">>X</a>","password":"xyz" }

```

Configure JSON Cross-Site Scripting action

You must configure one or more JSON cross-site scripting actions to protection your application from JSON Cross-Site Scripting attacks.

At the command prompt, type:

```
set appfw profile <name> - JSONcross-site scriptingAction [block] [log] [stats] [none]
```

Example

```
set appfw profile profile1 -JSONcross-site scriptingAction block
```

The available Cross-Site Scripting actions are:

Block - Block connections that violate this security check.

Log - Log violations of this security check.

Stats - Generate statistics for this security check.

None - Disable all actions for this security check.

Note:

To enable one or more actions, type “set appfw profile - JSONcross-site scriptingAction “followed by the actions to be enabled.

Example

```
set appfw profile profile1 -JSONSQLInjectionAction block log stat
```

Configure JSON Cross Site Scripting (cross-site scripting) protection by using GUI

Follow the procedure below to set the Cross Site Scripting (cross-site scripting) protection settings.

1. On the navigation pane, navigate to **Security > Profiles**.
2. In the **Profiles** page, click **Add**.
3. In the **NetScaler Web App Firewall Profile** page, click **Security Checks** under **Advanced Settings**.
4. In the **Security Checks** section, go to **JSON Cross-Site Scripting (cross-site scripting)** settings.
5. Click the executable icon near the checkbox.
6. Click **Action Settings** to access the **JSON Cross-Site Scripting Settings** page.
7. Select the JSON cross-site scripting actions.
8. Click **OK**.
9. In the **NetScaler Web App Firewall Profile** page, click **Relaxation Rules** under **Advanced Settings**.
10. In **Relaxation Rules** section, select JSON Cross-Site Scripting settings and click **Edit**.

11. In the **JSON Cross-Site Scripting Relaxation Rule** page, click **Add** to add a JSON Cross-Site Scripting relaxation rule.
12. Enter the URL to which the request has to be sent. All requests sent to this URL will not be blocked.
13. Click **Create**.

Configure fine grained relaxation for JSON-based cross-site scripting

The Web App Firewall gives you an option to relax a specific JSON key or value from the JSON based cross-site scripting (XSS) inspection check. You can configure multiple options to relax JSON payloads using fine grain relaxation rules.

Previously, the only way to configure relaxations for JSON protection checks is to specify the entire URL and that would bypass the verification of the entire URL.

The JSON based SQL security protection provides relaxation for the following:

- Key names
- Key values

JSON based cross-site scripting (XSS) protection enables you to configure relaxations that allow specific patterns and block the rest. For example, the Web App Firewall currently has a default set of more than 100 SQL keywords. Because hackers can use these keywords in SQL Injection attacks, the Web App Firewall flags all as potential threats. If you want to relax one or more keywords that are considered safe for the specific location, you can configure a relaxation rule that can bypass the security check and block the rest. The commands used in relaxations have optional parameters for Value Type and Value Expression. You can specify whether the value expression is a regular expression or a literal string. The value type can be left blank, or you have an option to select Keyword or Special String.

Note:

Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the URL that you want to add as an exception, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (.*) metacharacter or wildcard combination, can have results that you do not want, such as blocking access to web content that you did not intend to block or allowing an attack that the JSON SQL Injection check would otherwise have blocked.

Points to Consider

- Value expression is an optional argument. A field name might not have any value expression.
- A key name can be bound to multiple value expressions.
- Value expressions must be assigned a value type. The value types are tag, attribute, and pattern.
- You can have multiple relaxation rules per key name/URL combination.

Configure JSON fine grain relaxation for cross-site scripting (XSS) injection attacks using command interface

To configure JSON file grain relaxation rule, you must bind the fine grain relaxation entities to the Web App Firewall profile.

At the command prompt, type:

```
1 bind appfw profile <profile name> -jsonxssURL <URL> -key <key name> -
  isregex <REGEX/NOTREGEX> -valueType <keyword/SpecialString> <value
  Expression> -isvalueRegex <REGEX/NOTREGEX>
2 <!--NeedCopy-->
```

Example:

```
1 bind appfw profile appprofile1 -jsonxssurl www.example.com -key name -
  isRegex NOTREGEX -valueType Tag "sname" -isvalueRegex NOTREGEX
2 <!--NeedCopy-->
```

To configure an JSON based cross-site scripting (XSS) Injection fine grain relaxation rule by using the GUI

1. Navigate to **Application Firewall > Profiles**, select a profile, and click **Edit**.
2. In the **Advanced Settings** pane, click **Relaxation Rules**.
3. In the **Relaxation Rules** section, select a JSON SQL Injection record and click **Edit**.
4. In the **JSON Cross-Site Scripting Relaxation Rules** slider, click **Add**.
5. In the **JSON Cross-Site Scripting Relaxation Rule** page, set the following parameters.
 - a) Enabled
 - b) Is Name Regex
 - c) Key Name

JSON command injection protection check

May 8, 2024

The JSON command injection check examines the incoming JSON traffic for unauthorized commands that break the system security or modify the system. When examining the traffic, if any malicious commands are detected, the appliance blocks the request or performs the configured action.

In a command injection attack, the attacker aims to run unauthorized commands on the NetScaler operating system or the back-end server. To achieve this, the attacker injects operating system commands using a vulnerable application. The back-end application is vulnerable to injection attacks if the appliance simply forwards a request without any security check. Therefore, it is highly important to configure a security check, so the NetScaler appliance can protect your web application by blocking unsafe data.

How command injection protection works

1. For an incoming JSON request, WAF examines the traffic for keywords or special characters. If the JSON request has no patterns that match any of the denied keywords or special characters, the request is allowed. Otherwise, the request is blocked, dropped, or redirected based on the configured action.
2. If you prefer to exempt a keyword or a special character from the list, you can create a relaxation rule to bypass the security check under specific conditions.
3. You can enable logging to generate log messages. You can monitor the logs to determine whether responses to legitimate requests are getting blocked. A large increase in the number of log messages can indicate attempts to launch an attack.
4. You can also enable the statistics feature to gather statistical data about violations and logs. An unexpected surge in the stats counter might indicate that your application is under attack. If legitimate requests are getting blocked, you might have to revisit the configuration to see if you must configure the new relaxation rule or modify the existing one.

Keywords and special characters denied for command injection check

To detect and block JSON command injection attacks, the appliance has a set of patterns (keywords and special characters) defined in the default signature file. Following is a list of keywords blocked during command injection detection.

```
1 <commandinjection>
2     <keyword type="LITERAL" builtin="ON">7z</keyword>
3     <keyword type="LITERAL" builtin="ON">7za</keyword>
4     <keyword type="LITERAL" builtin="ON">7zr</keyword>
5 ...
6 </commandinjection>
7
8 <!--NeedCopy-->
```

Special characters defined in the signature file are:

```
| ; & $ > < ' \ ! >> #
```

Note:

You can find the list of keywords and patterns in the `/netscaler/default_signatures.xml` file.

Configuring JSON command injection check by using the CLI

You can use either the `set appfw profile` command or add an `appfw profile` command to configure the JSON command injection settings. You can enable the block, log, and stats actions. You

must also set the command injection type such as key words and string characters that you want to detect in the payloads.

At the command prompt, type:

```
set appfw profile <profile-name> -cmdInjectionAction <action-name> -  
CMDInjectionType <CMDInjectionType>]
```

Note:

By default, the command injection action is set as **Block, Log, and Stats**. Also, the default command injection type is set as **CmdSplCharANDKeyword**. After an upgrade, the existing Web app Firewall profiles have the action set as **None..**

Example:

```
set appfw profile profile1 -JSONCMDInjectionAction block -JSONCMDInjectionType  
CmdSplChar
```

Where, the available JSON command injection actions are:

None - Disable command injection protection.

Log - Log command injection violations for the security check.

Block - blocks traffic that violates the command injection security check.

Stats - Generates statistics for command injection security violations.

Where, the available JSON command injection types are:

Cmd SplChar - Checks special characters

CmdKeyword - Checks command injection Keywords

CmdSplCharANDKeyword - This is the default action. The action checks special characters and command injection. Keywords and blocks only if both are present.

CmdSplCharORKeyword - Checks special characters and command injection Keywords and blocks if either of them is found.

Configuring relaxation rules for JSON command injection protection check

If your application requires you to bypass the JSON command injection inspection for a specific ELEMENT or ATTRIBUTE in the payload, you can configure a relaxation rule.

The JSON command Injection inspection relaxation rules have the following syntax.

```
bind appfw profile <profile name> -JSONCMDURL <expression> -comment  
<string> -isAutoDeployed ( AUTODEPLOYED | NOTAUTODEPLOYED )-state (   
ENABLED | DISABLED )
```

Example for relaxation rule for Regex in header

```
bind appfw profile abc_json -jsoncmDURL http://1.1.1.1/hello.html
```

Whereas, the following relaxes requests from all URLs hosted on 1.1.1.1:

```
bind appfw profile abc_json -jsoncmDURL http://1.1.1.1/*
```

To remove the relaxation, use 'unbind'.

```
unbind appfw profile abc_json -jsoncmDURL " http://1.1.1.1/*"
```

Configure JSON command injection check by using the GUI

Complete the following steps to configure the JSON command injection check.

1. Navigate to **Security > NetScaler Web App Firewall and Profiles**.
2. On the **Profiles** page, select a profile and click **Edit**.
3. On the **NetScaler Web App Firewall Profile** page, go to **Advanced Settings** section and click **Security Checks**.
4. In **Security Checks** section, select **JSON Command Injection** and click **Action** settings.
5. In the **JSON Command Injection Settings** page, set the following parameters
 - a) Actions. Select one or more actions to perform for JSON command injection security check.
 - b) Check Request Containing. Select a command injection pattern to check if the incoming request has the pattern.
6. Click **OK**.

Viewing command injection traffic and violation statistics

The **NetScaler Web App Firewall Statistics** page shows security traffic and security violation details in a tabular or graphical format.

To view security statistics by using the command interface.

At the command prompt, type:

```
stat appfw profile profile1
```

| Appfw profile Traffic Statistics | Rate (/s) | Total |
|----------------------------------|-----------|-------|

| XML format logs | 0 | 0 |

Viewing JSON command injection statistics by using the NetScaler GUI

Complete the following steps to view the command injection statistics:

1. Navigate to **Security > NetScaler Web App Firewall > Profiles**.
2. In the details pane, select a Web App Firewall profile and click **Statistics**.
3. The **NetScaler Web App Firewall Statistics** page displays the JSON command injection traffic and violation details.
4. You can select **Tabular View** or switch to **Graphical View** to display the data in a tabular or graphical format.

Configure fine grain relaxation for JSON command injection

The Web App Firewall gives you an option to relax a specific JSON key or value from the JSON based command injection check. You can completely bypass the inspection for one or more fields by configuring the fine grain relaxation rules.

Previously, the only way to configure relaxations for JSON protection checks is to specify the entire URL and that would bypass the verification of the entire URL.

The JSON based command injection security protection provides relaxation for the following:

- Key names
- Key values

JSON based command injection protection enables you to configure relaxations that allow specific patterns and block the rest. For example, the Web App Firewall currently has a default set of more than 100 SQL keywords. Because hackers can use these keywords in command injection attacks, the Web App Firewall flags all as potential threats. If you want to relax one or more keywords that are considered safe for the specific location, you can configure a relaxation rule that can bypass the security check and block the rest. The commands used in relaxations have optional parameters for Value Type and Value Expression. You can specify whether the value expression is a regular expression or a literal string. The value type can be left blank, or you have an option to select Keyword or Special String.

Note:

Regular expressions are powerful. Especially if you are not thoroughly familiar with PCRE-format regular expressions, double-check any regular expressions you write. Make sure that they define exactly the URL that you want to add as an exception, and nothing else. Careless use of wildcards, and especially of the dot-asterisk (.*) metacharacter or wildcard combination, can have results that you do not want, such as blocking access to web content that you did not intend to block or allowing an attack that the JSON SQL Injection check would otherwise have blocked.

Points to Consider

- Value expression is an optional argument. A field name might not have any value expression.
- A key name can be bound to multiple value expressions.
- Value expressions must be assigned a value type. The value type can be: 1) Keyword, 2) Special-String.
- You can have multiple relaxation rules per key name/URL combination.

Configure JSON fine grain relaxation for command injection attacks using command interface

To configure JSON file grain relaxation rule, you must bind the fine grain relaxation entities to the Web App Firewall profile.

At the command prompt, type:

```
1 bind appfw profile <profile name> -jsoncmdURL <URL> -key <key name> -  
  valueType <keyword/SpecialString> <value Expression>  
2 <!--NeedCopy-->
```

Example:

```
bind appfw profile appprofile1 -jsoncmdurl www.example.com -key  
blg_cnt -isRegex NOTREGEX -valueType Keyword "cat" -isvalueRegex  
NOTREGEX
```

To configure fine grain relaxation rule for JSON-based command injection attacks by using the GUI

1. Navigate to **Application Firewall > Profiles**, select a profile, and click **Edit**.
2. In the **Advanced Settings** pane, click **Relaxation Rules**.
3. In the **Relaxation Rules** section, select a **JSON Command Injection** record and click **Edit**.
4. In the **JSON Command Injection Relaxation Rule** slider, click **Add**.
5. In the **JSON Command Injection Relaxation Rule** page, set the following parameters.
 - a) Enabled
 - b) Is Name Regex
 - c) Key Name
 - d) URL
 - e) Value Type
 - f) Comments
 - g) Resource ID
6. Click **Create**.

Managing content types

June 19, 2023

Web servers add a Content-Type header with a MIME/type definition for each content type. Web servers serve many different types of content. For example, standard HTML is assigned the “text/html” MIME type. JPG images are assigned the “image/jpeg” or “image/jpg” content type. A normal web server can serve different types of content, all defined in the Content Type header by the assigned MIME/type.

Many Web App Firewall filtering rules are designed to filter a specific content type. The filtering rules apply to one type of content such as HTML and are often inappropriate when filtering a different type of content (such as images). As a result, the Web App Firewall attempts to determine the content type of requests and responses before it filters them. If a web server or browser does not add a Content-Type header to a request or response, the Web App Firewall applies a default content type and filters content accordingly.

The default content type is usually “application/octet-stream” with the most generic MIME/type definition. The MIME/type is appropriate for any content type a web server is likely to serve. But does not provide much information to the Web App Firewall to allow it to choose appropriate filtering. If a protected web server is configured to add accurate content type headers, you can then create a profile for the web server and assign a default content type to it. This is done to improve both the speed and the accuracy of filtering.

You can also configure a list of allowed request content types for a specific profile. When this feature is configured, if the Web App Firewall filters a request that does not match one of the allowed content types, it blocks the request.

Requests must always be of either the “application/x-www-form-urlencoded”, “multipart/form-data,” or “text/x-gwt-rpc” types. The Web App Firewall blocks any request that has any other content type designated.

Note

You cannot include the “application/x-www-form-urlencoded” or “multipart/form-data” content types on the allowed response content types list.

To set the default request content type by using the command line interface

At the command prompt, type the following commands:

- `set appfw profile <name> -requestContentType <type>`
- `save ns config`

Example

The following example sets the “text/html” content type as the default for the specified profile:

```
1 set appfw profile profile1 -requestContentType "text/html"
2 save ns config
3 <!--NeedCopy-->
```

To remove the user-defined default request content type by using the command line interface

At the command prompt, type the following commands:

- `unset appfw profile <name> -requestContentType <type>`
- `save ns config`

Example

The following example unsets the default content type of “text/html” for the specified profile, allowing the type to revert to “application/octet-stream”:

```
1 unset appfw profile profile1 -requestContentType "text/html"
2 save ns config
3 <!--NeedCopy-->
```

Note

Always use last content-type header for processing and remove remaining content-type headers if any that ensures that the back-end server receives a request with only one content-type.

To block requests that can be bypassed, add a Web App Firewall policy with rule as HTTP.REQ.HEADER (“content-type”).COUNT.GT(1) and profile as *appfw_block*.

If a request is received without a Content-Type header or if the request has Content-Type header without any value, Web App Firewall applies the configured **RequestContentType** value and processes the request accordingly.

To set the default response content type by using the command line interface

At the command prompt, type the following commands:

- `set appfw profile <name> -responseContentType <type>`
- `save ns config`

Example

The following example sets the “text/html” content type as the default for the specified profile:

```
1 set appfw profile profile1 -responseContentType "text/html"
2 save ns config
3 <!--NeedCopy-->
```

To remove the user-defined default response content type by using the command line interface

At the command prompt, type the following commands:

- `unset appfw profile <name> -responseContentType <type>`
- `save ns config`

Example

The following example unsets the default content type of “text/html” for the specified profile, allowing the type to revert to “application/octet-stream”:

```
1 unset appfw profile profile1 -responseContentType "text/html"
2 save ns config
3 <!--NeedCopy-->
```

To add a content type to the allowed content types list by using the command line interface

At the command prompt, type the following commands:

- `bind appfw profile <name> -ContentType <contentTypeName>`
- `save ns config`

Example

The following example adds the “text/shtml” content type to the allowed content types list for the specified profile:

```
1 bind appfw profile profile1 -contentType "text/shtml"
2 save ns config
3 <!--NeedCopy-->
```

To remove a content type from the allowed content types list by using the command line interface

At the command prompt, type the following commands:

- `unbind appfw profile <name> -ContentType <contentTypeName>`
- `save ns config`

Example

The following example removes the “text/shtml” content type from the allowed content types list for the specified profile:

```
1 unbind appfw profile profile1 -contentType "text/shtml"
2 save ns config
3 <!--NeedCopy-->
```

Manage urlencoded and multipart-form content types

The NetScaler Web App Firewall now enables you to configure Urlencoded and Multipart-Form content types for forms. The content type configuration is similar to XML and JSON list. Based on the configuration, Web App Firewall classifies the requests and inspects for urlencoded or multipart-form content type.

To configure Web App Firewall profile with Urlencoded and Multipart-Form content types
At the command prompt, type:

```
bind appfw profile p2 -contentType <string>
```

Example:

```
bind appfw profile p2 -contentType UrlencodedFormContentType
bind appfw profile p2 -ContentType appfwmultipartform
```

To manage the default and allowed content types by using the GUI

1. Navigate to **Security > Web App Firewall > Profiles**.
2. In the details pane, select the profile that you want to configure, and then click **Edit**. The **Configure Web App Firewall Profile** dialog box is displayed.
3. The **Configure Web App Firewall Profile** dialog box, click the **Settings** tab.
4. On the **Settings** tab, scroll down about halfway to the Content Type area.
5. In the Content Type area, configure the default request or response content type:

- To configure the default request content type, type the MIME/type definition of the content type you want to use in the Default Request text box.
 - To configure the default response content type, type the MIME/type definition of the content type you want to use in the Default Response text box.
 - To create a new allowed content type, click **Add**. The **Add Allowed Content Type** dialog box is displayed.
 - To edit an existing allowed content type, select that content type, and then click **Open**. The **Modify Allowed Content Type** dialog box is displayed.
6. To manage the allowed content types, click Manage Allowed Content Types.
 7. To add a new content type or modify an existing content type, click Add or Open, and in the **Add Allowed Content Type** or **Modify Allowed Content Type** dialog box, do the following steps.
 - a) Select/clear the Enabled check box to include the content type in, or exclude it from, the list of allowed content types.
 - b) In the Content Type text box, type a regular expression that describes the content type that you want to add, or change the existing content type regular expression.
Content types are formatted exactly as MIME type descriptions are.
Note:
You can include any valid MIME type on the allowed contents type list. Since many types of document can contain active content and therefore can potentially contain malicious content, you must exercise caution when adding MIME types to this list.
 - c) Provide a short description that explains the reason for adding this particular MIME type to the allowed contents type list.
 - d) Click **Create** or **OK** to save your changes.
 8. Click **Close** to close the Manage Allowed Content Types dialog box and return to the **Settings** tab.
 9. Click **OK** to save your changes.

To manage Urlencoded and Multipart-form content types by using the NetScaler GUI

1. Navigate to **Security > Web App Firewall > Profiles**.
2. In the details pane, select the profile that you want to configure, and then click **Edit**.
3. In the **Configure Web App Firewall Profile** page, select the **Profile Settings** in the **Advanced Settings** section.
4. Under **Inspected Content Type** section, set the following parameters:
 - a) application/x-www-form-urlencoded. Select the checkbox to inspect Urlencoded content type.

- b) multipart/form-data. Select the check to inspect Multipart-form content type.
5. Click **OK**.

Profiles

April 17, 2024

A profile is a collection of security settings that are used to protect specific types of web content or specific parts of your website. In a profile, you determine how the Web App Firewall applies each of its filters (or checks) to requests to your websites, and responses from them. The Web App Firewall supports two types of profile: four built-in (default) profiles that do not require further configuration, and user-defined profiles that do require further configuration.

Built-in profiles

The four Web App Firewall built-in profiles provide simple protection for applications and websites that either do not require protection, or that must not be directly accessed by users at all. These profile types are:

- **APPFW_BYPASS:** Skips all Web App Firewall filtering and sends the unmodified traffic to the protected application or website, or to the client.
- **APPFW_RESET:** Resets the connection, requiring that the client re-establish his or her session by visiting a designated start page.
- **APPFW_DROP:** Drops all traffic to or from the protected application or website, and sends no response of any kind to the client.
- **APPFW_BLOCK:** Blocks traffic to or from the protected application or website.
- **ns-aaa-default-appfw-profile:** Protects the authentication virtual servers and ensures that network traffic is secure and compliant with the API specifications.
- **ns-aaatm-default-appfw-profile:** Protects the traffic management virtual servers and ensures that network traffic is secure and compliant with the API specifications.
- **ns-vpn-default-appfw-profile:** Protects the VPN virtual servers and ensures that network traffic is secure and compliant with the API specifications.

You use the built-in profiles exactly as you do user-defined profiles, by configuring a policy that selects the traffic to which you want to apply the profile and then associating the profile with your policy. Since you do not have to configure a built-in policy, it provides a quick way to allow or block specified types of traffic or traffic that is sent to specific applications or websites.

User-defined profiles

User-defined profiles are profiles that are build and configured by users. Unlike the default profiles, you must configure a user-defined profile before it will be of use filtering traffic to and from your protected applications.

There are three types of user-defined profile:

- **HTML.** Protects HTML-based web pages.
- **XML.** Protects XML-based web services and websites.
- **Web 2.0.** Protects Web 2.0 content that combines HTML and XML content, such as ATOM feeds, blogs, and RSS feeds.

The Web App Firewall has a number of security checks, all of which can be enabled or disabled, and configured in a number of ways in each profile. Each profile also has a number of settings that control how it handles different types of content. Finally, rather than manually configuring all of the security checks, you can enable and configure the learning feature. This feature observes normal traffic to your protected websites for a period of time, and uses those observations to provide you with a tailored list of recommended exceptions (*relaxations*) to some security checks, and additional rules for other security checks.

During initial configuration, whether by using the Web App Firewall Wizard or manually, you normally create one general purpose profile to protect all content on your websites that is not covered by a more specific profile. After that, you can create as many specific profiles as you want to protect more specialized content.

The Profiles pane consists of a table that contains the following elements:

Name. Displays all the Web App Firewall profiles configured in the appliance.

Bound signature. Displays the signatures object that is bound to the profile in the previous column, if any.

Policies. Displays the Web App Firewall policy that invokes the profile in the leftmost column of that row, if any.

Comments. Displays the comment associated with the profile in the leftmost column of that row, if any.

Profile Type. Displays the type of profile. Types are Built-In, HTML, XML, and Web 2.0.

Above the table is a row of buttons and a drop-down list that allow you to create, configure, delete, and view information about your profiles:

- **Add.** Add a new profile to the list.
- **Edit.** Edit the selected profile.
- **Delete.** Delete the selected profile from the list.

- **Statistics.** View the statistics for the selected profile.
- **Action.** Drop-down list that contains additional commands. Currently allows you to import a profile that was exported from another Web App Firewall configuration.

Creating Web App Firewall profiles

February 9, 2024

You can create a Web App Firewall profile in one of two ways: by using the command line, and by using the GUI. Creating a profile by using the command line requires that you specify options on the command line. The process is similar to that of [configuring a profile](#), and with a few exceptions the two commands take the same parameters.

Note

Core profile: This profile is available in the build 33.x and later. It contains limited but fundamental security checks enabled by default whereas the basic and advanced profiles have many other security checks enabled by default. The core profile contains the following security checks:

- Grammar-based SQL injection
- Grammar-based CMD injection
- Cross-site scripting
- Buffer overflow
- Block keywords

CVE profile: This profile is available in the build 42.x and later. Use this profile to only add and bind a signature. It disables all checks from the NetScaler Web App Firewall except the CVE check.

When creating a profile, specify one of these options: basic, advanced, core, or CVE. The default configuration for the various security checks and settings that are part of that profile are applied. You can also, optionally, add a comment. After you create the profile, you must then configure it by selecting it in the data pane, and then clicking **Edit**.

If you plan to use the learning feature or to enable and configure many advanced protections, you must choose advanced defaults. In particular, if you plan to configure either of the SQL injection checks, either of the cross-site scripting checks, any check that provides protection against Web form attacks, or the cookie consistency check, you must plan to use the learning feature. Unless you include the proper exceptions for your protected websites when configuring these checks, they can block legitimate traffic. Anticipating all exceptions without creating any that is too broad is difficult. The learning feature makes this task much easier. Otherwise, basic defaults are quick and must provide the protection that your web applications need.

There are three profile types:

- **HTML.** Protects standard HTML-based websites.
- **XML.** Protects XML-based web services and websites.
- **Web 2.0 (HTML XML).** Protects websites that contain both HTML and XML elements, such as ATOM feeds, blogs, and RSS feeds.

There are also a few restrictions on the name that you can give to a profile. A profile name cannot be the same as the name assigned to any other profile or action in any feature on the NetScaler appliance. Certain action or profile names are assigned to built-in actions or profiles, and can never be used for user profiles. A complete list of disallowed names can be found in the [Web App Firewall Profile Supplemental Information](#). If you attempt to create a profile with a name that has already been used for an action or a profile, an error message is displayed and the profile is not created.

To create a Web App Firewall profile by using the command line interface

At the command prompt, type the following commands:

- `add appfw profile <name> [-defaults (basic | advanced | core | cve)]`
- `set appfw profile <name> -type (HTML | XML | HTML XML)`
- `set appfw profile <name> -comment "<comment>"`
- `save ns config`

Example

The following example adds a profile named `pr-basic`, with basic defaults, and assigns a profile type of HTML. This is the appropriate initial configuration for a profile to protect an HTML website.

```
1 add appfw profile pr-basic -defaults basic -comment "Simple profile for
   websites."
2 set appfw profile pr-basic -type HTML
3 save ns config
4 <!--NeedCopy-->
```

To create a Web App Firewall profile by using the GUI

Complete the following procedure to create a Web App Firewall profile:

1. Navigate to **Security > NetScaler Web App Firewall > Profiles**.
2. In the details pane, click **Add**.

3. In the **Create Web App Firewall Profile** page, set the following basic parameters:
 - a) Name
 - b) Profile Type
 - c) Comments
 - d) Defaults
 - e) Description
4. Click **OK**.
5. Select the profile that you created and click **Edit**.
6. In the **Advanced Settings** section, complete the following configurations:
 - a) Security Checks
 - b) Profile Settings
 - c) Dynamic Profiling
 - d) Relaxation Rules
 - e) Deny Rules
 - f) Learned Rule
 - g) Extended Logging
7. In the **Security Checks** section, select a security protection and click **Action Settings**.
8. In the security check page, set the parameters.

Note:

The **Active Rule** setting is available only for **HTML SQL Injection** check to activate relaxation rule or deny rule for SQL injection check. For more information, see [Relaxation and Deny Rules](#) topic.
9. Click **OK** and **Close**.
10. In the **Profile Settings** section, set the profile parameters. For more information, see [Configure Web App Firewall Profile settings](#) topic.
11. In the **Dynamic Profiling** section, select a security check to add dynamic profile settings. For more information, see [Dynamic Profile](#) topic.
12. In the **Relaxation Rules** section, click **Edit** to add a relaxation rule for a security check. For more information, see [Relaxation Rule](#) for details.
13. In the **Deny Rules** section, add a deny rule for the HTML SQL Injection check. For more information, see [HTML Deny Rules](#) topic.
14. In the **Learnt Rule** section, set the learning settings. For more information, see [Web App Firewall Learning](#) topic.

15. In the **Extended logging** section, click **Add** for masking sensitive data. For more information, see [Extended logging](#) topic.
16. Click **Done**, and then click **Close**.

Configure fake account detection rules

Fake account creation is an automated process of creating many user accounts that are not associated to a real person or creating user accounts with the real person's details without their consent. Fake accounts that non-legitimate users create use registration details that do not correspond to a person's true identify. These accounts are created to abuse services offered by a web application for non-legitimate purposes such as phishing attacks, spreading of fake news, scalping and so forth. Most often, these accounts are created by bots run by malicious users.

The NetScaler appliance is enhanced to detect fake accounts by binding fake account detection rules to a Web App Firewall profile. The rule consists of form URLs and form parameters for each URL. If an incoming request matches an expression or form URL (sign up pages) configured for a fake account detection rule, the evaluation is true for a suspicious sign-up attempt and the request data is sent to the ADM server for further inspection.

Complete the following steps to configure fake account detection by using the command interface:

1. Enable fake account detection feature
2. Bind fake account rules

Enable fake account detection feature

At the command prompt, type:

```
add/set appfw profile <name> -FakeAccountDetection ( ON | OFF )
```

Example:

```
add appfw profile profile1 -FakeAccountDetection ON
```

Bind fake account rules

At the command prompt, type:

```
bind appfw profile <name> -FakeAccount (string|expression)isFieldNameRegex  
(ON|OFF)-tag <TagExpression> ([-formUrl <FormURL>]| [-formExpression  
<FormExpression>]))-state (ENABLED|DISABLED)
```

Where,

- `formUrl`: HTTP form action URL.
formExpression: Form expression to be evaluated.
- `fakeaccount`: Name of the fake account.
tag: Tag expression.
- `isFieldNameRegex`: Specifies whether the fieldName is regex. Default value OFF.

Example:

```
bind appfw profile profile1 -FakeAccount john -formURL "/signup.php"-tag "smith"
bind appfw profile profile2 -FakeAccount Will -formExpression "HTTP.REQ.HEADER(\"Authorization\").CONTAINS(\"/test_accounts\").NOT && HTTP.REQ.URL.CONTAINS(\"/login.php\")"-fieldName -tag "smith"
```

Example input for an HTTP post request for `example.com` signup page.

| S.no | Input | Example |
|------|--|---|
| 1 | Signup HTTP POST request endpoint URL | https://webapi.example.com/account/api/v1.0/contacts/ |
| 2 | Email Field name in HTTP post request | Email address |
| 3 | First name Field name in HTTP post request | First name |
| 4 | Last name Field name in HTTP post request | Last name |

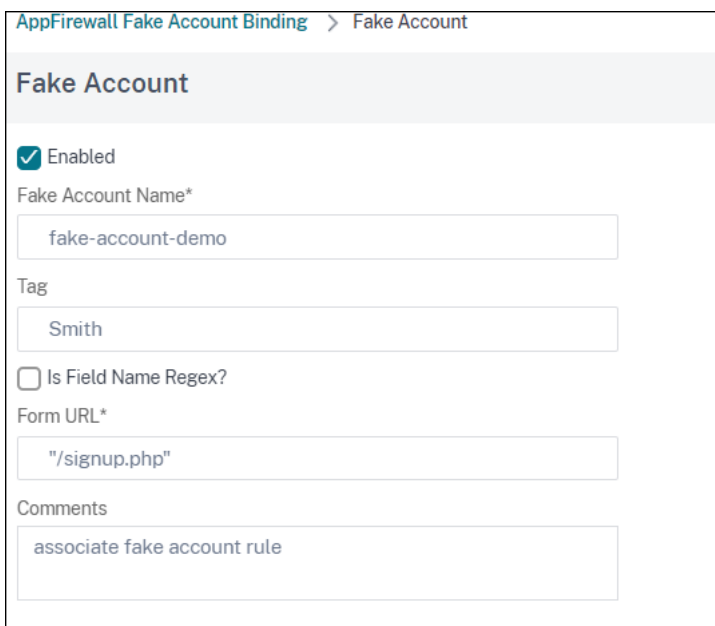

Configure Web App Firewall fake account detection rule by using the GUI

Complete the following steps to configure the fake account detection rule by using the GUI.

1. Navigate to **Configuration > Security > NetScaler Web App Firewall > Profile**.
2. Select a profile and click **Edit**.
3. In the **NetScaler Web App Firewall Profile** page, click **Security Checks** from **Advanced Settings**.
4. In the **Checks Integrated with Citrix Cloud** section, select a fake account rule and click **Edit**.
5. In the **AppFirewall Fake Account Binding** slider, select a rule to edit or click **Add**.
6. In the **Fake Account rule** page, set the following parameters:

- a) **Enabled.** Select to activate the fake account rule.
- b) **Fake Account Name.** Name of the fake account rule.
- c) **Tag.** First name in the fake account registration form.
- d) **Is Field Name Regex?** Select if the form field is a regular expression.
- e) **Form Expression.** Regular expression that defines the fake account.
- f) **Form URL.** Enter the fake account detection URL.
- g) **Comments.** A brief description about the fake account detection rule.

7. Click **Create**.

The screenshot shows the configuration page for a Fake Account rule in NetScaler. The breadcrumb path is "AppFirewall Fake Account Binding > Fake Account". The page title is "Fake Account". The configuration includes:

- Enabled
- Fake Account Name*: fake-account-demo
- Tag: Smith
- Is Field Name Regex?
- Form URL*: "/signup.php"
- Comments: associate fake account rule

Enforce HTTP RFC compliance

May 2, 2023

NetScaler Web App Firewall inspects the incoming traffic for HTTP RFC compliance and drops any request that has RFC violations by default. However, there are certain scenarios, where the appliance might have to bypass or block a non-RFC compliance request. In such cases, you can configure the appliance to bypass or block such requests at global or profile level.

Block or bypass non-RFC compliant requests at global level

The HTTP module identifies a request as invalid if it is incomplete and such requests cannot be processed by WAF. For example, an incoming HTTP request having a host header missing. To block

or bypass such invalid requests, you must configure the `malformedReqAction` option in the application firewall global settings.

The 'malformedReqAction' parameter validates the incoming request for invalid content length, invalid chunked request, no HTTP version, and incomplete header.

Note:

If you disable the block option in the `malformedReqAction` parameter, the appliance bypasses the entire app firewall processing for all non-RFC compliance requests and forwards the requests to the next module.

To block or bypass invalid non-RFC complaint HTTP requests by using the command line interface

To block or bypass invalid requests, enter the following command:

```
set appfw settings -malformedreqaction <action>
```

Example:

```
set appfw settings -malformedReqAction block
```

To display malformed request action settings

To display malformed request action settings, enter the following command:

```
show appfw settings
```

Output:

```
1 DefaultProfile: APPFW_BYPASS UndefAction: APPFW_BLOCK SessionTimeout:
  900      LearnRateLimit: 400      SessionLifetime: 0
  SessionCookieName: citrix_ns_id ImportSizeLimit: 134217728
  SignatureAutoUpdate: OFF SignatureUrl:"https://s3.amazonaws.com/
  NSAppFwSignatures/SignaturesMapping.xml" CookiePostEncryptPrefix:
  ENC GeoLocationLogging: OFF CEFLogging: OFF      EntityDecoding:
  OFF      UseConfigurableSecretKey: OFF SessionLimit: 100000
  MalformedReqAction: block log stats
2 Done
3 <!--NeedCopy-->
```

To block or bypass invalid non-RFC complaint HTTP requests by using the NetScaler GUI

1. Navigate to **Security > NetScaler Web App Firewall**.
2. In the **NetScaler Web App Firewall** page, click **Change Engine Settings** under **Settings**.

3. In the **Configure NetScaler Web App Firewall Settings** page, select the **Log Malformed Request** option as Block, Log, or Stats.
4. Click **OK** and **Close**.

Note:

If you unselect the block action or do not select any malformed request action, the appliance bypasses the request without intimating the user.

Block or bypass non-RFC compliant requests at profile level

Other non-RFC compliant requests can be configured to block or bypass at profile level. You must configure the RFC profile either in Block or Bypass mode. By doing this configuration, any invalid traffic that matches the Web App Firewall profile is either bypassed or blocked accordingly. The RFC profile validates the following security checks:

- Invalid GWT-RPC requests
- Invalid content type headers
- Invalid Multipart requests
- Invalid JSON requests
- Duplicate cookie name value pair checks

Note:

When you set the RFC profile in “Bypass” mode, you must make sure you disable the transformation option in the **HTML Cross-Site Scripting Settings** and in the **HTML SQL Injection Settings** sections. If you enable and set the RFC profile in Bypass mode, the appliance displays a warning message, “Transform cross-site scripts” and “Transform SQL special characters” are both currently ON. Recommend turning it off when used with APPFW_RFC_BYPASS.

Important:

Also, the appliance displays a warning note, “Appfw Security checks enabled might not be applicable to requests which violates RFC checks when this profile is set. Enabling any transformation setting is not recommended as requests might be partially transformed that contains RFC violations.”

To configure an RFC profile in the Web App Firewall profile by using the command line interface

At the command prompt, type the following commands:

```
set appfw profile <profile_name> -rfcprofile <rfcprofile_name>
```

Example

```
set appfw profile P1 -rfcprofile APPFW_RFC_BLOCK
```

Note:

By default, the RFC profile is bound to the Web App Firewall profile in Block mode.

To configure an RFC profile in the Web App Firewall profile by using the GUI

1. Navigate to **Security > NetScaler Web App Firewall > Profiles**.
2. In the **Profiles** page, select a profile and click **Edit**.
3. In the **Web App Firewall Profile** page, click **Profile settings** from the **Advanced Settings** section.
4. In the **HTML Settings** section, set the RFC profile in `APPFW_RFC_BYPASS` mode.
The system displays a warning message, “Appfw Security checks enabled might not be applicable to requests which violates RFC checks when this profile is set. Enabling any transformation setting is not recommended as requests might be partially transformed that contains RFC violations”.

Configuring Web App Firewall profiles

February 9, 2024

To configure a user-defined Web App Firewall profile, first configure the security checks, which are called *deep protections* or *advanced protections* in the Web App Firewall wizard. Certain checks require configuration if you are to use them at all. Others have default configurations that are safe but limited in scope; your websites might need or benefit from a different configuration that takes advantage of more features of certain security checks.

After you have configured the security checks, you can also configure some other settings that control the behavior, not of a single security check, but the Web App Firewall feature. The default configuration is sufficient to protect most websites, but you must review them to make sure that they are right for your protected websites.

Note:

The profile name length and all import object name length can be set up to 127 characters.

For more information about the Web App Firewall security checks, see [Advanced Protections](#).

To configure a Web App Firewall profile by using the command line

At the command prompt, type the following commands:

- `set appfw profile <name> <arg1> [<arg2> ...]`

where:

- `<arg1>` = a parameter and any associated options.
- `<arg2>` = a second parameter and any associated options.
- `...` = additional parameters and options.

For descriptions of the parameters to use when configuring specific security checks, see [Advanced Protections](#).

- `save ns config`

Example

The following example shows how to enable blocking for the HTML SQL Injection and HTML Cross-Site Scripting checks in a profile named `pr-basic`. This command enables blocking for those actions while making no other changes to the profile.

```
1 set appfw profile pr-basic -crossSiteScriptingAction block -
   SQLInjectionAction block
2 <!--NeedCopy-->
```

Bind relaxation rule to a Web App Firewall profile

When a Web App Firewall detects a violation, the user has the ability to bypass the action applied through relaxation rules. Relaxation rule is an exception applied to the detected security violation. For example, the Start URL relaxation rules protect against forceful browsing. Known web server vulnerabilities that are exploited by hackers can be detected and blocked by enabling a set of default Deny URL rules. Commonly launched attacks, such as Buffer Overflow, SQL, or Cross-site scripting can also be easily detected.

To bind security exemption or relaxation rules by using the CLI

At the command prompt, type:

```

1 bind appfw profile <name> ((-startURL <expression> [-resourceId <
  string>]) | -denyURL <expression> | (-fieldConsistency <string> <
  formActionURL> [-isRegex ( REGEX | NOTREGEX )]) | (-
  cookieConsistency <string> [-isRegex ( REGEX | NOTREGEX )]) | (-
  SQLInjection <string> <formActionURL> [-isRegex ( REGEX | NOTREGEX )
  ] [-location <location>] [-valueType <valueType> <valueExpression
  >....
2 <!--NeedCopy-->

```

To bind security exemption or relaxation rules by using the GUI

1. Navigate to **Security > NetScaler Web App Firewall > Profiles**.
2. In the details pane, select a profile and click **Edit**.
3. In the **NetScaler Web App Firewall Profile** page, click **Relaxation Rules** from the **Advanced Setting** section.
4. In the **Relaxation Rules** section, click **StartURL** and click **Edit**.
5. In the **Start URL Relaxation Rules** page, click **Add**.
6. In the **Start URL Relaxation Rule** page, set the following parameters:
 - a) Enabled. Select the check box to enable the relaxation rule
 - b) Start URL. Enter the regular expression value
 - c) Comments. Provide a short description about the relaxation rule.
7. Click **Create** and **Close**.

To configure a Web App Firewall profile by using the GUI

1. Navigate to **Security > NetScaler Web App Firewall > Profiles**.
2. In the details pane, select the profile that you want to configure, and then click **Edit**.
3. In the **Configure Web App Firewall Profile** dialog box, on the **Security Checks** tab, configure the security checks.
 - To enable or disable an action for a check, in the list, select or clear the check box for the action.
 - To configure the parameters for the security checks in the list, select the check box and click **Active Settings**.
 - To review log entries for the selected security check, select the check box and click **Logs**. You can use this information to determine the security checks that match attacks, so that

you can block the traffic for the security checks. You can also use the information to determine the checks that match legitimate traffic, so that you can configure an appropriate exemption to allow those legitimate connections. For more information about the logs, see [Logs, Statistics, and Reports](#).

- To completely disable a check, in the list, clear all of the check boxes to the right of that check.

4. On the **Settings** tab, configure the profile settings.

- To associate the profile with the set of signatures that you previously created and configured, under Common Settings, choose that set of signatures in the **Signatures** drop-down list.

Note:

You must use the scroll bar on the right of the dialog box to scroll down to display the Common Settings section.

- To configure an HTML or XML Error Object, select the object from the appropriate drop-down list.

Note:

You must first upload the error object that you want to use in the Imports pane. For more information about importing error objects, see [Imports](#).

- To configure the default XML Content Type, type the content type string directly into the Default Request and Default Response text boxes, or click Manage Allowed Content Types to manage the list of allowed content types. [»More...](#)

5. If you want to use the learning feature, click Learning, and configure the learning settings for the profile, as described in [Configuring and Using the Learning Feature](#).

6. Click **OK** to save your changes and return to the **Profiles** pane.

Confidential fields in WAF profile

Note

This feature is available in release 13.1 build 27.x and later.

You can now add confidential fields in a WAF profile. These fields are masked and not captured in the ADC logs when a violation occurs. Earlier you could add these fields using settings only. For more information about adding confidential fields using settings, see [Confidential fields](#).

1. Navigate to **Security > NetScaler Web App Firewall > Profiles**.

2. Select a profile and click **Edit**.
3. In **Advanced Settings**, click **Confidential Fields**.
4. Click **Add**.
5. Enter values for the following parameters:
 - Form Field Name*
 - Action URL*
 - Comments

A * indicates a mandatory field
6. Click **Create**.
7. Click **Done**.

Web Application Firewall profile settings

February 7, 2024

Following are the profile settings that you must configure on the appliance.

At the command prompt, type:

```

1 add appfw profile <name> [-invalidPercentHandling <
  invalidPercentHandling>] [-checkRequestHeaders ( ON | OFF )] [-
  URLDecodeRequestCookies ( ON | OFF )] [-optimizePartialReqs ( ON |
  OFF )] [-errorURL <expression>] [-logEveryPolicyHit ( ON | OFF )]
  [-stripHtmlComments <stripHtmlComments>] [-stripXmlComments ( none |
  all )] [-postBodyLimitSignature <positive_integer>][-
  fileUploadMaxNum <positive_integer>][-canonicalizeHTMLResponse ( ON
  | OFF )][-percentDecodeRecursively ( ON | OFF )] [-
  multipleHeaderAction <multipleHeaderAction> ...][-
  inspectContentTypes <inspectContentTypes> ...][-
  semicolonFieldSeparator ( ON | OFF )] [-fieldScan ( ON | OFF )] [-
  fieldScanLimit <positive_integer>] [-JSONFieldScan ( ON | OFF )] [-
  JSONFieldScanLimit <positive_integer>] [-messageScan ( ON | OFF )]
  [-messageScanLimit <positive_integer>] [-JSONMessageScan ( ON | OFF
  )] [-JSONMessageScanLimit
2 <positive_integer>] [-messageScanLimitContentTypes <
  messageScanLimitContentTypes> ]
3 <!--NeedCopy-->

```

invalidPercentHandling - Configure the method for handling percent-encoded names and values.

asp_mode - Strips and Parses Invalid Percent for Parsing.

Example:- `curl -v "http://<vip>/forms/login.html?field=sel%zzect ->`
 Invalid percent encoded char(%zz) is stripped of and the rest of the content is inspected and action taken for the SQLInjection check.

`secure_mode` - We detect the invalid percent coded value and ignore it.

Example:- `curl -v "http://<vip>/forms/login.html?field=sel%zzect ->`
Invalid percent encoded char(%zz) is detected, counters are incremented and content is passed as is to the server.

`apache_mode` - This mode works similar to secure mode.

Note:

Starting from release 13.1 build 45.x, the `apache_mode` function is deprecated.

Possible values: `apache_mode`, `asp_mode`, `secure_mode`

Default value: `secure_mode`

Example:

```
add appfw profile profile1 [-invalidPercentHandling secure_mode] [-  
checkRequestHeaders ON] [-URLDecodeRequestCookies OFF] [-optimizePartialReqs  
OFF]
```

optimizePartialReqs - When OFF/ON (without safe object), a NetScaler appliance sends the partial request to the back-end server. This partial response sent back to the client. `optimizePartialReqs` makes sense when the Safe object is configured. The appliance sends requests for full response from the server when OFF, requests only partial response when ON.

ON - Partial requests by the client result in partial requests to the back-end server.

OFF - Partial requests by the client are changed to full requests to the back-end server.

Possible values: ON, OFF

Default value: ON

URLDecodeRequestCookies. URL Decode request cookies before subjecting them to SQL and cross-site scripting checks.

Possible values: ON, OFF

Default value: OFF

Signature Post Body Limit (Bytes). Limits the request payload (in bytes) inspected for signatures with the location specified as 'HTTP_POST_BODY'.

Default value: 8096

Minimum value: 0

Maximum Value: 4294967295

Post Body Limit (Bytes). Limits the request payload (in bytes) inspected by Web Application Firewall.

Default value: 20000000

Minimum value: 0

Maximum Value: 10 GB

For more information about the Security setting and its GUI procedure, see [Configure Web App Firewall Profile](#) topic.

postBodyLimitAction. PostBodyLimit honors error settings when you specify the maximum size of HTTP body to be allowed. To honor error settings you must configure one or more Post Body Limit actions. The configuration is also applicable for requests where the transfer encoding header is chunked.

```
set appfw profile <profile_name> -PostBodyLimitAction block log stats
```

Where,

Block - This action blocks connection that violates the security check and it is based on the maximum size of the configured HTTP body (post body limit). You must always enable the option.

Log - Log violations of this security check.

Stats - Generate statistics for this security check.

Note:

The log format for post body limit action is now changed to follow the standard audit logging format, for example:

```
ns.log.4.gz:Jun 25 1.1.1.1. <local0.info> 10.101.10.100 06/25/2020:10:10:28  
GMT 0-PPE-0 : default APPFW APPFW_POSTBODYLIMIT 1506 0 : <Netscaler  
IP> 4234-PPE0 - testprof ><URL> Request post body length(<Post  
Body Length>)exceeds post body limit.
```

inspectQueryContentTypes Inspect request query and web forms for injected SQL and cross-site scripts for the following content types.

```
set appfw profile p1 -inspectQueryContentTypes HTML XML JSON OTHER
```

Possible values: HTML, XML, JSON, OTHER

By default, this parameter is set as “InspectQueryContentTypes: HTML JSON OTHER”for both basic and advanced appfw profiles.

Example for inspect query content type as XML:

```
1 > set appfw profile p1 -type XML  
2 Warning: HTML, JSON checks except “ InspectQueryContentTypes ” & “  
   Infer Content-Type XML Payload Action ” will not be applicable when  
   profile type is not HTML or JSON respectively.  
3 <!--NeedCopy-->
```

Example for inspect query content type as HTML:

```
1 > set appfw profile p1 -type HTML
2 Warning: XML, JSON checks except "InspectQueryContentTypes" & "Infer
  Content-Type XML Payload Action" will not be applicable when
  profile type is not XML or JSON respectively
3 Done
4 <!--NeedCopy-->
```

Example for inspect query content type as JSON:

```
1 > set appfw profile p1 -type JSON
2 Warning: HTML, XML checks except "InspectQueryContentTypes" & "Infer
  Content-Type XML Payload Action" will not be applicable when profile
  type is not HTML or XML respectively
3 Done
4 <!--NeedCopy-->
```

errorURL expression. The URL that the NetScaler Web App Firewall uses as an error URL. Maximum Length: 2047.

Note:

For blocking violations in a requested URL, if the error URL is similar to the signature URL the appliance resets the connection.

logEveryPolicyHit - Log every profile match, regardless of security checks results.

Possible values: ON, OFF.

Default value: OFF.

stripXmlComments - Strip XML comments before forwarding a webpage sent by a protected website in response to a user request.

Possible values: none, all, exclude_script_tag.

Default value: none

postBodyLimitSignature - Maximum allowed HTTP post body size for signature inspection for location HTTP_POST_BODY in the signatures, in bytes.

The changes in value can impact CPU and latency profile.

Default value: 2048.

Minimum value: 0

Maximum Value: 4294967295

fileUploadMaxNum - Maximum allowed number of file uploads per form-submission request. The maximum setting (65535) allows an unlimited number of uploads.

Default value: 65535

Minimum value: 0

Maximum value: 65535

fieldScan - Inspect the configured limit for each field value in the HTML requests.

fieldScanLimit - Enter the number of bytes that the Web App Firewall inspects for each field value in HTML requests.

- 1 Default Value: 2 KB
- 2 Maximum Limit - 8 KB

JSONFieldScan - Inspect the configured limit for each field value in JSON requests.

JSONFieldScanLimit - Enter the number of bytes that the Web App Firewall inspects for each field value in JSON requests.

- 1 Default Value: 2 KB
- 2 Maximum Limit - 8 KB

messageScan - Inspect the configured limit for each payload in the HTML requests.

messageScanLimit - Enter the number of bytes that the Web App Firewall inspects for each payload in the HTML requests.

- 1 Default Value: 1 MB
- 2 Maximum Limit - 8 MB

JSONMessageScan - Inspect the configured limit for each payload in the JSON requests.

JSONMessageScanLimit - Enter the number of bytes that the Web App Firewall inspects for each payload in the JSON requests.

- 1 Default Value: 1 MB
- 2 Maximum Limit - 8 MB

messageScanLimitContentTypes –Select any one of the following:

- 1 - Form-Data - Select to inspect the payload **for** the HTML requests.
- 2
- 3 - Json - Select to inspect the payload **for** the JSON requests.

canonicalizeHTMLResponse - Perform HTML entity encoding for any special characters in responses sent by your protected websites.

Possible values: ON, OFF

Default value: ON

percentDecodeRecursively - Configure whether the application firewall should use percentage recursive decoding.

Possible values: ON, OFF

Default value: ON

multipleHeaderAction - One or more multiple header actions. Available settings function as follows:

- **Block.** Block connections that have multiple headers.
- **Log.** Log connections that have multiple headers.
- **KeepLast.** Keep only the last header when multiple headers are present.

inspectContentTypes –One or more InspectContentType lists.

- application/x-www-form-urlencoded
- multipart/form-data
- text/x-gwt-rpc

Possible values: none, application/x-www-form-urlencoded, multipart/form-data, text/x-gwt-rpc

semicolonFieldSeparator - Allow ';' as a form field separator in URL queries and POST form bodies.

Possible values: ON, OFF

Default value: OFF

Changing an Web App Firewall profile type

May 2, 2023

If you chose the wrong profile type for an Web App Firewall profile, or the type of content on the protected website has changed, you can change the profile type.

Note When you change the profile type, you lose all configuration settings and learned relaxations or rules for the features that the new profile type does not support. For example, if you change the profile type from Web 2.0 to XML, you lose any configuration options for Start URL, Form Field Consistency Check, and the other HTML-specific security checks. The configuration for any options that is supported by both the old and the new profile types remains unchanged.

To change an Web App Firewall profile type by using the command line interface

At the command prompt, type the following commands:

- `set appfw profile <name> -type (**HTML** | **XML** | **HTML XML**)`
- `save ns config`

Example

The following example changes the type of a profile named pr-basic, from HTML to HTML XML, which is equivalent to the Web 2.0 type in the GUI.

```
1 set appfw profile pr-basic -type HTML XML
2 save ns config
3 <!--NeedCopy-->
```

To change an Web App Firewall profile type by using the GUI

1. Navigate to **Security > NetScaler Web App Firewall > Policies**.
2. In the details pane, click **Action**, and then **Change Profile Type**.
3. In the **Change Web App Firewall Profile Type** dialog box, **Profile Type** drop-down list, select a new profile type.
4. Click **OK** to save your changes and return to the **Profiles** pane.

Exporting and importing an Web App Firewall profile

December 4, 2020

You can replicate the entire configuration of an Web App Firewall profile (including all bound objects, such as HTML error object, XML error object, WSDL or XML schema, signatures, and so on) across multiple appliances. You can select a target profile and export the configuration to save it in your computer's local file system, or you can transfer the archived configuration to store it on a server. Similarly, you can browse your computer's local file system or import the archive from the server to select a previously exported profile and import it into your NetScaler appliance.

The option to export the entire profile configuration and then import it into another appliance can be useful in various use cases. For example, you might want to configure an Web App Firewall profile in a test bed set-up to test and validate that it is working as expected. Once you are satisfied, you can export the profile and import the profile configuration to your production NetScaler appliances. This functionality is also useful for backing up your configuration. You can export the profile before making changes, so that you can easily roll back the configuration to a known state if necessary.

Note

Web App Firewall profiles that are exported and archived from one build cannot be restored to a system running a different build, because changes introduced in the newer releases can lead to compatibility issues. If you attempt to restore an archived profile to a different build than the one from which it was exported, an error message is logged in ns.log.

The export and import profile functionality is available in both the GUI (GUI) and the command line interface (CLI). The GUI is recommended, because it offers easy to use **Action** options. With a click of a button you can **Export** or **Import** the entire configuration of a profile.

Exporting Web App Firewall profiles with the CLI

If you use CLI to **export** a profile, you must **archive** the configuration and then **export** it. To **import** a profile, you must **import** the archive into the NetScaler appliance and then run the **restore** command to extract the configuration. The following set of CLI commands can be used for exporting, importing and managing the profile configurations.

CLI commands to export archives:

- `archive appfw profile <name> <archivename> [-comment <string>]`
- `export appfw archive <name> <target>`

CLI commands to import archives:

- `import appfw archive <src> <name> [-comment <string>]`
- `restore appfw profile <archivename>`

CLI commands to manage archives:

- `show appfw archive`
- `rm appfw archive <name>`

Exporting a profile from one appliance and importing it to another requires five steps in CLI. The first 3 steps are performed on the source appliance on which profile configuration is originally created, and the next 2 steps are performed on the target appliance on which the profile configuration is to be replicated.

Export profile from the source NetScaler appliance:

Step 1: Create an archive of the configured profile.

Step 2: Export the archive to the NetScaler file system.

Step 3: Use a file transfer utility such as scp to transfer the exported archive file from NetScaler appliance A to the target NetScaler appliance.

Import profile to the target NetScaler appliance:

Step 4: Run the import command to import the archived file. You can import the archive from your NetScaler's local file system, or you can use HTTP or HTTPS protocol to import the archive from a server by using the URL.

Step 5: Run the restore command to restore the profile configuration from the imported archive

To export an Web App Firewall profile by using the command line interface:

First, **archive** the profile's configuration, and then **export** the archive to a target location. At the command prompt, type the following commands:

```
archive appfw profile <profileName> <archiveName>
```

where:

- `<profileName>` is the name of the profile to archive.
- `<archiveName>` is the name of the archive file to create.

Execution of the above command creates 2 instances of the archive file. One in `/var/tmp` folder and another in the `/var/archive/appfw` folder.

```
export appfw archive <archiveName> <target>
```

where:

- `<archiveName>` is the name of the archive to export. (The same name as in the previous command.
- `<target>` is a file path starting with `local:` as the prefix, followed by `<archiveName>`.

Execution of the export command saves the exported archive file on the file system of your NetScaler appliance in the `/var/tmp` folder.

Examples:

```
> archive appfw profile test_pr archived_test_pr
```

```
> export appfw archive archived_test_pr local:dutA_test_pr
```

After the above two commands are run, the `/var/tmp` folder contains the `archived_test_pr` file and the exported copy, `dutA_test_pr`, which are identical in size. From the CLI, you can drop into the shell to navigate to the folder to verify that these files are there.

After exporting the archive file, you can use **scp** or some other such file transfer utility to transfer a copy of the archive file from the NetScaler appliance on which they were created to your target NetScaler appliance.

Importing Web App Firewall Profiles with the CLI

After you have successfully scp'd the archived file from the source appliance to the target appliance, you are ready to **import** the profile's archive, and then run the **restore** command to replicate the profile's configuration on the target appliance.

Log onto the target appliance. Drop into the shell and `cd` to the `/var/tmp` folder to verify that the size of the scp'd file on this appliance matches the size of the original archived file on the source appliance. Exit the shell to return to the command line.

To import a profile by using the CLI:

At the command prompt, type the following commands:

```
import appfw archive <src> <name> [-comment <string>]
```

where

- `<src>` is the location of the archive file after it has been transferred from the source appliance on which it was created. You can use a local file system and file name. If you have placed the archive on a server, you can use a URL to import the archived file. If the path or file name contains spaces, enclose the URL in straight double quotation marks.
- `<name>` is the name of the archive file to be imported.
- `<string>` is an optional description of the purpose of the Archive.

```
restore appfw profile <archiveName>
```

Examples:

A. Import from local file followed by restore:

```
> import appfw archive local:dutA_test_pr dut2_test_pr
> restore appfw profile dut2_test_pr
```

B. Import from URL followed by restore:

```
import appfw archive http://10.217.30.16/FFC/Profile_ImportExport
/dutA_test_pr.tgz my_archive
restore appfw profile my_archive
```

This example restores the test_pr profile along with all bound objects (such as signatures, html error page, relaxation rules and so on) on the target NetScaler appliance.

You can use the following CLI commands to access man pages for additional details.

- man archive appfw profile
- man export appfw archive
- man import appfw archive
- man restore appfw profile
- man show appfw archive
- man rm appfw archive

Exporting and Importing Web App Firewall Profiles with the GUI

The GUI is easier to use than the CLI. The utility performs both archive and export operations when you click **Export**. Similarly it runs both import and restore when you click **Import**. The GUI can access the local file system of the computer from which you access the utility. You can export a copy of the archive and save it on your local computer. You can then import this copy directly in the target appliance without having to manually transfer the archive file from one appliance to the other(s).

To export an Web App Firewall profile by using the GUI:

1. Navigate to **Configuration > Security > Web App Firewall > Profiles**.

2. In the details pane, select a profile to export. Click **Actions** and select **Export** to download and save a copy in your computer's local file system.

To import an Web App Firewall profile by using the GUI:

1. Navigate to **Configuration > Security > Web App Firewall > Profiles**.
2. In the details pane, click **Actions** and select **Import**. In the Import Web App Firewall Profile pane, the Import From* selection box gives you 2 options:

URL: You can choose to import an archive by specifying a **URL**. When this option is selected, you must provide an absolute path for the archived file in the **URL** input box.

File: You can choose to import an archive from the local **File**. When this option is selected, a **Local File** selection field is displayed. You can browse your computer's local files to select the target archive file.

Click **Create** to import the specified archive. Successful completion of the import operation creates the profile configuration on the target appliance.

Highlights

- You can replicate the entire configuration (including all import objects as well as configured relaxation rules for the profile) on multiple appliances, without needing to repeat configuration steps, by using export and import profile functionality.
- The imported objects, such as signatures, WSDL, Schema, error page and so on, are included in the archived tar file and replicated on the target appliance.
- Customized field types are included in the archived tar file and replicated on the target appliance.
- The policy bindings of the archived profile are not replicated when the configuration is restored. You must configure the policy and bind it to the profile after importing the profile to the appliance.
- The name of the archive file can be up to 31 character long. As with profile names, an archive name must begin with an alphanumeric character or underscore and contain only alphanumeric and underscore (`_`), number (`#`), period (`.`), space (), colon (`:`), at (`@`), equals (`=`) or hyphen (`-`) characters.
- Comments associated with the archive must be descriptive enough to convey the purpose of the archived configuration. The maximum allowed length for a comment is 255 characters.
- The `clear config -force basic` command does not remove the archived profiles.
- The import and export profile functionality is supported in high availability (HA) deployments.

Debugging Tips

- Monitor the `/var/log/ns.log` during command executions to see if there are any ERROR messages.
- Additional logs (`_restore.log`, `remove.log`, `import.log`) are generated in the `/var/tmp/` folder. They can help debug issues during the corresponding operations. When these logs reach one MB in size, the log messages are purged to shrink the log file to one fourth of the original size.
- If the import command fails when you are using the URL option instead of the local file system, verify that DNS name server and route settings are accurately configured.
- If you are using the HTTPS protocol to import the archive, the command might fail if the HTTPS server requires client certificate authentication.

Ease of troubleshooting with Web Application Firewall logs

May 2, 2023

When there is a security attack, it is important to capture detailed WAF logging on the appliance. For this, you can configure the “VerboseLogLevel” parameter on an Application Firewall profile.

Consider a web traffic having a security attack. When the appliance receives the traffic, violation details such as HTTP header details, log pattern, and pattern payload information are logged and sent to the ADM server. The ADM server monitors the detailed logs and displays it on the Security Insight page for monitoring and tracking purpose.

Configuring verbose log level by using the command interface

To capture detailed WAF logs, configure the following command.

At the command interface, type:

```
set appfw profile <profile_name> -VerboseLogLevel (pattern|patternPayload|patternPayloadHeader)
```

Example

```
set appfw profile profile1 -VerboseLogLevel patternPayloadHeader
```

The available log levels are:

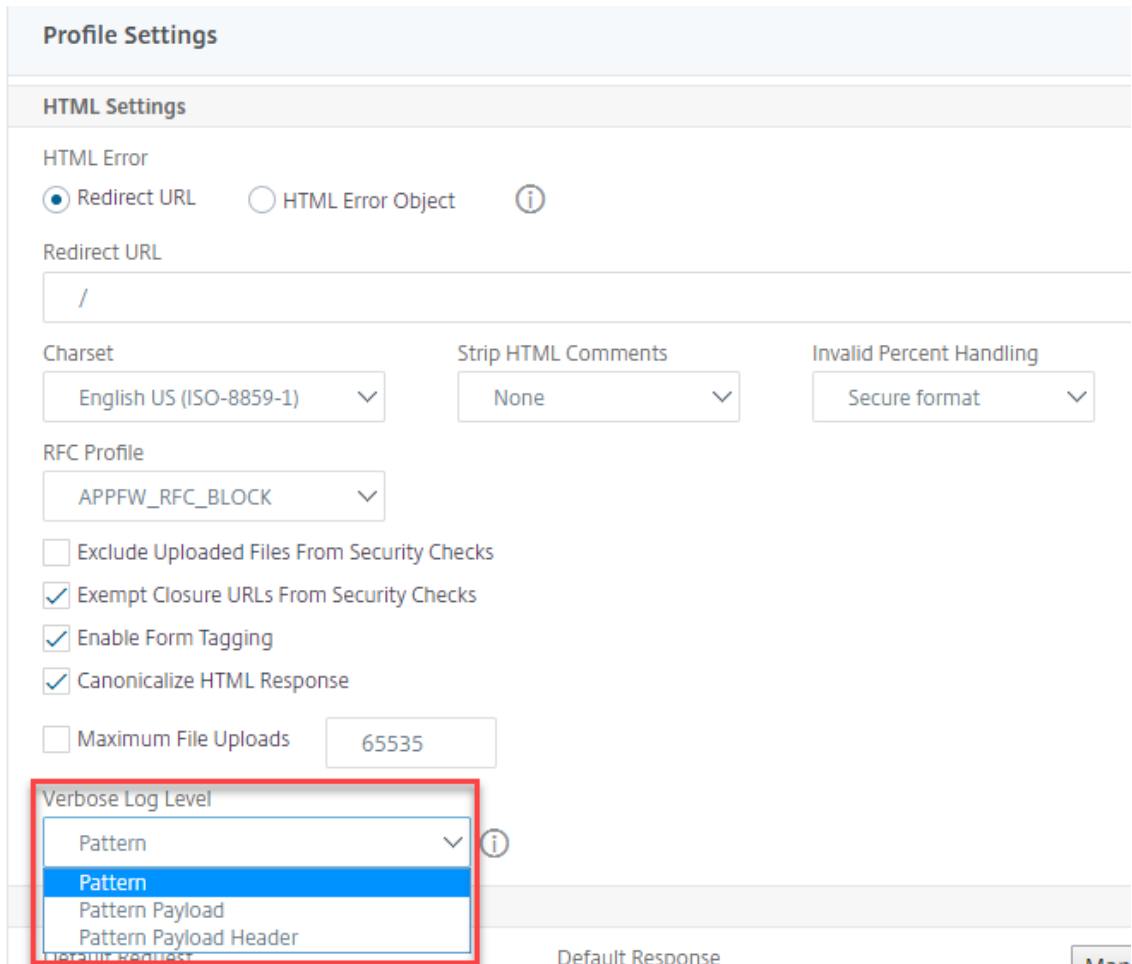

1. Pattern. Logs only violation pattern.
2. Pattern payload. Logs violation pattern and 150 bytes of extra field element payload.

3. Pattern payload header. Logs violation patter, 150 bytes of extra field element payload and HTTP header information.

Configuring verbose log level by using the NetScaler GUI

Complete the following procedure to configure the verbose log level in the WAF profile.

1. On the navigation pane, navigate to **Security > Profiles**.
2. In the **Profiles** page, click **Add**.
3. In the **NetScaler Web App Firewall Profile** page, click **Profile Settings** under **Advanced Settings**.
4. In the **Profile Settings** section, select the detailed WAF log level in the Verbose Log Level field.
5. Click **OK** and **Done**.

Verbose logging for JSON security checks (SQL, CMD, and cross-site scripting)

When an incoming request type is of JSON, you can configure the verbose log level parameter to capture detailed violation logs such as pattern, pattern payload, and HTTP header information. The log details are then sent to the NetScaler Console server for monitoring and troubleshooting JSON violations. The verbose log message is not stored in the ns.log file.

Verbose logging for JSON content type security protection can be configured for the following violation types:

- SQL Injection
- Cross-site scripting
- Command Injection

Configure verbose logging for JSON security protection by using the CLI

To capture detailed HTTP header information as logs, you can configure the verbose logging parameter in the Web App Firewall profile. At the command prompt, type:

```
1 set appfw profile <profile_name> -VerboseLogLevel ( pattern |
   patternPayload | patternPayloadHeader )
2 <!--NeedCopy-->
```

Example:

```
set appfw profile profile1 -VerboseLogLevel patternPayloadHeader
```

The available log levels are:

Pattern. Logs only violation pattern.

Pattern payload. Logs violation pattern and 150 bytes of extra JSON payload.

Pattern payload header. Logs violation pattern, 150 bytes of extra JSON payload and HTTP header information.

Configuring verbose log level by using the NetScaler GUI

Follow the procedure below to configure the verbose log level for JSON security protection.

1. On the navigation pane, navigate to **Security > Profiles**.
2. In the **Profiles** page, click **Add**.
3. In the **NetScaler Web App Firewall Profile** page, click **Security Checks** under **Advanced Settings**.
4. In the **Security Checks** section, select **JSON** and click **Action Settings**.
5. In the **JSON Security Settings** page, set the **Verbose log level** parameter.

6. Click **OK** and **Done**.

Based on the details captured by NetScaler WAF JSON verbose logging, the following violation details can be inspected on the NetScaler Console server.

| Violation Information | | |
|--------------------------|------------------------------|--|
| Violation information | | |
| Attack Time | Oct 07 04:56 PM | |
| Signature Category | -NA- | |
| Violation Name | x | |
| Violation Value | FROM | |
| Security Check Violation | SQL Injection Grammar | |
| Violation Category | Injection | |
| Threat Index | 6 | |
| Severity | Critical | |
| Action Taken | Not Blocked | |
| URL | http://[REDACTED]/index.html | |
| Found in | Form Field | |
| Client IP | [REDACTED] | |
| Location | -NA- | |
| Total Attacks | 1 | |

File upload protection

February 13, 2024

Many attackers try to upload malicious code, virus, or malware as file attachments during multi-form submission. It is important to protect our network and overcome such threats. To prevent such malicious file uploads, a NetScaler admin configures a set of allowable file upload formats in the WAF profile. By doing this, you restrict file uploads to specific formats and protect the appliance against malicious file uploads. The protection works only when you disable the `ExcludeFileUploadFormChecks` option in the WAF profile.

How file upload works

When you configure allowable file upload formats, the component interaction is as follows:

- Client request has a form submission with a file upload type, for example PDF.
- As part of the security check, WAF inspects the request payload and validates the file type (based on magic signature numbers).
- If the file type is not in a supported format, the corresponding action based on file type binding is applied.
- To validate the file type the appliance inspects the payload and checks for the known magic numbers at known offsets. Each file type has a sequence of magic numbers that validates the file type.

Configure file type upload by using NetScaler CLI

To configure allowable file formats, the appliance uses a WAF profile that is bound to file upload parameters.

1. Configure Web Application Firewall profile

At the command prompt, type:

```
set appfw profile <profile_name> [-fileUploadTypesAction <fileUploadTypesAction>] <fileUploadTypesAction> = ( none | block | log | stats )
```

Example

```
set appfw profile profile1 -fileUploadTypesAction block
```

1. Bind Web Application Firewall profile with file upload parameters. The command binds the specified exemption (relaxation) or rule to the specified application firewall profile.

At the command prompt, type:

```
bind appfw profile <profile_name> - fileUploadType <form_field >  
<form_action_url> [-isNameRegex ( REGEX | NOTREGEX )] -fileType <  
fileType> ( pdf | msdoc | text | image | any)
```

Note:

The form field name is a regular expression type. The default value is NOTREGEX.

Example

```
> bind appfw profile test -fileuploadType thefile "http://10.10.10.10/  
fileupload_sample/upload.php"-isNameRegex NOTREGEX -filetype image  
→
```

Configure file upload security protection by using NetScaler GUI

1. In the navigation pane, navigate to **Security > Profiles**.
2. In the Profiles page, click **Add**.
3. In the **NetScaler Web App Firewall Profile** page, click **Security Checks** under **Advanced Settings**.
4. In the **Security Checks** section, select **File Upload Types** and click **Action Settings**.
5. In the **File Upload Types Settings** page, set the file upload action.
6. Click **OK**.
7. In the **NetScaler Web App Firewall Profile** page, click **OK** and **Done**.

Configure file upload relaxation rule by using NetScaler GUI

You can relax a file upload security protection to avoid false positives. For example, the appliance might block file uploads but you can add a relaxation rule to allow file uploads from specific websites. By doing this, the appliance bypasses security inspection for the specified form field and allow users to upload files from the website mentioned in the action URL.

Note:

The file upload validation fails if the **File Upload Types Relaxation Rule** is not enabled.

Perform the following steps to create a relaxation rule.

1. In the navigation pane, navigate to **Security > NetScaler Web App Firewall > Profiles**.
2. In the Profiles page, click **Add**.
3. In the **NetScaler Web App Firewall Profile** page, click **Relaxation Rules** under **Advanced Settings**.
4. In the **Relaxation Rules** section, select **File Upload Types** and click **Edit**.

| Relaxation Rules × | | |
|--|---|--|
| <input type="button" value="Edit"/> | <input type="button" value="Visualizer"/> | <input type="button" value="Export All Relaxation Rules"/> |
| <input type="button" value="Import All Relaxation Rules"/> | | |
| <input type="checkbox"/> | NAME | CHECK TYPE |
| <input type="checkbox"/> | Start URL | Common |
| <input type="checkbox"/> | Deny URL | Common |
| <input type="checkbox"/> | Cookie Consistency | Common |
| <input type="checkbox"/> | Credit Card | Common |
| <input type="checkbox"/> | Content-type | Common |
| <input type="checkbox"/> | Safe Object | Common |
| <input checked="" type="checkbox"/> | File Upload Types | HTML |

5. In the **File Upload Types Relaxation Rules** page, click **Add**.
6. In the **File Upload Types Relaxation Rule** page, set the following parameters:
 - a) Enabled - Select to enable the relaxation rule.
 - b) Is Form Field Name Regex - Select to update a regex pattern for the form field name.
 - c) Form Field Name - Enter the file name that does not require a security check.
 - d) Action URL - The form submission URL that must be exempted from security checks.
 - e) File Type - Supported file format that can be uploaded.
 - f) Comments - A brief description about the file upload.
7. Click **Create**.

The screenshot shows the configuration interface for a File Upload Types Relaxation Rule. The title is "File Upload Types Relaxation Rule". The configuration includes the following elements:

- Enabled:** A checked checkbox.
- Is Form Field Name Regex:** A checked checkbox.
- Form Field Name:** A text input field containing the text "Resume".
- Action URL*:** A text input field containing the text "www.example.com".
- RegEx Editor:** A section with no visible content.
- File Type:** A group of radio buttons with the following options:
 - PDF (with an information icon)
 - Microsoft Word Document
 - Text
 - Image
 - Any
- Comments:** A text area containing the text "File upload valication is relaxed to allow PDF uploads." (Note the typo "valication").

8. In the **NetScaler Web App Firewall Profile** page, click **OK** and **Done**.

Configuring and using the Learning feature

March 6, 2024

The learning feature is a repetitive pattern filter that observes activity on a website or application protected by the Web App Firewall, to determine what constitutes normal activity on that website or application. It then generates a list of up to 2,000 suggested rules or exceptions (relaxations) for each security checks that include support for the learning feature. Users normally find it easier to configure relaxations by using the learning feature than by entering the necessary relaxations manually.

The security checks that support the learning feature are:

- Start URL check
- Cookie Consistency check
- Form Field Consistency check
- Field Formats check
- CSRF Form Tagging check
- HTML SQL Injection check
- HTML Cross-Site Scripting check
- XML Denial-of-Service check
- XML Attachment check
- Web Services Interoperability check

You perform two different types of activities when using the learning feature. First, you enable and configure the feature to use it. You can learn all traffic to your protected web applications, or you can configure a list of IP addresses (called the *Add Trusted Learning Clients* list) from which the learning feature can generate recommendations. Second, after the feature has been enabled and has processed a certain amount of traffic to your protected websites, you review the list of suggested rules and relaxations (learned rules) and mark each with one of the following designations:

- **Edit & Deploy.** The rule is pulled into the Edit dialog box so that you can modify it, and the modified form is deployed.
- **Deploy.** The unmodified learned rule is placed on the list of rules or relaxations for this security check.
- **Skip.** The learned rule is placed on a list of rules or relaxations that are not deployed. The learned rule is removed when skipped. However, as they are not added to relaxations, they might get learned again.

Learning is not performed only when relaxations are in place, except for field format rules. When rules are skipped, they are only removed from the learned database. As relaxations are not added, they might get learned again. When the rules are deployed, they are removed from learned database and also relaxations are added for the rules. As relaxations are added, they would not be learned again. For field format protection, learning is performed irrespective of relaxations.

Although you can use the command line interface for basic configuration of the learning feature, the feature is designed primarily for configuration through the Web App Firewall wizard or the GUI. You can perform only limited configuration of the learning feature by using the command line.

The wizard integrates configuration of learning features with configuration of the Web App Firewall as a whole, and is therefore the easiest method for configuring this feature on a new NetScaler appliance or when managing a simple Web App Firewall configuration. The GUI visualizer and manual interface both provide direct access to all learned rules for all security checks, and are therefore often preferable when you must review learned rules for many security checks.

The learning database is limited to 20 MB in size, which is reached after approximately 2,000 learned rules or relaxations are generated per security check for which learning is enabled. If you do not regularly review and either approve or ignore learned rules and this limit is reached, an error is logged to the NetScaler log and no more learned rules are generated until you review the existing learned rules and relaxations.

If learning stops because the database has reached its size limit, you can restart learning either by reviewing the existing learned rules and relaxations or by resetting the learning data. After learned rules or relaxations are approved or ignored, they are removed from the database. After you reset the learning data, all existing learning data is removed from the database and it is reset to its minimum size. When the database falls below 20 MB in size, learning restarts automatically.

We recommend that you enable learning in the staging environment and not in the production environment.

To configure the learning settings by using the command line interface

Specify the Web App Firewall profile to be configured and, for each security check that you want to include in that profile, specify the minimum threshold or the percent threshold. The minimum threshold is an integer representing the minimum number of user sessions that the Web App Firewall must process before it learns a rule or relaxation (default: 1). The percent threshold is an integer representing the percentage of user sessions in which the Web App Firewall must observe a particular pattern (URL, cookie, field, attachment, or rule violation) before it learns a rule or relaxation (default: 0). Use the following commands:

- `set appfw learningsettings <profileName> [-startURLMinThreshold <positive_integer>] [-startURLPercentThreshold <positive_integer>] [-cookieConsistencyMinThreshold <positive_integer>] [-cookieConsistencyPercentThreshold <positive_integer>] [-CSRFtagMinThreshold <positive_integer>] [-CSRFtagPercentThreshold <positive_integer>] [-fieldConsistencyMinThreshold <positive_integer>] [-fieldConsistencyPercentThreshold <positive_integer>] [-crossSiteScriptingMinThreshold <positive_integer>] [-crossSiteScriptingPercentThreshold <positive_integer>] [-SQLInjectionMinThreshold <positive_integer>] [-SQLInjectionPercentThreshold <positive_integer>] [-fieldFormatMinThreshold <positive_integer>] [-fieldFormatPercentThreshold <positive_integer>] [-XMLWSIMinThreshold <positive_integer>] [-XMLWSIPercentThreshold <positive_integer>] [-XMLAttachmentMinThreshold <positive_integer>] [-XMLAttachmentPercentThreshold <positive_integer>]`
- `save ns config`

Example

The following example enables and configures the learning settings in the profile for the HTML SQL Injection security check. This is an appropriate initial test bed learning configuration, where you have complete control over the traffic that is sent to the Web App Firewall.

```
1 set appfw learningsettings pr-basic -SQLInjectionMinThreshold 10
2 set appfw learningsettings pr-basic -SQLInjectionPercentThreshold 70
3 save ns config
4 <!--NeedCopy-->
```

To reset learning settings to their defaults by using the command line interface

To remove any custom configuration of the learning settings for the specified profile and security check, and return the learning settings to their defaults, at the command prompt type the following commands:

- `unset appfw learningsettings <profileName> [-startURLMinThreshold] [-startURLPercentThreshold] [-cookieConsistencyMinThreshold] [-cookieConsistencyPercentThreshold] [-CSRFtagMinThreshold] [-CSRFtagPercentThreshold] [-fieldConsistencyMinThreshold] [-fieldConsistencyPercentThreshold] [-crossSiteScriptingMinThreshold] [-crossSiteScriptingPercentThreshold] [-SQLInjectionMinThreshold] [-SQLInjectionPercentThreshold] [-fieldFormatMinThreshold] [-fieldFormatPercentThreshold] [-XMLWSIMinThreshold] [-XMLWSIPercentThreshold] [-XMLAttachmentMinThreshold] [-XMLAttachmentPerco]`
- `save ns config`

To display the learning settings for a profile by using the command line interface

At the command prompt, type the following command:

```
show appfw learningsettings <profileName>
```

To display unreviewed learned rules or relaxations for a profile by using the command line interface

At the command prompt, type the following command:

```
show appfw learningdata <profileName> <securityCheck>
```

To remove specific unreviewed learned rules or relaxations from the learning database by using the command line interface

At the command prompt, type the following command:

```
rm appfw learningdata <profileName> (-startURL <expression> | -
cookieConsistency <string> | (-fieldConsistency <string> <formActionURL
>)| (-crossSiteScripting <string> <formActionURL>)| (-SQLInjection <
string> <formActionURL>)| (-fieldFormat <string><formActionURL>)| (-
CSRFTag <expression> <CSRFFormOriginURL>)| -XMLDoSCheck <expression
> | -XMLWSICheck <expression> | -XMLAttachmentCheck <expression>)[-
TotalXMLRequests]
```

Example

The following example removes all unreviewed learned relaxations for the profile, HTML SQL Injection security check, that apply to the **LastName form** field.

```
1 rm appfw learningdata pr-basic -SQLInjection LastName
2 <!--NeedCopy-->
```

To remove all unreviewed learned data by using the command line interface

At the command prompt, type the following command:

```
reset appfw learningdata
```

To export learning data by using the command line interface

At the command prompt, type the following command:

```
export appfw learningdata <profileName> <securitycheck>[-target <
string>]
```

Example

The following example exports learned relaxations for the profile and the HTML SQL Injection security check to a comma-separated values (CSV) format file in the /var/learn_data/ directory under the file name specified in the -target parameter.

```
1 export appfw learningdata pr-basic SQLInjection -target sqli_ld
2 <!--NeedCopy-->
```

To configure the Learning feature by using the GUI

1. Navigate to **Security > Web App Firewall > Profiles**.
2. In the **Profiles** pane, select the profile, and then click **Edit**.
3. Click **Learnt Rules** under **Advanced Settings** section.
4. In the **Learnt Rules** section, select a security check and click **Settings**.
5. In the **Security Check Settings** page, set the following parameters:
 - a) **Minimum number threshold.** Depending on which security check’s learning settings you are configuring, the minimum number threshold might refer to the minimum number of total user sessions that must be observed, the minimum number of requests that must be observed, or the minimum number of times a specific form field must be observed, before a learned relaxation is generated. Default: 1
 - b) **Percentage of times threshold.** Depending on which security check’s learning settings you are configuring, the percentage of times threshold might refer to the percentage of total observed user sessions that violated the security check, the percentage of requests, or the percentage of times a form field matched a particular field type, before a learned relaxation is generated. Default: 0
6. Click **OK** and **Close**.

Percentage of sessions field has been seen:

7. Click **Remove All Learned Data** to remove all learned data and reset the learning feature, so that it must start its observations again from the beginning.

Note:

This button removes only learned recommendations that have not been reviewed and either approved or skipped. It does not remove learned relaxations that have been accepted and deployed.

8. To restrict the learning engine to traffic from a specific set of IPs, click **Trusted Learning Clients**, and add the IP addresses that you want to use to the list.
 - a) To add an IP address or IP address range to the Trusted Learning Clients list, click **Add**.
 - b) In the **Add Trusted Learning Clients** dialog box, Trusted Clients IP list box, type the IP address or an IP address range in CIDR format.
 - c) In the Comments text area, type a comment that describes this IP address or range.
 - d) Click **Create** to add your new IP address or range to the list.
 - e) To modify an existing IP address or range, click the IP address or range, and then click **Open**. Except for the name, the dialog box that appears is identical to the **Add Trusted Learning Clients** dialog box.
 - f) To disable or enable an IP address or range, but leave it on the list, click the IP address or range, and then click **Disable or Enable**, as appropriate.
 - g) To remove an IP address or range completely, click the IP address or range, and then click **Remove**.
9. Click **Close** to return to the Configure Web App Firewall Profile page.
10. Click **Done**.

To review learned rules or relaxations by using the GUI

1. Navigate to **Security > Web App Firewall > Profiles**.
2. In the **Profiles** pane, select the profile, and then click **Edit**.
3. Click **Learnt Rules** under **Advanced Settings** section.
4. In the **Learnt Rules** section, select a security check and click **Settings**.
5. To review the learned data hierarchically as a branching tree, enabling you to choose general patterns that match many of the learned patterns, click **Visualizer**.
6. If you have chosen to review actual learned patterns, perform the following steps.
7. Select the first learned relaxation and choose how to handle it.
 - a) To modify and then accept the relaxation, click **Edit & Deploy**, edit the relaxation regular expression, and then click **OK**.
 - b) To accept the relaxation without modifications, click **Deploy**.

- c) To remove the relaxation from the list without deploying it, click **Skip**.
 - d) Repeat the previous step to review each additional learned relaxation.
8. Click **Close** to return to the **Manage Learned Rules** dialog box.
 9. Click **Done**.

Dynamic profiling

February 13, 2024

The learning feature is a pattern filter that observes and learns activities on the back-end server. Based on the observation, the learning engine generates up to 2000 rules or exceptions (relaxations) for each security check. To automate the process and auto deploy the relaxation rules, NetScaler appliance uses dynamic profiling.

With dynamic profiling, the appliance records the learnt data for a pre-defined threshold and sends an SNMP alert to the user. If the user does not skip the data within a grace period, the appliance auto deploys it as a relaxation rule. Earlier, the user had to manually deploy the relaxation rules. Currently, dynamic profiling is available only for the follow security checks:

1. HTML SQL injection
2. HTML Cross Site scripting
3. Field format
4. Start URL
5. Content-type
6. Field formats
7. CSRF form tagging
8. Cookie consistency
9. Deny URL
10. Buffer Overflow
11. Credit Card
12. Content-type protection
13. JSON Cmd Injection protection

For example, consider the HTML SQL Injection security check enabled with dynamic profiling. You can use learning for a list of IPs (called the Trusted Learning Clients list) from which the learning feature must generate recommendations. To configure a list of trusted clients, see Learning Trusted Clients topic. If the incoming traffic has violations, it is recorded as a learnt data. If the learned data is recorded in the learning engine, the appliance sends an SNMP alert to the user. If the user does not

recognize a false positive and does not skip the learnt data within a grace period, the appliance auto deploys it as a relaxation rule.

Note:

After you configure the dynamic profile, you must periodically review the appliance configuration for the auto-deployment of the relaxation rules and save it on the appliance.

Configure dynamic profiling by using the NetScaler command interface

Dynamic profiling is available for Start URL, HTML Cross-Site Scripting, Field Format, or HTML SQL Injection security checks. To configure dynamic profiling, you must complete the following steps.

1. Configure dynamic learning
2. Configure auto deployment grace period

Configure dynamic learning

As a first step, you must configure dynamic learning on your appliance. At the command prompt, type:

```
set appfw profile <profile_name> dynamicLearning <security_checks>
```

Example `set appfw profile test1 dynamicLearning SQLInjection CrossSiteScripting fieldFormat startURL`

Configure auto deployment grace period

Once you enable the feature on specific security checks, you must configure the grace period for the auto deployment.

```
set appfw learningsettings <profile name> -crossSiteScriptingAutoDeployGracePeriod <seconds>
```

```
set appfw learningsettings <profile name> fieldFormatAutoDeploymentGracePeriod <seconds>
```

```
set appfw learningsettings <profile name> SQLInjectionAutoDeploymentGracePeriod <seconds>
```

```
set appfw learningsettings <profile name> -startURLAutoDeployGracePeriod <seconds>
```

```
Example set appfw learningsettings test1 -crossSiteScriptingAutoDeployGracePer
30
set appfw learningsettings test1 -startURLAutoDeployGracePeriod 7
set appfw learningsettings test1 -fieldFormatAutoDeploymentGracePeriod
10
set appfw learning settings test1 -SQLInjectionAutoDeploymentGracePeriod
12
```

Note:

Here, the auto deployment grace period is in minutes.

Configuring dynamic profiling by using the NetScaler GUI

1. Navigate to **Security > NetScaler Web App Firewall > Profile**.
2. In the details pane, select a profile and click **Edit**.
3. In the **Citrix Web App Profile** page, click **Dynamic Profiling** under **Advanced Settings**.
4. In the **Dynamic Profiling** section, select a security check and click **Edit**.
5. In the **Dynamic Profiling and Learning Settings** page, set the grace period the security check.

6. Click **OK** and **Done**.

Export and import of relaxation rules

When you enable dynamic profiling, the learnt data is auto deployed as relaxation rules. Along with this, the appliance also enables you to export the dynamic profiling based relaxation rules and regular relaxation rules. You can export the rules from staging environment and import it to the production environment.

Note:

When you import rules to the production environment, you must ensure the process is additive and does not override the existing configuration.

How to export and import relaxation rules

To export and import the relaxation rules, you must complete the following steps:

1. You must first export the dynamic profiling-based data. For this, the export option is available for the relaxation rules in the WAF profile. When you select this option, you export the dynamic

profiling relaxation rules and regular relaxation rules. You can use the export option to download the configuration as a compressed bundle on the appliance.

2. Once you have exported the data from the staging environment, you must import it to another NetScaler appliance. For this, you must use the import option available in the relaxation rules of the WAF profile. When you select this option, the appliance imports the specified relaxation rules bundled and restores it to the WAF profile of the selected appliance.

Note:

If you are going to import relaxation rules in a WAF profile, there are two types of action:

Augment –This action ensures import is additive, thus not overriding any existing configuration.

Overwrite –This action overwrites the existing configuration with configuration present in the compressed export bundle.”

Import archived relaxation rules file by using CLI

To import the relaxation rules, you must import the archive into the NetScaler appliance and then run the restore command to extract the configuration. The following set of CLI commands can be used for exporting, importing, and managing the configurations.

To import the archived file from the specific location and restore, at the command prompt, type:

```
import appfw archive <src> <name> [-comment <string>]
```

Where,

“src”: Indicates the source of the tar archive file in the form, <protocol>://<host>[:<port>][/<path>]

“name”: Indicates name of archive.

“comment”: Comments associated with this archive.

```
restore appfw profile <archivename> [-relaxationRules] [-importProfileName  
  <string>] [-matchUrlString <string>] [-replaceUrlString <string>] [-  
  overwrite] [-augment]
```

Where,

archivename: Indicates source for tar archive. This is a mandatory argument.

“relaxationRules”: Option to import all appfw relaxation rules.

importProfileName: Indicates profile name created or updated to associate the relaxation rules during restore operation.

“matchUrlString”: Indicates action URL string to match in archived relaxation rules.

replaceUrlString: Indicates string to replace in action URL while restoring relaxation rules.

overwrite: Existing rules action to purge existing relaxation rules and replace during import.

`augment`: Existing rules action to augment relaxation rules during import.

Example:

```
import appfw archive local: dutA_test_pr.tgz demo
restore appfw profile dutA_test_pr
```

Export the archived file to the selected appliance by using the CLI

If you use CLI to export the appfw relaxation rules, you must archive the configuration and then export it.

To archive and export the archived file, at the command prompt, type:

```
archive appfw profile <name> <archivename> [-comment <string>]
```

Where,

`archive name`: Indicates source for tar archive. This is a mandatory argument.

`name`: Indicates the appfw profile name containing the relaxation rules to export

```
export appfw archive <name> <target>
```

Where,

`Name`. Name of tar archive. This is a mandatory argument. Maximum Length: 31

`Target`. Path to the file to be exported. This is a mandatory argument. Maximum Length: 2047

Example:

```
> archive appfw profile test_pr archived_test_pr
> export appfw archive archived_test_pr local:dutA_test_pr
```

To export relaxation rules by using NetScaler GUI

Follow the steps given below to export relaxation rules:

1. Navigate to **Security > NetScaler Web App Firewall**.
2. In the details page, click **NetScaler Web App Firewall Profiles** link under **Configuration Summary** section.
3. In the **NetScaler Web App Firewall Profile** page, click the **Relaxation Rules** link under **Advanced Settings** section.
4. In the **Relaxation Rules** section, click **Export All Relaxation Rules**. The action applies to all security checks and on the ones which dynamic learning is enabled on that profile.

| Relaxation Rules | | | |
|-------------------------------------|---|--|--|
| <input type="button" value="Edit"/> | <input type="button" value="Visualizer"/> | <input type="button" value="Export All Relaxation Rules"/> | <input type="button" value="Import All Relaxation Rules"/> |
| <input type="checkbox"/> | NAME | CHECK TYPE | |
| <input type="checkbox"/> | Start URL | Common | |
| <input type="checkbox"/> | Deny URL | Common | |
| <input type="checkbox"/> | Cookie Consistency | Common | |

To import relaxation rules by using NetScaler GUI

Complete the steps to import relaxation rules:

1. Navigate to **Security > NetScaler Web App Firewall**.
2. In the details page, click the **NetScaler Web App Firewall Profiles** link under **Configuration Summary** section.
3. In the **NetScaler Web App Firewall Profile** page, click the **Relaxation Rules** link under **Advanced Settings** section.
4. In the **Relaxation Rules** section, click **Import All Relaxation Rules**.
5. In the **Configure NetScaler Web App Firewall Profile** page, set the following parameters:
 - a) Local file. Name of the compressed archived file containing the relaxation rules.
 - b) Profile Name. Name of the profile to which the relaxation rules are bound.
 - c) Matching URL String. Portion of the URL that matches.
 - d) Replace URL String. Portion of the URL that replaces the URL string.
 - e) Existing Rule Action. Select if the rule must overwrite existing rules or augment the existing rules.
6. Click **OK**.

Supplemental Information about profiles

May 2, 2023

Following is supplemental information about particular aspects of Web App Firewall profiles. This information explains how to include special characters in a security check rule or relaxation, and how to use variables when configuring profiles.

Configuration variable support

Instead of using static values, to configure the Web App Firewall's security checks and settings, you can now use standard NetScaler named variables. By creating variables, you can more easily export and then import configurations to new NetScaler appliances, or update existing NetScaler appliances from a single set of configuration files. This simplifies updates when you use a test bed setup to develop a complex Web App Firewall configuration that is tuned for your local network and servers and then transfer that configuration to your production NetScaler appliances.

You create Web App Firewall configuration variables in the same manner as you do any other NetScaler named variables, following standard NetScaler conventions. You can create a named expression variable using the NetScaler command line or GUI.

The following URLs and expressions can be configured with variables instead of static values:

- **Start URL** (-starturl)
- **Deny URL** (-denyurl)
- **Form Action URL** for *Form Field Consistency Check* (-fieldconsistency)
- **Action URL** for *XML SQL Injection Check* (-xmlSQLInjection)
- **Action URL** for *XML Cross-Site Scripting Check* (-xmlcross-site scripting)
- **Form Action URL** for *HTML SQL Injection Check* (-sqlInjection)
- **Form Action URL** for *Field Format Check* (-fieldFormat)
- **Form Origin URL** and **Form Action URL** for *Cross-Site Request Forgery (CSRF) Check* (-csrfTag)
- **Form Action URL** for *HTML Cross-Site Scripting Check* (-crossSiteScripting)
- **Safe Object** (-safeObject)
- **Action URL** for *XML Denial-of-Service (XDoS) check* (-XMLDoS)
- **URL** for *Web Services Interoperability check* (-XMLWSIURL)
- **<URL** for *XML Validation check* (-XMLValidationURL)
- **URL** for *XML Attachment check* (-XMLAttachmentURL)

For more information, see [Policies and Expressions](#).

To use a variable in the configuration, you enclose the variable name between two at (@) symbols and then use it exactly as you would the static value that it replaces. For example, if you are configuring the Deny URL check by using the GUI and want to add the named expression variable myDenyURL to the configuration, you would type @myDenyURL@ into the Add Deny URL dialog box, Deny URL text area. To do the same task by using the NetScaler command line, you would type add appfw profile <name> -denyURLAction @myDenyURL@.

PCRE character encoding format

The NetScaler operating system supports direct entry of characters in the printable ASCII character set only—characters with hexadecimal codes between HEX 20 (ASCII 32) and HEX 7E (ASCII 127). To

include a character with a code outside that range in your Web App Firewall configuration, you must enter its UTF-8 hexadecimal code as a PCRE regular expression.

A number of character types require encoding using a PCRE regular expression if you include them in your Web App Firewall configuration as a URL, form field name, or Safe Object expression. They include:

- **Upper-ASCII characters.** Characters with encodings from HEX 7F (ASCII 128) to HEX FF (ASCII 255). Depending on the character map used, these encodings can refer to control codes, ASCII characters with accents or other modifications, non-Latin alphabet characters, and symbols not included in the basic ASCII set. These characters can appear in URLs, form field names, and safe object expressions.
- **Double-Byte characters.** Characters with encodings that use two 8-byte words. Double-byte characters are used primarily for representing Chinese, Japanese, and Korean text in electronic format. These characters can appear in URLs, form field names, and safe object expressions.
- **ASCII control characters.** Non-printable characters used to send commands to a printer. All ASCII characters with hexadecimal codes less than HEX 20 (ASCII 32) fall into this category. These characters must never appear in a URL or form field name, however, and would rarely if ever appear in a safe object expression.

The NetScaler appliance does not support the entire UTF-8 character set, but only the characters found in the following eight charsets:

- **English US (ISO-8859-1).** Although the label reads, “English US,” the Web App Firewall supports all characters in the ISO-8859-1 character set, also called the Latin-1 character set. This character set fully represents most modern western European languages and represents all but a few uncommon characters in the rest.
- **Chinese Traditional (Big5).** The Web App Firewall supports all characters in the BIG5 character set, which includes all of the Traditional Chinese characters (ideographs) commonly used in modern Chinese as spoken and written in Hong Kong, Macau, Taiwan, and by many people of Chinese ethnic heritage who live outside of mainland China.
- **Chinese Simplified (GB2312).** The Web App Firewall supports all characters in the GB2312 character set, which includes all of the Simplified Chinese characters (ideographs) commonly used in modern Chinese as spoken and written in mainland China.
- **Japanese (SJIS).** The Web App Firewall supports all characters in the Shift-JIS (SJIS) character set, which includes most characters (ideographs) commonly used in modern Japanese.
- **Japanese (EUC-JP).** The Web App Firewall supports all characters in the EUC-JP character set, which includes all characters (ideographs) commonly used in modern Japanese.
- **Korean (EUC-KR).** The Web App Firewall supports all characters in the EUC-KR character set, which includes all characters (ideographs) commonly used in modern Korean.

- **Turkish (ISO-8859-9).** The Web App Firewall supports all characters in the ISO-8859-9 character set, which includes all letters used in modern Turkish.
- **Unicode (UTF-8).** The Web App Firewall supports certain additional characters in the UTF-8 character set, including those used in modern Russian.

When configuring the Web App Firewall, you enter all non-ASCII characters as PCRE-format regular expressions using the hexadecimal code assigned to that character in the UTF-8 specification. Symbols and characters within the normal ASCII character set, which are assigned single, two-digit codes in that character set, are assigned the same codes in the UTF-8 character set. For example, the exclamation point (!), which is assigned hex code 21 in the ASCII character set, is also hex 21 in the UTF-8 character set. Symbols and characters from another supported character set have a paired set of hexadecimal codes assigned to them in the UTF-8 character set. For example, the letter a with an acute accent (á) is assigned UTF-8 code C3 A1.

The syntax you use to represent these UTF-8 codes in the Web App Firewall configuration is “xNN” for ASCII characters; “\xNN\xNN” for non-ASCII characters used in English, Russian, and Turkish; and “\xNN\xNN\xNN” for characters used in Chinese, Japanese, and Korean. For example, if you want to represent a ! in an Web App Firewall regular expression as a UTF-8 character, you would type \x21. If you want to include an á, you would type \xC3\xA1.

Note:

Normally you do not need to represent ASCII characters in UTF-8 format, but when those characters might confuse a web browser or an underlying operating system, you can use the character’s UTF-8 representation to avoid this confusion. For example, if a URL contains a space, you might want to encode the space as x20 to avoid confusing certain browsers and web server software.

Below are examples of URLs, form field names, and safe object expressions that contain non-ASCII characters that must be entered as PCRE-format regular expressions to be included in the Web App Firewall configuration. Each example shows the actual URL, field name, or expression string first, followed by a PCRE-format regular expression for it.

- A URL containing extended ASCII characters.

Actual URL: <http://www.josénuñez.com>

Encoded URL: `^http://www\[.\]jos\xC3\xA9nu\xC3\xB1ez\[.\]com$`

- Another URL containing extended ASCII characters.

Actual URL: <http://www.example.de/trömsö.html>

Encoded URL: `^http://www\[.\]example\[.\]de/tr\xC3\xB6msö\[.\]html$`

- A form field name containing extended ASCII characters.

Actual Name: `nome_do_usuário`

Encoded Name: `^nome_do_usu\xC3\xA1rio$`

- A safe object expression containing extended ASCII characters.

Unencoded Expression `[A-Z]{3,6}¥[1-9][0-9]{6,6}`

Encoded Expression: `[A-Z]{3,6}\xC2\xA5[1-9][0-9]{6,6}`

You can find a number of tables that include the entire Unicode character set and matching UTF-8 encodings on the Internet. A useful website that contains this information is located at the following URL:

<http://www.utf8-chartable.de/unicode-utf8-table.pl>

For the characters in the table on this website to display correctly, you must have an appropriate Unicode font installed on your computer. If you do not, the visual display of the character may be in error. Even if you do not have an appropriate font installed to display a character, however, the description and the UTF-8 and UTF-16 codes on this set of web pages will be correct.

Inverted PCRE Expressions

In addition to matching content that contains a pattern, you can match content that does not contain a pattern by using an inverted PCRE expression. To invert an expression, you simply include an exclamation point (!) followed by white space as the first character in the expression.

Note: If an expression consists only of an exclamation point with nothing following, the exclamation point is treated as a literal character, not syntax indicating an inverted expression.

The following Web App Firewall commands support inverted PCRE expressions:

- Start URL (URL)
- Deny URL (URL)
- Form Field Consistency (form action URL)
- Cookie Consistency (form action URL)
- Cross Site Request Forgery (CSRF) (form action URL)
- HTML Cross-site Scripting (form action URL)
- Field Format (form action URL)
- Field Type (type)
- Confidential Field (URL)

Note: If the security check contains an isRegex flag or check box, it must be set to YES or checked to enable regular expressions in the field. Otherwise the contents of that field are treated as literal and no regular expressions (inverted or not) are parsed.

Disallowed Names for Web App Firewall Profiles

The following names are assigned to built-in actions and profiles on the NetScaler appliance, and cannot be used as names for a user-created Web App Firewall profile.

- AGRESSIVE
- ALLOW
- BASIC
- CLIENTAUTH
- COMPRESS
- CSSMINIFY
- DEFLATE
- DENY
- DNS-NOP
- DROP
- GZIP
- HTMLMINIFY
- IMGOPTIMIZE
- JSMINIFY
- MODERATE
- NOCLIENTAUTH
- NOCOMPRESS
- NONE
- NOOP
- NOREWRITE
- RESET
- SETASLEARNNSLOG_ACT
- SETNSLOGPARAMS_ACT
- SETSYSLOGPARAMS_ACT
- SETTMESSPARAMS_ACT
- SETVPNPARAMS_ACT
- SET_PREAUTHPARAMS_ACT
- default_DNS64_action
- dns_default_act_Cachebypass
- dns_default_act_Drop
- nshttp_default_profile
- nshttp_default_strict_validation
- nstcp_default_Mobile_profile
- nstcp_default_XA_XD_profile
- nstcp_default_profile

- nstcp_default_tcp_interactive_stream
- nstcp_default_tcp_lan
- nstcp_default_tcp_lan_thin_stream
- nstcp_default_tcp_lfp
- nstcp_default_tcp_lfp_thin_stream
- nstcp_default_tcp_lnp
- nstcp_default_tcp_lnp_thin_stream
- nstcp_internal_apps

Custom error status and message for HTML, XML, and JSON error object

May 2, 2023

When the NetScaler Web App Firewall detects a violation, the appliance handles the error scenario using either a redirect URL or the error object (imported into the profile and enabled). If the scenario is handled using an error object configuration, the WAF profile provides a custom response status code and message. You can customize the response error details for an HTML, XML, or JSON error object in the WAF profile.

Note:

By default, the error code and error message are set as “200” and “OK” if error object settings are configured.

When handling error scenarios, it is important for the appliance to respond with appropriate HTTP response status code and message for resolving issues. By providing a custom error status message and custom error status code, the appliance can provide better user intervention to resolve a problem when a violation occurs. For example, if you set the response error code to “404” and the status message to “Not Found”, the user can inspect the response status code and message to check if a violation has occurred. This can help the user to filter responses that contain the error object

Configure custom status code and message for HTML error object in a WAF profile by using the CLI

At the command prompt, type:

```
1 set appfw profile <profile-name> -HTMLErrorStatusCode <value> -  
   HTMLErrorStatusMessage <value> -useHTMLErrorObject ON  
2 <!--NeedCopy-->
```

Example:

```
set appfw profile profile_1 -HTMLErrorStatusCode 404 -HTMLErrorMessage  
"Not Found" -useHTMLErrorObject ON
```

Configure custom status code and message for XML error object in a WAF profile by using the CLI

At the command prompt, type:

```
1 set appfw profile <profile-name> -XMLErrorStatusCode <value> -  
XMLErrorMessage <value>  
2 <!--NeedCopy-->
```

Example:

```
set appfw profile profile_1 -XMLErrorStatusCode 406 - XMLErrorMessage  
"Not Acceptable"
```

Configure custom status code and message for JSON error object in a WAF profile by using the CLI

At the command prompt, type:

```
1 set appfw profile <profile-name> -JSONErrorStatusCode <value> -  
JSONErrorMessage <value>  
2 <!--NeedCopy-->
```

Example:

```
set appfw profile profile_1 -JSONErrorStatusCode 500 - JSONErrorMessage  
"Internal Server Error"
```

Configure custom status code and message for HTML, JSON, or XML error object in a WAF profile by using the GUI

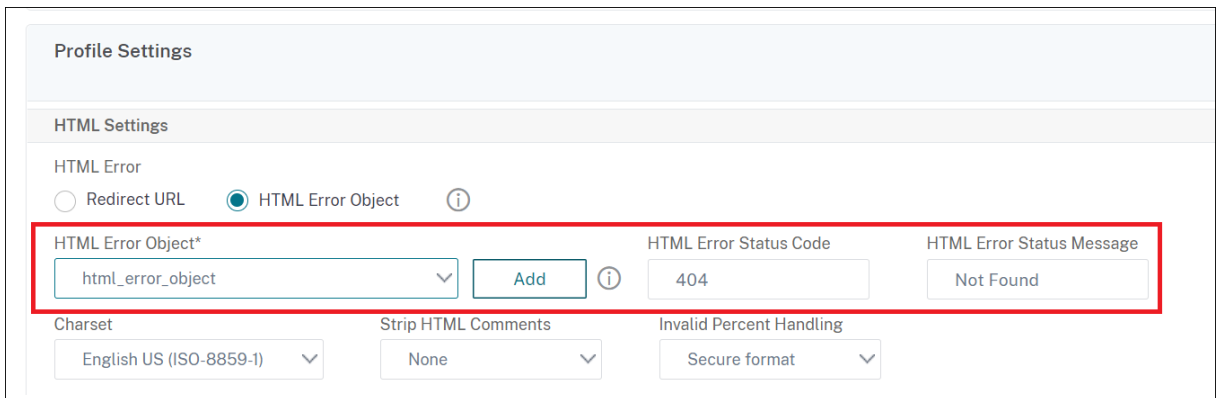

1. Navigate to **Security > NetScaler Web App Firewall > Profiles**.
2. In the details pane, click **Edit**.
3. In the **Create Web App Firewall Profile** page, click **Profile Settings** from the **Advanced Settings** section.
4. In the **Profile settings** section, set the following parameters.

- a. HTML Error Object. Select the option for handing error scenarios using an HTML error object. Import the error object from a URL, file, or text.
- b. HTML Error Status Code. Provide a custom error status code.
- c. HTML Error Status Message. Provide a customer error message.

5. Click **OK** and **Done**.

Note:

The same procedure is applicable for JSON and XML custom error object settings.

Policy labels

May 2, 2023

A policy label consists of a set of policies, other policy labels, and virtual server-specific policy banks. The Web App Firewall evaluates each policy bound to the policy label in order of priority. If the policy matches, it filters the connection as specified in the associated profile. Then it does whatever the Goto parameter specifies, which can be to terminate policy evaluation, go to the next policy, or go to the policy with the specified priority. If the Invoke parameter is set, it terminates processing of the current policy label and begins to process the specified policy label or virtual server.

To create an Web App Firewall policy label by using the command line

At the command prompt, type the following commands:

- `add appfw policylabel <labelName> http_req`
- `save ns config`

Example

The following example creates a policy label named policylbl1.

```
1 add appfw policylabel policylbl1 http_req
2 save ns config
3 <!--NeedCopy-->
```

To bind a policy to a policy label by using the command line

At the command prompt, type the following commands:

- `bind appfw policylabel <labelName> <policyName> <priority> [<gotoPriorityExpression>] [-invoke (<labelType> <labelName>)]`
- `save ns config`

Example

The following example binds the policy1 to the policy label policylbl1 with a priority of 1.

```
1 bind appfw policylabel policylbl1 policy1 1
2 save ns config
3 <!--NeedCopy-->
```

To configure an Web App Firewall policy label by using the GUI

1. Navigate to **Security > NetScaler Web App Firewall > Policy Labels**.
2. In the details pane, do one of the following:
 - To add a new policy label, click **Add**.
 - To configure an existing policy label, select the policy label and the click **Open**.

The **Create Web App Firewall Policy Label** or the **Configure Web App Firewall Policy Label** dialog box opens. The dialog boxes are nearly identical.

3. If you are creating a new policy label, in the Create Web App Firewall Policy Label dialog box, type a name for your new policy label.

The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 127 letters, numbers, and the hyphen (-), period (.) pound (#), space (), at (@), equals (=), colon (:), and underscore (_) symbols.

4. Select **Insert Policy** to insert a new row and display a drop-down list with all existing Web App Firewall policies.

5. Select the policy you want to bind to the policy label, or select New Policy to create a new policy and follow the instructions in [To create and configure a policy by using the GUI](#). The policy that you selected or created is inserted into the list of globally bound Web App Firewall policies.
6. Make any additional adjustments.
 - To modify the policy priority, click the field to enable it, and then type a new priority. You can also select Regenerate Priorities to renumber the priorities evenly.
 - To modify the policy expression, double click that field to open the Configure Web App Firewall Policy dialog box, where you can edit the policy expression.
 - To set the Goto Expression, double click field in the Goto Expression column heading to display the drop-down list, where you can choose an expression.
 - To set the Invoke option, double click field in the Invoke column heading to display the drop-down list, where you can choose an expression
7. Repeat steps 5 through 7 to bind any additional Web App Firewall policies you want to the policy label.
8. Click **Create** or **OK**, and then click **Close**. A message appears in the status bar, stating that you have successfully created or modified the policy label.

Policies

May 2, 2023

The Web App Firewall uses two types of policies: firewall policies and auditing policies. Firewall policies control which traffic is sent to the Web App Firewall. Auditing policies control the log server to which Web App Firewall logs are sent.

Firewall policies can be complex because the policy rule can consist of multiple expressions in the NetScaler expressions language, which is a full-fledged object oriented programming language capable of defining with extreme precision exactly which connections to filter. Because firewall policies operate within the context of the Web App Firewall, they must meet certain criteria that are connected to how the Web App Firewall functions and what traffic is appropriately filtered by it. As long as you keep these criteria in mind, however, firewall policies are similar to policies for other NetScaler features. The instructions here do not attempt to cover all aspects of writing firewall policies, but only provide an introduction to policies and cover those criteria that are unique to the Web App Firewall.

Auditing policies are simple because the policy rule is always `ns_true`. You need only specify the log server that you want to send logs to, the logging levels that you want to use, and a few other criteria that are explained in detail.

Web App Firewall Policies

May 2, 2023

A firewall policy is a rule associated with a profile. The rule is an expression or group of expressions that define the types of request/response pairs that the Web App Firewall is to filter by applying the profile. Firewall policy expressions are written in the NetScaler expressions language, an object-oriented programming language with special features to support specific NetScaler functions. The profile is the set of actions that the Web App Firewall is to use to filter request/response pairs that match the rule.

Firewall policies enable you to assign different filtering rules to different types of web content. Not all web content is alike. A simple website that uses no complex scripting and accesses and handles no private data might require only the level of protection provided by a profile created with basic defaults. Web content that contains JavaScript-enhanced web forms or accesses an SQL database probably requires more tailored protection. You can create a different profile to filter that content and create a separate firewall policy that can determine which requests are attempting to access that content. You then associate the policy expression with a profile you created and globally bind the policy to put it into effect.

The Web App Firewall processes only HTTP connections, and therefore uses a subset of the overall NetScaler expressions language. The information here is limited to topics and examples that are likely to be useful when configuring the Web App Firewall. Following are links to additional information and procedures for firewall policies:

- For procedures that explain how to create and configure a policy, see [Creating and Configuring Web App Firewall Policies](#).
- For a procedure that explains in detail how to create a policy rule (expression), see [To create or configure an Web App Firewall rule \(expression\)](#).
- For a procedure that explains how to use the Add Expression dialog box to create a policy rule, see [To add a firewall rule \(expression\) by using the Add Expression dialog box](#).
- For a procedure that explains how to view the current bindings for a policy, see [Viewing a Firewall Policy's Bindings](#).
- For procedures that explain how to bind an Web App Firewall policy, see [Binding Web App Firewall Policies](#).
- For detailed information about the NetScaler expressions language, see [Policies and Expressions](#).

Note

Web App Firewall evaluates the policies based on the configured priority and goto expressions. At the end of the policy evaluation, the last policy that evaluates to true is used and the security

configuration of the corresponding profile is invoked for processing the request.

For example, Consider a scenario where there are 2 policies.

- Policy_1 is a generic policy with Expression=ns_true and has a corresponding profile_1 which is a basic profile. The priority is set to 100.
- Policy_2 is more specific with Expression=HTTP.REQ.URL.CONTAINS(“XYZ”) and has a corresponding profile_2 which is an advance profile. The GoTo Expression is set to NEXT and the priority is set to 95 which is a higher priority compared to Policy_1.

In this scenario, if the target string “XYZ” is detected in the URL of the processed request, Policy_2 match is triggered as it has a higher priority even though Policy_1 is also a match. However, as per the GoTo expression configuration of Policy_2, the policy evaluation continues and the next policy_1 is also processed. At the end of the policy evaluation, Policy_1 evaluates as true and the basic security checks configured in Profile_1 are invoked.

If the Policy_2 is modified and the GoTo Expression is changed from **NEXT** to **END**, the processed request that has the target string “XYZ”, triggers the Policy_2 match due to priority consideration and as per the GoTo expression configuration, the policy evaluation ends at this point. Policy_2 evaluates as true and the advanced security checks configured in Profile_2 are invoked.

NEXT

END

Policy evaluation is completed in one pass. Once the policy evaluation is completed for the request and the corresponding profile actions are invoked, the request does not go through another round of policy evaluation.

Creating and configuring Web App Firewall policies

May 2, 2023

A firewall policy consists of two elements: a *rule*, and an associated *profile*. The rule selects the HTTP traffic that matches the criteria that you set, and sends that traffic to the Web App Firewall for filtering. The profile contains the filtering criteria that the Web App Firewall uses.

The policy rule consists of one or more expressions in the NetScaler expressions language. The NetScaler expressions syntax is a powerful, object-oriented programming language that enables you to precisely designate the traffic that you want to process with a specific profile. For users who are not familiar with the NetScaler expressions language syntax, or who prefer to configure their NetScaler appliance by using a web-based interface, the GUI provides two tools: the **Prefix** menu and the **Add Expression** dialog box. Both help you to write expressions that select exactly the traffic

that you want to process. Experienced users who are thoroughly familiar with the syntax may prefer to use the NetScaler command line to configure their NetScaler appliances.

Note:

In addition to the default expressions syntax, for backward compatibility the NetScaler operating system supports the NetScaler classic expressions syntax on NetScaler Classic and nCore appliances and virtual appliances. Classic expressions are not supported on NetScaler Cluster appliances and virtual appliances. Current NetScaler users who want to migrate existing configurations to the NetScaler Cluster must migrate any policies that contain classic expressions to the default expressions syntax.

For detailed information about the NetScaler expressions languages, see [Policies and Expressions](#).

You can create a firewall policy by using the GUI or the NetScaler command line.

To create and configure a policy by using the command line interface

At the command prompt, type the following commands:

- `add appfw policy <name><rule> <profileName>`
- `save ns config`

Example

The following example adds a policy named pl-blog, with a rule that intercepts all traffic to or from the host blog.example.com, and associates that policy with the profile pr-blog. This is an appropriate policy to protect a blog hosted on a specific host name.

```
1 add appfw policy pl-blog "HTTP.REQ.HOSTNAME.DOMAIN.EQ("blog.example.com  
  ") " pr-blog  
2 <!--NeedCopy-->
```

To create and configure a policy by using the GUI

1. Navigate to **Security > Web App Firewall > Policies**.
2. In the details pane, do one of the following:
 - To create a firewall policy, click **Add**. The **Create Web App Firewall Policy** is displayed.
 - To edit an existing firewall policy, select the policy, and then click **Edit**.

The **Create Web App Firewall Policy** or **Configure Web App Firewall Policy** is displayed.

3. If you are creating a firewall policy, in the **Create Web App Firewall Policy** dialog box, Policy Name text box, type a name for your new policy.

The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 128 letters, numbers, and the hyphen (-), period (.) pound (#), space (), at (@), equals (=), colon (:), and underscore (_) symbols.

If you are configuring an existing firewall policy, this field is read-only. You cannot modify it.

4. Select the profile that you want to associate with this policy from the Profile drop-down list. You can create a profile to associate with your policy by clicking New, and you can modify an existing profile by clicking Modify.
5. In the Expression text area, create a rule for your policy.
 - You can type a rule directly into the text area.
 - You can click Prefix to select the first term for your rule, and follow the prompts.
 - You can click Add to open the Add Expression dialog box, and use it to construct the rule.
6. Click **Create** or **OK**, and then click **Close**.

To create or configure a Web App Firewall rule (expression)

The policy rule, also called the *expression*, defines the web traffic that the Web App Firewall filters by using the profile associated with the policy. Like other NetScaler policy rules (or *expressions*), the Web App Firewall rules use NetScaler expressions syntax. This syntax is powerful, flexible, and extensible. It is too complex to describe completely in this set of instructions. You can use the following procedure to create a simple firewall policy rule, or you can read it as an overview of the policy creation process.

1. If you have not already done so, navigate to the appropriate location in the **Web App Firewall** wizard or the NetScaler GUI to create your policy rule:
 - If you are configuring a policy in the **Web App Firewall** wizard, in the navigation pane, click **Web App Firewall**, then in the details pane click **Web App Firewall Wizard**, and then navigate to the **Specify Rule** screen.
 - If you are configuring a policy manually, in the navigation pane, expand **Web App Firewall**, then **Policies**, and then **Firewall**. In the details pane, to create a policy, click **Add**. To modify an existing policy, select the policy, and then click **Open**.
2. On the **Specify Rule** screen, the **Create Web App Firewall Profile** dialog box, or the **Configure Web App Firewall Profile** dialog box, click **Prefix**, and then choose the prefix for your expression from the drop-down list. Your choices are:

- **HTTP.** Choose an HTTP protocol if you want to examine some aspect of the request that pertains to the protocol.
- **SYS.** Choose protected websites if you want to examine some aspect of the request that pertains to the recipient of the request.
- **CLIENT.** Choose a client that sent the request. Choose this if you want to examine some aspect of the sender of the request.
- **SERVER.** Choose a client to which the request was sent and if you want to examine some aspect of the recipient of the request.

After you choose a prefix, the Web App Firewall displays a two-part prompt window that displays the possible next choices at the top, and a brief explanation of what the selected choice means at the bottom.

3. Choose your next term.

If you chose the HTTP protocol as your prefix, your only choice is REQ, which specifies the Request/Response pair. (The Web App Firewall operates on the request and response as a unit instead of on each separately.) If you chose another prefix, your choices are more varied. For help on a specific choice, click that choice once to display information about it in the lower prompt window.

When you have decided which term you want, double-click it to insert it into the **Expression** window.

4. Type a period after the term you just chose. You are then prompted to choose your next term, as described in the previous step. When a term requires that you type a value, fill in the appropriate value. For example, if you choose HTTP.REQ.HEADER(""), type the header name between the quotation marks.
5. Continue choosing terms from the prompts and filling in any values that are needed, until your expression is finished.

Following are some examples of expressions for specific purposes.

- **Specific web host.** To match traffic from a particular web host:

```
1 HTTP.REQ.HEADER("Host").EQ("shopping.example.com")
2 <!--NeedCopy-->
```

For `shopping.example.com`, substitute the name of the web host that you want to match.

- **Specific web folder or directory.** To match traffic from a particular folder or directory on a Web host:

```
1 HTTP.REQ.URL.STARTSWITH("https://www.example.com/folder")
2 <!--NeedCopy-->
```

For `www.example.com`, substitute the name of the web host. For the folder, substitute the folder or path to the content that you want to match. For example, if your shopping cart is in a folder called `/solutions/orders`, you substitute that string for folder.

- **Specific type of content: GIF images.** To match GIF format images:

```
1 HTTP.REQ.URL.ENDSWITH(".png")
2 <!--NeedCopy-->
```

To match other format images, substitute another string in place of `.png`.

- **Specific type of content: scripts.** To match all CGI scripts located in the CGI-BIN directory:

```
1 HTTP.REQ.URL.STARTSWITH("https://www.example.com/CGI-BIN")
2 <!--NeedCopy-->
```

To match all JavaScript with `.js` extensions:

```
1 HTTP.REQ.URL.ENDSWITH(".js")
2 <!--NeedCopy-->
```

For more information about creating policy expressions, see [Policies and Expressions](#).

Note:

If you use the command line to configure a policy, remember to escape any double quotation marks within NetScaler expressions. For example, the following expression is correct if entered in the GUI:

```
1 HTTP.REQ.HEADER("Host").EQ("shopping.example.com")
2 <!--NeedCopy-->
```

If entered at the command line, however, you must type the following command instead:

```
1 HTTP.REQ.HEADER("Host").EQ("shopping.example.com")
2 <!--NeedCopy-->
```

To add a firewall rule (expression) by using the Add Expression dialog box

The **Add Expression** dialog box (also referred to as the Expression Editor) helps users who are not familiar with the NetScaler expressions language to construct a policy that matches the traffic that they want to filter.

1. If you have not already done so, navigate to the appropriate location in the **Web App Firewall** wizard or the NetScaler GUI:

- If you are configuring a policy in the **Web App Firewall** wizard, in the navigation pane, click **Web App Firewall**, then in the details pane click **Web App Firewall Wizard**, and then navigate to the **Specify Rule** screen.
 - If you are configuring a policy manually, in the navigation pane, expand **Web App Firewall**, then **Policies**, and then **Firewall**. In the details pane, to create a policy, click **Add**. To modify an existing policy, select the policy, and then click **Open**.
2. On the **Specify Rule** screen, in the **Create Web App Firewall Profile** dialog box, or in the **Configure Web App Firewall Profile** dialog box, click **Add**.
 3. In the **Add Expression dialog** box, in the Construct Expression area, in the first list box, choose one of the following prefixes:
 - **HTTP**. Choose HTTP protocol if you want to examine some aspect of the request that pertains to the HTTP protocol. The default choice.
 - **SYS**. Choose protected websites if you want to examine some aspect of the request that pertains to the recipient of the request.
 - **CLIENT**. Choose the computer that sent the request if you want to examine some aspect of the sender of the request.
 - **SERVER**. Choose the computer to which the request was sent and to examine some aspect of the recipient of the request.
 4. In the second list box, choose your next term. The available terms differ depending on the choice you made in the previous step, because the dialog box automatically adjusts the list to contain only those terms that are valid for the context. For example, if you selected HTTP in the previous list box, the only choice is REQ, for requests. Because the Web App Firewall treats requests and associated responses as a single unit and filters both, you do not need to specific responses separately. After you choose your second term, a third list box appears to the right of the second. The Help window displays a description of the second term, and the **Preview Expression** window displays your expression.
 5. In the third list box, choose the next term. A new list box appears to the right, and the Help window changes to display a description of the new term. The **Preview Expression** window updates to display the expression as you have specified it to that point.
 6. Continue choosing terms, and when prompted filling in arguments, until your expression is complete. If you make a mistake or want to change your expression after you have already selected a term, you can simply choose another term. The expression is modified, and any arguments or more terms that you added after the term that you modified are cleared.
 7. When you have finished constructing your expression, click **OK** to close the **Add Expression** dialog box. Your expression is inserted into the **Expression** text area.

Binding Web App Firewall policies

September 19, 2023

After you have configured your Web App Firewall policies, you bind them to Global or a bind point to put them into effect. After binding, any request or response that matches an Web App Firewall policy is transformed by the profile associated with that policy.

When you bind a policy, you assign a priority to it. The priority determines the order in which the policies you define are evaluated. You can set the priority to any positive integer. In the NetScaler OS, policy priorities work in reverse order - the higher the number, the lower the priority.

Because the Web App Firewall feature implements only the first policy that a request matches, not any additional policies that it might also match, policy priority is important for achieving the results that you intend. If you give your first policy a low priority (such as 1000), you configure the Web App Firewall to perform it only if other policies with a higher priority do not match a request. If you give your first policy a high priority (such as 1), you configure the Web App Firewall to perform it first, and skip any other policies that might also match. You can leave yourself plenty of room to add other policies in any order, without having to reassign priorities, by setting priorities with intervals of 50 or 100 between each policy when you bind your policies.

For more information about binding policies on the NetScaler appliance, see [“Policies and Expressions.”](#)

To bind an Web App Firewall policy by using the command line interface

At the command prompt, type the following commands:

- `bind appfw global <policyName>`
- `bind appfw profile <profile_name> -crossSiteScripting data`

Example

The following example binds the policy named pl-blog and assigns it a priority of 10.

```
1 bind appfw global pl-blog 10
2 save ns config
3 <!--NeedCopy-->
```

Configure log expressions

The log expression support for binding Web App Firewall is added to log HTTP header information when violations occur.

Log expression is bound to the Web App Firewall profile. This log expression is evaluated and sent to the logging framework when a violation occurs.

The Web App Firewall violation log record with HTTP header information is recorded. You can specify a custom log expression and that helps in analysis and diagnosis when violations are generated for the current flow (request/response).

Example configuration

```

1 bind appfw profile <profile> -logexpression <string> <expression>
2 add policy expression headers "\" HEADERS(100):\"+HTTP.REQ.FULL_HEADER"
3 add policy expression body_100 "\"BODY:~\"+HTTP.REQ.BODY(100)"
4 bind appfw profile test -logExpression log_body body_100
5 bind appfw profile test -logExpression log_headers headers
6 bind appfw profile test -logExpression "\"URL:~\"+HTTP.REQ.URL+\" IP:~\"+
  CLIENT.IP.SRC"
7 <!--NeedCopy-->

```

2 <!--NeedCopy-->
```

Note

1. Only auditlog support is available. Support for logstream and visibility in security insight would be added in future release versions.
2. If auditlogs are generated, then only 1024 bytes of data can be generated per log message.
3. If log streaming is used, then the limits are based on maximum supported size of log stream/ipfix protocol size limitations. Maximum support size for log stream is larger than 1024 bytes.

To bind an Web App Firewall policy by using the GUI

1. Do one of the following:
 - Navigate to **Security > Web App Firewall**, and in the details pane, click Web App Firewall policy manager.
 - Navigate to **Security > Web App Firewall > Policies > Firewall Policies**, and in the details pane, click **Policy Manager**.
2. In the **Web App Firewall Policy Manager** dialog, choose the bind point to which you want to bind the policy from the drop-down list. The choices are:
 - **Override Global** - Policies that are bound to this bind point process traffic from all interfaces on the NetScaler appliance, and are applied before any other policies.
 - **VPN Virtual Server** - Policies that are bound to a VPN virtual server are applied to the processed traffic or a specific web app in the policy expression. After selecting the VPN virtual server, you must also select the specific VPN virtual server to which you want to bind this policy.

By binding a security policy to the VPN virtual server, you can protect all the applications behind it.

- **LB Virtual Server.** Policies that are bound to a load balancing virtual server are applied only to traffic that is processed by that load balancing virtual server, and are applied before any Default Global policies. After selecting LB Virtual Server, you must also select the specific load balancing virtual server to which you want to bind this policy.
 - **CS Virtual Server.** Policies that are bound to a content switching virtual server are applied only to traffic that is processed by that content switching virtual server, and are applied before any Default Global policies. After selecting CS Virtual Server, you must also select the specific content switching virtual server to which you want to bind this policy.
 - **Default Global.** Policies that are bound to this bind point process all traffic from all interfaces on the NetScaler appliance.
 - **Policy Label.** Policies that are bound to a policy label process traffic that the policy label routes to them. The policy label controls the order in which policies are applied to this traffic.
 - **None.** Do not bind the policy to any bind point.
3. Click **Continue**. A list of existing Web App Firewall policies appears.
 4. Select the policy you want to bind by clicking it.
 5. Make any additional adjustments to the binding.
 - To modify the policy priority, click the field to enable it, and then type a new priority. You can also select Regenerate Priorities to renumber the priorities evenly.
 - To modify the policy expression, double click that field to open the **Configure Web App Firewall Policy** dialog box, where you can edit the policy expression.
 - To set the Goto Expression, double click **field** in the Goto Expression column heading to display the drop-down list, where you can choose an expression.
 - To set the Invoke option, double click field in the Invoke column heading to display the drop-down list, where you can choose an expression
 6. Repeat steps 3 through 6 to add any additional Web App Firewall policies you want to globally bind.
 7. Click **OK**. A message appears in the status bar, stating that the policy has been successfully bound.

Viewing a policy bindings

May 2, 2023

You can quickly check to determine what bindings are in place for any firewall policy by viewing the bindings in the GUI.

To view bindings for an Web App Firewall policy

1. Navigate to **Security > NetScaler Web App Firewall > Policies > Firewall Policies**
2. In the details pane, select the policy that you want to check, and then click Show Bindings. The Binding Details for Policy: Policy message box is displayed, with a list of bindings for the selected policy.
3. Click **Close**.

Supplemental information about Web App Firewall policies

May 2, 2023

Following is supplemental information about particular aspects of Web App Firewall policies that system administrators who manage the Web App Firewall might need to know.

Correct but unexpected behavior

Web application security and modern websites are complex. In a number of scenarios, a NetScaler policy might cause the Web App Firewall to behave differently in certain situations than a user who is familiar with policies would normally expect. Following are a number of cases where the Web App Firewall may behave in an unexpected fashion.

- **Request with a missing HTTP Host header and an absolute URL.** When a user sends a request, in the majority of cases the request URL is relative. That is, it takes as its starting point the Referer URL, the URL where the user's browser is located when it sends the request. If a request is sent without a Host header, and with a relative URL, the request is normally blocked both because it violates the HTTP specification and because a request that fails to specify the host can under some circumstances constitute an attack. If a request is sent with an absolute URL, however, even if the Host header is missing, the request bypasses the Web App Firewall and is forwarded to the web server. Although such a request violates the HTTP specification, it poses no possible threat because an absolute URL contains the host.

Auditing policies

February 13, 2024

Auditing policies determine the messages generated and logged during a Web App Firewall session. The messages are logged in SYSLOG format to the local NSLOG server or to an external logging server. Different types of messages are logged based on the level of logging selected.

To create an auditing policy, you must first create either an NSLOG server or a SYSLOG server. And then you create the policy and specify log type and the server to which logs are sent.

To create an auditing server by using the command line interface

You can create two different types of auditing server: an NSLOG server or a SYSLOG server. The command names are different, but the parameters for the commands are the same.

To create an auditing server, at the command prompt, type the following commands:

- `add audit syslogAction <name> <serverIP> [-serverPort <port>] -logLevel <logLevel> ... [-dateFormat (MMDDYYYY | DDMMYYYY)] [-logFacility <logFacility>] [-tcp (NONE | ALL)] [-acl (ENABLED | DISABLED)] [-timeZone (GMT_TIME | LOCAL_TIME)] [-userDefinedAuditlog (YES | NO)] [-appflowExport (ENABLED | DISABLED)]`
- `save ns config`

Example

The following example creates a syslog server named `syslog1` at IP `10.124.67.91`, with log levels of emergency, critical, and warning, log facility set to `LOCAL1`, that logs all TCP connections:

```
1 add audit syslogAction syslog1 10.124.67.91 -logLevel emergency
   critical warning -logFacility
2 LOCAL1 -tcp ALL
3 save ns config
4 <!--NeedCopy-->
```

To modify or remove an auditing server by using the command line interface

- To modify an auditing server, type the `set audit <type>` command, the name of the auditing server, and the parameters to be changed, with their new values.

- To remove an auditing server, type the `rm audit <type>` command and the name of the auditing server.

Example

The following example modifies the syslog server named `syslog1` to add errors and alerts to the log level:

```
1 set audit syslogAction syslog1 10.124.67.91 -logLevel emergency
   critical warning alert error
2 -logFacility LOCAL1 -tcp ALL
3 save ns config
4 <!--NeedCopy-->
```

To create or configure an auditing server by using the GUI

1. Navigate to **Security > NetScaler Web App Firewall > Policies > Auditing > Nslog**.
2. In the Nslog Auditing page, click **Servers** tab.
3. Do one of the following:
 - To add a new auditing server, click **Add**.
 - To modify an existing auditing server, select the server, and then click **Edit**.
4. In the **Create Auditing Server** page, set the following parameters:
 - Name
 - Server Type
 - IP Address
 - Port
 - Log Levels
 - Log Facility
 - Date Format
 - Time Zone
 - TCP Logging
 - ACL Logging
 - User Configurable Log Messages
 - AppFlow Logging
 - Large Scale NAT Logging
 - ALG messages logging
 - Subscriber logging
 - SSL Interception
 - URL Filtering

- Content Inspection Logging

5. Click **Create** and **Close**.

To create an auditing policy by using the command line interface

You can create an NSLOG policy or a SYSLOG policy. The type of policy must match the type of server. The command names for the two types of policy are different, but the parameters for the commands are the same.

At the command prompt, type the following commands:

- `add audit syslogPolicy <name> <-rule > <action>`
- `save ns config`

Example

The following example creates a policy named syslogP1 that logs Web App Firewall traffic to a syslog server named syslog1.

```
add audit syslogPolicy syslogP1 rule "ns_true"action syslog1
save ns config
```

To configure an auditing policy by using the command line interface

At the command prompt, type the following commands:

- `set audit syslogPolicy <name> [-rule <expression>] [-action <string>]`
- `save ns config`

Example

The following example modifies the policy named syslogP1 to log Web App Firewall traffic to a syslog server named syslog2.

```
set audit syslogPolicy syslogP1 rule "ns_true"action syslog2
save ns config
```

To configure an auditing policy by using the GUI

1. Navigate to **Security > NetScaler Web App Firewall > Policies**.
2. In the details pane, click **Audit Nslog Policy**.
3. In the Nslog Auditing page, click **Policies** tab and do one of the following:
 - To add a new policy, click **Add**.
 - To modify an existing policy, select the policy, and then click **Edit**.
4. In the **Create Auditing Nslog Policy** page, set the following parameters:
 - Name
 - Auditing Type
 - Expression Type
 - Server
5. Click **Create**.

Imports

April 15, 2024

Several Web App Firewall features make use of external files that you upload to the Web App Firewall when configuring it. Using the GUI, you manage those files in the Imports pane, which has four tabs corresponding to the four types of files you can import: HTML error objects, XML error objects, XML schemas, and Web Services Description Language (WSDL) files. Using the NetScaler command line, you can import these types of files, but you cannot export them.

HTML error object

When a user's connection to an HTML or Web 2.0 page is blocked, or a user asks for a non-existent HTML or Web 2.0 page, the Web App Firewall sends an HTML-based error response to the user's browser. When configuring which error response the Web App Firewall must use, you have two choices:

- You can configure a redirect URL, which can be hosted on any Web server to which users also have access. For example, if you have a custom error page on your Web server, 404.html, you can configure the Web App Firewall to redirect users to that page when a connection is blocked.
- You can configure an HTML error object, which is an HTML-based Web page that is hosted on the Web App Firewall itself. If you choose this option, you must upload the HTML error object to the Web App Firewall. You do that in the Imports pane, on the HTML Error Object tab.

The error object must be a standard HTML file that contains no non-HTML syntax except for Web App Firewall error object customization variables. It cannot contain any CGI scripts, server-parsed code, or PHP code. The customization variables enable you to embed troubleshooting information in the error object that the user receives when a request is blocked. While most requests that the Web App Firewall blocks are illegitimate, even a properly configured Web App Firewall can occasionally block legitimate requests, especially when you first deploy it or after you make significant changes to your protected websites. By embedding information in the error page, you provide the user with the information that he or she needs to give to the technical support person so that any issues can be fixed.

The Web App Firewall error page customization variables are:

- `#{NS_TRANSACTION_ID}`. The transaction ID that the Web App Firewall assigned to this transaction.
- `#{NS_APPFW_SESSION_ID}`. The Web App Firewall session ID.
- `#{NS_APPFW_VIOLATION_CATEGORY}`. The specific Web App Firewall security check or rule that was violated.
- `#{NS_APPFW_VIOLATION_LOG}`. The detailed error message associated with the violation.
- `#{COOKIE}` The contents of the specified cookie. For `<CookieName>`, substitute the name of the specific cookie that you want to display on the error page. If you have multiple cookies whose contents you want to display for troubleshooting, you can use multiple instances of this customization variable, each with the appropriate cookie name.

Note: If you have blocking enabled for the Cookie Consistency Check, any blocked cookies are not displayed on the error page because the Web App Firewall blocks them.

To use these variables, you embed them in the HTML or XML of the error page object as if they were an ordinary text string. When the error object is displayed to the user, for each customization variable the Web App Firewall substitutes the information to which the variable refers. An example HTML error page that uses custom variables is shown below.

```

1 <!doctype html public "-//w3c//dtd html 4.0//en"> <html> <head> <
  title>Page Not Accessible</title> </head> <body> <h1>Page Not
  Accessible</h1> <p>The page that you accessed is not available. You
  can:</p> <ul> <li>return to the <b><a href="[homePage]">home page
  </a></b>, re-establish your session, and try again, or,</li> <li>
  report this incident to the help desk via <b><a href="mailto:[
  helpDeskEmailAddress]">email</a></b> or by calling [
  helpDeskPhoneNumber].</li> </ul> <p>If you contact the help desk,
  please provide the following information:</p> <table cellpadding=8
  width=80%> <tr><th align="right" width=30%>Transaction ID:</th><td
  align="left" valign="top" width=70%>${
2   NS_TRANSACTION_ID }
3 </td></tr> <tr><th align="right" width=30%>Session ID:</th><td align=
  "left" valign="top" width=70%>${
4   NS_APPFW_SESSION_ID }

```

```

5  </td></tr> <tr><th align="right" width=30%>Violation Category:</th><
      td align="left" valign="top" width=70%>${
6  NS_APPFW_VIOLATION_CATEGORY }
7  </td></tr> <tr><th align="right" width=30%>Violation Log:</th><td
      align="left" valign="top" width=70%>${
8  NS_APPFW_VIOLATION_LOG }
9  </td></tr> <tr><th align="right" width=30%>Cookie Name:</th><td align
      ="left" valign="top" width=70%>${
10 COOKIE("[cookieName]") }
11 </td></tr> </table> <body> <html>
12 <!--NeedCopy-->

```

To use this error page, copy it into a text or HTML editor. Substitute the appropriate local information for the following variables, which are enclosed in square brackets to distinguish them from the NetScaler variables. (Leave those unchanged.):

- `[homePage]`. The URL for your website's home page.
- `[helpDeskEmailAddress]`. The email address that you want users to use to report blocking incidents.
- `[helpDeskPhoneNumber]`. The phone number that you want users to call to report blocking incidents.
- `[cookieName]`. The name of the cookie whose contents you want to display on the error page.

XML error object

When a user's connection to an XML page is blocked, or a user asks for a nonexistent XML application, the Web App Firewall sends an XML-based error response to the user's browser. You configure the error response by uploading an XML-based error page to the Web App Firewall in the Imports Pane, on the XML Error Object tab. All XML error responses are hosted on the Web App Firewall. You cannot configure a redirect URL for XML applications.

Note:

You can use the same customization variables in an XML error object as in an HTML error object.

XML Schema

When the Web App Firewall performs a validation check on a user's request for an XML or Web 2.0 application, it can validate the request against the XML schema or design type document (DTD) for that application and reject any request that does not follow the schema or DTD. Both an XML schema and a DTD are standard XML configuration files that describe the structure of a specific type of XML document.

WSDL

When the Web App Firewall performs a validation check on a user's request for an XML SOAP-based web service, it can validate the request against the web services type definition (WSDL) file for that web service. A WSDL file is a standard XML SOAP configuration file that defines the elements of a specific XML SOAP web service.

API Specification Import Object

API specification defines the design of an API, including endpoints, methods, parameters, and data formats. The import API specification capability allows you to import the open API specification, which is generally used to describe the REST API. When the Web App Firewall performs a validation check on a user's request for an API-based web service, it validates the request against the schema specified in the API specification file for that web service. NetScaler supports schema validations for a REST API with payload being application JSON and ProtoBuf for gRPC API requests.

NetScaler supports the following specification formats:

- Open API - Swagger 2.0, OAS 3.0,3.1
- ProtoBuf - v3 and v2

For more information, see [API Specification Import](#).

Import and export files

April 15, 2024

You can import HTML or XML error objects, XML schemas, DTDs, and WSDLs to the Web App Firewall by using the GUI or the command line. You can edit any of these files in a web-based text area after importing them, to make small changes directly on the NetScaler instead of having to make them on your computer and then reimport them. Finally, you can export any of these files to your computer, or delete any of these files, by using the GUI.

Note:

You cannot delete or export an imported file by using the command line.

To import a file by using the command line interface

At the command prompt, type the following commands:

- **import** appfw htmlerrorpage <src> <name>
- <save> ns config

Example

The following example imports an HTML error object from a file named error.html and assigns it the name HTMLError.

```
1 import htmlerrorpage error.html HTMLError
2 save ns config
3 <!--NeedCopy-->
```

To import a file by using the GUI

Before you attempt to import an XML schema, DTD, or WSDL file, or an HTML or XML error object from a network location, verify that the NetScaler can connect to the Internet or LAN computer where the file is located. Otherwise, you cannot import the file or object.

1. Navigate to **Security > NetScaler Web App Firewall > Imports**.
2. Navigate to **Application Firewall > Imports**.
3. In the **Application Firewall Imports** pane, select the tab for the type of file you want to import, and then click **Add**.

The tabs are HTML Error Page, XML Error Page, XML Schema or WSDL. The upload process is identical on all four tabs from the user point of view.

4. Fill in the dialog fields.
 - **Name**—A name for the imported object.
 - **Import From**—Choose the location of the HTML file, XML file, XML schema or WSDL that you want to import in the drop-down list:
 - **URL**: A web URL on a website accessible to the appliance.
 - **File**: A file on a local or networked hard disk or other storage device.
 - **Text**: Type or paste the text of the custom response directly into a text field in the GUI.

The third text box changes to the appropriate value. The three possible values are provided below.

- **URL**—Type the URL into the text box.
- **File**—Type the path and filename to the HTML file directly, or click Browse and browse to the HTML file.

- **Text**—The third field is removed, leaving a blank space.
5. Click **Continue**. The File Contents dialog is displayed. If you chose URL or File, the File Contents text box contains the HTML file that you specified. If you chose Text, the File Contents text box is empty.
 6. If you chose Text, type or copy and paste the custom response HTML that you want to import.
 7. Click **Done**.
 8. To delete an object, select the object, and then click **Delete**.

To export a file by using the GUI

Before you attempt to export an XML schema, DTD, or WSDL file, or an HTML or XML error object, verify that the Web App Firewall appliance can access the computer where the file is to be saved. Otherwise, you cannot export the file.

1. Navigate to **Security > Web App Firewall > Imports**.
2. In the **Web App Firewall Imports** pane, select the tab for the type of file you want to export.
The export process is identical on all four tabs from the user point of view.
3. Select the file that you want to export.
4. Expand the Action drop-down list, and select **Export**.
5. In the dialog box, choose **Save File** and click **OK**.
6. In the **Browse** dialog box, navigate to the local file system and directory where you want to save the exported file, and click **Save**.

To edit an HTML or XML Error Object in the GUI

You edit the text of HTML and XML error objects in the GUI without exporting and then reimporting them.

1. Navigate to **Security > NetScaler Web App Firewall > Imports**, and then select the tab for the type of file that you want to modify.
2. Navigate to **Application Firewall > Imports**, and then select the tab for the type of file that you want to modify.
3. Select the file that you want to modify, and then click **Edit**.

The text of the HTML or XML error object is displayed in a browser text area. You can modify the text by using the standard browser-based editing tools and methods for your browser.

Note: The edit window is designed to allow you to make minor changes to your HTML or XML error object. To make extensive changes, you may prefer to export the error object to your local computer and use standard HTML or XML web page editing tools.

4. Click **OK**, and then click **Close**.

Global configuration

December 4, 2020

The Web App Firewall global configuration affects all profiles and policies. The Global Configuration items are:

- **Engine Settings.** A collection of global settings—session cookie name, session time-out, maximum session lifetime, logging header name, undefined profile, default profile, and import size limit—that pertain to all connections that the Web App Firewall processes, rather than to a specific subset of connections.
- **Confidential Fields.** A set of form fields in web forms that contain sensitive information that must not be logged to the Web App Firewall logs. Form fields such as password fields on a logon page or credit card information on a shopping cart checkout form are normally designated as confidential fields.
- **Field Types.** The list of web form field types used by the Field Formats security check. Each of these field types is defined by a PCRE-compliant regular expression that defines the type of data and the minimum/maximum length of data that must be allowed in that type of form field.
- **XML Content Types.** The list of content types recognized as XML and subjected to XML-specific security checks. Each of these content types is defined by a PCRE-compliant regular expression that defines the exact MIME type assigned to that content.
- **JSON Content Types.** The list of content types recognized as JSON and subjected to JSON-specific security checks. Each of these content types is defined by a PCRE-compliant regular expression that defines the exact MIME type assigned to that content.

Engine settings

May 2, 2023

The engine settings affect all requests and responses that the NetScaler Web App Firewall processes. Following are the settings:

- **Cookie name**—The name of the cookie that stores the NetScaler session ID.
- **Session timeout**—The maximum inactive period allowed. If a user session shows no activity for this length of time, the session is terminated and the user is required to reestablish it by visiting a designated start page.
- **Cookie post-encrypts prefix**—The string that precedes the encrypted portion of any encrypted cookies.
- **Maximum session lifetime**—The maximum amount of time, in seconds, that a session is allowed to remain live. After this period is reached, the session is terminated and the user is required to reestablish it by visiting a designated start page. This setting cannot be less than the session timeout. To disable this setting, so that there is no maximum session lifetime, set the value to zero (0).
- **Logging header name**—The name of the HTTP header that holds the Client IP, for logging.
- **Undefined profile**—The profile applied when the corresponding policy action evaluates as undefined.
- **Default profile**—The profile applied to connections that do not match a policy.
- **Import size limit**—The maximum byte count of all files imported to the appliance, including signatures, WSDLs, schemas, HTML, and XML error pages. During an import, if the size of the imported object causes the cumulative count of all imported files to exceed the configured limit, the import operation fails. And the appliance displays the following error message: “*ERROR: Import failed - exceeding the configured total size limit on the imported objects*”.
- **Learn message rate limit**—The maximum number of requests and responses per second that the learning engine is to process. Any additional requests or responses over this limit are not sent to the learning engine.
- **Proxy Server** - A proxy server is an intermediate server that retrieves data from the internet on behalf of the user. It provides as an additional layer of security for your appliance. The NetScaler appliance that has proxy authentication enabled authenticates itself with the proxy server before downloading the updates from the internet. This way, it protects the appliances from malicious downloads. Configure the following parameters:
 - **Proxy Server** –The IP address of the proxy server from which the latest AWS signatures are downloaded.
 - **Proxy Port** - The port number of the proxy server from which the latest AWS signatures are downloaded.
 - **Proxy Username** - The port number of the proxy server from which the latest AWS signatures are downloaded.
 - **Proxy Password** - Password to authenticate to the proxy server for downloading signature updates.
- **Entity decoding**—Decode HTML entities when running Web App Firewall checks.
- **Log malformed request**—Enable logging of malformed HTTP requests.
- **Use configurable secret key**—Use a configurable secret key for Web App Firewall operations.

This secret key is used for signing and verifying data. When “useConfigurableSecretKey” is turned ON, you must use the key enabled in the “set ns encryptionParams” parameter.

- **Reset learned data**—Remove all learned data from the Web App Firewall. Restarts the learning process by collecting fresh data.

Two settings, *Reset Learned Data* and *Signatures Auto-Update*, are found in different places depending on whether you use the command interface or the NetScaler GUI to configure your NetScaler Web App Firewall. When using the command interface, you configure Reset Learned Data by using the `reset appfw learning data` command. This takes no parameters and has no other functions. You can configure the signature auto-Update in the `set appfw settings` command. The `-signatureAutoUpdate` parameter enables or disables auto-updating of the signatures, and `-signatureUrl` configures the URL which hosts the updated signatures file.

When using the NetScaler GUI, you configure Reset Learned Data in **Security > NetScaler Web App Firewall > Engine Settings**. The **Reset Learned Data** option is at the bottom of the dialog box. You configure Signatures Auto-Update for each set of signatures in **Security > NetScaler Web App Firewall > Signatures**, by selecting the signatures file, clicking the right mouse button and selecting **Auto Update Settings**.

Normally, the default values for the **Web App Firewall** settings are correct. If the default settings cause a conflict with other servers or cause premature disconnection of your users, however, you have to modify them.

The **Web App Firewall** session limit is configurable using the following command:

```
1 > set appfw settings -sessionLimit 500000
2
3 Done
4
5 Default value:100000    Max value:500000 per PE
6 <!--NeedCopy-->
```

To configure engine settings by using the command line interface

At the command prompt, type the following commands:

- `set appfw settings [-sessionCookieName <name>] [-sessionTimeout <positiveInteger>] [-sessionLifetime <positiveInteger>][-clientIPLoggingHeader <headerName>] [-undefaction <profileName>] [-defaultProfile <profileName>] [-importSizeLimit <positiveInteger>] [-logMalformedReq (ON | OFF)] [-signatureAutoUpdate (ON | OFF)] [-signatureUrl <expression>] [-cookiePostEncryptPrefix <string>] [-entityDecoding (ON | OFF)] [-useConfigurableSecretKey (ON | OFF)] [-learnRateLimit <positiveInteger>] [-proxyServer <`

```
proxy server ip>] [-proxyPort <proxy server port>] [-proxyUsername  
  <username>] [-proxyPassword <password>]
```

- save ns config

Example

```
1 set appfw settings -sessionCookieName citrix-appfw-id -sessionTimeout  
  3600  
2 -sessionLifetime 14400 -clientIPLoggingHeader NS-AppFW-Client-IP -  
  undefaction APPFW_RESET  
3 -defaultProfile APPFW_RESET -importSizeLimit 4096 -proxyServer  
  10.102.30.112 -proxyPort 3128 -proxyUsername defaultusername -  
  proxyPassword defaultpassword  
4 save ns config  
5 <!--NeedCopy-->
```

To configure engine settings by using the NetScaler GUI

1. Navigate to **Security > NetScaler Web App Firewall**
2. In the details pane, click **Change Engine Settings** under **Settings**.
3. In the **Web App Firewall Engine Settings** dialog box, set the following parameters:
 - Cookie Name
 - Session Timeout
 - Cookie Post Encrypt Prefix
 - Maximum Session Lifetime
 - Logging Header Name
 - Undefined Profile
 - Default Profile
 - Import Size Limit
 - Learn Messages Rate Limit
 - Proxy Server
 - Proxy Port
 - Proxy Username
 - Proxy Password
 - Entity Decoding
 - Log Malformed Request
 - Use Secret Key
 - Learn Message Rate Limit
 - Signatures Auto Update

4. Click **OK**.

Confidential fields

May 2, 2023

You can designate web-form fields as confidential to protect the information users type into them. Normally, any information a user types into a web form on one of your protected web servers is logged in the NetScaler logs. The information typed into a web-form field designated as confidential, however, is not logged. That information is saved only where the website is configured to save such data, normally in a secure database.

Common types of information that you may want to protect with a confidential field designation include:

- Passwords
- Credit card numbers, validation codes, and expiration dates
- Social security numbers
- Tax ID numbers
- Home addresses
- Private telephone numbers

In addition to being good practice, proper use of confidential field designations may be necessary for PCI-DSS compliance on ecommerce servers, HIPAA compliance on servers that manage medical information in the United States, and compliance with other data protection standards.

Important:

In the following two cases, the Confidential Field designation does not function as expected:

- If a Web form has either a confidential field or an action URL longer than 256 characters, the field or action URL is truncated in the NetScaler logs.
- With certain SSL transactions, the logs are truncated if either the confidential field or the action URL is longer than 127 characters.

In either of these cases, the Web App Firewall masks a fifteen-character string with the letter “x,” instead of the normal eight character string. To ensure that any confidential information is removed, the user must use form field name and action URL expressions that match the first 256, or (in cases where SSL is used) the first 127 characters.

To configure your Web App Firewall to treat a web-form field on a protected website as confidential, you add that field to the Confidential Fields list. You can enter the field name as a string, or you can enter a PCRE-compatible regular expression specifying one or more fields. You can enable the confidential-field designation when you add the field, or you can modify the designation later.

Note

From release 13.1 build 27.x, confidential fields are also supported in WAF profiles. For more information, see [Confidential fields in WAF profile](#).

To add a confidential field by using the command line interface

At the command prompt, type the following commands:

- `add appfw confidField <fieldName> <url> [-isRegex (REGEX | NOTREGEX)] [-comment "<string>"] [-state (ENABLED | DISABLED)]`
- `save ns config`

Example

The following example adds all web form fields whose names begin with Password to the confidential fields list.

```
1 add appfw confidField Password "https?://www[.]example[.]com/[^<>]*[^a-z]password[0-9a-z._-]*[.](asp|cgi|htm|html|http|js|php)" -isRegex
  REGEX -state ENABLED
2 save ns config
3 <!--NeedCopy-->
```

To modify a confidential field by using the command line interface

At the command prompt, type the following commands:

- `set appfw confidField <fieldName> <url> [-isRegex (REGEX | NOTREGEX)][-comment "<string>"] [-state (ENABLED | DISABLED)]`
- `save ns config`

Example

The following example modifies the confidential field designation to add a comment.

```
1 set appfw confidField Password "https?://www[.]example[.]com/[^<>]*[^\a-z]password[0-9a-z._-]*[.](asp|cgi|htm|html|http|js|php)" -comment "
  Protect password fields." -isRegex REGEX -state ENABLED
2 save ns config
3 <!--NeedCopy-->
```

To remove a confidential field by using the command line interface

At the command prompt, type the following commands:

- `rm appfw confidField <fieldName> <url>`
- `save ns config`

To configure a confidential field by using the GUI

1. Navigate to **Security > Application Firewall**.
2. In the details pane, under **Settings**, click **Manage Confidential Fields**.
3. In the Manage Confidential Fields dialog box, do one of the following:
 - To add a new form field to the list, click **Add**.
 - To change an existing confidential field designation, select the field, and then click **Edit**. The **Web App Firewall Confidential Fields** dialog box appears.

Note:

If you select an existing confidential field designation and then click **Add**, the **Create Confidential Form Field** dialog box displays the information for that confidential field. You can modify that information to create your new confidential field.

4. In the dialog box, fill out the elements. They are:
 - **Enabled check box.** Select or clear to enable/disable this confidential field designation.

- **Is form field name a regular expression check box.** Select or clear to enable PCRE-format regular expressions in the form field name.
 - **Field Name.** Enter a literal string or PCRE-format regular expression that either represents a specific field name or that matches multiple fields with names that follow a pattern.
 - **Action URL.** Enter a literal URL or a regular expression that defines one or more URLs of the web page(s) on which the web form(s) that contains the confidential field are located.
 - **Comments.** Enter a comment. Optional.
5. Click **Create** or **OK**.
 6. To remove a confidential field designation from the confidential fields list, select the confidential field listing you want to remove, then click Remove to remove it, and then click **OK** to confirm your choice.
 7. When you have finished adding, modifying, and removing confidential field designations, click **Close**.

Examples

Following are some regular expressions that define form field names that you might find useful:

- `^passwd_` (Applies confidential-field status to all field names that begin with the “passwd_” string.)
- `^((\[0-9a-zA-Z._-]*|\x\[0-9A-Fa-f][0-9A-Fa-f])+)?passwd_` (Applies confidential-field status to all field names that begin with the string `passwd_`, or that contain the string `-passwd_` after another string that might contain non-ASCII special characters.)

Following are some regular expressions that define specific URL types that you might find useful. Substitute your own web host(s) and domain(s) for those in the examples.

- If the web form appears on multiple web pages on the web host `www.example.com`, but all of those web pages are named `logon.pl?`, you can use the following regular expression:

```
1 https?://www[.]example[.]com/([0-9A-Za-z][0-9A-Za-z_.-]*)*logon
  [.]pl\?
2 <!--NeedCopy-->
```

- If the web form appears on multiple web pages on the web host `www.example-español.com`, which contains the n-tilde (ñ) special character, you can use the following regular expression, which represents the n-tilde special character as an encoded UTF-8 string containing C3 B1, the hexadecimal code assigned to that character in the UTF-8 charset:

```

1 https?://www[.]example-espá\xC3\xB1oł[.]com/([0-9A-Za-z][0-9A-Za-z_-.]*)*/logon[.]pl\?
2 <!--NeedCopy-->

```

- If the web form containing query.pl appears on multiple web pages on different hosts within the example.com domain, you can use the following regular expression:

```

1 https?://([0-9A-Za-z][0-9A-Za-z_-.]*)example[.]com/([0-9A-Za-z][0-9A-Za-z_-.]*)*/logon[.]pl\?
2 <!--NeedCopy-->

```

- If the web form containing query.pl appears on multiple web pages on different hosts in different domains, you can use the following regular expression:

```

1 https?://([0-9A-Za-z][0-9A-Za-z_-.]*)*([a-z]{2,6})*/([0-9A-Za-z][0-9A-Za-z_-.]*)*/logon[.]pl\?
2 2,6 }
3 /([0-9A-Za-z][0-9A-Za-z_-.]*)*/logon[.]pl\?
4 <!--NeedCopy-->

```

- If the web form appears on multiple web pages on the web host www.example.com, but all of those web pages are named logon.pl?, you can use the following regular expression:

```

1 https?://www[.]example[.]com/([0-9A-Za-z][0-9A-Za-z_-.]*)*/logon[.]pl\?
2 <!--NeedCopy-->

```

Field types

December 4, 2020

A field type is a PCRE-format regular expression that defines a particular data format and minimum/-maximum data lengths for a form field in a web form. Field types are used in the Field Formats check.

The Web App Firewall comes with several default field types, which are:

- integer. A string of any length consisting of numbers only, without a decimal point, and with an optional preceding minus sign (-).
- alpha. A string of any length consisting of letters only.
- alphanum. A string of any length consisting of letters and/or numbers.
- nohtml. A string of any length consisting of characters, including punctuation and spaces, that does not contain HTML symbols or queries.

- any. Anything at all.

Important:

Assigning the any field type as the default field type, or to a field, allows active scripts, SQL commands, and other possibly dangerous content to be sent to your protected websites and applications in that form field. You must use the any type sparingly, if you use it at all.

You can also add your own field types to the Field Types list. For example, you might want to add a field type for a social security number, postal code, or phone number in your country. You might also want to add a field type for a customer identification number or store credit card number.

To add a field type to the Field Types list, you enter the field name as a literal string or PCRE-format regular expression.

To add a field type by using the command line interface

At the command prompt, type the following commands:

- `add appfw fieldType <name> <regex> <priority> [-comment "<string>"]`
- `save ns config`

Example

The following example adds a field type named SSN that matches US Social Security numbers to the Field Types list, and sets its priority to 1.

```
1 add appfw fieldType SSN "[1-9][0-9]{
2 2,2 }
3 -[0-9 ]
4 {
5 2,2 }
6 -[0-9]{
7 4,4 }
8 $" 1
9 save ns config
10 <!--NeedCopy-->
```

To modify a field type by using the command line interface

At the command prompt, type the following commands:

- `set appfw fieldType <name> <regex> <priority> [-comment "<string>"]`

- `save ns config`

Example

The following example modifies the field type to add a comment.

```
1 set appfw fieldType SSN "[1-9][0-9]{
2   2,2 }
3   -[0-9 ]
4   {
5     2,2 }
6   -[0-9]{
7     4,4 }
8   $" 1 -comment "US Social Security Number"
9 save ns config
10 <!--NeedCopy-->
```

To remove a field type by using the command line interface

At the command prompt, type the following commands:

- `>rm appfw fieldType <name>`
- `save ns config`

To configure a field type by using the GUI

1. Navigate to Security > Application Firewall.
2. In the details pane, under **Settings**, click **Manage Field Types**.
3. In the **Manage Field Types** dialog box, do one of the following:
 - To add a new field type to the list, click **Add**.
 - To change an existing field type, select the field type, and then click **Edit**.
The **Configure Field Type** dialog box appears.

Note:

If you select an existing field type designation and then click **Add**, the dialog box displays the information for that field type. You can modify that information to create your new field type.

4. In the dialog box, fill out the elements. They are:
 - Name

- Regular Expression
 - Priority
 - Comment
5. Click Create or OK.
 6. To remove a field type from the Field Types list, select the field type listing you want to remove, then click **Remove** to remove it, and then click **OK** to confirm your choice.
 7. When you have finished adding, modifying, and removing field types, click **Close**.

Examples

Following are some regular expressions for field types that you might find useful:

`^[1-9][0-9]{ 2,2 } -[0-9] { 2,2 } -[0-9]{ 4,4 } $` U.S. Social Security numbers

`^[A-C]\[0-9\]{ 7,7 } $` California driver's license numbers

`^[+][0-9]{ 1,3 } [0-9()-]{ 1,40 } $` International phone numbers with country codes

`^[0-9]{ 5,5 } -[0-9]{ 4,4 } $` U.S. ZIP code numbers

`^[0-9A-Za-z][0-9A-Za-z._-]{ 0,25 } @[0-9A-Za-z][0-9A-Za-z_-]*[.]{ 1,4 } [A-Za-z]{ 2,6 } $` Email addresses

XML content types

January 11, 2021

By default, the Web App Firewall treats files that follow certain naming conventions as XML. You can configure the Web App Firewall to examine web content for additional strings or patterns that indicate that those files are XML files. This can ensure that the Web App Firewall recognizes all XML content on your site, even if certain XML content does not follow normal XML naming conventions, ensuring that XML content is subjected to XML security checks.

To configure the XML content types, you add the appropriate patterns to the XML Content Types list. You can enter a content type as a string, or you can enter a PCRE-compatible regular expression specifying one or more strings. You can also modify the existing XML content types patterns.

To add an XML content type pattern by using the command line interface

At the command prompt, type the following commands:

- `add appfw XMLContentType <XMLContenttypevalue> [-isRegex (REGEX | NOTREGEX)]`
- `save ns config`

Example

The following example adds the pattern `.*/xml` to the XML Content Types list and designates it as a regular expression.

```
1 add appfw XMLContentType ".*xml" -isRegex REGEX
2 <!--NeedCopy-->
```

To remove an XML content type pattern by using the command line interface

At the command prompt, type the following commands:

- `rm appfw XMLContentType <XMLContenttypevalue>`
- `save ns config`

To configure the XML content type list by using the GUI

1. Navigate to **Security > Web App Firewall**.
2. In the details pane, under **Settings**, click **Manage XML Content Types**.
3. In the **Manage XML Content Types** dialog box, do one of the following:
 - To add a new XML content type, click **Add**.
 - To modify an existing XML content type, select that type and then click **Edit**.
The Configure Web App Firewall XML Content Type dialog appears. Note: If you select an existing XML content type pattern and then click **Add**, the dialog box displays the information for that XML content type pattern. You can modify that information to create your new XML content type pattern.
4. In the dialog box, fill out the elements. They are:
 - **IsRegex**. Select or clear to enable PCRE-format regular expressions in the form field name.
 - **XML Content Type** Enter a literal string or PCRE-format regular expression that matches the XML content type pattern that you want to add.
5. Click **Create**.
6. To remove an XML content type pattern from the list, select it, then click **Remove** to remove it, and then click **OK** to confirm your choice.
7. When you have finished adding and removing XML content type patterns, click **Close**.

JSON content types

January 11, 2021

By default, the Web App Firewall treats files with the content type “application/json” as JSON files. The default setting enables the Web App Firewall to recognize JSON content in requests and responses, and to handle that content appropriately.

You can configure the Web App Firewall to examine web content for additional strings or patterns that indicate that those files are JSON files. This can ensure that the Web App Firewall recognizes all JSON content on your site, even if certain JSON content does not follow normal JSON naming conventions, ensuring that JSON content is subjected to JSON security checks.

To configure the JSON content types, you add the appropriate patterns to the JSON Content Types list. You can enter a content type as a string, or you can enter a PCRE-compatible regular expression specifying one or more strings. You can also modify the existing JSON content types patterns.

To add a JSON content type pattern by using the command line interface

At the command prompt, type the following commands:

- `add appfw JSONContentType <JSONContenttypevalue> [-isRegex (REGEX | NOTREGEX)]`
- `save ns config`

Example

The following example adds the pattern `*/json` to the JSON Content Types list and designates it as a regular expression.

```
1 add appfw JSONContentType "*/json" -isRegex REGEX
2 <!--NeedCopy-->
```

To configure the JSON content type list by using the GUI

1. Navigate to **Security > Application Firewall**.
2. In the details pane, under **Settings**, click **Manage JSON Content Types**.
3. In the Manage JSON Content Types dialog box, do one of the following:
 - To add a new JSON content type, click **Add**.

- To modify an existing JSON content type, select that type and then click **Edit**. The Configure Web App Firewall JSON Content Type dialog appears.
Note: If you select an existing JSON content type pattern and then click **Add**, the dialog box displays the information for that JSON content type pattern. You can modify that information to create your new JSON content type pattern.
4. In the dialog box, fill out the elements. They are:
 - **IsRegex**. Select or clear to enable PCRE-format regular expressions in the form field name.
 - **JSON Content Type** Enter a literal string or PCRE-format regular expression that matches the JSON content type pattern that you want to add.
 5. Click **Create** or **OK**.
 6. To remove a JSON content type pattern from the list, select it, then click **Remove** to remove it, and then click **OK** to confirm your choice.
 7. When you have finished adding and removing XML content type patterns, click **Close**.

Statistics and reports

May 2, 2023

The information maintained in the logs and statistics, and displayed in the reports, provides important guidance for configuring and maintaining the Web App Firewall.

The Web App Firewall statistics

When you enable the statistics action for Web App Firewall signatures or security checks, the Web App Firewall maintains information about connections that match that signature or security check. You can view the accumulated statistics information on the

Monitoring tab by selecting one of the following choices in the Select Group list box:

- **Web App Firewall**. A summary of all statistics information gathered by your Web App Firewall appliance for all profiles.
- **Web App Firewall (per profile)**. The same information, but displayed per-profile rather than summarized.

You can use this information to monitor how your Web App Firewall is operating and determine whether there is any abnormal activity or abnormal amounts of hits on a signature or security check. If you see such a pattern of abnormal activity, you can check the logs for that signature or security check to diagnose and take corrective action.

Relaxation hit statistical counter

Based on the relaxation that is applied on the violated traffic, you can also display statistical details such as the number of times a violation is occurring on the appliance, number of relaxation rules applied at the time of violation, and its last applied timestamp. By performing this, the centralized learning engine can automatically deletes unused or redundant relaxation bindings. For more information, see [WAF Learn Engine](#) topic.

The relaxation hit statistical counter is available only for the following security checks.

- Cross-site scripting
- SQL Injection
- Cookie consistency
- JSON SQL
- JSON Cross-site scripting
- JSON DoS
- JSON CMD injection
- Cross-Site request forgery
- Field format
- Starturl
- Denyurl
- Content-Type protection

To display statistics for relaxation rule hit counters by using the CLI

At the command prompt, type:

```
stat appfw profile p1
```

Example:

```
stat appfw profile p1 -fullvalues
```

Starturl Rules Statistics

| Rule | hits | Rate | last hit time |
|--------------|------|------|---------------|
| 87a4...51177 | 0 | 0 | Thu ...1970 |
| 5b83...dc12a | 0 | 0 | Thu ...1970 |
| 12345 | 0 | 0 | Thu ...1970 |

To display statistics for relaxation rule hit counters by using the GUI

Complete the following steps to view the relaxation rule hit counter statistics:

1. Navigate to **Security > NetScaler Web App Firewall > Profiles**.
2. In the details pane, select a **Web App Firewall profile** and click **Statistics**.
3. The **NetScaler Web App Firewall Statistics** page displays the statistics details.
4. You can select Tabular View or switch to Graphical View to display the data in a tabular or graphical format.

The Web App Firewall Reports

The Web App Firewall reports provide information about your Web App Firewall configuration and how it is handling traffic for your protected websites.

The PCI DSS report

The Payment Card Industry (PCI) Data Security Standard (DSS), version 1.2, consists of 12 security criteria that most credit card companies require businesses who accept online payments through credit and debit cards to meet. The criteria is designed to prevent identity theft, hacking, and other types of fraud. If an ISP does not meet the PCI DSS criteria, the ISP or merchant might lose authorization to accept credit card payments through the website.

ISPs and online merchants prove that they are in compliance with PCI DSS by having an audit conducted by a PCI DSS Qualified Security Assessor (QSA) Company. The PCI DSS report is designed to assist them both before and during the audit. Before the audit, it shows which Web App Firewall settings are relevant to PCI DSS, how they must be configured, and (most important) whether your current Web App Firewall configuration meets the standard. During the audit, the report can be used to demonstrate compliance with a relevant PCI DSS criteria.

The PCI DSS report consists of a list of those criteria that are relevant to your Web App Firewall configuration. Under each criterion, it lists your current configuration options, indicates whether your current configuration complies with the PCI DSS criterion, and explains how to configure the Web App Firewall so that your protected websites are in compliance with the criterion.

The PCI DSS report is located under **System > Reports**. To generate the report as an Adobe PDF file, click **Generate PCI DSS Report**. Depending on your browser settings, the report is displayed in the pop-up window or you are prompted to save it to your hard disk.

Note:

To view this and other reports, you must have the Adobe Reader program installed on your com-

puter.

The PCI DSS report consists of the following sections:

- **Description.** A description of the PCI DSS Compliance Summary report.
- **Firewall License and Feature Status.** Tells you whether the Web App Firewall is licensed and enabled on your NetScaler appliance.
- **Executive Summary.** A table that lists the PCI DSS criteria and tells you which of those criteria are relevant to the Web App Firewall.
- **Detailed PCI DSS Criteria Information.** For each PCI DSS criterion that is relevant to your Web App Firewall configuration, the PCI DSS report provides a section that contains information about whether your configuration is in compliance and, if it is not, how to bring it into compliance.
- **Configuration.** Data for individual profiles, which you access either by clicking Web App Firewall Configuration at the top of the report, or directly from the Reports pane. The Web App Firewall Configuration report is the same as the PCI DSS report, with the PCI DSS-specific summary omitted.

The Web App Firewall configuration report

The Web App Firewall Configuration report is located under **System > Reports**. To display it, click **Generate Web App Firewall Configuration Report**. Depending on your browser settings, the report is displayed in the pop-up window or you are prompted to save it to your hard disk.

The Web App Firewall Configuration report starts with a Summary page, which consists of the following sections:

- **Web App Firewall Policies.** A table that lists your current Web App Firewall policies, showing the policy name, the content of the policy, the action (or profile) it is associated with, and global binding information.
- **Web App Firewall Profiles.** A table that lists your current Web App Firewall profiles and indicates which policy each profile is associated with. If a profile is not associated with a policy, the table displays INACTIVE in that location.

To download all report pages for all policies, at the top of the Profiles Summary page click **Download All Profiles**. You display the report page for each individual profile by selecting that profile in the table at the bottom of the screen. The Profile page for an individual profile shows whether each check action is enabled or disabled for each check, and the other configuration settings for the check.

To download a PDF file containing the PCI DSS report page for the current profile, click **Download Current Profile** at the top of the page. To return to the Profiles Summary page, click **Web App Fire-**

wall Profiles. To go back to the main page, click **Home**. You can refresh the PCI DSS report at any time by clicking **Refresh** in the upper right corner of the browser.

Web App Firewall logs

February 13, 2024

The Web App Firewall generates log messages for tracking configuration, policy invocation, and security check violation details.

When you enable the log action for security checks or signatures, the resulting log messages provide information about the requests and responses that the Web App Firewall has observed when protecting your websites and applications. The most important information is the action taken by the Web App Firewall when a signature or a security check violation was observed. For some security checks, the log message can provide useful information, such as, user location or detected pattern that triggered a violation. An excessive increase in the number of violation messages in the logs can indicate a surge in malicious requests. The message alerts you that your application might be under attack to exploit a specific vulnerability that is detected and thwarted by Web App Firewall protections.

Note:

If you want to segregate NetScaler Web App Firewall logs from the System Logs, you must use an external SYSLOG server.

NetScaler (Native) format logs

The Web App Firewall uses the NetScaler format logs (also called native format logs) by default. These logs have the same format as those generated by other NetScaler features. Each log contains the following fields:

- **Timestamp.** Date and time when the connection occurred.
- **Severity.** Severity level of the log.
- **Module.** NetScaler module that generated the log entry.
- **Event Type.** Type of event, such as signature violation or security check violation.
- **Event ID.** ID assigned to the event.
- **Client IP.** IP address of the user whose connection was logged.
- **Transaction ID.** ID assigned to the transaction that caused the log.
- **Session ID.** ID assigned to the user session that caused the log.
- **Message.** The log message. Contains information identifying the signature or security check that triggered the log entry.

You can search for any of these fields, or any combination of information from different fields. Your selection is limited only by the capabilities of the tools you use to view the logs. You can observe the Web App Firewall log messages in the GUI by accessing the NetScaler syslog viewer, or you can manually connect to the NetScaler appliance and access logs from the command line interface, or you can drop into the shell and tail the logs directly from the `/var/log/` folder.

Example of a native format log message

```

1 Jun 22 19:14:37 <local0.info> 10.217.31.98 06/22/2015:19:14:37 GMT ns

9 <!--NeedCopy-->

```

Common Event Format (CEF) logs

The Web App Firewall also supports CEF logs. CEF is an open log management standard that improves the interoperability of security-related information from different security and network devices and applications. CEF enables customers to use a common event log format so that data can be easily collected and aggregated for analysis by an enterprise management system. The log message is broken into different fields so that you can easily parse the message and write scripts to identify important information.

Analyzing the CEF Log Message

In addition to date, timestamp, client IP, log format, appliance, company, build version, module, and security check information, Web App Firewall CEF log messages include the following details:

- src –source IP address
- spt –source port number
- request –request URL
- act –action (for example blocked, transformed)
- msg –message (Message regarding the observed security check violation)
- Offset - represents the bytes from the beginning of the file.
- cn1 –event ID
- cn2 –HTTP Transaction ID
- cs1 –profile name

- cs2 –PPE ID (for example PPE1)
- cs3 - Session ID
- cs4 –Severity (for example INFO, ALERT)
- cs5 –event year
- cs6 - Signature Violation Category
- method –Method (for example GET/POST)

For example, consider the following CEF format log message, which was generated when a Start URL violation was triggered:

```

1 Jun 12 23:37:17 <local0.info> 10.217.31.98 CEF:0|Citrix|NetScaler|NS11
  .0
2 |APPFW|APPFW_STARTURL|6|src=10.217.253.62 spt=47606 method=GET
3 request=http://aaron.stratum8.net/FFC/login.html msg=Disallow Illegal
  URL. cn1=1340
4 cn2=653 cs1=pr_ffc cs2=PPE1 cs3=EsdGd3VD00aaURLcZnj05Y6D0mE0002 cs4=
  ALERT cs5=2015
5 act=blocked
6 <!--NeedCopy-->

```

The above message can be broken down into different components. Refer to the [CEF log components](#) table.

Example of a request check violation in CEF log format: request is not blocked

```

1 Jun 13 00:21:28 <local0.info> 10.217.31.98 CEF:0|Citrix|NetScaler|NS11

  blocked
6 <!--NeedCopy-->

```

Example of a response check violation in CEF format for an Offset:

```

1 Jan 24 10:00:00 <local0.warn> 10.175.4.47 CEF:0|Citrix|NetScaler|NS13
  .0|APPPFW|APPPFW_XML_ERR_NOT_WELLFORMED|4|src=5.31.100.129 spt=20644
  method=GET request=https://wifiuae.duwifi.ae/publishApplications/en
  /5dafe3e74fa8015599009bc1/images/fallback_photo.svg msg=XML Format
  check failed: Message is not a well-formed XML.Error string is '
  unclosed token'. Offset:-517597 cn1=547290214 cn2=974226675 cs1=
  WIFI_UAE_AppFw cs2=PPE0 cs4=ERROR cs5=2023 act=blocked
2 <!--NeedCopy-->

```

In this example, the XML_ERR_NOT_WELLFORMED violation occurred because of `unclosed token`. This violation is at 517597 location from the beginning of the file.

Log geolocation in the Web App Firewall violation messages

The log details identify the location from which requests originate, and help you configure the Web App Firewall for the optimal level of security. To bypass security implementations such as rate limiting, which rely on the IP addresses of the clients, malware or rogue computers can keep changing the source IP address in requests. Identifying the specific region from where requests are coming can help determine whether the requests are from a valid user or a device attempting to launch cyberattacks. For example, if an excessively large number of requests are received from a specific area, it is easy to determine whether they are being sent by users or a rogue machine. Geolocation analysis of the received traffic can be useful in deflecting attacks such as denial of service (DoS) attacks.

The Web App Firewall offers you the convenience of using the built-in NetScaler database for identifying the locations corresponding to the IP addresses from which malicious requests are originating. You can then enforce a higher level of security for requests from those locations. NetScaler default syntax (PI) expressions give you the flexibility to configure location based policies that can be used with the built-in location database to customize firewall protection, bolstering your defense against coordinated attacks launched from rogue clients in a specific region.

You can use the NetScaler built-in database, or you can use any other database. If the database does not have any location information for the particular client IP address, the CEF log shows the geolocation as an Unknown geolocation.

Note:

Geolocation logging uses the Common Event Format (CEF). By default, `CEF logging` and `GeoLocationLogging` are OFF. You must explicitly enable both parameters.

Example of a CEF log message showing geolocation information

```
1 June 8 00:21:09 <local0.info> 10.217.31.98 CEF:0|Citrix|NetScaler|NS11
  .0|APPFW|
2 APPFW_STARTURL|6|src=10.217.253.62 geolocation=NorthAmerica.US.Arizona.
  Tucson.*.*

5 cs4=ALERT cs5=2015 act=not blocked
6 <!--NeedCopy-->
```

Configure log action and other log parameters using command interface

To configure the log action for a security check of a profile by using the command line

At the command prompt, type one of the following commands:

- `set appfw profile <name> SecurityCheckAction ([log] | [none])`
- `unset appfw profile <name> SecurityCheckAction`

Examples

```
set appfw profile pr_ffc StartURLAction log
```

```
unset appfw profile pr_ffc StartURLAction
```

To configure CEF logging by using the command line

The CEF logging is disabled by default. At the command prompt, type one of the following commands to change or display the current setting:

- `set appfw settings CEFLogging on`
- `unset appfw settings CEFLogging`
- `sh appfw settings | grep CEFLogging`

To configure the logging of the credit card numbers by using the command line

At the command prompt, type one of the following commands:

- `set appfw profile <name> -doSecureCreditCardLogging ([ON] | [OFF])`
- `unset appfw profile <name> -doSecureCreditCardLogging`

To configure Geolocation logging by using the command line

1. Use the `set` command to enable `GeoLocationLogging`. You can enable the CEF logging at the same time. Use the `unset` command to disable geolocation logging. The `show` command shows the current settings of all the Web App Firewall parameters, unless you include the `grep` command to show the setting for a specific parameter.

- `set appfw settings GeoLocationLogging ON [CEFLogging ON]`
- `unset appfw settings GeoLocationLogging`
- `sh appfw settings | grep GeoLocationLogging`

2. Specify the database

```
add locationfile /var/netscaler/inbuilt_db/Citrix_netscaler_InBuilt_GeoIP_
.csv
```

or

```
add locationfile <path to database file>
```

Customize Web App Firewall logs

Default format (PI) expressions give you the flexibility to customize the information included in the logs. You have the option to include the specific data that you want to capture in the Web App Firewall generated log messages. For example, if you are using AAA-TM authentication along with the Web App Firewall security checks, and would like to know the accessed URL that triggered the security check violation, the name of the user who requested the URL, the source IP address, and the source port from which the user sent the request, you can use the following commands to specify customized log messages that include all the data:

```
1 > sh version
2 NetScaler NS12.1: Build 50.0013.nc, Date: Aug 28 2018, 10:51:08 (64-
  bit)
3 Done
4 <!--NeedCopy-->
```

```
1 > add audit messageaction custom1 ALERT 'HTTP.REQ.URL + " " + HTTP.REQ.
  USER.NAME + " " + CLIENT.IP.SRC + ":" + CLIENT.TCP.SRCPORT'
2 Warning: HTTP.REQ.USER has been deprecated. Use AAA.USER instead.
3 Done
4 <!--NeedCopy-->
```

```
1 > add appfw profile test_profile
2 Done
3 <!--NeedCopy-->
```

```
1 > add appfw policy appfw_pol true test_profile -logAction custom1
2 Done
3 <!--NeedCopy-->
```

Configure Syslog policy to segregate Web App Firewall logs

The Web App Firewall offers you an option to isolate and redirect the Web App Firewall security log messages to a different log file. This might be desirable if the Web App Firewall is generating many logs, making it difficult to view other NetScaler log messages. You can also use this option when you are interested only in viewing the Web App Firewall log messages and do not want to see the other log messages.

To redirect the Web App Firewall logs to a different log file, configure a syslog action to send the Web App Firewall logs to a different log facility. You can use this action when configuring the syslog policy, and bind it globally for use by Web App Firewall.

Notes:

- To globally bind Web App Firewall policies, you can configure the global binding parameter, “APFW_GLOBAL” in the “bind audit syslogGlobal” and “bind audit nslogGlobal” commands. The global bound audit log policies can evaluate log messages in the Web App Firewall logging context.
- You cannot segregate Web Application Firewall logs from a local audit or SYSLOG server running on NetScaler. Using the local2 log facility results in receiving both Web Application Firewall and IP Reputation logs in the same log file.

Example:

1. Switch to the shell and use an editor such as vi to edit the /etc/syslog.conf file. Add a new entry to use local2.* to send logs to a separate file as shown in the following example:

```
local2.* /var/log/ns.log.appfw
```

2. Restart the syslog process. You can use the grep command to identify the syslog process ID (PID), as shown in the following example:

```
root@ns\|# **ps -A | grep syslog**
1063 ?? Ss 0:03.00 /usr/sbin/syslogd -b 127.0.0.1 -n -v -v -8 -C
root@ns# **kill -HUP** 1063
```

3. From the command line interface, configure either advanced or classic SYSLOG policy with action and bind it as a global Web App Firewall policy. Citrix recommends you to configure the advanced SYSLOG policy.

Advanced SYSLOG policy configuration

```
add audit syslogAction sysact1 1.1.1.1 -logLevel ALL -logFacility
LOCAL2
```

```
add audit syslogPolicy syspol1 true sysact1
```

```
bind audit syslogGlobal -policyName syspol1 -priority 100 -
globalBindType APPFW_GLOBAL
```

Classic SYSLOG policy configuration

```
add audit syslogAction sysact1 1.1.1.1 -logLevel ALL -logFacility
LOCAL2
```

```
add audit syslogPolicy syspol1 ns_true sysact1
```

```
bind appfw global syspol1 100
```

4. All Web App Firewall security check violations will now be redirected to the `/var/log/ns.log.appfw` file. You can tail this file to view the Web App Firewall violations that are getting triggered during the processing of the ongoing traffic.

```
root@ns# tail -f ns.log.appfw
```

Notes:

- If you want to send logs to a different log file on the local NetScaler appliance, you can create a syslog server on that local NetScaler appliance. Add `syslogaction` to its own IP, and configure the ADC as you would configure an external server. The ADC acts as the server to store your logs. Two actions cannot be added with the same IP and port. In the `syslogaction`, by default, the value of IP is set to `127.0.0.1` and the value of port is set to `514`.
- If you have configured the syslog policy to redirect the logs to a different log facility, the Web App Firewall log messages no longer appear in the `/var/log/ns.log` file.

Send the Application Firewall messages to a separate SYSLOG server

To send the Application Firewall messages to a separate SYSLOG server, you must complete the following steps:

- A secure File transfer utility such as WinSCP
- A utility to open an SSH console to the appliance such as PuTTY

The following steps are involved to send the Application Firewall messages to a separate SYSLOG server:

1. Log on to the NetScaler appliance through WinSCP.
2. Update the `/etc/syslog.conf` file and add the following line in the file:

```
local5.* /var/log/appfw.log
```

```
# $FreeBSD: src/etc/syslog.conf,v 1.13.2.4 2003/05/12 13:59:23 yar Exp $
#
# Spaces ARE valid field separators in this file. However,
# other *nix-like systems still insist on using tabs as field
# separators. If you are sharing this file between systems, you
# may want to use only tabs as field separators here.
# Consult the syslog.conf(5) manpage.
#
# .err;kern.debug;auth.notice;mail.crit      /dev/console
# .notice;authpriv.none;kern.debug;lpr.info;mail.crit;news.err /var/log/messages
security.* /var/log/security
auth.info;authpriv.info /var/log/auth.log
mail.info /var/log/maillog
lpr.info /var/log/lpd-errs
cron.* /var/log/cron
local0.* /var/log/ns.log
local1.* /var/log/nsvpn.log
local2.* /var/log/callhomedebug.log
local3.* /var/log/callhome.log
local4.* /var/log/ctxslboc.log
local5.* /var/log/appfw.log
*.emerg *
# uncomment this to log all writes to /dev/console to /var/log/console.log
#console.info /var/log/console.log
# uncomment this to enable logging of all log messages to /var/log/all.log
#*. * /var/log/all.log
# uncomment this to enable logging to a remote loghost named loghost
#*. * @loghost
```

1. Run the following command from the command line interface to restart the syslog PID:

```
kill -HUP <PID>
```
2. Run the following command from the command line interface to add a syslog action such as `sysact1`:

```
add audit syslogAction sysact1 127.0.0.1 -logLevel ALL -logFacility LOCAL5
```
3. Run the following command to add `sypol1` policy, which uses `sysact1` server:

```
add audit syslogPolicy sypol1 ns_true sysact1
```

Or, add advanced syslog policy:

```
add audit syslogPolicy syspol1 true sysact1
```

- Run the following command to bind the Application Firewall policy and ensure that it is saved in ns.conf file:

```
bind appfw global syspol1 100
```

Or, run the following command to bind the Advanced Syslog policy:

```
bind audit syslogGlobal -policyName syspol1 -priority 100 -globalBindType APPFW_GLOBAL
```

Syslog Auditing

| <input type="checkbox"/> | NAME | SERVER | GLOBALLY BOUND? | PRIORITY | EXPRESSION TYPE | EXPRESSION |
|--------------------------|---------|---------|-----------------|------------|-----------------|------------|
| <input type="checkbox"/> | syspol1 | sysact1 | ✓ | 2000000010 | Advanced Policy | true |

Total 1

All the Application Firewall security check violations are redirected to the `/var/log/appfw.log` and will no longer appear in the `ns.log`. You can now run the tail command and view latest entries in the `/var/log/appfw.log`.

View Web App Firewall logs

You can view the logs by using the syslog viewer, or by logging on to the NetScaler appliance, opening a UNIX shell, and using the UNIX text editor of your choice.

To access the log messages by using the command line

Switch to the shell and tail the ns.logs in the `/var/log/` folder to access the log messages pertaining to the **Web App Firewall security** check violations:

- `Shell`
- `tail -f /var/log/ns.log`

You can use the vi editor, or any Unix text editor or text search tool, to view and filter the logs for specific entries. For example, you can use the `grep` command to access the log messages pertaining to the Credit Card violations:

- `tail -f /var/log/ns.log | grep SAFECOMMERCE`

To access the log messages by using the GUI

The GUI includes a useful tool (Syslog Viewer) for analyzing the log messages. You have multiple options for accessing the Syslog Viewer:

- To view log messages for a specific security check of a profile, navigate to **Web App Firewall > Profiles**, select the target profile, and click Security Checks. Highlight the row for the target security check and click Logs. When you access the logs directly from the selected security check of the profile, it filters out the log messages and displays only the logs pertaining to the violations for the selected security check. Syslog viewer can display Web App Firewall logs in the Native format and the CEF format. However, for the syslog viewer to filter out the target profile specific log messages, the logs must be in the CEF log format when accessed from the profile.
- You can also access the Syslog Viewer by navigating to **NetScaler > System > Auditing**. In the Audit Messages section, click the Syslog messages link to display the Syslog Viewer, which displays all log messages, including all Web App Firewall security check violation logs for all profiles. The log messages are useful for debugging when multiple security check violations might be triggered during request processing.
- Navigate to **Web App Firewall > policies > Auditing**. In the Audit Messages section, click the Syslog messages link to display the Syslog Viewer, which displays all log messages, including all security check violation logs for all profiles.

The HTML based Syslog Viewer provides the following filter options for selecting only the log messages that are of interest to you:

- **File**—The current `/var/log/ns.log` file is selected by default, and the corresponding messages appear in the Syslog Viewer. A list of other log files in the `/var/log` directory is available in a compressed `.gz` format. To download and uncompress an archived log file, select the log file from the drop-down list option. The log messages pertaining to the selected file are then displayed in the syslog viewer. To refresh the display, click the Refresh icon (a circle of two arrows).
- **Module list box**—You can select the NetScaler module whose logs you want to view. You can set it to APPFW for Web App Firewall logs.
- **Event Type list box**—This box contains a set of check boxes for selecting the type of event you are interested in. For example, to view the log messages pertaining to the signature violations, you can select the **APPFW_SIGNATURE_MATCH** check box. Similarly, you can select a check box to enable the specific security check that is of interest to you. You can select multiple options.
- **Severity**—You can select a specific severity level to show just the logs for that severity level. Leave all the check boxes blank if you want to see all the logs.

To access the Web App Firewall security check violation log messages for a specific security check, filter by selecting **APPFW** in the drop-down list options for Module. The Event Type displays a rich set of options to further refine your selection. For example, if you select the **APPFW_FIELDFORMAT** check box and click the Apply button, only log messages pertaining to the Field Formats security check violations appear in the Syslog Viewer. Similarly, if you select the **APPFW_SQL** and **APPFW_STARTURL** check boxes and click the **Apply** button, only log mes-

sages pertaining to these two security check violations appear in the syslog viewer.

If you place the cursor in the row for a specific log message, multiple options, such as **Module**, **Event-Type**, **EventID**, or **Message** are displayed below the log message. You can select any of these options to highlight the corresponding information in the logs.

Highlights

- **CEF Log Format support**—The CEF log format option provides a convenient option to monitor, parse, and analyze the Web App Firewall log messages to identify attacks, fine-tune configured settings to decrease false positives, and gather statistics.
- **Option to customize log message**—You can use advanced PI expressions to customize log messages and include the data you want to see in the logs.
- **Segregate Web App Firewall specific logs**—You have an option to filter and redirect application-firewall specific logs to a separate log file.
- **Remote Logging**—You can redirect the log messages to a remote syslog server.
- **Geolocation Logging**—You can configure the Web App Firewall to include the geolocation of the area from where the request is received. A built-in geolocation database is available, but you have the option to use an external geolocation database. The NetScaler appliance supports both IPv4 and IPv6 static geolocation databases.
- **Information rich log message**—Following are some examples of the type of information that can be included in the logs, depending on the configuration:
 - A Web App Firewall policy was triggered.
 - A security check violation was triggered.
 - A request was considered to be malformed.
 - A request or the response was blocked or not blocked.
 - Request data (such as SQL or cross-site scripting special characters) or response data (such as Credit card numbers or safe object strings) was transformed.
 - The number of credit cards in the response exceeded the configured limit.
 - The credit card number and type.
 - The log strings configured in the signature rules, and the signature ID.
 - Geolocation information about the source of the request.
 - Masked (X'd out) user input for protected confidential fields.

Mask sensitive data using regex pattern

The `REGEX_REPLACE` advanced policy (PI) function in a log expression (bound to a Web Application Firewall (WAF) profile) enables you to mask sensitive data in WAF logs. You can use the option to mask

data using a regex pattern and provide a character or a string pattern to mask the data. Also, you can configure the PI function to replace the first occurrence or all occurrences of the regex pattern.

By default the GUI interface provides the following mask:

- SSN
- Credit Card
- Password
- User name

Mask sensitive data in Web Application Firewall logs

You can mask sensitive data in WAF logs by configuring the `REGEX_REPLACE` advanced policy expression in the log expression bound to a WAF profile.

To mask sensitive data, you must complete the following steps:

1. Add a Web Application Firewall profile
2. Bind a log expression to the WAF profile

Add a Web Application Firewall profile At the command prompt, type:

```
add appfw profile <name>
```

Example:

```
Add appfw profile testprofile1
```

Bind a log expression with the Web Application Firewall profile At the command prompt, type:

```
bind appfw profile <name> -logExpression <string> <expression> -  
comment <string>
```

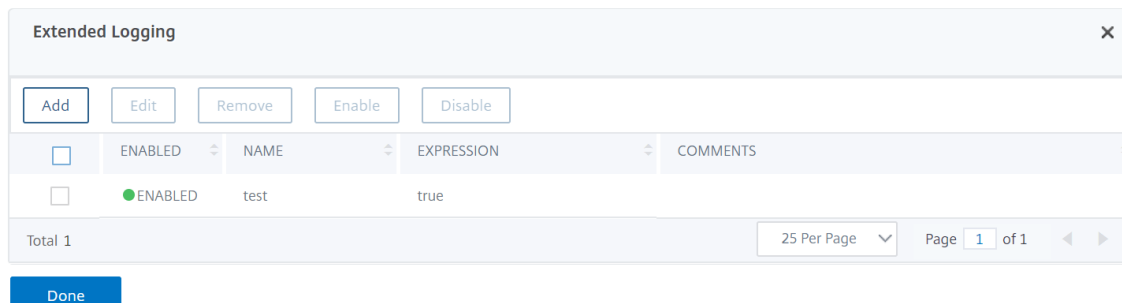

Example:

```
bind appfw profile testProfile -logExpression "MaskSSN""HTTP.REQ.BODY  
(10000).REGEX_REPLACE(re!\b\d{ 3 } -\d{ 2 } -\d{ 4 } \b!, "xxx", ALL)  
"-comment "SSN Masked"
```

Mask sensitive data in Web Application Firewall logs by using NetScaler GUI

1. On the navigation pane, expand **Security > NetScaler Web App Firewall > Profiles**.
2. On the **Profiles** page, click **Edit**.

3. On the **NetScaler Web App Firewall Profile** page, navigate to **Advanced Settings** section and click **Extended Logging**.
4. In the **Extended Logging** section, click **Add**.

5. On the **Create NetScaler Web App Firewall Extended Log Binding** page, set the following parameters:
 - a) Name. Name of the log expression.
 - b) Enabled. Select this option to mask sensitive data.
 - c) Log mask. Select the data to be masked.
 - d) Expression. Enter the advanced policy expression that enables you to mask sensitive data in WAF logs
 - e) Comments. Brief description about the masking sensitive data.
6. Click **Create** and **Close**.

Appendices

September 21, 2020

The following supplemental material provides additional detail about complex or peripheral Web App Firewall tasks.

PCRE character encoding format

May 2, 2023

The **NetScaler operating system supports direct** entry of characters in the printable ASCII character set only—characters with hexadecimal codes between HEX 20 (ASCII 32) and HEX 7E (ASCII 127). To include a character with a code outside that range in your Web App Firewall configuration, you must enter its UTF-8 hexadecimal code as a PCRE regular expression.

Many character types require encoding using a PCRE regular expression if you include them in your Web App Firewall configuration as a URL, form field name, or Safe Object expression. They include:

- **Upper-ASCII characters.** Characters with encodings from HEX 7F (ASCII 128) to HEX FF (ASCII 255). Depending on the character map used, these encodings can refer to control codes, ASCII characters with accents or other modifications, non-Latin alphabet characters, and symbols not included in the basic ASCII set. These characters can appear in URLs, form field names, and safe object expressions.
- **Double-Byte characters.** Characters with encodings that use two 8-byte words. Double-byte characters are used primarily for representing Chinese, Japanese, and Korean text in electronic format. These characters can appear in URLs, form field names, and safe object expressions.

ASCII control characters. Non-printable characters used to send commands to a printer. All ASCII characters with hexadecimal codes less than HEX 20 (ASCII 32) fall into this category. These characters must never appear in a URL or form field name, however, and would rarely if ever appear in a safe object expression.

The NetScaler appliance does not support the entire UTF-8 character set, but only the characters found in the following eight charsets:

- **English US (ISO-8859-1).** Although the label reads, “English US,” the Web App Firewall supports all characters in the ISO-8859-1 character set, also called the Latin-1 character set. This character set fully represents most modern western European languages and represents all but a few uncommon characters in the rest.
- **Chinese Traditional (Big5).** The Web App Firewall supports all characters in the BIG5 character set, which includes all of the Traditional Chinese characters (ideographs) commonly used in modern Chinese as spoken and written in Hong Kong, Macau, Taiwan, and by many people of Chinese ethnic heritage who live outside of mainland China.
- **Chinese Simplified (GB2312).** The Web App Firewall supports all characters in the GB2312 character set, which includes all of the Simplified Chinese characters (ideographs) commonly used in modern Chinese as spoken and written in mainland China.
- **Japanese (SJIS).** The Web App Firewall supports all characters in the Shift-JIS (SJIS) character set, which includes most characters (ideographs) commonly used in modern Japanese.
- **Japanese (EUC-JP).** The Web App Firewall supports all characters in the EUC-JP character set, which includes all characters (ideographs) commonly used in modern Japanese.
- **Korean (EUC-KR).** The Web App Firewall supports all characters in the EUC-KR character set, which includes all characters (ideographs) commonly used in modern Korean.
- **Turkish (ISO-8859-9).** The Web App Firewall supports all characters in the ISO-8859-9 character set, which includes all letters used in modern Turkish.

- **Unicode (UTF-8).** The Web App Firewall supports certain more characters in the UTF-8 character set, including those used in modern Russian.

When configuring the Web App Firewall, you enter all non-ASCII characters as PCRE-format regular expressions using the hexadecimal code assigned to that character in the UTF-8 specification. Symbols and characters within the normal ASCII character set, which is assigned single, two-digit codes in that character set, are assigned the same codes in the UTF-8 character set. For example, the exclamation point (!), which is assigned hex code 21 in the ASCII character set, is also hex 21 in the UTF-8 character set. Symbols and characters from another supported character set have a paired set of hexadecimal codes assigned to them in the UTF-8 character set. For example, the letter a with an acute accent (á) is assigned UTF-8 code C3 A1.

The syntax you use to represent these UTF-8 codes in the Web App Firewall configuration is “\xNN” for ASCII characters; “\xNN\xNN” for non-ASCII characters used in English, Russian, and Turkish; and “\xNN\xNN\xNN” for characters used in Chinese, Japanese, and Korean. For example, if you want to represent a ! in a Web App Firewall regular expression as a UTF-8 character, you would type \x21. If you want to include an á, you would type \xC3\xA1.

Note:

Normally you do not need to represent ASCII characters in UTF-8 format, but when those characters might confuse a web browser or an underlying operating system, you can use the character’s UTF-8 representation to avoid this confusion. For example, if a URL contains a space, you might want to encode the space as \x20 to avoid confusing certain browsers and web server software.

Below are examples of URLs, form field names, and safe object expressions that contain non-ASCII characters that must be entered as PCRE-format regular expressions to be included in the Web App Firewall configuration. Each example shows the actual URL, field name, or expression string first, followed by a PCRE-format regular expression for it.

- A URL containing extended ASCII characters.

Actual URL: <http://www.josénuñez.com>

Encoded URL: `^http://www\[.\]jos\xC3\xA9nu\xC3\xB1ez\[.\]com$`

- Another URL containing extended ASCII characters.

Actual URL: <http://www.example.de/trömsö.html>

Encoded URL: `^http://www[.]example[.]de/tr\xC3\xB6msö[.]html$`

A form field name containing extended ASCII characters.

Actual Name: nome_do_usuario

Encoded Name: `^nome_do_usu\xC3\xA1rio$`

- A safe object expression containing extended ASCII characters.

Unencoded Expression [A-Z]{3,6}¥[1-9][0-9]{6,6}

Encoded Expression: [A-Z]{3,6}\xC2\xA5[1-9][0-9]{6,6}

You can find several tables that include the entire Unicode character set and matching UTF-8 encodings on the Internet. A useful website that contains this information is available in the following table.

<http://www.utf8-chartable.de/unicode-utf8-table.pl>

For the characters in the table on this website to display correctly, you must have an appropriate Unicode font installed on your computer. If you do not, the visual display of the character may be in error. Even if you do not have an appropriate font installed to display a character, however, the description and the UTF-8 and UTF-16 codes on this set of webpages are correct.

Whitehat WASC signature types for WAF use

May 2, 2023

The NetScaler Web App Firewall accepts and generates blocking rules for all vulnerability types that the Whitehat scanners generate. However, certain vulnerabilities are most applicable to a web App Firewall. Following are lists of those vulnerabilities, categorized by whether they are addressed by WASC 1.0, WASC 2.0, or best practices signature types.

WASC 1.0 signature types

- HTTP Request Smuggling
- HTTP Response Splitting
- HTTP Response Smuggling
- Null Byte Injection
- Remote File Inclusion
- URL Redirector Abuse

WASC 2.0 signature types

- Abuse of Functionality
- Brute Force
- Content Spoofing
- Denial of Service
- Directory Indexing

- Information Leakage
- Insufficient Anti-automation
- Insufficient Authentication
- Insufficient Authorizatio
- Insufficient Session Expiration
- LDAP Injection
- Session Fixation

Best Practices

- Autocomplete Attribute
- Insufficient Cookie Access Control
- Insufficient Password Strength
- Invalid HTTP Method Usage
- Non-HttpOnly Session Cookie
- Persistent Session Cookie
- Personally Identifiable Information
- Secured Cachable HTTP Messages
- Unsecured Session Cookie

Streaming support for request processing

May 2, 2023

NetScaler Web App Firewall supports request side streaming to provide a significant performance boost. Instead of buffering a request, the appliance examines the incoming traffic for security violation such as SQL, cross-site scripting, field consistency, field formats. When the appliance completes processing data for a field, the request is forwarded to the back-end server while the appliance continues to evaluate other fields. This data processing significantly improves the processing time in handling forms have many fields.

Citrix recommends you to enable streaming for payload content greater than 20MB. Also, the back-end server must accept the chunked requests if streaming is enabled.

Note:

Post Body Limit action is always set to block and is applicable for both streaming and non-streaming modes. If the incoming traffic is greater than 20MB, Citrix recommends you configure the `PostBodyLimit` to the expected value.

Although the streaming process is transparent to the users, minor configuration adjustments are required due to the following changes:

RegEx Pattern Match: RegEx pattern match is now restricted to 4K for contiguous character string match.

Field Name Match: The Web App Firewall learning engine can only distinguish the first 128 bytes of the name. If a form has multiple fields with names that have an identical string match for the first 128 bytes, the learning engine does not distinguish them. Similarly, the deployed relaxation rule might inadvertently relax all such fields.

Removal of white spaces, percent decoding, Unicode decoding, and charset conversion are done during canonicalization to provide security check inspection. The 128 byte limit is applicable for the canonicalized representation of the field name in UTF-8 character format. The ASCII characters are 1 byte in length but the UTF-8 representation of the characters in some international languages might range from 1 byte to 4 bytes. If each character in a name takes 4 bytes for converting to UTF-8 format, only the first 32 characters in the name might be distinguished by the learned rule.

Field Consistency Check: When you enable Field Consistency, all the forms in the session are stored based on the “as_fid” tag inserted by the Web App Firewall without considering the “action_url.”

- **Mandatory Form tagging for Form Field consistency:** When the field consistency check is enabled, the form tag must be enabled also. The Field Consistency protection might not work if form tagging is turned off.
- **Sessionless Form Field Consistency:** The Web App Firewall no longer carries out the “GET” to “POST” conversion of forms when the sessionless field consistency parameter is enabled. The form tag is required for sessionless field consistency also.
- **Tampering of as_fid:** If a form is submitted after tampering as_fid, it triggers field consistency violation even if no field was tampered. In non-streaming requests, this was allowed because the forms can be validated using the “action_url” stored in the session.

Signatures: The signatures now have the following specifications:

- **Location:** It is now a mandatory requirement that location must be specified for each pattern. All patterns in the rule **MUST** have a <Location> tag.
- **Fast Match:** All signature rules must have a fast match pattern. If there is no fast match pattern, an attempt is made to select one if possible. Fast match is a literal string but **PCRE** can be used for fast match if they contain a usable literal string.
- **Deprecated Locations:** Following locations are no longer supported in signature rules.
 - HTTP_ANY
 - HTTP_RAW_COOKIE
 - HTTP_RAW_HEADER

- HTTP_RAW_RESP_HEADER
- HTTP_RAW_SET_COOKIE

cross-site scripting/SQL Transform: Raw data is used for transformation because the SQL special characters such as single quote ('), backslash (\), and semicolon (;), and cross-site scripting tags are the same and do not require canonicalization of data. Representation of special characters such as HTML entity encoding, percent encoding, or ASCII are evaluated for transform operation.

The Web App Firewall no longer inspects both the attribute name and value for the cross-site scripting transform operation. Now only cross-site scripting attribute names are transformed when streaming is engaged.

Processing cross-site scripting Tags: As part of the streaming changes in NetScaler 10.5.e build and later, the processing of the cross-site scripting tags has changed. In earlier releases, the presence of either open bracket (<), or close bracket (>), or both open and close brackets (<>) was flagged as cross-site scripting Violation. The behavior has changed in 10.5.e build onwards. Presence of only the open bracket character (<), or only the close bracket character (>) is no longer considered as an attack. This is when an open bracket character (<) is followed by a close bracket character (>), the Cross-site scripting attack gets flagged. Both characters must be present in the right order (< followed by >) to trigger the Cross-site scripting violation.

Note:

Change in SQL violation log Message: As part of the streaming changes in the NetScaler release 10.5.e onwards, we now process the input data in blocks. RegEx pattern matching is now restricted to 4K for contiguous character string matching. With this change, the SQL violation log messages might include different information compared to the earlier builds. The keyword and special character in the input are separated by many bytes. The appliance has a track of the SQL keywords and special strings when processing the data, instead of buffering the entire input value. In addition to the field name, the log message includes the SQL keyword, SQL special character, or both the SQL keyword and the SQL special character. The rest of the input is no longer included in the log message, as shown in the following example:

Example:

In 10.5, when the Web App Firewall detects the SQL violation, the entire input string might be included in the following log message:

SQL Keyword check failed for field **text="select a name from testbed1\;(\;)"***<blocked>

In 11.0, we log only the field name, keyword, and special character (if applicable) in the following log message.

SQL Keyword check failed for field **text="select(;)"**<blocked>

This change is applicable to requests that contain **application/x-www-form-urlencoded**, or

multipart/form-data, or **text/x-gwt-rpc** content-types. Log messages generated during processing of **JSON** or **XML** payloads are not affected in this change.

RAW POST Body: The security check inspections are always done on the RAW POST body.

Form ID: The Web App Firewall inserted “as_fid”tag, which is a computed hash of the form is longer unique for the user session. It is an identical value for a specific form irrespective of the user or the session.

Charset: If a request does not have a charset, the default charset specified in the application profile is used when processing the request.

Counters:

Counters with a prefix “se”and “appfwreq”are added to track the streaming engine and streaming engine request counters.

```
nsconsmg -d statswt0 -g se_err_
```

```
nsconsmg -d statswt0 -g se_tot_
```

```
nsconsmg -d statswt0 -g se_cur_
```

```
nsconsmg -d statswt0 -g appfwreq_err_
```

```
nsconsmg -d statswt0 -g appfwreq_tot_
```

```
nsconsmg -d statswt0 -g appfwreq_cur_
```

_err counters: indicate the rare event which must have succeeded but failed due to either memory allocation problem or some other resource crunch.

_tot counters: ever increasing counters.

_cur counters: counters indicating current values that keep changing based on usage from current transactions.

Tips:

- The Web App Firewall security checks must work the same as before.
- There is no set ordering for the processing of the security checks.
- The response side processing is not affected and remains unchanged.
- Streaming is not engaged if clientless VPN is used.

Important:

Calculating the Cookie length: In release 10.5.e in addition to NetScaler release 11.0 (in builds before 65.x), Web App Firewall way of processing the cookie header was changed. The appliance evaluated the cookie individually, and if the length of a cookie in the cookie header exceeded the configured length, the Buffer Overflow violation was triggered. As a result, requests blocked in

the NetScaler 10.5 version or earlier releases might be allowed. The length of the entire cookie header is not calculated for determining the cookie length. In some situations, the total cookie size might be larger than the accepted value, and the server might respond with “400 Bad Request”.

Note:

The change has been reverted. The behavior in NetScaler version 10.5.e to version 59.13xx.e and its subsequent builds is similar to the non-enhancement builds of release 10.5. The entire raw Cookie header is now considered when calculating the length of the cookie. Surrounding spaces and the semicolon (;) characters separating the name-value pairs are also included in determining the cookie length.

Trace HTML requests with security logs

May 2, 2023

Note:

This feature is available in NetScaler release 10.5.e.

Troubleshooting requires analysis of data received in the client request and can be challenging. Especially if there is heavy traffic flowing through the appliance. Diagnosing issues might affect the functionality or application security might require a quick response.

The NetScaler isolates traffic for a Web App Firewall profile and collects `nstrace` for the HTML requests. The `nstrace` collected in appfw mode includes request details with log messages. You can use “Follow TCP stream” in the trace to view the details of the individual transaction including headers, payload, and the corresponding log message in the same screen.

This gives you a comprehensive overview regarding your traffic. Having a detailed view of the request, payload, and associated log records can be useful to analyze security check violation. You can easily identify the pattern that is triggering the violation. If the pattern must be allowed, you can take a decision to modify the configuration or add a relaxation rule.

Benefits

1. **Isolate traffic for specific profile:** This enhancement is useful when you isolate traffic for only one profile or specific transactions of a profile for troubleshooting. You no longer have to skim through the entire data collected in the trace or need special filters to isolate requests interest you which can be tedious with heavy traffic. You can view the data that you prefer.

2. **Collect data for specific requests:** The trace can be collected for a specified duration. You can collect trace for only a couple of requests to isolate, analyze, and debug specific transactions if needed.
3. **Identify resets or aborts:** Unexpected closing of connections is not easily visible. The trace collected in `-appfw` mode captures a reset or an abort, triggered by the Web App Firewall. This allows a quicker isolation of an issue when you do not see a security check violation message. Malformed requests or other non-RFC compliant requests terminated by Web App Firewall will now be easier to identify.
4. **View decrypted SSL traffic:** HTTPS traffic is captured in plain text to allow for easier troubleshooting.
5. **Provides comprehensive view:** Allows you to look at the entire request at the packet level, check the payload, look at the logs to check what security check violation is being triggered and identify the match pattern in the payload. If the payload consists of any unexpected data, junk strings, or non-printable characters (null character, `\r` or `\n` and so forth), they are easy to discover in the trace.
6. **Modify configuration:** The debugging can provide useful information to decide if the observed behavior is the correct behavior or the configuration must be modified.
7. **Expedite response time:** Faster debugging on target traffic can improve the response time to provide explanations or root cause analysis by the NetScaler engineering and support team.

For more information, see [Manual Configuration by using the command line interface](#) topic.

To configure debug tracing for a profile by using the command line interface

Step 1. Enable ns trace.

You can use the `show` command to verify the configured setting.

- `set appfw profile <profile> -trace ON`

Step 2. Collect trace. You can continue to use all the options which are applicable for the `nstrace` command.

- `start nstrace -mode APPFW`

Step 3. Stop trace.

- `stop nstrace`

Location of the trace: The `nstrace` is stored in a time-stamped folder which is created in the `/var/nstrace` directory and can be viewed using `wireshark`. You can tail the `/var/log/ns.log` to see the log messages providing details regarding the location of the new trace.

Tips:

- When the `appfw` mode option is used, the `nstrace` will only collect the data for one or more profiles for which the “`nstrace`” was enabled.

- Enabling the trace on the profile will not automatically start collecting the traces until you explicitly run the “start ns trace” command to collect the trace.
- Although enabling trace on a profile may not have any adverse effect on the performance of the Web App Firewall but you may want to enable this feature only for the duration for which you want to collect the data. It is recommended that you turn the `-trace` flag off after you have collected the trace. The option prevents the risk of inadvertently getting data from profiles for which you had enabled this flag in the past.
- The block or log action must be enabled for the security check for the transaction record to be included in the `nstrace`.
- Resets and aborts are logged independently of security checks actions when trace is “On” for the profiles.
- The feature is only applicable for troubleshooting the requests received from the client. The traces in `-appfw` mode do not include the responses received from the server.
- You can continue to use all the options which are applicable for the `nstrace` command. For example,

```
start nstrace -tcpdump enabled -size 0 -mode appFW
```
- If a request triggers multiple violations, the `nstrace` for that record includes all the corresponding log messages.
- CEF log message format is supported for this functionality.
- Signature violations triggering block or log action for request side checks will also be included in the trace.
- Only HTML (non-XML) requests are collected in the trace.

Web App Firewall support for cluster configurations

May 2, 2023

Note:

NetScaler Web App Firewall for striped and partially striped configurations was introduced in NetScaler 11.0 version.

A cluster is a group of NetScaler appliances configured and managed as a single system. Each appliance in the cluster is called a node. Depending on the number of nodes the configurations are active on, cluster configurations are referred to as striped, partially striped, or spotted configurations. The Web App Firewall is fully supported in all configurations.

The two main advantages of striped and partially striped virtual server support in cluster configurations are the following:

1. **Session failover support**—striped and partially striped virtual server configurations support session failover. The advanced Web App Firewall security features, such as Start URL closure and the Form Field Consistency check, maintain, and use sessions during transaction processing. In a high availability configuration, or in a spotted cluster configuration, when the node that is processing the Web App Firewall traffic fails, all the session information is lost and the user has to re-establish the session. In striped virtual server configurations, user sessions are replicated across multiple nodes. If a node goes down, a node running the replica becomes the owner. Session information is maintained without any visible impact to the user.
2. **Scalability**—Any node in the cluster can process the traffic. Multiple nodes of the cluster can process the incoming requests served by the striped virtual server. This improves the Web App Firewall's ability to handle multiple simultaneous requests, thereby improving the overall performance.

Security checks and signature protections can be deployed without the need for any additional cluster-specific Web App Firewall configuration. You can do the usual Web App Firewall configuration on the configuration coordinator (CCO) node for propagation to all the nodes.

Note:

The session information is replicated across multiple nodes, but not across all the nodes in the striped configuration. Therefore, failover support accommodates a limited number of simultaneous failures. If multiple nodes fail simultaneously, the Web App Firewall might lose the session information if a failure occurs before the session is replicated on another node.

Highlights

- Web App Firewall offers scalability, high throughput, and session failover support in cluster deployments.
- All Web App Firewall security checks and signature protections are supported in all cluster configurations.
- Character-maps are not yet supported for a cluster. The learning engine recommends Field-Types in learned rules for the Field Format security check.
- Stats and learned rules are aggregated from all the nodes in a cluster.
- Distributed Hash Table (DHT) provides the caching of the session and offers the ability to replicate session information across multiple nodes. When a request comes to the virtual server, the NetScaler appliance creates Web App Firewall sessions in the DHT, and can also retrieve the session information from the DHT.
- Clustering is licensed with the Advanced and Premium licenses. This feature is not available with the Standard license.

Debugging and troubleshooting

September 21, 2020

Refer to the following troubleshooting and debugging information related to each of the Web App Firewall functionality:

- [Application Firewall - High CPU](#)
- [Memory](#)
- [Large File Upload Failure](#)
- [Learning](#)
- [Signatures](#)
- [Trace log](#)
- [Miscellaneous](#)

High CPU

May 2, 2023

Following are some of the functionality and high CPU related debugging issues encountered and the best practices to follow when working with Web App Firewall:

Check Policy hits, Bindings, Network configuration, Web App Firewall configuration:

- Identify misconfiguration
- Identify *vserver* that is serving the affected traffic

Inspect logs in the following log files for security violations and recent configuration changes:

- `/var/log/ns.log`
- `/var/nslog/import.log`
- `/var/nslog/aslearn.log`
- `tail -f /var/log/ns.log | grep APPFW_SIGNATURE_MATCH`

Example:

```
1 Jun 13 01:11:09 <local0.info> 10.217.31.98 CEF:0|Citrix|NetScaler|NS11
  .0|APPFW| APPFW_SIGNATURE_MATCH|6|src=10.217.253.62 spt=61141 method
  =GET request= http://aaron.stratum8.net/FFC/wwwboard/passwd.txt msg=
  Signature violation rule ID 807: web-cgi /wwwboard/passwd.txt access
  cn1=140 cn2=841 cs1=pr_ffc cs2=PPE0 cs3=
  OyTgjbXBqcpBFENKdLde30kMQ00001 cs4=ALERT cs5=2015 cs6=web-cgi act=
  not blocked
```

```
2 <!--NeedCopy-->
```

Isolate the traffic that is effected:

- Isolate the profile
- Isolate the security check
- Isolate the URL, virtual server and traffic parameters

Conditional profile level trace helps identify the traffic and violation records:

- `set appfw profile <profile> -trace ON`
- `start nstrace -mode APPFW -size 0`
- `stop nstrace`

Note: Ensure that the trace is collected with -size 0 option.

Check appfw, dht, IP reputation activity counters:

- `nsconmsg -g as_ -g appfwreq_ -g iprep -d current`

Monitor window size for resets in connection:

Appfw sets the window size to 9845 when NetScaler resets the connection due to an invalid http message.

Examples:

- Malformed request received - connection reset
- High CPU related issues
- Check data sheets for system limits
- Inspect for cpu usage, appfw, DHT and memory related activity. Monitor appfw sessions
- `nsconmsg -g cc_cpu_use -g appfwreq -g as -g dht -g mem_AS_OBJ -g mem_AS_COMPONENT -d current`

Monitor memory allocated and freed from Web App Firewall components and objects during the target time period. It helps in isolating the protection leading to high CPU usage.

- Profiler output
- Observe logs

Isolate appfw check leading to high CPU:

- startURLClosure
- Formfiledconsistency
- CSRF
- Cookie protections
- Referer header check

Ascertain that autoupdate of signatures is not leading to high CPU (Disable to confirm).

Memory

September 21, 2020

Following are some of the best practices to follow when encountered with Web App Firewall usage memory related issues:

nsconmsg command usage:

- Look for global memory statistics to ascertain that there is enough memory in the system and there are no memory allocation failures by executing the following command:

```
* *- nsconmsg -d memstats
```

- Observe current allocated and maximum memory limits for appsecure, IP reputation, cache and compression by executing the following command:

```
nsconmsg -d memstats | egrep -i APPSECURE|IPREP|CACHE|CMP
```

- Check appfw, DHT, IP reputation activity counters by executing the following command:

```
nsconmsg -g as -g appfwreq_ -g iprep -d current
```

- Check all Web App Firewall error counters by executing the following command:

```
nsconmsg -g as_ -g appfwreq_ -g iprep_ -d stats | grep err
```

- Check all system error counters by executing the following command:

```
nsconmsg -g err -d current
```

- Inspect for CPU, APPFWREQ, AS and DHT counters by executing the following command:

```
nsconmsg -g cc_cpu_use -g appfwreq -g as -g dht -d current
```

- Check the configured Cache memory by executing the following command:

- `show cacheparameter`

- Check the configured memory by executing the following command:

```
nsconmsg -d memstats | egrep -i CACHE
```

- Identify distribution of memory in Web App Firewall components and objects:

Display AS_OBJ_memory:

```
nsconmsg -K newnslog -d stats | grep AS_OBJ | egrep -v AppFW_cpu0|total | sort -k3
```

Display AS_COMPONENT_memory:

```
nsconmsg -K newslog -d stats | grep AS_COMPONENT | egrep -v AppFW_cpu0  
|total | sort -k3
```

Check for number of alive sessions by executing the following command:

Monitor/plot active session counts:

```
nsconmsg -g as_alive_sessions -d current
```

Monitor/plot total allocated, free, updated sessions:

- `nsconmsg -g as_tot_alloc_sessions -g as_tot_free_sessions -d current`
- `nsconmsg -g as_tot_update_sessions -d current`

If required, reduce session timeout to ensure that session limits are not used by executing the following command:

```
set appfwsettings -sessionTimeout <300>
```

If required, set maximum lifetime of session by executing the following command:

```
set appfwsettings -sessionLifetime <7200>
```

Checking allocated and used memory

To check the total allocated memory and used memory:

- Use the `nsconmsg -d memstats` command. Observe the **MEM_APPSECURE** field.
- Use the `stat appfw` command to obtain memory consumption information.

Web App Firewall does not automatically delete the logs after certain period of time or size.

- All AppFw logs are archived in the `*/var/log/ns.log*` file. The `ns.log` file performs the rollover task.

For more information, refer to the following link: <http://support.citrix.com/article/CTX121898>

Increasing Web App Firewall memory:

- There is no CLI option to increase Web App Firewall memory. Web App Firewall memory is platform-specific.
- You may use the `nsapimgr` option to increase memory but it is not recommended.

The max allowed memory for Web App Firewall is determined by the platform and disabling IC does not impact memory allocation.

Large file upload failures

October 13, 2023

When you encounter large file upload failures, ensure that you check the following:

- Misconfigured application firewall postbody limit.
- Enabled file upload scanning leading to increased processing time.
- Hitting system limits.

For payloads greater than 19 MB, we recommend you to enable streaming on the application firewall profile. Ensure that the back-end server supports chunked requests before enabling streaming.

Learning

December 4, 2020

Following are some of the best practices recommended when encountered with Learning functionality issues:

Aslearn process:

- Verify that the process *aslearn* is running.
- Check top command output
- Check output of *ps* command by executing the following command:

```
ps -ax | grep aslearn | grep -v "grep"
```

Example:

```
1 root@ns\# ps -ax | grep aslearn | grep -v "grep"
2 1439 ?? Ss      0:03.86 /netScaler/aslearn -start -f /netScaler/
   aslearn.conf
3 <!--NeedCopy-->
```

- Identify recent configuration commands ran prior to the observed problem by verifying the *ns.log* file:

```
/var/log/ns.log
```

- Inspect *aslearn* logs to check for *aslearn* messages:

```
/var/log/aslearn.log
```

- Isolate the profile and security check that is effected

- Identify the GUI and CLI command which is failing by executing the following command:

```
show appfw learningdata <profileName> <securityCheck>
```

Examples:

- show learningdata test_profile starturl
- show learningdata test_profile crosssiteScripting
- show learningdata test_profile sqlInjection
- show learningdata test_profile csRFtag
- show learningdata test_profile fieldformat
- show learningdata test_profile fieldconsistency

- Perform integrity check of sqlite from bsd shell prompt:

```
nsshell # sqlite3 /var/nslog/asl/<profile_name_in_lowercase>.db '
pragma integrity_check;
```

Examples:

```
1 root@ns# sqlite3 /var/nslog/asl/tsk0247284.db 'pragma
   integrity_check;'
2 ok
3 <!--NeedCopy-->
```

- Deploy or remove rules to start learning again:

- If 2000 learn items (per protection) are reached, you cannot start learning any more for that protection
- If 20 MB size is reached for the database, stop learning for all protections
- Restart aslearn process

```
*/netscaler/aslearn -start -f/netscaler/aslearn.conf*
```

- Check the space in the /var folder by executing the following:

```
du -h /var
```

- Check the learning threshold limits by executing the following command:

```
show appfwlearningsettings <profile_name> <securityCheck>
```

- Collect learned data by executing the following command:

```
export appfwlearningdata <profile_name> <securityCheck>
```

- Ascertain that learned data is uploaded in the collector.

Signatures

September 21, 2020

Getting started with signatures

To add signature:

1. Select the **Default**-signature and click **add** to make a copy.
2. Give a meaningful name. The new sig object is added as a User-Defined object.
3. Enable the target rules that are pertinent to your specific need.
 - The rules are disabled by default.
 - more rules require more processing
4. Configure the actions:

Block and Log actions are enabled by default. Stats is another option
5. Set the signature to be used by your profile.

Tips for Using Signatures

- Optimize the processing overhead by enabling only those signatures that are applicable for protecting your application.
- Every pattern in the rule must match to trigger a signature match.
- You can add your own customized rules to inspect incoming requests to detect various types of attacks, such as SQL injection or cross-site scripting attacks.
- You can also add rules to inspect the responses to detect and block leakage of sensitive information such as credit card numbers.
- Add multiple security check conditions to create your own customized check.

Best Practices for Using Signatures

Following are some of the best practices you can follow when encountered with issues related to Signatures:

- Verify that the import command has succeeded on primary as well as secondary.

- Verify that CLI and GUI outputs are consistent.
- Check ns.log to identify any errors during signature import and auto update.
- Check if the DNS name server is configured properly.
- Check schema version incompatibility.
- Check if the device is unable to access the Signature Update URL hosted on AWS for auto-update.
- Check for the version mismatch between Default signature and user-added ones.
- Check for version mismatch between signature objects on the primary and secondary nodes.
- Monitor for High CPU Utilization (disable auto-update to rule out issue with signature update).

Trace Log

September 21, 2020

To record trace logs:

1. Enable tracing for the profile. You can use the show command to verify the configured setting.

```
set appfw profile <profile> -trace ON
```

1. Start collecting trace. You can continue to use all the options which are applicable for the nstrace command.

```
start nstrace -mode APPFW
```

1. Stop collecting the trace

```
stop nstrace
```

Location of the trace: The nstrace is stored in a time-stamped folder which is created in the `/var/nstrace` directory and can be viewed using wireshark. You can tail the `/var/log/ns.log` file to see the log messages providing details regarding the location of the new trace.

Advantages of trace logs:

- Isolate traffic for specific profile
- Collect data for specific requests
- Identify resets or aborts
- View decrypted SSL traffic: HTTPS traffic is captured in plain text to allow for easier troubleshooting.

- Provides comprehensive view: Allows you to look at the entire request at the packet level, check the payload, view logs to check what security check violation is being triggered and identify the match pattern in the payload. If the payload consists of any unexpected data, junk strings, or non-printable characters (null character, \r or \n etc), they are easy to discover in the trace.
- Expedite response time: Faster debugging on target traffic to do root cause analysis.

Miscellaneous

December 4, 2020

Following are the resolutions for some of the issues that you might encounter when using Web App Firewall.

- Web App Firewall sets window size to 9845 when resetting connection for invalid http messages.
 - Malformed request received - connection reset [Client/Server sending invalid content-length header]
 - Unknown content-type in request headers
- System Limit: the application appears frozen
 - Occurs when maximum session limit is reached. (100K)
 - Less system memory for operation.
 - IP Reputation feature not working
 - The iprep process takes about five minutes to start after you enable the reputation feature. The IP reputation feature might not work for that duration.
- Unexpected Web App Firewall violations being triggered
 - Session timeout has a default value of 900 seconds. If session timeout is set to a low value, browser may trigger false positives for checks which rely on sessionization (e.g CSRF, FFC). Check for session timeout and look at the session ID (cs3 in CEF logs). If the sessionID is different, the session timeout might be the reason.
 - If form is dynamically generated by javascript, it may trigger false FFC violations.
- Empty field name in FFC violation logs (prior to 11.0 release)

This may be seen in scenarios where we come across a form field which is not in the forms in our session.

Scenarios where this may occur:

 - The session has timed out from when the form was sent to the client and when it was received.
 - The form was generated on the client side using a java script.

Use case - Binding Web App Firewall policy to a VPN virtual server

February 13, 2024

NetScaler provides a solution to protect multiple applications that are managed by the VPN virtual server. By binding application security policies to the VPN virtual server, you can protect all the applications behind it.

The following are the ways to deploy application security at a VPN virtual server:

- Protect all the applications behind the VPN virtual server with a single Web App Firewall profile
- Protect each application behind the VPN virtual server with a different Web App Firewall profile

Protect all the applications behind the VPN virtual server with a single Web App Firewall profile

To protect all your applications that are behind the VPN virtual server with a single Web App Firewall policy, you must create a Web App Firewall policy and bind it to a VPN virtual server.

Example:

A company hosts three critical applications - SAP, Workday, and Tally - on a VPN virtual server. As a network administrator, you decide to protect these applications against the OWASP Top 10 security risks.

To achieve this use case, perform the following operations:

1. Create the Web App Firewall profile with appropriate checks for OSWAP Top 10 security risks.

```
add appfw profile pr-basic -crossSiteScriptingAction block -
SQLInjectionAction block
```

For more information on configuring OSWAP Top 10 security risks, see [Add security protection](#).

2. Add the app firewall policy and associate that policy with the profile pr-basic.

```
add appfw policy owasp_policy true pr-basic
```

3. Bind the Web App Firewall policy to the VPN virtual server.

```
bind appfw vpn vserver vserver10 -policy owasp_policy -priority
10
```

Protect each application behind VPN virtual server with a different Web App Firewall profile

To perform specific security checks based on the Web App Firewall architecture (server, OS, JavaScript library, and so on.), individual security checks might be required for each web application. In such scenarios, multiple Web App Firewall policies can be configured.

Example:

A company hosts three critical applications (SAP, Workday, and Tally) behind a VPN virtual server. As a network administrator, you decide to create a unique Web App Firewall policy for optimal protection for each application.

To achieve this use case, perform the following operations:

1. Create multiple profiles based on the required application. Configure the profile with the necessary security checks based on the application's need.

```
1 add appfw profile pr-basic1 -crossSiteScriptingAction block -
  SQLInjectionAction block
2 add appfw profile pr-basic 2-crossSiteScriptingAction block -
  SQLInjectionAction block
3 add appfw profile pr-basic 3 -crossSiteScriptingAction block -
  SQLInjectionAction block
4 <!--NeedCopy-->
```

2. Add the app firewall policies that are applicable for each application and associate the policy with the profile.

```
1   add appfw policy sap_policy true HTTP.REQ.URL.CONTAINS ( " sap.com " )
    pr-basic1
2   add appfw policy workday_policy true HTTP.REQ.URL.CONTAINS ( "
    workday.com " ) pr-basic2
3   add appfw policy tally_policy true HTTP.REQ.URL.CONTAINS ( " tally.
    com " ) pr-basic3
4   <!--NeedCopy-->
```

1. Bind the created policy to VPN vserver1

```
1 . bind appfw vpn vserver vserver1 -policy sap_policy -priority 10
2 . bind appfw vpn vserver vserver1 -policy workday_policy -priority 20
3 . bind appfw vpn vserver vserver1 -policy tally_policy -priority 30
4 <!--NeedCopy-->
```

Signature alert Articles

May 2, 2023

NetScaler Web App Firewall (WAF) announces signature updates that you can download and apply on your appliance. When you detect a security attack, you will receive an email notification about the new signature update. You can download the signature and apply it on your appliance.

How to receive signature alert notification

This article explains how to subscribe to RSS feeds to receive notifications for new signature updates. Once subscribed, you receive regular RSS feeds whenever new signatures are available for download.

Note:

- To get updates about Web App Firewall signatures, you must configure the signature auto-update feature. For more information, see [Signature Auto Update](#) topic.

- To get updates about new bot signatures, you must configure the bot signature auto-update feature. For more information, see [Bot Signature Auto Update](#) topic.

To subscribe to RSS feeds for new signature updates, follow the steps given below:

1. Open the [Signature alert article document history](#) topic on a web browser.
2. On the top right of the page, click the RSS button and copy the [RSS feed URL](#).
3. Add the copied [RSS feed URL](#) to a desired RSS feed reader.

Signature update version 129

May 14, 2024

New signatures rules are generated for the vulnerabilities identified in the week 2024-05-14. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 129 applicable for NetScaler 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0, NetScaler 13.1, NetScaler 14.1 platforms.

Note

Enabling Post body and Response body signature rules might affect NetScaler CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

| Signature rule | CVE ID | Description |
|----------------|----------------|--|
| 998492 | CVE-2024-31136 | WEB-MISC JetBrains TeamCity Prior to 2024.03 - Two-Factor Authentication Bypass Vulnerability (CVE-2024-31136) |

| Signature rule | CVE ID | Description |
|-----------------------|----------------|---|
| 998493 | CVE-2024-25600 | WEB-WORDPRESS Bricks Builder Prior to 1.9.6.1 - RCE Vulnerability Via AJAX content parameter (CVE-2024-25600) |
| 998494 | CVE-2024-25600 | WEB-WORDPRESS Bricks Builder Prior to 1.9.6.1 - RCE Vulnerability Via AJAX element and elements parameters (CVE-2024-25600) |
| 998495 | CVE-2024-25600 | WEB-WORDPRESS Bricks Builder Prior to 1.9.6.1 - RCE Vulnerability Via REST API render_element Via rest_route (CVE-2024-25600) |
| 998496 | CVE-2024-25600 | WEB-WORDPRESS Bricks Builder Prior to 1.9.6.1 - RCE Vulnerability Via REST API render_element (CVE-2024-25600) |
| 998497 | CVE-2023-46302 | WEB-MISC Apache Submarine Prior To 0.8.0 - Deserialization of Untrusted Data Vulnerability (CVE-2023-46302) |

Signature update version 128

April 29, 2024

New signature rules are generated for the vulnerabilities identified in the week 2024-04-26. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 128 applicable for NetScaler 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0, NetScaler 13.1, NetScaler 14.1 platforms.

Note

Enabling Post body and Response body signature rules might affect NetScaler CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

| Signature rule | CVE ID | Description |
|----------------|-----------------------------------|---|
| 998498 | CVE-2024-4040 | WEB-MISC CrushFTP Prior to 10.7.1 and 11.1.0 - Server Side Template Injection Vulnerability (CVE-2024-4040) |
| 998499 | CVE-2024-30162 | WEB-MISC Invision Community - Arbitrary File Upload Vulnerability (CVE-2024-30162) |
| 998500 | CVE-2024-23538,
CVE-2024-23539 | WEB-MISC Apache Fineract Prior to 1.9 - SQL Injection Vulnerabilities (CVE-2024-23538,CVE-2024-23539) |
| 998501 | CVE-2024-23538,
CVE-2024-23539 | WEB-MISC Apache Fineract Prior to 1.9 - SQL Injection Vulnerabilities (CVE-2024-23538,CVE-2024-23539) |
| 998502 | CVE-2024-20767 | WEB-MISC Adobe ColdFusion Multiple Versions - Improper Access Control Vulnerability (CVE-2024-20767) |
| 998503 | CVE-2024-1981 | WEB-WORDPRESS WordPress Plugin WPVivid Backup & Migration - SQLi Vulnerability (CVE-2024-1981) |
| 998504 | CVE-2023-6019 | WEB-MISC Anyscale Ray - OS Command Injection Vulnerability (CVE-2023-6019) |

| Signature rule | CVE ID | Description |
|-----------------------|-----------------------------------|---|
| 998505 | CVE-2023-44092 | WEB-MISC Pandora FMS Prior to 776 - Remote Code Execution Vulnerability (CVE-2023-44092) |
| 998506 | CVE-2023-40000 | WEB-WORDPRESS LiteSpeed Cache Prior To 5.7.0.1 - Stored Cross Site Scripting Vulnerability (CVE-2023-40000) |
| 998507 | CVE-2023-40000 | WEB-WORDPRESS LiteSpeed Cache Prior To 5.7.0.1 - Stored Cross Site Scripting Vulnerability (CVE-2023-40000) |
| 998508 | CVE-2023-37679,
CVE-2023-43208 | WEB-MISC NextGen Mirth Connect < 4.4.1 - Unauthenticated RCE Vulnerability Via /server (CVE-2023-37679, CVE-2023-43208) |
| 998509 | CVE-2023-37679,
CVE-2023-43208 | WEB-MISC NextGen Mirth Connect < 4.4.1 - Unauthenticated RCE Vulnerability Via /users (CVE-2023-37679, CVE-2023-43208) |
| 998510 | CVE-2023-25196 | WEB-MISC Apache Fineract Prior to 1.8.4 - SQL Injection Vulnerabilities (CVE-2023-25196) |
| 998511 | CVE-2023-25195 | WEB-MISC Apache Fineract Prior to 1.8.4 - Server-Side Request Forgery Vulnerability (CVE-2023-25195) |

Signature update version 127

April 5, 2024

New signature rules are generated for the vulnerabilities identified in the week 2024-04-04. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 127 applicable for NetScaler 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0, NetScaler 13.1, NetScaler 14.1 platforms.

Note

Enabling Post body and Response body signature rules might affect NetScaler CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

| Signature rule | CVE ID | Description |
|----------------|----------------|---|
| 998512 | CVE-2024-25153 | WEB-MISC Fortra FileCatalyst Workflow Prior to 5.1.6 - Arbitrary File Upload Vulnerability (CVE-2024-25153) |
| 998513 | CVE-2024-24401 | WEB-MISC NagiosXI Up To 2024R1.01 - SQL Injection Vulnerability (CVE-2024-24401) |
| 998514 | CVE-2024-21726 | WEB-MISC Joomla! Prior to 5.0.3 and 4.4.3 - XSS Vulnerability via forceLanguage parameter (CVE-2024-21726) |
| 998515 | CVE-2024-21726 | WEB-MISC Joomla! Prior to 5.0.3 and 4.4.3 - XSS Vulnerability via forcedItemType parameter (CVE-2024-21726) |

| Signature rule | CVE ID | Description |
|-----------------------|---------------|--|
| 998516 | CVE-2024-2055 | WEB-MISC Artica Proxy Prior to 4.50 - Authentication Bypass Vulnerability (CVE-2024-2055) |
| 998517 | CVE-2024-2054 | WEB-MISC Artica Proxy Prior to 4.50 - Unauthenticated PHP Object Deserialization Vulnerability (CVE-2024-2054) |
| 998518 | CVE-2024-2053 | WEB-MISC Artica Proxy Prior to 4.50 - Unauthenticated Arbitrary File Inclusion Vulnerability (CVE-2024-2053) |
| 998519 | CVE-2023-6063 | WEB-WORDPRESS WP Fastest Cache Plugin Prior to 1.2.2 - Unauthenticated SQL Injection Vulnerability (CVE-2023-6063) |
| 998520 | CVE-2023-3550 | WEB-MISC MediaWiki Prior to 1.41 - Stored XSS Vulnerability (CVE-2023-3550) |

Signature update version 126

March 15, 2024

New signatures rules are generated for the vulnerabilities identified in the week 2024-03-15. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 126 applicable for NetScaler 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0, NetScaler 13.1, NetScaler 14.1 platforms.

Note

Enabling Post body and Response body signature rules might affect NetScaler CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

| Signature rule | CVE ID | Description |
|----------------|----------------|---|
| 998521 | CVE-2024-27198 | WEB-MISC JetBrains TeamCity Prior to 2023.11.4 - Authentication Bypass Vulnerability (CVE-2024-27198) |
| 998522 | CVE-2024-25065 | WEB-MISC Apache Ofbiz Prior 18.12.12 - Authentication Bypass Vulnerability (CVE-2024-25065) |
| 998523 | CVE-2024-20738 | WEB-MISC Adobe Framemaker Publishing Server Prior to 2022 Update 2 - Authentication Bypass Via /doxserver/ (CVE-2024-20738) |
| 998524 | CVE-2024-20738 | WEB-MISC Adobe Framemaker Publishing Server Prior to 2022 Update 2 - Authentication Bypass Via /server/ (CVE-2024-20738) |
| 998525 | CVE-2024-1708 | WEB-MISC ConnectWise ScreenConnect Prior to 23.9.8 - Path Traversal Vulnerability via ZipSlip Attack (CVE-2024-1708) |
| 998526 | CVE-2024-1071 | WEB-WORDPRESS Ultimate Member From 2.1.3 To 2.8.2 - SQL Injection Vulnerability (CVE-2024-1071) |
| 998527 | CVE-2023-5204 | WEB-WORDPRESS AI ChatBot Up To 4.8.9 - SQL Injection Vulnerability (CVE-2023-5204) |
| 998528 | CVE-2023-44313 | WEB-MISC Apache ServiceComb Service-Center Prior to 2.2.0 - Server-Side Request Forgery Vulnerability (CVE-2023-44313) |

| Signature rule | CVE ID | Description |
|-----------------------|----------------|---|
| 998529 | CVE-2023-41474 | WEB-MISC Ivanti Avalanche Up to 6.3.4.153 - Path Traversal Vulnerability (CVE-2023-41474) |
| 998530 | CVE-2023-41474 | WEB-MISC Ivanti Avalanche Up to 6.3.4.153 - Path Traversal Vulnerability (CVE-2023-41474) |
| 998531 | CVE-2023-40597 | WEB-MISC Splunk Enterprise Prior to 8.2.12 9.0.6 and 9.1.1 - Absolute Path Traversal Vulnerability (CVE-2023-40597) |

Signature update version 125

February 28, 2024

New signatures rules are generated for the vulnerabilities identified in the week 2024-02-26. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 125 applicable for NetScaler 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0, NetScaler 13.1, NetScaler 14.1 platforms.

Note

Enabling Post body and Response body signature rules might affect NetScaler CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

| Signature rule | CVE ID | Description |
|-----------------------|----------------|---|
| 998532 | CVE-2024-24830 | WEB-MISC OpenObserve Prior to 0.8.0 - Privilege Escalation (CVE-2024-24830) |
| 998533 | CVE-2024-25106 | WEB-MISC OpenObserve Prior to 0.8.0 - Unauthorized Access Vulnerability (CVE-2024-25106) |
| 998534 | CVE-2024-24747 | WEB-MISC MinIO Prior to RELEASE.2024-01-31T20-20-33Z - Improper Privilege Management Vulnerability (CVE-2024-24747) |
| 998535 | CVE-2024-1709 | WEB-MISC ConnectWise ScreenConnect Prior to 23.9.8 - Authentication Bypass Vulnerability (CVE-2024-1709) |
| 998536 | CVE-2024-1207 | WEB-WORDPRESS WP Booking Calendar Plugin Prior to 9.9.1 - Unauthenticated SQL Injection Vulnerability (CVE-2024-1207) |
| 998537 | CVE-2024-0221 | WEB-WORDPRESS Photo Gallery Up To 1.8.19 - Directory Traversal Vulnerability (CVE-2024-0221) |
| 998538 | CVE-2024-0221 | WEB-WORDPRESS Photo Gallery Up To 1.8.19 - Directory Traversal Vulnerability (CVE-2024-0221) |
| 998539 | CVE-2023-46266 | WEB-MISC Ivanti Avalanche Prior to 6.4.2 - Authentication Bypass Vulnerability (CVE-2023-46266) |
| 998540 | CVE-2023-46264 | WEB-MISC Ivanti Avalanche Prior to 6.4.2 - Arbitrary File Upload Vulnerability (CVE-2023-46264) |

| Signature rule | CVE ID | Description |
|-----------------------|----------------|---|
| 998541 | CVE-2023-46263 | WEB-MISC Ivanti Avalanche Prior to 6.4.2 - Arbitrary File Upload Vulnerability (CVE-2023-46263) |
| 998542 | CVE-2023-46214 | WEB-MISC Splunk Enterprise Prior to 9.0.7 and 9.1.2 - Insecure XML Parsing Vulnerability (CVE-2023-46214) |
| 998543 | CVE-2021-22962 | WEB-MISC Ivanti Avalanche Prior to 6.4.2 - Authentication Bypass vulnerability (CVE-2021-22962) |

Signature update version 124

February 15, 2024

New signature rules are generated for the vulnerabilities identified in the week 2024-02-14. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 124 applicable for NetScaler 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0, NetScaler 13.1, NetScaler 14.1 platforms.

Note

Enabling Post body and Response body signature rules might affect NetScaler CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

| Signature rule | CVE ID | Description |
|-----------------------|----------------|---|
| 998544 | CVE-2024-21893 | WEB-MISC Ivanti Connect Secure Multiple Versions - Server Side Request Forgery vulnerability (CVE-2024-21893) |
| 998545 | CVE-2024-21893 | WEB-MISC Ivanti Connect Secure Multiple Versions - Server Side Request Forgery vulnerability (CVE-2024-21893) |
| 998546 | CVE-2023-7028 | WEB-MISC GitLab CE/EE Multiple Versions - Improper Access Control Vulnerability (CVE-2023-7028) |
| 998547 | CVE-2023-50721 | WEB-MISC xWiki Platform Multiple Versions - Code Injection Vulnerability (CVE-2023-50721) |

Signature update version 123

January 25, 2024

New signatures rules are generated for the vulnerabilities identified in the week 2024-01-25. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 123 applicable for NetScaler 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0, NetScaler 13.1, NetScaler 14.1 platforms.

Note

Enabling Post body and Response body signature rules might affect NetScaler CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

| Signature rule | CVE ID | Description |
|----------------|--------------------------------|---|
| 998548 | CVE-2024-21650 | WEB-MISC xWiki Platform Prior Multiple Versions - Remote Code Execution Vulnerability (CVE-2024-21650) |
| 998549 | CVE-2023-6875, CVE-2023-7027 | WEB-WORDPRESS POST SMTP Plugin Prior to 2.8.8 - Missing Authorization/XSS Vulnerability (CVE-2023-6875, CVE-2023-7027) |
| 998550 | CVE-2023-51409 | WEB-WORDPRESS AI Engine Plugin Prior To 1.9.99 - Unauthenticated Arbitrary File Upload (CVE-2023-51409) |
| 998551 | CVE-2023-46805, CVE-2024-21887 | WEB-MISC Ivanti Connect Secure Multiple Versions - Remote Code Execution vulnerability (CVE-2023-46805, CVE-2024-21887) |
| 998552 | CVE-2023-46805, CVE-2024-21887 | WEB-MISC Ivanti Connect Secure Multiple Versions - Remote Code Execution vulnerability (CVE-2023-46805, CVE-2024-21887) |
| 998553 | CVE-2023-22527 | WEB-MISC Atlassian Confluence Server and Data Center Multiple Versions - Remote Code Execution Vulnerability (CVE-2023-22527) |

Signature update version 122

January 17, 2024

New signatures rules are generated for the vulnerabilities identified in the week 2024-01-17. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 122 applicable for NetScaler 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0, NetScaler 13.1, NetScaler 14.1 platforms.

Note

Enabling Post body and Response body signature rules might affect NetScaler CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

| Signature rule | CVE ID | Description |
|----------------|----------------|--|
| 998554 | CVE-2023-51467 | WEB-MISC Apache Ofbiz Multiple Versions - Server-Side Request Forgery Vulnerability (CVE-2023-51467) |
| 998555 | CVE-2023-50968 | WEB-MISC Apache Ofbiz Multiple Versions - Server-Side Request Forgery Vulnerability (CVE-2023-50968) |

Signature update version 121

January 10, 2024

New signatures rules are generated for the vulnerabilities identified in the week 2024-01-09. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 121 applicable for NetScaler 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0, NetScaler 13.1, NetScaler 14.1 platforms.

Note

Enabling Post body and Response body signature rules might affect NetScaler CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

| Signature rule | CVE ID | Description |
|----------------|----------------|--|
| 998556 | CVE-2023-6553 | WEB-WORDPRESS Backup Migration Plugin Up to 1.3.7 - Remote Code Execution Vulnerability (CVE-2023-6553) |
| 998557 | CVE-2023-48777 | WEB-WORDPRESS Elementor Plugin Prior to 3.18.1 - File Upload/Remote Code Execution Vulnerability Via ID (CVE-2023-48777) |
| 998558 | CVE-2023-44350 | WEB-MISC Adobe ColdFusion Multiple Versions - Remote Code Execution Vulnerability (CVE-2023-44350) |

Signature update version 120

December 19, 2023

New signatures rules are generated for the vulnerabilities identified in the week 2023-12-19. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 120 applicable for NetScaler 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0, NetScaler 13.1, NetScaler 14.1 platforms.

Note

Enabling Post body and Response body signature rules might affect NetScaler CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

| Signature rule | CVE ID | Description |
|----------------|----------------|---|
| 998559 | CVE-2023-50164 | WEB-STRUTS Apache Struts Prior to 6.3.0.2 - Path Traversal Vulnerability (CVE-2023-50164) |
| 998560 | CVE-2023-49105 | WEB-MISC ownCloud Prior to 10.13.1 - Access Control Bypass Vulnerability (CVE-2023-4105) |
| 998561 | CVE-2023-49103 | WEB-MISC ownCloud Multiple Versions - Information Disclosure Vulnerability (CVE-2023-49103) |
| 998562 | CVE-2023-47246 | WEB-MISC SysAid Server On-Premise Prior to 23.3.36 - Path Traversal Vulnerability (CVE-2023-47246) |
| 998563 | CVE-2023-46509 | WEB-MISC Contec SolarView Compact 6.0 and Prior - OS Command Injection Vulnerability (CVE-2023-46509) |
| 998564 | CVE-2023-44450 | WEB-MISC NETGEAR ProSAFE Network Management System Prior to 1.7.0.31 - SQL Injection Vulnerability (CVE-2023-44450) |
| 998565 | CVE-2023-44449 | WEB-MISC NETGEAR ProSAFE Network Management System Prior to 1.7.0.31 - SQL Injection Vulnerability (CVE-2023-44449) |

| Signature rule | CVE ID | Description |
|-----------------------|-----------------------------------|--|
| 998566 | CVE-2023-44351,
CVE-2023-44353 | WEB-MISC Adobe ColdFusion -
Deserialization of Untrusted
Data Vulnerability
(CVE-2023-44351,
CVE-2023-44353) |
| 998567 | CVE-2023-43177 | WEB-MISC CrushFTP Prior to
10.5.1 - Improper Control of
Dynamically-Managed Code
Resources Vulnerability
(CVE-2023-43177) |
| 998568 | CVE-2023-40062 | WEB-MISC SolarWinds Orion
Prior to 2023.4.0 - Improper
Input Validation Vulnerability
Via TestAction
(CVE-2023-40062) |
| 998569 | CVE-2023-40062 | WEB-MISC SolarWinds Orion
Prior to 2023.4.0 - Improper
Input Validation Vulnerability
Via /api/WriteToFile/
(CVE-2023-40062) |
| 998570 | CVE-2023-40055 | WEB-MISC SolarWinds NCM
Prior to 2023.4.1 - Directory
Traversal Vulnerability Via
SaveResultsToFile
(CVE-2023-40055) |
| 998571 | CVE-2023-40054 | WEB-MISC SolarWinds NCM
Prior to 2023.4.1 - Directory
Traversal Vulnerability Via
txtConfigTemplate
(CVE-2023-40054) |
| 998572 | CVE-2023-40054 | WEB-MISC SolarWinds NCM
Prior to 2023.4.1 - Directory
Traversal Vulnerability Via
txtPath (CVE-2023-40054) |
| 998573 | CVE-2023-39912 | Zoho ADManager Plus Prior to
7203 - Directory traversal
Vulnerability (CVE-2023-39912) |

| Signature rule | CVE ID | Description |
|-----------------------|----------------|--|
| 998574 | CVE-2023-35150 | WEB-MISC XWiki Multiple Versions - Arbitrary Code Injection Vulnerability (CVE-2023-35150) |
| 998575 | CVE-2023-32707 | WEB-MISC Splunk Enterprise - Escalation of Privileges Vulnerability (CVE-2023-32707) |
| 998576 | CVE-2023-30943 | WEB-MISC Moodle Prior to 4.1.3 - TinyMCE Loaders Stored Cross-Site Scripting Vulnerability Via loader (CVE-2023-30943) |
| 998577 | CVE-2023-30943 | WEB-MISC Moodle Prior to 4.1.3 - TinyMCE Loaders Stored Cross-Site Scripting Vulnerability Via lang (CVE-2023-30943) |
| 998578 | CVE-2023-2943 | WEB-MISC OpenEMR Prior to 7.0.1 - HTML Code Injection Vulnerability (CVE-2023-2943) |

Signature update version 119

November 24, 2023

New signature rules are generated for the vulnerabilities identified in the week 2023-11-23. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 119 applicable for NetScaler 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0, NetScaler 13.1, NetScaler 14.1 platforms.

Note

Enabling Post body and Response body signature rules might affect NetScaler CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

| Signature rule | CVE ID | Description |
|-----------------------|----------------|--|
| 998579 | CVE-2023-40934 | WEB-MISC NagiosXI Prior to 5.11.2 - SQL Injection Vulnerability (CVE-2023-40934) |
| 998580 | CVE-2023-40932 | WEB-MISC NagiosXI Prior to 5.11.2 - XSS Vulnerability (CVE-2023-40932) |
| 998581 | CVE-2023-40045 | WEB-MISC Progress WS_FTP Server Prior to 8.7.4 and 8.8.2 - Ad Hoc Cross-Site Scripting Vulnerability |
| 998582 | CVE-2023-37265 | WEB-MISC CasaOS Prior To 0.4.4 - Remote Code Execution Vulnerability via apps_restart (CVE-2023-37265) |
| 998583 | CVE-2023-37265 | WEB-MISC CasaOS Prior To 0.4.4 - Remote Code Execution Vulnerability via /app_management/compose (CVE-2023-37265) |
| 998584 | CVE-2023-3256 | WEB-MISC Advantech R-SeeNet Prior to 2.4.23 - Use of Hard-Coded Credentials Vulnerability (CVE-2023-3256) |
| 998585 | CVE-2023-28323 | WEB-MISC Ivanti Endpoint Manager Up to 2022 Su3 - Deserialization of Untrusted Data Vulnerability (CVE-2023-28323) |

| Signature rule | CVE ID | Description |
|-----------------------|----------------|---|
| 998586 | CVE-2023-1669 | WEB-WORDPRESS WP
SEOPress Plugin Prior To
6.5.0.3 - PHP Object Injection
Vulnerability (CVE-2023-1669) |
| 998587 | CVE-2022-3214 | WEB-MISC Delta Electronics
DIAEnergie - Unauthenticated
Arbitrary File Upload Via
HandlerUploadCalendar
(CVE-2022-3214) |
| 998588 | CVE-2022-3214 | WEB-MISC Delta Electronics
DIAEnergie - Unauthenticated
Arbitrary File Upload Via
HandlerUploadTag
(CVE-2022-3214) |
| 998589 | CVE-2022-3214 | WEB-MISC Delta Electronics
DIAEnergie - Unauthenticated
Arbitrary File Upload Via
HandlerUploadCarbon
(CVE-2022-3214) |
| 998590 | CVE-2022-27665 | WEB-MISC Progress WS_FTP
Server 8.6.0 - Cross-Site
Scripting Vulnerability
(CVE-2022-27665) |

Signature update version 118

November 13, 2023

New signature rules are generated for the vulnerabilities identified in the week 2023-11-10. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 118 applicable for NetScaler 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0, NetScaler 13.1, NetScaler 14.1 platforms.

Note

Enabling Post body and Response body signature rules might affect NetScaler CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

| Signature rule | CVE ID | Description |
|----------------|----------------|--|
| 998591 | CVE-2023-39968 | WEB-MISC Jupyter Server Prior to 2.7.2 - Open Redirect Vulnerability (CVE-2023-39968) |
| 998592 | CVE-2023-38743 | WEB-MISC Zoho ManageEngine ADManager Plus Prior to 7200 - Remote Code Execution Vulnerability (CVE-2023-38743) |
| 998593 | CVE-2023-22518 | WEB-MISC Confluence Data Center and Server Multiple Versions - Improper Authorization Vulnerability (CVE-2023-22518) |
| 998594 | CVE-2023-20890 | WEB-MISC VMware Aria Operations for Networks - Arbitrary File Write Vulnerability (CVE-2023-20890) |
| 998595 | CVE-2023-20889 | WEB-MISC VMware Aria Operations for Networks - Command Injection Vulnerability (CVE-2023-20889) |
| 998596 | CVE-2023-20273 | WEB-MISC Cisco IOS XE Software - Command Injection Vulnerability (CVE-2023-20273) |

Signature update version 117

November 1, 2023

New signatures rules are generated for the vulnerabilities identified in the week 2023-11-01. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 117 applicable for NetScaler 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0, NetScaler 13.1, NetScaler 14.1 platforms.

Note

Enabling Post body and Response body signature rules might affect NetScaler CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

| Signature rule | CVE ID | Description |
|----------------|----------------|---|
| 998597 | CVE-2023-20198 | WEB-MISC Cisco IOS XE Software - Authentication Bypass Vulnerability (CVE-2023-20198) |

Signature update version 116

October 16, 2023

Updated signatures rule is generated for the vulnerabilities identified in the week 2023-10-16. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 116 applicable for NetScaler 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0, NetScaler 13.1, NetScaler 14.1 platforms.

Note

Enabling Post body and Response body signature rules might affect NetScaler CPU.

Common Vulnerability Entry (CVE) insight

Following is the updated signature rule, CVE ID, and its description.

| Signature rule | CVE ID | Description |
|----------------|----------------|---|
| 998599 | CVE-2023-22515 | WEB-MISC Atlassian Confluence Server - Broken Access Control Vulnerability via /setup/*.action (CVE-2023-22515) |

Signature update version 115

October 16, 2023

New signatures rules are generated for the vulnerabilities identified in the week 2023-10-14. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 115 applicable for NetScaler 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0, NetScaler 13.1, NetScaler 14.1 platforms.

Note

Enabling Post body and Response body signature rules might affect NetScaler CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

| Signature rule | CVE ID | Description |
|----------------|----------------|---|
| 998598 | CVE-2023-24955 | WEB-MISC Microsoft SharePoint Server - Remote Code Execution Vulnerability (CVE-2023-24955) |
| 998599 | CVE-2023-22515 | WEB-MISC Atlassian Confluence Server - Broken Access Control Vulnerability via /setup/*.action (CVE-2023-22515) |
| 998600 | CVE-2023-22515 | WEB-MISC Atlassian Confluence Server - Broken Access Control Vulnerability via /server-info.action (CVE-2023-22515) |

Signature update version 114

October 5, 2023

New signatures rules are generated for the vulnerabilities identified in the week 2023-10-05. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 114 applicable for NetScaler 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0, NetScaler 13.1, NetScaler 14.1 platforms.

Note

Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

| Signature rule | CVE ID | Description |
|----------------|----------------|--|
| 998601 | CVE-2023-42793 | WEB-MISC JetBrains TeamCity Prior to 2023.05.4 - Authentication Bypass Vulnerability (CVE-2023-42793) |
| 998602 | CVE-2023-40931 | WEB-MISC NagiosXI Prior to 5.11.2 - SQL Injection Vulnerability (CVE-2023-40931) |
| 998603 | CVE-2023-40044 | WEB-MISC Progress WS_FTP Server - Deserialization of Untrusted Data Vulnerability (CVE-2023-40044) |
| 998604 | CVE-2023-39362 | WEB-MISC Cacti Prior To 1.2.25 - OS Command Injection Vulnerability (CVE-2023-39362) |
| 998605 | CVE-2023-39361 | WEB-MISC Cacti Prior to 1.2.25 - SQL Injection Vulnerability (CVE-2023-39361) |
| 998606 | CVE-2023-39359 | WEB-MISC Cacti Prior to 1.2.25 - SQL Injection Vulnerability (CVE-2023-39359) |
| 998607 | CVE-2023-39358 | WEB-MISC Cacti Prior to 1.2.25 - SQL Injection Vulnerability via reports_admin (CVE-2023-39358) |
| 998608 | CVE-2023-39358 | WEB-MISC Cacti Prior to 1.2.25 - SQL Injection Vulnerability via reports_user (CVE-2023-39358) |
| 998609 | CVE-2023-35813 | WEB-MISC Sitecore Through 10.3 - Remote Code Execution Vulnerability (CVE-2023-35813) |
| 998610 | CVE-2023-20890 | WEB-MISC VMware Aria Operations for Networks - Path Traversal Vulnerability Via infra API (CVE-2023-20890) |

| Signature rule | CVE ID | Description |
|-----------------------|----------------|---|
| 998611 | CVE-2023-20890 | WEB-MISC VMware Aria Operations for Networks - Path Traversal Vulnerability Via data-sources API (CVE-2023-20890) |
| 998612 | CVE-2022-43719 | WEB-MISC Apache Superset Multiple Versions - CSRF Vulnerability (CVE-2022-43719) |
| 998613 | CVE-2022-40881 | WEB-MISC Contec SolarView Compact Prior to 7.21 - OS Command Injection Vulnerability (CVE-2022-40881) |

Signature update version 113

September 22, 2023

New signature rules are generated for the vulnerabilities identified in the week 2023-09-22. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 113 applicable for NetScaler 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0, NetScaler 13.1, NetScaler 14.1 platforms.

Note

Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

| Signature rule | CVE ID | Description |
|-----------------------|-----------------------------------|--|
| 998614 | CVE-2023-38035 | WEB-MISC Ivanti Sentry Up To 9.18.0 - Incorrect Authorization Vulnerability via /asproxy/services/ (CVE-2023-38035) |
| 998615 | CVE-2023-38035 | WEB-MISC Ivanti Sentry Up To 9.18.0 - Incorrect Authorization Vulnerability via /mics/services/ (CVE-2023-38035) |
| 998616 | CVE-2023-36846 | WEB-MISC Juniper JunOS SRX - Missing Authentication for Critical Function Vulnerability Via webauth_operation (CVE-2023-36846) |
| 998617 | CVE-2023-3486 | WEB-MISC PaperCut NG Prior to 22.1.3 - Unrestricted File Upload Vulnerability (CVE-2023-3486) |
| 998618 | CVE-2023-34468,
CVE-2023-40037 | WEB-MISC Apache NiFi Multiple Versions - Command Injection Vulnerability (CVE-2023-34468, CVE-2023-40037) |
| 998619 | CVE-2023-33653 | WEB-MISC Sitecore - Remote Code Execution Vulnerability (CVE-2023-33653) |
| 998620 | CVE-2023-33224,
CVE-2023-23843 | WEB-MISC SolarWinds Orion Platform Prior to 2023.3 - Remote Code Execution Vulnerability (CVE-2023-33224, CVE-2023-23843) |
| 998621 | CVE-2023-32566 | WEB-MISC Ivanti Avalanche - SecureFilter Authentication Bypass Vulnerability (CVE-2023-32566) |

| Signature rule | CVE ID | Description |
|-----------------------|----------------|---|
| 998622 | CVE-2023-32562 | WEB-MISC Ivanti Avalanche Prior to 6.4.1 - Unrestricted File Upload Vulnerability (CVE-2023-32562) |
| 998623 | CVE-2023-32315 | WEB-MISC Ignite Realtime Openfire - Path Traversal Vulnerability (CVE-2023-32315) |
| 998624 | CVE-2023-28128 | WEB-MISC Ivanti Avalanche Prior to 6.4.0 - Unrestricted Upload Vulnerability (CVE-2023-28128) |
| 998625 | CVE-2023-27066 | WEB-MISC Sitecore Up To 10.2 - Path Traversal Vulnerability (CVE-2023-27066) |
| 998626 | CVE-2022-23333 | WEB-MISC Contec SolarView Compact Prior to 7.21 - OS Command Injection Vulnerability (CVE-2022-23333) |
| 998627 | CVE-2022-37044 | WEB-MISC Zimbra Collaboration Suite Prior to 8.8.15 P33 - XSS Vulnerability via onload (CVE-2022-37044) |
| 998628 | CVE-2022-37044 | WEB-MISC Zimbra Collaboration Suite Prior to 8.8.15 P33 - XSS Vulnerability via extra (CVE-2022-37044) |
| 998629 | CVE-2022-37044 | WEB-MISC Zimbra Collaboration Suite Prior to 8.8.15 P33 - XSS Vulnerability via title (CVE-2022-37044) |
| 998630 | CVE-2022-24086 | WEB-MISC Adobe Magento - Arbitrary Code Execution Vulnerability Via wishlist (CVE-2022-24086) |

| Signature rule | CVE ID | Description |
|-----------------------|----------------|---|
| 998631 | CVE-2022-24086 | WEB-MISC Adobe Magento - Arbitrary Code Execution Vulnerability via checkout (CVE-2022-24086) |

Signature update version 112

September 21, 2023

New signatures rules are generated for the vulnerabilities identified in the week 2023-08-30. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 112 applicable for NetScaler 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0, NetScaler 13.1, NetScaler 14.1 platforms.

Note

Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

| Signature rule | CVE ID | Description |
|-----------------------|----------------|--|
| 998632 | CVE-2023-39526 | WEB-MISC PrestaShop Prior to 8.0.5, 8.1.1 and 1.7.8.10 - Arbitrary File Write Vulnerability via OUTFILE (CVE-2023-39526) |

| Signature rule | CVE ID | Description |
|-----------------------|----------------|--|
| 998633 | CVE-2023-39526 | WEB-MISC PrestaShop Prior to 8.0.5, 8.1.1 and 1.7.8.10 - Arbitrary File Write Vulnerability via DUMPFILER (CVE-2023-39526) |
| 998634 | CVE-2023-39143 | WEB-MISC PaperCut NG/MF Prior to 22.1.3 - Path Traversal Vulnerability in CustomReportExampleServlet (CVE-2023-39143) |
| 998635 | CVE-2023-37979 | WEB-WORDPRESS Ninja Forms Contact Form Plugin Up to 3.6.25 - Cross-Site Scripting Vulnerability (CVE-2023-37979) |
| 998636 | CVE-2023-33652 | WEB-MISC Sitecore - Remote Code Execution Vulnerability (CVE-2023-33652) |
| 998637 | CVE-2023-32563 | WEB-MISC Ivanti Avalanche Prior to 6.4.1 - Arbitrary File Upload Vulnerability (CVE-2023-32563) |
| 998638 | CVE-2023-29357 | WEB-MISC Microsoft SharePoint Server - Elevation of Privilege Vulnerability via access_token/prooftoken (CVE-2023-29357) |
| 998639 | CVE-2023-29357 | WEB-MISC Microsoft SharePoint Server - Elevation of Privilege Vulnerability via Authorization Header (CVE-2023-29357) |
| 998640 | CVE-2023-22480 | WEB-MISC KubeOperator Prior to 3.16.4 - Improper Authorization Vulnerability (CVE-2023-22480) |

Signature update version 111

September 21, 2023

New signatures rules are generated for the vulnerabilities identified in the week 2023-08-04. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 111 applicable for NetScaler 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0, NetScaler 13.1, NetScaler 14.1 platforms.

Note

Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

| Signature rule | CVE ID | Description |
|----------------|----------------|---|
| 998641 | CVE-2023-37580 | WEB-MISC Zimbra Collaboration Suite Multiple Versions - XSS Vulnerability (CVE-2023-37580) |
| 998642 | CVE-2023-35082 | WEB-MISC MobileIron Core (Ivanti EPMM) prior to 11.2 - Authentication Bypass (CVE-2023-35082) |
| 998643 | CVE-2023-35078 | WEB-MISC Ivanti EndPoint Manager Mobile - Authentication Bypass (CVE-2023-35078) |
| 998644 | CVE-2023-34192 | WEB-MISC Zimbra Collaboration Suite Multiple Versions - XSS Vulnerability (CVE-2023-34192) |

| Signature rule | CVE ID | Description |
|-----------------------|----------------|---|
| 998645 | CVE-2023-29382 | WEB-MISC Zimbra Collaboration Suite Multiple Versions - RCE Via sfdc_preauth.jsp (CVE-2023-29382) |

Signature update version 110

September 21, 2023

New signatures rules are generated for the vulnerabilities identified in the week 2023-07-25. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 110 applicable for NetScaler 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0, NetScaler 13.1, NetScaler 14.1 platforms.

Note

Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

| Signature rule | CVE ID | Description |
|-----------------------|----------------|--|
| 998646 | CVE-2023-35036 | WEB-MISC Progress MOVEit Transfer - Authenticated SQL Injection Vulnerability Via X-siLock-FolderID Smuggling (CVE-2023-35036) |

| Signature rule | CVE ID | Description |
|-----------------------|----------------|--|
| 998647 | CVE-2023-35036 | WEB-MISC Progress MOVEit Transfer - Authenticated SQL Injection Vulnerability Via X-siLock-FolderID (CVE-2023-35036) |
| 998648 | CVE-2023-3460 | WEB-WORDPRESS Ultimate Member Wordpress plugin before 2.6.7 Improper Privilege Management (CVE-2023-3460) |
| 998649 | CVE-2023-33651 | WEB-MISC Sitecore - Authorization Rules Bypass Vulnerability Via MVC Device Simulator (CVE-2023-33651) |
| 998650 | CVE-2023-33157 | WEB-MISC Microsoft SharePoint - Remote Code Execution Vulnerability (CVE-2023-33157) |
| 998651 | CVE-2023-30777 | WEB-WORDPRESS WordPress Plugin Advanced Custom Fields Up to 6.1.5 - Reflected XSS Vulnerability (CVE-2023-30777) |
| 998652 | CVE-2023-30545 | WEB-MISC PrestaShop Prior to 8.0.4 and 1.7.8.9 - Arbitrary File Read Vulnerability via LOAD_FILE (CVE-2023-30545) |
| 998653 | CVE-2023-2986 | WEB-WORDPRESS Abandoned Cart Lite for WooCommerce plugin up to 5.14.2 Authentication Bypass (CVE-2023-2986) |
| 998654 | CVE-2023-2982 | WEB-WORDPRESS Wordpress Plugin Social Login and Register prior to 7.6.4 - Authentication Bypass (CVE-2023-2982) |
| 998655 | CVE-2023-29489 | WEB-MISC cPanel prior to 11.102.0.31 - XSS Vulnerability (CVE-2023-29489) |

| Signature rule | CVE ID | Description |
|-----------------------|--|---|
| 998656 | CVE-2023-29300,
CVE-2023-38203,
CVE-2023-38204 | WEB-MISC Adobe ColdFusion -
Deserialization of Untrusted
Data Vulnerability
(CVE-2023-29300,
CVE-2023-38203,
CVE-2023-38204) |
| 998657 | CVE-2023-29298,
CVE-2023-38205 | WEB-MISC Adobe ColdFusion
Multiple Versions - Access
Control Bypass Vulnerability via
restplay (CVE-2023-29298,CVE-
2023-38205) |
| 998658 | CVE-2023-29298,
CVE-2023-38205 | WEB-MISC Adobe ColdFusion
Multiple Versions - Access
Control Bypass Vulnerability via
cfide (CVE-2023-29298,CVE-
2023-38205) |
| 998659 | CVE-2023-28121 | WEB-WORDPRESS WordPress
Plugin WooCommerce
Payments Up to 5.6.1 - Privilege
Elevation Vulnerability
(CVE-2023-28121) |
| 998660 | CVE-2023-27372 | WEB-MISC SPIP up to 3.2.17,
4.0.0 to 4.0.9, 4.1.0 to 4.1.7,
4.2.0 Remote Code Execution
(CVE-2023-27372) |
| 998661 | CVE-2023-27372 | WEB-MISC SPIP up to 3.2.17,
4.0.0 to 4.0.9, 4.1.0 to 4.1.7,
4.2.0 Remote Code Execution
(CVE-2023-27372) |
| 998662 | CVE-2023-27350 | WEB-MISC PaperCut NG -
Authentication Bypass
Vulnerability (CVE-2023-27350) |
| 998663 | CVE-2023-27067 | WEB-MISC Sitecore Up To 10.2 -
Path Traversal Vulnerability
(CVE-2023-27067) |

| Signature rule | CVE ID | Description |
|-----------------------|----------------|---|
| 998664 | CVE-2023-26360 | WEB-MISC Adobe ColdFusion 2018 prior to update 16 and 2021 prior to update 6 - Improper Access Control (CVE-2023-26360) |
| 998665 | CVE-2023-26262 | WEB-MISC Sitecore - Unrestricted Language File Upload Vulnerability (CVE-2023-26262) |
| 998666 | CVE-2023-2611 | WEB-MISC Advantech R-SeeNet Prior to 2.4.23 - Use of Hard-Coded Credentials Vulnerability (CVE-2023-2611) |
| 998667 | CVE-2023-25804 | WEB-MISC Roxy-WI Prior to 6.3.6.0 - Path Traversal Vulnerability (CVE-2023-25804) |
| 998668 | CVE-2023-2575 | WEB-MISC Advantech EKI-15XX - Stack-based Buffer Overflow Vulnerability (CVE-2023-2575) |
| 998669 | CVE-2023-2574 | WEB-MISC Advantech EKI-15XX - OS Command Injection Vulnerability (CVE-2023-2574) |
| 998670 | CVE-2023-2573 | WEB-MISC Advantech EKI-15XX - OS Command Injection Vulnerability (CVE-2023-2573) |
| 998671 | CVE-2023-25690 | WEB-MISC Apache HTTP Server 2.4.0 Through 2.4.55 - Request Smuggling Vulnerability Via Line Feed (CVE-2023-25690) |
| 998672 | CVE-2023-25690 | WEB-MISC Apache HTTP Server 2.4.0 Through 2.4.55 - Request Smuggling Vulnerability Via Carriage Return (CVE-2023-25690) |

| Signature rule | CVE ID | Description |
|-----------------------|----------------|--|
| 998673 | CVE-2023-23489 | WEB-WORDPRESS Wordpress plugin Easy Digital Downloads prior to v3.1.0.2 - SQL Injection Vulnerability (CVE-2023-23489) |
| 998674 | CVE-2023-20887 | WEB-MISC VMware Aria Operations for Networks - Command Injection Vulnerability (CVE-2023-20887) |
| 998675 | CVE-2023-1671 | WEB-MISC Sophos Web Appliance prior to 4.3.10.4 - Command Injection (CVE-2023-1671) |
| 998676 | CVE-2023-1196 | WEB-WORDPRESS WordPress plugin Advanced Custom Fields prior to 5.12.5 and 6.1.0 - Untrusted Deserialization (CVE-2023-1196) |
| 998677 | CVE-2023-1138 | WEB-MISC Delta Electronics InfraSuite Device Master Prior to 1.0.5 - Information Disclosure Via Report (CVE-2023-1138) |
| 998678 | CVE-2023-1138 | WEB-MISC Delta Electronics InfraSuite Device Master Prior to 1.0.5 - Information Disclosure Via ModuleConfig (CVE-2023-1138) |
| 998679 | CVE-2023-1137 | WEB-MISC Delta Electronics InfraSuite Device Master Prior to 1.0.5 - Information Disclosure Vulnerability (CVE-2023-1137) |
| 998680 | CVE-2023-0255 | WEB-WORDPRESS Wordpress plugin Enable Media Replace prior to 4.0.2 - Arbitrary File Upload Vulnerability (CVE-2023-0255) |

| Signature rule | CVE ID | Description |
|-----------------------|----------------|---|
| 998681 | CVE-2022-36963 | WEB-MISC SolarWinds Platform Prior to 2023.2 - Command Injection Vulnerability Via TestCredentials (CVE-2022-36963) |
| 998682 | CVE-2022-29303 | WEB-MISC Contec SolarView Compact Prior to 7.21 - OS Command Injection Vulnerability (CVE-2022-29303) |
| 998683 | CVE-2022-2185 | WEB-MISC GitLab Multiple Versions Prior to 14.10.5 and 15.1.1 - Remote Execution Vulnerability (CVE-2022-2185) |
| 998684 | CVE-2020-5284 | WEB-MISC Next.js Prior to 9.3.2 - Path Traversal Vulnerability (CVE-2020-5284) |

Signature update version 109

September 21, 2023

New signatures rules are generated for the vulnerabilities identified in the week 2023-07-14. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 109 applicable for NetScaler 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0, NetScaler 13.1, NetScaler 14.1 platforms.

Note

Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

| Signature rule | CVE ID | Description |
|----------------|----------------|--|
| 998685 | CVE-2023-36933 | WEB-MISC Progress MOVEit Transfer Multiple Versions - Denial Of Service Vulnerability (CVE-2023-36933) |

Signature update version 108

September 21, 2023

New signatures rules are generated for the vulnerabilities identified in the week 2023-07-12. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 108 applicable for NetScaler 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0, NetScaler 13.1, NetScaler 14.1 platforms.

Note

Enabling Post body and Response body signature rules might affect Citrix ADC CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

| Signature rule | CVE ID | Description |
|----------------|----------------|--|
| 998686 | CVE-2023-36934 | WEB-MISC Progress MOVEit Transfer Multiple Versions - SQL Injection Vulnerability (CVE-2023-36934) |

| Signature rule | CVE ID | Description |
|-----------------------|----------------|--|
| 998687 | CVE-2023-36932 | WEB-MISC Progress MOVEit Transfer Multiple Versions - SQL Injection Vulnerability Via folderlistrecursive (CVE-2023-36932) |

Signature update version 107

September 21, 2023

New signatures rules are generated for the vulnerabilities identified in the week 2023-06-16. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 107 applicable for NetScaler 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0, NetScaler 13.1, NetScaler 14.1 platforms.

Note

Enabling Post body and Response body signature rules might affect NetScaler CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

| Signature rule | CVE ID | Description |
|-----------------------|----------------|--|
| 998688 | CVE-2023-35708 | WEB-MISC Progress MOVEit Transfer Multiple Versions - Unauthenticated SQL Injection Vulnerability (CVE-2023-35708) |

| Signature rule | CVE ID | Description |
|-----------------------|----------------|--|
| 998689 | CVE-2023-35036 | WEB-MISC Progress MOVEit Transfer Multiple Versions - Unauthenticated SQL Injection Vulnerability (CVE-2023-35036) |

Signature update version 106

September 21, 2023

New signatures rules are generated for the vulnerabilities identified in the week 2023-06-16. You can download and configure these signature rules to protect your appliance from security vulnerable attacks.

Signature version

Signature version 106 applicable for NetScaler 11.1, NetScaler 12.0, Citrix ADC 12.1, Citrix ADC 13.0, NetScaler 13.1, NetScaler 14.1 platforms.

Note

Enabling Post body and Response body signature rules might affect NetScaler CPU.

Common Vulnerability Entry (CVE) insight

Following is a list of signature rules, CVE IDs, and its description.

| Signature rule | CVE ID | Description |
|-----------------------|----------------|--|
| 998690 | CVE-2023-34362 | WEB-MISC Progress MOVEit Transfer Multiple Versions - SQL Injection Vulnerability (CVE-2023-34362) |

| Signature rule | CVE ID | Description |
|-----------------------|----------------|---|
| 998691 | CVE-2023-32243 | WEB-WORDPRESS WordPress Plugin Essential Addons for Elementor Up to 5.7.1 - Privilege Escalation Vulnerability (CVE-2023-32243) |
| 998692 | CVE-2023-29084 | WEB-MISC Zoho ManageEngine ADManager Plus Prior to 7181 - OS Command Injection Vulnerability (CVE-2023-29084) |
| 998693 | CVE-2023-29004 | WEB-MISC Roxy-WI Prior to 6.3.9.0 - Absolute Path Traversal Vulnerability (CVE-2023-29004) |
| 998694 | CVE-2023-27351 | WEB-MISC PaperCut NG - Authentication Bypass Vulnerability Via /autosetup/setStatus (CVE-2023-27351) |
| 998695 | CVE-2023-27351 | WEB-MISC PaperCut NG - Authentication Bypass Vulnerability vi /register or /registerCreate (CVE-2023-27351) |
| 998696 | CVE-2023-27351 | WEB-MISC PaperCut NG - Authentication Bypass Vulnerability via /keepalive (CVE-2023-27351) |
| 998697 | CVE-2023-27350 | WEB-MISC PaperCut NG - Authentication Bypass Vulnerability (CVE-2023-27350) |
| 998698 | CVE-2023-25812 | WEB-MISC MinIO Prior to RELEASE.2023-02-17T17-52-43Z - Improper Preservation of Permissions Vulnerability (CVE-2023-25812) |

| Signature rule | CVE ID | Description |
|-----------------------|----------------|--|
| 998699 | CVE-2023-25812 | WEB-MISC MinIO Prior to RELEASE.2023-02-17T17-52-43Z - Improper Preservation of Permissions Vulnerability (CVE-2023-25812) |
| 998700 | CVE-2023-25803 | WEB-MISC Roxy-WI Prior to 6.3.6.0 - Path Traversal Vulnerability (CVE-2023-25803) |
| 998701 | CVE-2023-24031 | WEB-MISC Zimbra Collaboration Suite Prior to 9.0.0 P30 - XSS Vulnerability via clazz (CVE-2023-24031) |
| 998702 | CVE-2023-24031 | WEB-MISC Zimbra Collaboration Suite Prior to 9.0.0 P30 - XSS Vulnerability via altkey (CVE-2023-24031) |
| 998703 | CVE-2023-24031 | WEB-MISC Zimbra Collaboration Suite Prior to 9.0.0 P30 - XSS Vulnerability via title (CVE-2023-24031) |

Bot Management

May 2, 2023

Sometimes the incoming web traffic is comprised of bots and most organizations suffer from bot attacks. Web and mobile applications are significant revenue drivers for business and most companies are under the threat of advanced cyberattacks, such as bots.

A bot is a software program that automatically performs certain actions repeatedly at a much faster rate than a human. Bots can interact with webpages, submit forms, run actions, scan texts, or download content. They can access videos, post comments, and tweet on social media platforms. Some bots, known as chatbots, can hold basic conversations with human users.

A bot that performs a helpful service, such as customer service, automated chat, and search engine crawlers are good bots. At the same time, a bot that can scrape or download content from a website, steal user credentials, spam content, and perform other kinds of cyberattacks are bad bots.

With a good number of bad bots performing malicious tasks, it is essential to manage bot traffic and protect your web applications from bot attacks. By using NetScaler bot management, you can detect the incoming bot traffic and mitigate bot attacks to protect your web applications.

NetScaler bot management helps identify bad bots and protect your appliance from advanced security attacks. It detects good and bad bots and identifies if incoming traffic is a bot attack. By using bot management, you can mitigate attacks and protect your web applications.

NetScaler bot management provides the following benefits:

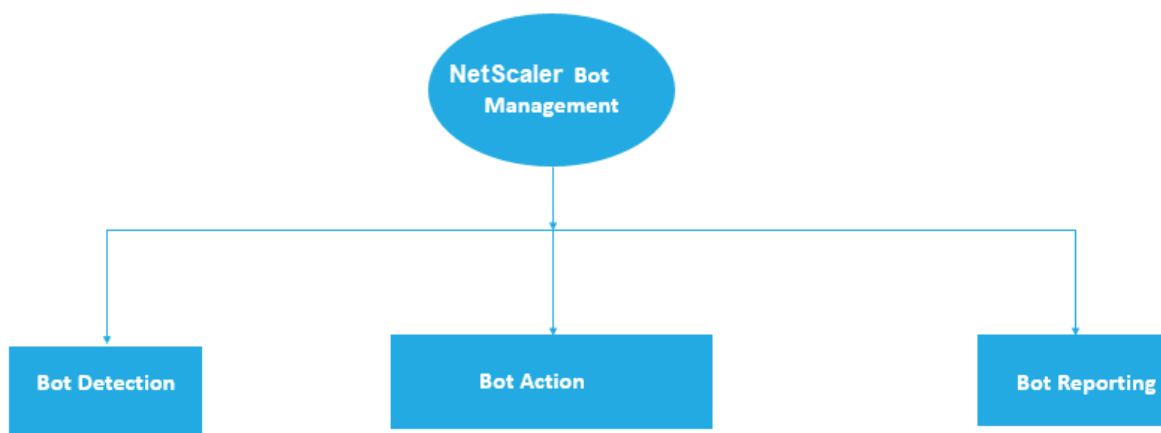

- **Defend against bots, scripts, and toolkits.** Provides real-time threat mitigation using static signature based defense and device fingerprinting.
- **Neutralize automated basic and advanced attacks.** Prevents attacks, such as App layer DDoS, password spraying, password stuffing, price scrapers, and content scrapers.
- **Protect your APIs and investments.** Protects your APIs from unwarranted misuse and protects infrastructure investments from automated traffic.

Some use cases where you can benefit by using the NetScaler bot management system are:

- **Brute force login.** A government web portal is constantly under attack by bots attempting to brute force user logins. The organization discovered the attack by looking through web logs and seeing specific users being select over and over again with rapid login attempts and passwords incrementing using a dictionary attack approach. By law, they must protect themselves and their users. By deploying the NetScaler bot management, they can stop brute force login using device fingerprinting and rate limiting techniques.
- **Block bad bots and device fingerprint unknown bots.** A web entity gets 100,000 visitors each day. They have to upgrade the underlying footprint and they are spending a fortune. In a recent audit, the team discovered that 40 percent of the traffic came from bots, scraping content, picking news, checking user profiles, and more. They want to block this traffic to protect their users and reduce their hosting costs. Using bot management, they can block known bad bots, and fingerprint unknown bots that are hammering their site. By blocking these bots, they can reduce bot traffic by 90 percent.

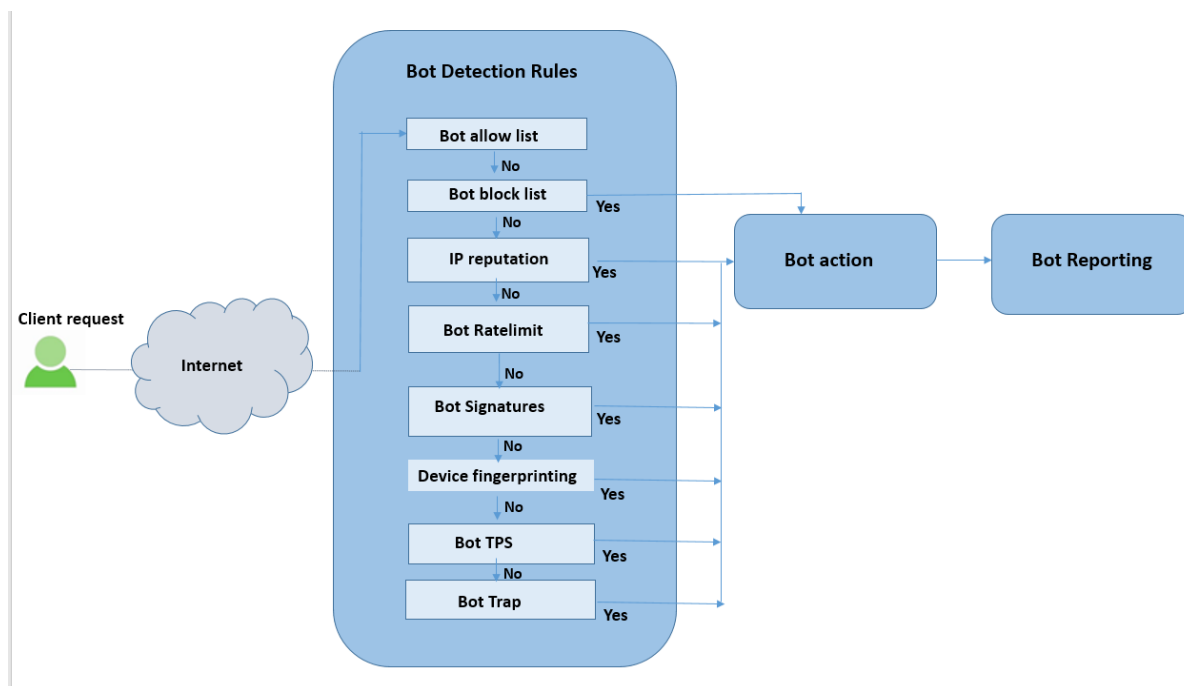

What does NetScaler bot management do

The NetScaler bot management helps organizations protect their web applications and public assets from advanced security attacks. When an incoming traffic is a bot, the bot management system detects the bot type, assigns an action, and generates bot insights, as shown in the following diagram.

How does NetScaler bot management work

The following diagram shows how the NetScaler bot management works. The process involves eight detection techniques that help in detecting the incoming traffic as a good or a bad bot. By default good bots detected by signatures are allowed and bad bots detected by signatures are dropped.

1. The process starts by enabling the bot management feature on the appliance.
2. When a client sends a request, the appliance evaluates the traffic using bot policy rules. If the incoming request is identified as a bot, the appliance applies a bot detection profile.
3. You must bind the default or custom bot signature file to the bot detection profile. The bot signature file has a list of bot signature rules for identifying the incoming bot type.

4. The bot detection rules are available under eight detection categories in the signature file. The categories are allow list, block list, static signature, IP reputation, device fingerprint, and rate limiting. Based on the bot traffic, the system applies a detection rule to the traffic.
5. If the incoming bot traffic matches an entry in the bot allow list, the system bypasses other detection techniques and the associated action logs the data.
6. For detection techniques other than bot allow list, if an incoming request matches a configured rule, the corresponding action is applied. The possible actions are drop, redirect, reset, mitigation, and log. CAPTCHA is a mitigation action which is supported for IP reputation, device fingerprinting, and TPS detection techniques.

Bot Detection

January 4, 2024

The NetScaler bot management system uses various techniques to detect the incoming bot traffic. The techniques are used as detection rules to detect the bot type. The techniques are as follows:

Note:

Bot management supports a maximum of 32 configuration entities for block list, allow list, and rate limiting techniques.

Bot Allowed list - A customized list of IP addresses (IPv4 and IPv6), subnets (IPv4 and IPv6), and policy expressions that can be bypassed as an allowed list.

Bot Blocked list - A customized list of IP addresses (IPv4 and IPv6), subnets (IPv4 and IPv6), and policy expressions that have to be blocked from accessing your web applications.

IP reputation - This rule detects if the incoming bot traffic is from a malicious IP address.

Device fingerprint - This rule detects if the incoming bot traffic has the device fingerprint ID in the incoming request header and browser attributes of an incoming client bot traffic.

Limitation:

1. Java Script must be enabled in the client browser.
2. Does not work for XML responses.

Bot log expression - The detection technique enables you to capture additional information as log messages. The data can be the name of the user who requested the URL, the source IP address, and the source port from which the user sent the request or data generated from an expression.

Rate limit - This rule rate limits multiple requests coming from the same client.

Bot trap - Detects and blocks automated bots by advertising a trap URL in the client response. The URL appears invisible and not accessible if the client is a human user. The detection technique is effective in blocking attacks from automated bots.

TPS - Detects incoming traffic as bots if the maximum number of requests and percentage increase in requests exceeds the configured time interval.

CAPTCHA - This rule uses a CAPTCHA for mitigating bot attacks. A CAPTCHA is a challenge-response validation to determine if the incoming traffic is from a human user or an automated bot. The validation helps block automated bots that cause security violations to web applications. You can configure CAPTCHA as a bot action in IP reputation and device fingerprint detection techniques.

Now, let us see how you can configure each technique to detect and manage your bot traffic.

How to upgrade your appliance to NetScaler CLI-based bot management configuration

If you are upgrading your appliance from an older version (NetScaler release 13.0 build 58.32 or earlier), you must first manually convert the existing bot management configuration to the NetScaler CLI based bot management configuration only once. Complete the following steps to manually convert your bot management configuration.

1. After upgrading to the latest version connect to the upgrade tool “upgrade_bot_config.py” by using the following command

At the command prompt, type:

```
shell "/var/python/bin/python /netscaler/upgrade_bot_config.py > /var/bot_upgrade_commands.txt"
```

2. Run the configuration using the following command.

At the command prompt, type:

```
batch -f /var/bot_upgrade_commands.txt
```

3. Save the upgraded configuration.

```
save ns config
```

Configure NetScaler CLI-based bot management

The bot management configuration enables you to bind one or more bot detection techniques to a specific bot profile.

You must complete the following steps to configure NetScaler-based bot management:

1. Enable bot management

2. Import bot signature
3. Add bot profile
4. Bind bot profile
5. Add bot policy
6. Bind bot policy
7. Configure bot settings

Note:

If you are upgrading your appliance from an older version, you must first manually convert the existing bot management configuration. For more information, see [How to upgrade to NetScaler CLI-based bot management configuration](#) section.

Enable bot management

Before you can begin, ensure that the Bot Management feature is enabled on the appliance. If you have a new NetScaler or VPX, you must enable the feature before you configure it. If you are upgrading a NetScaler appliance from an earlier version to the current version, you must need to enable the feature before you configure it. At the command prompt, type:

```
enable ns feature Bot
```

Import bot signature

You can import the default signature bot file and bind it to the bot profile. At the command prompt, type:

```
import bot signature [<src>] <name> [-comment <string>] [-overwrite]
```

Where:

`src` - Local path name, or URL (protocol, host, path, and file name). Maximum Length: 2047.

> **Note:**

>

> The import fails if the object to be imported is on an HTTPS server that requires client certificate authentication for access.

`name` - Name of the bot signature file object. This is a mandatory argument. Maximum Length: 31.

`comment` - Description about the signature file object. Maximum Length: 255.

`overwrite` - Action that overwrites the existing file.

> **Note:**

>

> Use the `overwrite` option to update the content in the signature file. Alternately, use the `update bot signature <name>` command to update the signature file on the NetScaler appliance.

Example `import bot signature http://www.example.com/signature.json signaturefile -comment commentsforbot -overwrite`

Note:

You can use the `overwrite` option to update the content in the signature file. Also, you can use the `update bot signature <name>` command to update the signature file in the NetScaler appliance.

Add bot profile

A bot profile is a collection of profile settings to configure bot management on the appliance. You can configure the settings to perform bot detection.

At the command prompt, type:

```
add bot profile <name> [-signature <string>] [-errorURL <string>]
[-trapURL <string>] [-whiteList ( ON | OFF )] [-blackList ( ON |
OFF )] [-rateLimit ( ON | OFF )] [-deviceFingerprint ( ON | OFF )]
[-deviceFingerprintAction ( none | log | drop | redirect | reset |
mitigation )] [-ipReputation ( ON | OFF )] [-trap ( ON | OFF )]
```

Example:

```
add bot profile profile1 -signature signature -errorURL http://www.
example.com/error.html -trapURL /trap.html -whitelist ON -blacklist
ON -rateLimit ON -deviceFingerprint ON -deviceFingerprintAction drop
-ipReputation ON -trap ON
```

Bind bot profile

After you create a bot profile, you must bind the bot detection mechanism to the profile.

At the command prompt, type:

```
bind bot profile <name> | (-ipReputation [-category <ipReputationCategory
>] [-enabled ( ON | OFF )] [-action ( none | log | drop | redirect |
reset | mitigation )] [-logMessage <string>]
```

Example:

The following example is for binding the IP reputation detection technique to a specific bot profile.

```
bind bot profile profile5 -ipReputation -category BOTNET -enabled ON
-action drop -logMessage message
```

Add bot policy

You must add the bot policy for evaluating bot traffic.

At the command prompt, type:

```
add bot policy <name> -rule <expression> -profileName <string> [-
undefAction <string>] [-comment <string>] [-logAction <string>]
```

Where,

Name- Name for the bot policy. Must begin with a letter, number, or the underscore character (_), and must contain only letters, numbers, and the hyphen (-), period (.) pound (#), space (), at (@), equals (=), colon (:), and underscore characters. Can be changed after the bot policy is added.

Rule- An expression that the policy uses to determine whether to apply the bot profile on the specified request. This is a mandatory argument. Maximum Length: 1499

profileName- Name of the bot profile to apply if the request matches this bot policy. This is a mandatory argument. Maximum Length: 127

undefAction- Action to perform if the result of policy evaluation is undefined (UNDEF). An UNDEF event indicates an internal error condition. Maximum Length: 127

Comment- Description about this bot policy. Maximum Length: 255

logAction - Name of the log action to use for requests that match this policy. Maximum Length: 127

Example:

```
add bot policy pol1 -rule "HTTP.REQ.HEADER(\"header\").CONTAINS(\"
custom\")"- profileName profile1 -undefAction drop -comment commentforbotpolic
-logAction log1
```

Bind bot policy global

At the command prompt, type:

```
bind bot global -policyName <string> -priority <positive_integer>
> [-gotoPriorityExpression <expression>][ -type ( REQ_OVERRIDE |
REQ_DEFAULT )] [-invoke (-labelType ( vserver | policylabel )-
labelName <string>)]
```

Example:

```
bind bot global -policyName pol1 -priority 100 -gotoPriorityExpression  
NEXT -type REQ_OVERRIDE
```

Bind bot policy to a virtual server

At the command prompt, type:

```
bind lb vserver <name>@ ((<serviceName>@ [-weight <positive_integer  
>] ) | <serviceName>@ | (-policyName <string>@ [-priority <  
positive_integer>] [-gotoPriorityExpression <expression>]
```

Example:

```
bind lb vserver lb-server1 -policyName pol1 -priority 100 -gotoPriorityExpressi  
NEXT -type REQ_OVERRIDE
```

Configure bot settings

You can customize the default settings if necessary.

At the command prompt, type:

```
1 set bot settings [-defaultProfile <string>] [-javascriptName <string>]  
  [-sessionTimeout <positive_integer>] [-sessionCookieName <string>]  
  [-dfpRequestLimit <positive_integer>] [-signatureAutoUpdate ( ON |  
  OFF )] [-signatureUrl <URL>] [-proxyServer <ip_addr|ipv6_addr|*>] [-  
  proxyPort <port|*>]  
2 <!--NeedCopy-->
```

Where,

defaultProfile - Profile to use when a connection does not match any policy. Default setting is "", which sends unmatched connections back to the NetScaler without attempting to filter them further. Maximum Length: 31

javascriptName - Name of the JavaScript that the BotNet feature uses in response. Must begin with a letter or number, and can consist of from 1 to 31 letters, numbers, and the hyphen (-) and underscore (_) symbols. The following requirement applies only to the NetScaler CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my cookie name" or 'my cookie name'). Maximum Length: 31

sessionTimeout - Session times out, in seconds, after which a user session is terminated.

Minimum value - 1, Maximum value: 65535

sessionCookieName - Name of the SessionCookie that the BotNet feature uses it for tracking. Must begin with a letter or number, and can consist of from 1 to 31 letters, numbers, and the hyphen (-)

and underscore (_) symbols. The following requirement applies only to the NetScaler CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, “my cookie name” or ‘my cookie name’). Maximum Length: 31

`dfpRequestLimit` - Number of requests to allow without bot session cookie if device fingerprint is enabled. Minimum value: 1, Maximum Value: 4294967295

`signatureAutoUpdate` - Flag used to enable/disable bot auto update signatures. Possible values: ON, OFF.

Default value: OFF

`signatureUrl` - URL to download the bot signature mapping file from the server. Default value: <https://nsbotsignatures.s3.amazonaws.com/BotSignatureMapping.json>. Maximum Length: 2047

`proxyServer` - Proxy Server IP to get updated signatures from AWS.

`proxyPort` - Proxy Server Port to get updated signatures from AWS. Default value: 8080

`proxyUsername` - User name to authenticate to the proxy server for downloading signature updates.

`proxyPassword` - Password to authenticate to the proxy server for downloading signature updates.

Example:

```
set bot settings -defaultProfile profile1 -javascriptName json.js -
sessionTimeout 1000 -sessionCookieName session -proxyServer 10.102.30.112
-proxyPort 3128 -proxyUsername defaultuser -proxyPassword defaultPassword
```

Configuring bot management by using NetScaler GUI

You can configure NetScaler bot management by first enabling the feature on the appliance. Once you enable, you can create a bot policy to evaluate the incoming traffic as bot and send the traffic to the bot profile. Then, you create a bot profile and then bind the profile to a bot signature. As an alternative, you can also clone the default bot signature file and use the signature file to configure the detection techniques. After creating the signature file, you can import it into the bot profile.

NetScaler Bot Management

NetScaler Bot Management mitigates automated threats and unwanted bot traffic against your public apps, APIs, and websites. If incoming traffic is determined to be a bot, the system takes an action assigned by the ADC administrator, and generates robust reporting for accountability and auditability.

Bot Management provides the following benefits:

- ✓ **Defend against bots, scripts, and toolkits** — Static-signature based defense and device fingerprinting provide threat mitigation against both basic and advanced bots.
- ✓ **Neutralize basic and advanced attacks** — Prevent attacks such as App layer DDoS, password spraying, password stuffing, price scrapers, content scrapers, and more.
- ✓ **Protect your APIs and investments** — Protect your APIs from misuse, probing, and data leaks, and protects infrastructure investments from unwanted traffic.

1. Enable bot management feature
2. Configure bot management settings
3. Clone NetScaler bot default signature
4. Import NetScaler bot signature
5. Configure bot profile and signature settings
6. Create bot profile
7. Create bot policy

Enable bot management feature

Complete the following steps to enable bot management:

1. On the navigation pane, expand **System** and then click **Settings > Configure Advanced Features**.
2. On the **Configure Advanced Features** page, select the **NetScaler Bot Management** checkbox.
3. Click **OK**.

Configure bot management settings

Complete the following step to configure the device fingerprint technique:

1. Navigate to **Security > NetScaler bot Management**.
2. In the details pane, under **Settings** click **Change NetScaler bot Management Settings**.
3. In the **Configure NetScaler bot Management Settings**, set the following parameters.
 - a) Default Profile. Select a bot profile.
 - b) JavaScript Name. Name of the JavaScript file that bot management uses in its response to the client.

- c) Session Timeout. Timeout in seconds after which the user session is terminated.
- d) Session Cookie. Name of the session cookie that the bot management system uses for tracking.
- e) Device Fingerprint Request Limit. Number of requests to allow without a bot session cookie, if device fingerprint is enabled.
- f) Proxy Server - Proxy server IP address from where the latest signatures are uploaded.
- g) Proxy Port –Port number of machine from where the latest signatures are uploaded.
- h) Proxy Username –User name for the authentication of the proxy server
- i) Proxy Password - Password for the authentication of the proxy server.

Note:

Proxy User name and the Proxy Password fields are enabled if the Proxy Server and the Proxy Port fields are configured.

4. Click **OK**.

Clone bot signature file

Complete the following step to clone the bot signature file:

1. Navigate to **Security > NetScaler Bot Management and Signatures**.
2. In the **NetScaler Bot Management Signatures** page, select the default bot signatures record and click **Clone**.
3. In the **Clone Bot Signature** page, enter a name and edit the signature data.
4. Click **Create**.

Import bot signature file

If you have your own signature file, then you can import it as a file, text, or URL. Perform the following steps to import the bot signature file:

1. Navigate to **Security > NetScaler Bot Management and Signatures**.
2. On the **NetScaler Bot Management Signatures** page, import the file as URL, File, or text.
3. Click **Continue**.
4. On the Import NetScaler Bot Management Signature page, set the following parameters.
 - a) Name - Name of the bot signature file.
 - b) Comment - Brief description about the imported file.
 - c) Overwrite - Select the checkbox to allow overwriting of data during file update.

- d) Signature Data - Modify signature parameters
5. Click **Done**.

Configure IP reputation

The IP reputation bot technique uses Webroot's IP reputation database and cloud service provider database to verify if a client request is a malicious IP address or a public cloud IP address. As part of the bot categories is configured and then a bot action is associated to it. Complete the following steps to configure Webroot IP reputation and cloud service provider database categories.

1. Navigate to **Security > NetScaler bot Management** and **Profiles**.
2. On the **NetScaler bot Management Profiles** page, select a profile and click **Edit**.
3. On the **NetScaler bot Management Profile** page, go to the **Profile Settings** section and click **IP Reputation**.
4. On the **IP Reputation** section, set the following parameters:
 - a) Enabled. Select the checkbox to validate incoming bot traffic as part of the detection process.
 - b) Configure Categories. You can use the IP reputation technique for incoming bot traffic under different categories. Based on the configured category, you can drop or redirect the bot traffic. Click **Add** to configure a malicious bot category.
 - c) In the **Configure NetScaler bot Management Profile IP Reputation Binding** page, set the following parameters:
 - i. Category. Select a Webroot IP reputation bot category to validate a client request as a malicious IP address.
 - A. IP_BASED - This category checks whether the client IP address (IPv4 and IPv6) is malicious or not.
 - B. BOTNET - This category includes Botnet C&C channels, and infected zombie machines controlled by Bot master.
 - C. SPAM_SOURCES - This category includes tunneling spam messages through a proxy, anomalous SMTP activities, and forum spam activities.
 - D. SCANNERS - This category includes all reconnaissance such as probes, host scan, domain scan, and password brute force attack.
 - E. DOS - This category includes DOS, DDOS, anomalous sync flood, and anomalous traffic detection.
 - F. REPUTATION - This category denies access from IP addresses (IPv4 and IPv6) currently known to be infected with malware. This category also includes IP

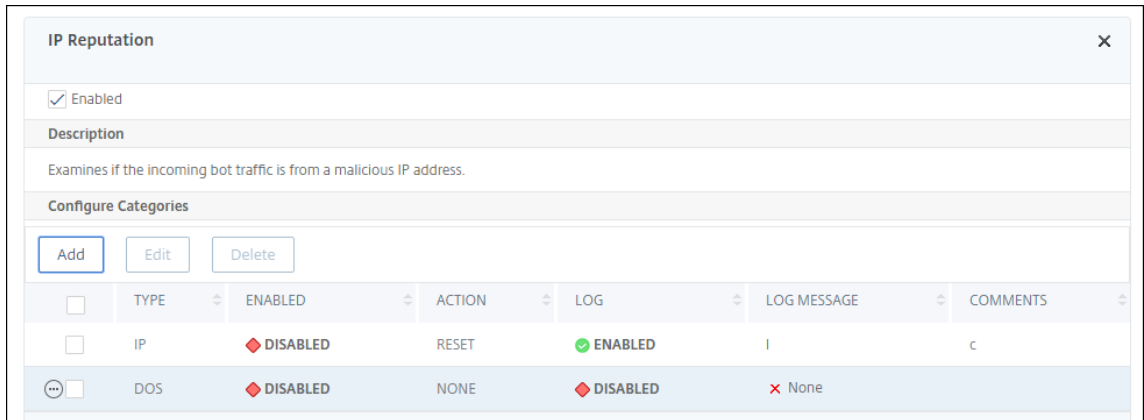

addresses with average low Webroot Reputation Index score. Enabling this category prevents access from sources identified to contact malware distribution points.

- G. PHISHING - This category includes IP addresses (IPv4 and IPv6) hosting phishing sites and other kinds of fraud activities such as ad click fraud or gaming fraud.
 - H. PROXY - This category includes IP addresses (IPv4 and IPv6) providing proxy services.
 - I. NETWORK - IPs providing proxy and anonymization services including The Onion Router aka TOR or dark net.
 - J. MOBILE_THREATS - This category checks the client IP address (IPv4 and IPv6) with the list of addresses harmful for mobile devices.
- ii. Category. Select a Webroot public cloud service provider category to validate a client request is a public cloud IP address.
- A. AWS - This category checks client IP address with list of public cloud addresses from AWS.
 - B. GCP - This category checks client IP address with list of public cloud addresses from the Google Cloud Platform.
 - C. AZURE - This category checks client address with list of public cloud addresses from Azure.
 - D. ORACLE - This category checks client IP address with list of public cloud addresses from Oracle
 - E. IBM - This category checks client IP address with list of public cloud addresses from IBM.
 - F. SALESFORCE - This category checks client IP address with list of public cloud addresses from Salesforce.
- Possible values for Webroot IP reputation bot category: IP, BOTNETS, SPAM_SOURCES, SCANNERS, DOS, REPUTATION, PHISHING, PROXY, NETWORK, MOBILE_THREATS.
- Possible values for Webroot public cloud service provider category: AWS, GCP, AZURE, ORACLE, IBM, SALESFORCE.
- iii. Enabled. Select the checkbox to validate the IP reputation signature detection.
- iv. Bot action. Based on the configured category, you can assign no action, drop, redirect, or mitigation action.
- v. Log. Select the checkbox to store log entries.
- vi. Log Message. Brief description of the log.
- vii. Comments. Brief description about the bot category.

5. Click **OK**.

6. Click **Update**.

7. Click **Done**.

Note

If you disable **IP reputation**, ensure to stop its downloads. Complete the following steps to stop the IP reputation downloads:

1. Navigate to **Security > NetScaler bot Management > Change NetScaler bot Management Settings**
2. Change the **Default Nonintrusive Profile** to **BOT_BYPASS**.

For more information on profile settings, see [Configure bot profile setting](#)

Configure bot static signatures

This detection technique enables you to identify the user agent info from the browser details. Based on user agent information, the bot is identified as a bad or a good bot and then you assign a bot action to it.

Perform the following the steps to configure the static signature technique:

1. On the navigation pane, expand **Security > NetScaler Bot Management > Signatures**.
2. On the **NetScaler Bot Management Signatures** page, select a signature file and click **Edit**.
3. On the **NetScaler Bot Management Signature** page, go to the **Signature Settings** section and click **Bot Signatures**.
4. In the **Bot Signatures** section, set the following parameters:
 - a) Configure Static Signatures. This section has a list of bot static signature records. You can select a record and click **Edit** to assign a bot action to it.
 - b) Click **OK**.
5. Click **Update Signature**.

6. Click **Done**.

The screenshot shows the 'Bot Signatures' configuration window. At the top, there is a title bar 'Bot Signatures' with a close button. Below it is a sub-header 'Configure Static Signatures' and an 'Edit' button. The main area contains a table with the following data:

| <input type="checkbox"/> | ID | ENABLED | NAME | VERSION | DROP | TYPE | CATEGORY | LOG |
|--------------------------|----|---------|--------------------|---------|----------|----------|----------|----------|
| <input type="checkbox"/> | 1 | ENABLED | a.pr-cy.ru | 2.1 | ENABLED | Bad Bot | Crawler | DISABLED |
| <input type="checkbox"/> | 2 | ENABLED | AddThis.com | 2.1 | DISABLED | Good Bot | Crawler | DISABLED |
| <input type="checkbox"/> | 3 | ENABLED | Adidxbot | 2.1 | DISABLED | Good Bot | Crawler | DISABLED |
| <input type="checkbox"/> | 4 | ENABLED | ADmantx | 2.1 | ENABLED | Bad Bot | Crawler | DISABLED |
| <input type="checkbox"/> | 5 | ENABLED | archive.org bot | 2.1 | DISABLED | Good Bot | Crawler | DISABLED |
| <input type="checkbox"/> | 6 | ENABLED | Artmixx Spider Bot | 2.1 | DISABLED | Good Bot | Crawler | DISABLED |

Below the table are two buttons: 'Update Signature' and 'Done'.

Bot static signature delineation NetScaler bot management protects your web application against bots. Bot static signatures help in identifying good and bad bots based on request parameters such as user-agent in the incoming request.

The list of signatures in the file is huge and also new rules get added and stale ones are removed periodically. As an administrator, you might want to search for a specific signature or list of signatures under a category. To filter signatures easily, the bot signature page provides an enhanced search capability. The search function enables you to find signature rules and configure its property based on one or more signature parameters like action, signature ID, developer, and signature name.

Action - Select a bot action that you prefer to configure for a specific category of signature rules. Following are the available action types:

- Enable Selected - Enable all the selected signature rules.
- Disable Selected - Disable all the selected signatures rules.
- Drop Selected - Select the “Drop” action to all the selected signature rules.
- Redirect Selected - Apply the “Redirect” action to all the selected signature rules.
- Reset Selected - Apply the “Reset” action to all the selected signature rules.
- Log Selected - Apply the “Log” action to all the selected signature rules.
- Remove Drop Selected - Unset the drop action to all the selected signature rules.
- Remove Redirect Selected - Unset the redirect action to all the selected signature rules.
- Remove Reset Selected - Unset the reset action to all the selected signature rules.
- Remove Log Selected - Unset the log action to all the selected signature rules.

Category - Select a category to filter signature rules accordingly. Following is the list of categories that are available for sorting signature rules.

- Action - Sort based on bot action.
- Category - Sort based on bot category.
- Developer - Sort based on the host company publisher.
- Enabled - Sort based on signature rules that are enabled.
- Id - Sort based on signature rule ID.
- Log - Sort based on signature rules that have logging enabled.
- Name - Sort based on signature rule name.
- Type - Sort based on signature type.
- Version - Sort based on signature rule version.

Search bot static signature rules based on action and category types by using the NetScaler GUI

1. Navigate to **Security > NetScaler Bot Management > Signature**.
2. In the details page, click **Add**.
3. In the **NetScaler Bot Management Signatures** page, click edit in the **Static Signature** section.
4. In the **Configure Static Signature** section, select a signature action from the drop-down list.
5. Use the search function to select a category and filter the rules accordingly.
6. Click **Update**.

Edit the bot static signature rule property by using the NetScaler GUI

1. Navigate to **Security > NetScaler Bot Management > Signature**.
2. In the details page, click **Add**.
3. In the **NetScaler Bot Management Signatures** page, click edit in the **Static Signature** section.
4. In the **Configure Static Signature** section, select an action from the drop-down list.
5. Use the search function to select a category and filter the rules accordingly.
6. From the static signature list, select a signature to modify its property.
7. Click **OK** to confirm.

For more information on profile settings, see [Configure bot signature setting](#)

Create bot management profile

A bot profile is a collection of bot management settings that are used for detecting the bot type. In a profile, you determine how the Web App Firewall applies each of its filters (or checks) to bot traffic to your websites, and responses from them.

Complete the following steps to configure the bot profile:

1. Navigate to **Security > NetScaler Bot Management > Profiles**.

2. In the details pane, click **Add**.
3. In the **Create NetScaler Bot Management Profile** page, set the following parameters.
 - a) Name. Bot profile name.
 - b) Signature. Name of the bot signature file.
 - c) Error URL. URL for redirects.
 - d) Comment. Brief description about the profile.
4. Click **Create** and **Close**.

Create bot policy

The bot policy controls the traffic going to the bot management system and also to control the bot logs sent to the auditlog server. Follow the procedure to configure the bot policy.

1. Navigate to **Security > NetScaler Bot Management > Bot Policies**.
2. In the details pane, click **Add**.
3. In the **Create NetScaler Bot Management Policy** page, set the following parameters.
 - a) Name. Name of the Bot policy.
 - b) Expression. Type the policy expression or rule directly in the text area.
 - c) Bot Profile. Bot profile to apply the bot policy.
 - d) Undefined Action. Select an action that you prefer to assign.
 - e) Comment. Brief description about the policy.
 - f) Log Action. Audit log message action for logging bot traffic. For more information about audit log action, see Audit logging topic.
4. Click **Create** and **Close**.

Request headers dropped by the NetScaler bot Management

Many of the request headers related to caching is dropped to view every request within the context of a session. Similarly, if the request includes an encoding header to allow the web server to send compressed responses, the bot management deletes this header so that the contents in the uncompressed server response is inspected by the bot management to insert the JavaScript.

The bot management drops the following request headers:

Range - Used to recover from a failed or partial file transfers.

If-Range - Allows a client to retrieve a partial object when it contains a part of that object in its cache already (conditional GET).

If-Modified-Since - If the requested object is not modified since the time specified in this field, an entity is not returned from the server. You get an HTTP 304 not modified error.

If-None-Match - Allows efficient updates of cached information with a minimum amount of overhead.

Accept-Encoding - What encoding methods are allowed for a particular object, such as gzip.

Configure bot profile setting

May 8, 2024

You can configure the following settings in the bot profile:

- Configure bot rate limit technique
- Configure bot log expression
- Configure bot trap technique
- Configure device fingerprint technique for mobile (Android) applications
- Bot detection based on mouse and keyboard dynamics
- Verbose logging for bot traffic
- Configure an action for spoofed bot requests

Configure bot rate limit technique

The bot rate limit technique enables you to limit bot traffic within certain timeframe based on the user's geolocation, client IP address, session, cookie, or configured resource (URL).

By configuring the bot rate limit technique, you can ensure the following:

- Block malicious bot activity.
- Reduce traffic strain to web servers.

Configure bot rate limit by using NetScaler CLI

At the command prompt, type:

```
1 bind bot profile <name>... -ratelimit -type <type> Geolocation -  
   countryCode <countryName> -rate <positive_integer> -timeSlice <  
   positive_integer> [-action <action> ...] [-limitType ( BURSTY |  
   SMOOTH )] [-condition <expression>] [-enabled ( ON | OFF )]  
2 <!--NeedCopy-->
```

Where,

- ***SOURCE_IP** - Rate-limiting based on the client IP address.
- ***SESSION** - Rate-limiting based on the configured cookie name.
- ***URL** - Rate-limiting based on the configured URL.
- ***GEOLOCATION** - Rate-limiting based on the configured country name.

Possible values - SESSION, SOURCE_IP, URL, GEOLOCATION

Example:

```
1 bind bot profile geo_prof -ratelimit -type Geolocation -countryCode IN
   -rate 100 -timeSlice 1000 -limitType SMOOTH -condition HTTP.REQ.
   HEADER("User-Agent").contains("anroid") -action log,drop -enabled
   on
2 <!--NeedCopy-->
```

Configure bot rate limit by using NetScaler GUI

Complete the following steps to configure the bot rate limit detection technique:

1. Navigate to **Security > NetScaler Bot Management** and **Profiles**.
2. In the **NetScaler Bot Management Profiles** page, select a profile and click **Edit**.
3. In the **NetScaler Bot Management Profile** page, go to the **Profile Settings** section and click **Rate Limit**.
4. In the **Rate Limit** section, set the following parameters:
 - a) Enabled. Select the checkbox to validate the incoming bot traffic as part of the detection process.
 - b) Click **Add** to configure rate limit bindings.
5. In the **Configure NetScaler Bot Management Rate Limit** page, set the following parameters.
 - a) Type - Rate limit bot traffic is based on the following parameters:
 - i. Geolocation - Rate limit based on the user's geographic location.
 - ii. Source_IP - Rate limit traffic based on client IP address.
 - iii. Session - Rate limit bot traffic based on session or cookie name.
 - iv. URL - Rate limit bot traffic based on the configured URL.
 - b) Country - Select a geolocation as country or region.
 - c) Rate Limit Type –Limits the type of traffic based on the following types.

- Bursty –Forward all requests that are within the set threshold and specified time period.
- Smooth –Forward the requests evenly across the specified time period.

- d) Rate Limit Connection - Allows you to create multiple rules for a condition.
- e) Enabled - Select the checkbox to validate the incoming bot traffic.
- f) Request Threshold - Maximum number of requests allowed within a certain timeframe.
- g) Period - Timeframe in milliseconds.
- h) Action - Select one of the following options:
 - i. None - Allows the request.
 - ii. Drop - Drop the request.
 - iii. Redirect - Redirect the request to the URL specified.
 - iv. Reset - Blocks the request and resets the connection.
 - v. Respond with status too many requests - Responds with an error message when the volume of incoming requests is high.
- i) Log - Select to store the log entries.
- j) Log Message - Brief description of the log.
- k) Comments - Brief description about the bot category.

6. Click **OK**.

7. Click **Update**.

8. Click **Done**.

The screenshot shows the 'Configure NetScaler Bot Management Signature Rate Limit Binding' configuration page. The form includes the following fields and options:

- Type***: A dropdown menu set to 'GEOLOCATION'.
- Country***: A dropdown menu set to 'AFGHANISTAN'.
- Rate Limit Type**: Radio buttons for 'Bursty' (selected) and 'Smooth'.
- Rate Limit Condition**: An empty text input field.
- RegEx Editor**: A link to open a regular expression editor.
- Enabled**: A checkbox that is currently unchecked.
- Request Threshold***: A text input field containing '1', with the unit 'Requests' indicated to the right.
- Period***: A text input field containing '1000', with the unit 'Milliseconds' indicated to the right.
- Action***: Radio buttons for 'None' (selected), 'Drop', 'Redirect', 'Reset', and 'Respond with status too many requests'.
- Log**: A checkbox that is currently unchecked.
- Log Message**: An empty text input field.
- Comments**: An empty text input field.

Configure bot log expression

If the client is identified as a bot, the NetScaler bot management enables you to capture additional information as log messages. The data can be the name of the user who requested the URL, the source IP address, and the source port from which the user sent the request or data generated from an expression. To perform custom logging, you must configure a log expression in the bot management profile.

Bind the log expression in the bot profile by using the CLI

At the command prompt, type:

```
1 bind bot profile <name> (-logExpression -name <string> -expression <
  expression> [-enabled ( ON | OFF )]) -comment <string>
2 <!--NeedCopy-->
```

Example:

```
bind bot profile profile1 -logExpression exp1 -expression HTTP.REQ.
URL -enabled ON -comment "testing log expression"
```

Bind log expression to bot profile by using the GUI

1. Navigate to **Security > NetScaler Bot Management > Profiles**.
2. On the **NetScaler Bot Management Profiles** page, select **Bot Log Expressions** from the **Profile Settings** section.
3. In the **Bot Log Expression Settings*** section, click ****Add**.
4. In the **Configure NetScaler Bot Management Profile Bot Log Expression Binding** page, set the following parameters.
 - a) Log Expression Name. Name of the log expression.
 - b) Expression. Enter the log expression.
 - c) Enabled. Enable or disable the log expression binding.
 - d) Comments. A brief description about the bot log expression binding.
5. Click **OK** and **Done**.

Client IP policy expression for bot detection

The NetScaler bot management now enables you to configure an advanced policy expression to extract the client IP address from an HTTP request header, HTTP request body, HTTP request URL, or using an advanced policy expression. The extracted values are used by a bot detection mechanism (such as TPS, bot trap, or rate limit) to detect if the incoming request is a bot.

Note:

If you have not configured a client IP expression, the default or existing source client IP address is used for bot detection. If an expression is configured, then the evaluation result provides the client IP address that can be used for bot detection.

You can configure and use the client IP expression to extract the actual client IP address if the incoming request is coming through a proxy server and if the client IP address is present in the header. By adding this configuration, the appliance can use the bot detection mechanism in providing more security to software clients and servers.

Configure client IP policy expression in bot profile by using the CLI At the command prompt, type:

```
1 add bot profile <name> [-clientIPExpression <expression>]
2 <!--NeedCopy-->
```

Example:

```
add bot profile profile1 -clientIPExpression 'HTTP.REQ.HEADER("X-Forwarded-For")ALT CLIENT.IP.SRC.TYPECAST_TEXT_T'
```

```
add bot profile profile1 -clientIPExpression 'HTTP.REQ.HEADER("X-Forwarded-For")ALT CLIENT.IPv6.SRC.TYPECAST_TEXT_T'
```

Configure client IP policy expression in bot profile by using the GUI

1. Navigate to **Security > NetScaler Bot Management > Profiles**.
2. In the details pane, click **Add**.
3. In the **Create NetScaler Bot Management Profile** page, set the Client IP Expression.
4. Click **Create** and **Close**.

Configure bot trap technique

NetScaler bot trap technique randomly or periodically inserts a trap URL in the server response. You can also create a trap URL list and add URLs for that The URL appears invisible and not accessible if the client is a human user. However, if the client is an automated bot, the URL is accessible and when accessed, the attacker is categorized as bot and any subsequent request from the bot is blocked. The trap technique is effective in blocking attacks from bots.

The trap URL is an alpha-numeric URL of configurable length and it is auto-generated at configurable interval. Also the technique allows you to configure a trap insertion URL for top visited websites or frequently visited websites. By doing this, you can mandate the purpose of inserting the bot trap URL for requests matching the trap insertion URL.

Note:

Although the bot trap URL is auto-generated, the NetScaler bot management still allows you to configure a customized trap URL in the bot profile. This is done to strengthen the bot detection technique and make it harder for attackers to access the trap URL.

To complete the bot trap configuration, you must complete the following steps.

1. Enable bot trap URL
2. Configure bot trap URL in bot profile
3. Bind bot trap insertion URL to bot profile
4. Configure bot trap URL length and interval in bot settings

Enable bot trap URL protection

Before you can begin, you must ensure that the Bot trap URL protection is enabled on the appliance.

At the command prompt, type:

```
enable ns feature Bot
```

Configure bot trap URL in bot profile

You can configure the bot trap URL and specify a trap action in the bot profile.

At the command prompt, type:

```
add bot profile <name> -trapURL <string> -trap ( ON | OFF )-trapAction  
<trapAction>
```

Where,

- `trapURL` is the URL that Bot protection uses as the Trap URL. Maximum Length: 127
- `trap` is to enable bot trap detection. Possible values: ON, OFF. Default value: OFF
- `trapAction` is an action to be taken based on bot detection. Possible values: NONE, LOG, DROP, REDIRECT, RESET, MITIGATION. Default value: NONE

Example:

```
add bot profile profile1 -trapURL www.bottrap1.com trap ON -trapAction  
RESET
```

Bind bot trap insertion URL to bot profile

You can configure the bot trap insertion URL and bind it to the bot profile.

At the command prompt, type:

```
bind bot profile <profile_name> trapInsertionURL -url <url> -enabled  
ON|OFF -comment <comment>
```

Where,

URL - The request URL regex pattern for which the bot trap URL is inserted. Maximum Length: 127

Example:

```
bind bot profile profile1 trapInsertionURL -url www.example.com -  
enabled ON -comment insert a trap URL randomly
```

Configure bot trap URL length and interval in bot settings

You can configure the bot trap URL length and also set the interval to auto generate the bot trap URL.

At the command prompt, type:

```
set bot settings -trapURLAutoGenerate ( ON | OFF )-trapURLInterval <  
positive_integer> -trapURLLength <positive_integer>
```

Where,

- `trapURLInterval` is the time in seconds after which the bot trap URL is updated. Default value: 3600, Minimum value: 300, Maximum value: 86400
- `trapURLLength`. Length of the auto-generated bot trap URL. Default value: 32, Minimum value: 10, Maximum value: 255

Example:

```
set bot settings -trapURLAutoGenerate ON -trapURLInterval 300 -trapURLLength  
60
```

Configure bot trap URL by using the GUI

1. Navigate to **Security > NetScaler Bot Management > Profiles**.
2. In the **NetScaler Bot Management Profiles** page, click **Edit** to configure the bot trap URL technique.
3. In the **Create NetScaler Bot Management Profile** page, edit basic settings to enter the trap URL and click **OK**.

4. In the **NetScaler Bot Management Profile** page, click **Bot Trap** under **Profile Settings**.
5. In the **Bot Trap** section, set the following parameters.
 - a) Enabled. Select the checkbox to enable bot trap detection.
 - b) Description. Brief description about the URL.
 - c) In the **Configure Action** section, set the following parameters.
 - Action. Action to be taken for bot detected by bot trap access.
 - Log. Enable or disable logging for bot trap binding.
 - d) In the **Configure Trap Insertion URLs** section, click **Add**.
 - e) In the **Configure NetScaler Bot Management Profile Bot Trap Binding** page, set the following parameters.
 - URL. Type the URL that you want to confirm as the bot trap insertion URL.
 - Enabled. Enable or disable bot trap insertion URL.
 - Comment. A brief description about the trap insertion URL.
 - f) Click **OK**.
6. Click **Update** and **Done**.

Configure bot trap URL settings

Complete the following steps to configure bot trap URL settings:

1. Navigate to **Security > NetScaler Bot Management**.
2. In the details pane, under **Settings** click **Change NetScaler Bot Management Settings**.
3. In the **Configure NetScaler Bot Management Settings**, set the following parameters.
 - a) Trap URL Interval. Time in seconds after which the bot trap URL is updated.
 - b) Trap URL Length. Length of the auto-generated bot trap URL.
4. Click **OK** and **Done**.

Configure device fingerprint technique for mobile (Android) applications

Device fingerprint technique detects an incoming traffic as a bot by inserting a JavaScript script in the HTML response to the client. The JavaScript script when invoked by the browser, it collects browser and client attributes and sends a request to the appliance. The attributes are examined to determine whether the traffic is a Bot or a human.

The detection technique is further extended to detect bots on a mobile (Android) platform. Unlike web applications, in mobile (Android) traffic, bot detection based on JavaScript script do not apply. To detect bots in a mobile network, the technique uses a bot mobile SDK which is integrated with mobile applications on the client-side. The SDK intercepts the mobile traffic, collects device details, and sends the data to the appliance. On the appliance side, the detection technique examines the data and determines whether the connection is from a Bot or a human.

How the device fingerprint technique for the mobile application works

The following steps explain the bot detection workflow to detect if a request from a mobile device is from a human or a bot.

1. When a user interacts with a mobile application, the bot mobile SDK records the device's behavior.
2. Client sends a request to NetScaler appliance.
3. When sending the response, the appliance inserts a bot session cookie with session details, and parameters to collect client parameters.
4. When the mobile application receives the response, the NetScaler bot SDK that is integrated with the mobile application validates the response, retrieves the recorded device fingerprint parameters, and sends it to the appliance.
5. The device fingerprint detection technique on the appliance side validates the device details and updates the bot session cookie if it is a suspected bot or not.
6. When the cookie is expired or device fingerprint protection prefers to validate and collect device parameters periodically, the whole procedure or challenge is repeated.

Pre-requisite To get started with the NetScaler device fingerprint detection technique for mobile applications, you must download and install the bot mobile SDK in your mobile application.

Configure fingerprint detection technique for mobile (Android) applications by using the CLI

At the command prompt, type:

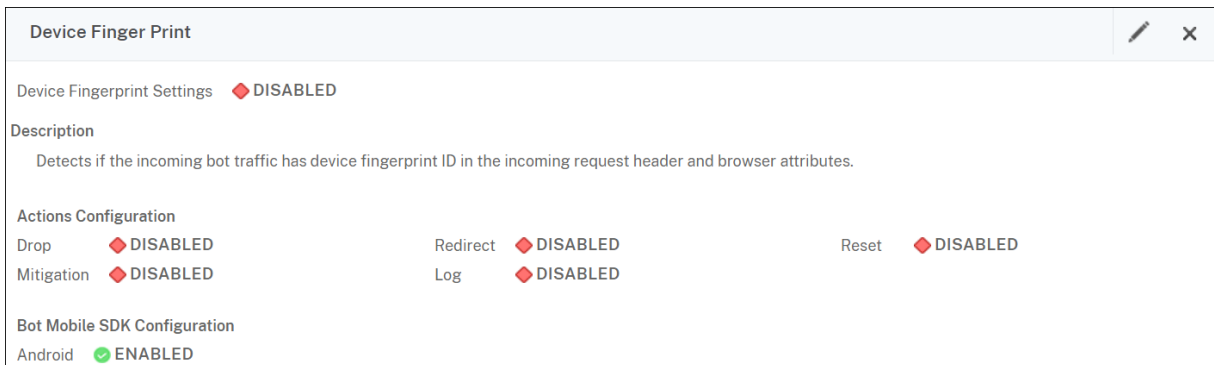

```
set bot profile <profile name> -deviceFingerprintMobile ( NONE |  
Android )
```

Example:

```
set bot profile profile 1 -deviceFingerprintMobile Android
```

Configure device fingerprint detection technique for mobile (Android) applications by using the GUI

1. Navigate to **Security > NetScaler Bot Management** and **Profiles**.
2. On the **NetScaler Bot Management Profiles** page, select a file and click **Edit**.
3. On the **NetScaler Bot Management Profile** page, click **Device Fingerprint** under **Profile Settings**.
4. In the **Configure Bot Mobile SDK** section, select the mobile client type.
5. Click **Update** and **Done**.

Configure device fingerprint technique by using NetScaler GUI

This detection technique sends a Java script challenge to the client and extracts the device information. Based on device information, the technique drops or bypasses the bot traffic. Follow the steps to configure the detection technique.

1. Navigate to **Security > NetScaler Bot Management** and **Profiles**.
2. On the **NetScaler Bot Management Profiles** page, select a signature file and click **Edit**.
3. On the **NetScaler Bot Management Profile** page, go to the **Signature Settings** section and click **Device Fingerprint**.

In the **Device Fingerprint** section, set the following parameters:

- a) Enabled - Select to enable the rule.
- b) Configuration - Select one of the following options:
 - i. None - Allows the traffic.
 - ii. Drop - Drop the traffic.
 - iii. Redirect - Redirects the traffic to an error URL.
 - iv. Mitigation, or CAPTCHA - Validates and allows the traffic.

Note:

During session replay attacks using the device fingerprint cookies, requests are dropped even if the device fingerprint configuration is set to **Mitigation**.

4. Click **Update**.

5. Click **Done**.

| |
|--|
| Device Fingerprint |
| <input checked="" type="checkbox"/> Enabled |
| Description |
| Detects if the incoming bot traffic has device fingerprint ID in the incoming request header and browser attributes. |
| Configuration |

| <input checked="" type="checkbox"/> Log |

Bot detection based on mouse and keyboard dynamics

To detect bots and mitigate web scraping anomalies, the NetScaler bot management uses an enhanced bot detection technique based on mouse and keyboard behavior. Unlike conventional bot techniques that require direct human interaction (for example, CAPTCHA validation), the enhanced technique passively monitors the mouse and the keyboard dynamics. The NetScaler appliance then collects the real-time user data and analyses the behavioral between a human and a bot.

The passive bot detection using mouse and keyboard dynamics has the following benefits over existing bot detection mechanisms:

- Provides continuous monitoring throughout the user session, and eliminates single checkpoint.
- Requires no human interaction and it is transparent to users.

How bot detection using mouse and keyboard dynamics works

The bot detection technique using keyboard and mouse dynamics consists of two components, a webpage logger and bot detector. The webpage logger is a JavaScript that records keyboard and mouse movements when a user is performing a task on the webpage (for example, filling a registration form). The logger then sends the data in batches to the NetScaler appliance. The appliance then stores the data as a KM record and sends it to the bot detector on the NetScaler Console server, which analyses if the user is a human or bot.

The following steps explain how the components interact with each other:

1. The NetScaler admin configures policy expression through the ADM StyleBook, CLI, or NITRO or any other method.
2. The URL is set in the bot profile when the admin enables the feature on the appliance.
3. When a client sends a request, the NetScaler appliance tracks the session and all requests in the session.

4. The appliance inserts a JavaScript (webpage logger) in the response if the request matches the configured expression on the bot profile.
5. The JavaScript then collects all the keyboard, mouse activity and sends the KM data in a POST URL (transient).
6. The NetScaler appliance stores the data and sends it to the NetScaler Console server at the end of the session. Once the appliance receives the complete data of a POST request, the data is sent it to the ADM server.
7. The NetScaler Console Service analyses the data and based on the analysis, the result is available on the NetScaler Console service GUI.

The JavaScript logger records the following mouse and keyboard movements:

- Keyboard events –all events
- Mouse events - mouse move, mouse up, mouse down
- Clipboard events - paste
- Custom events - autofill, autofill cancel
- timestamp of each event

Configure bot detection using mouse and keyboard dynamics

The NetScaler bot management configuration includes enabling or disabling the keyboard and mouse-based detection feature, and configures the JavaScript URL in the bot profile.

Complete the following steps to configure bot detection using mouse and keyboard dynamics:

1. Enable keyboard and mouse-based detection
2. Configure an expression to decide when the JavaScript can be injected in the HTTP response

Enable keyboard mouse-based bot detection Before you begin the configuration, ensure you have enabled the keyboard and mouse-based bot detection feature on the appliance.

At the command prompt, type:

```
1 add bot profile <name> -KMDetection ( ON | OFF )
2 <!--NeedCopy-->
```

Example:

```
add bot profile profile1 -KMDetection ON
```

Configure bot expression for JavaScript insertion Configure bot expression to evaluate the traffic and insert JavaScript. The JavaScript is inserted only if the expression is evaluated as true.

At the command prompt, type:

```
1 bind bot profile <name> -KMDetectionExpr -name <string> -expression <
  expression> -enabled ( ON | OFF ) - comment <string>
2 <!--NeedCopy-->
```

Example:

```
bind bot profile profile1 -KMDetectionExpr -name test -expression
http.req.url.startswith("/testsite")-enabled ON
```

Configure JavaScript file name inserted in the HTTP response for keyboard-mouse based bot detection To collect the user action details, the appliance sends a JavaScript file name in the HTTP response. The JavaScript file collects all the data in a KM record and sends it to the appliance.

At the command prompt, type:

```
1 set bot profile profile1 - KMJavaScriptName <string>
2 <!--NeedCopy-->
```

Example:

```
set bot profile profile1 -KMJavaScriptName script1
```

Configure behavior biometrics size You can configure the maximum size of mouse and keyboard behavior data that can be sent as KM record to the appliance and processed by the ADM server.

At the command prompt, type:

```
1 set bot profile profile1 -KMEventsPostBodyLimit <positive_integer>
2 <!--NeedCopy-->
```

Example:

```
set bot profile profile1 - KMEventsPostBodyLimit 25
```

After you have configured the NetScaler appliance to configure the JavaScript and collect keyboard and mouse behavior biometrics, the appliance sends the data to the NetScaler Console server. For more information on how the NetScaler Console server detects bots from behavior biometrics, see [Bot Violations](#) topic.

Configure keyboard and mouse bot expression settings by using the GUI

1. Navigate to **Security > NetScaler Bot Management and Profiles**.
2. On the **NetScaler Bot Management Profiles** page, select a profile and click **Edit**.
3. In the **Keyboard and mouse based bot detection** section, set the following parameters:

- a) Enable detection. Select the checkbox to detect the bot based keyboard and mouse dynamics behavior.
 - b) Event post body limit. Size of the keyboard and mouse dynamics data sent by the browser to be processed by the NetScaler appliance.
4. Click **OK**.
 5. On the **NetScaler bot Management Profile** page, go to the **Profile Settings** section and click **Keyboard and Mouse Based Bot Expression Settings**.
 6. In the **Keyboard and Mouse Based Bot Expression Settings** section, click **Add**.
 7. In the **Configure NetScaler bot Management Profile Bot Keyboard and Mouse Expression Binding** page, set the following parameters:
 - a) Expression Name. Name of the bot policy expression for detection keyboard and mouse dynamics.
 - b) Expression. Bot policy expression.
 - c) Enabled. Select the checkbox to enable the keyboard and bot keyboard and mouse expression binding.
 - d) Comments. A brief description about the bot policy expression and its binding to the bot profile.
 - e) Click **OK** and **Close**.
 8. In the **Keyboard and Mouse Based Bot Expression Settings** section, click **Update**.

Verbose logging for bot traffic

When an incoming request is identified as a bot, the NetScaler appliance logs more HTTP header details for monitoring and troubleshooting. The bot verbose logging capability is similar to the verbose logging in the Web App Firewall module.

Consider an incoming traffic from a client. If the client is identified as a bot, the NetScaler appliance uses the verbose logging functionality to log full HTTP header information such as domain address, URL, user-agent header, cookie header. The log details are then sent to the ADM server for monitoring and troubleshooting the purpose. The verbose log message is not stored in the “ns.log” file.

Configure bot verbose logging by using the CLI

To capture detailed HTTP header information as logs, you can configure the verbose logging parameter in the bot profile. At the command prompt, type:

```
1 set bot profile <name> [-verboseLogLevel ( NONE | HTTP_FULL_HEADER ) ]
2 <!--NeedCopy-->
```

Example:

```
set bot profile p1 -verboseLogLevel HTTP_FULL_HEADER
```

Configure bot verbose logging by using the NetScaler GUI

Follow the procedure to configure the verbose log level in the bot profile.

1. On the navigation pane, navigate to **Security > NetScaler Bot Management**.
2. In the **NetScaler Bot Management Profiles** page, click **Add**.
3. In the **Create NetScaler Bot Management Profile** page, select a verbose log level as **HTTP Full Header**.
4. Click **OK** and **Done**.

Configure an action for spoofed bot requests

An attacker might attempt to impersonate a good bot and send requests to your application server. Such bots are identified as spoofed bots using the bot signature. Configure the following actions against spoofed bots to protect your application server:

- DROP
- NONE
- REDIRECT
- RESET

Note:

Requests identified as good bots are further evaluated for spoofing. Client IP addresses with RDNS errors during client host validation are treated as spoof requests.

Configure an action for spoofed bot requests using CLI

Run the following command to configure an action for spoofed bot requests:

```
1 set bot profile <bot-profile-name> -spoofedReqAction <action> LOG
2 <!--NeedCopy-->
```

Example:

```
1 set bot profile bot_profile -spoofedReqAction DROP LOG
2 <!--NeedCopy-->
```

In this example, the requests from spoofed bots are dropped and logged in a NetScaler appliance.

Tip

To log events from the spoofed bots, specify `LOG` in the command.

Configure an action for spoofed bot requests using GUI

Follow the steps to configure an action for the spoofed bot requests:

1. Navigate to **Security > NetScaler Bot Management**.
2. In the **NetScaler Bot Management Profiles** page, click **Add**.
3. Select an action from the **Spoofed Request Action** list.
4. Select **Log Spoofed Request**.

This action logs the events from spoofed bots.

5. Click **Create**.

Configure bot signature setting

February 14, 2024

You can configure the following settings in the bot signature settings:

- Configure bot allow list
- Configure bot block list
- Configure CAPTCHA for IP reputation
- Bot Transactions Per second (TPS)

Configure bot allow list by using NetScaler GUI

This detection technique enables you to bypass the URLs that you configure as allowed URLs. Complete the following step to configure an allow list URL:

1. Navigate to **Security > NetScaler Bot Management** and **Profiles**.
2. On the **NetScaler Bot Management Profiles** page, select a file and click **Edit**.
3. On the **NetScaler Bot Management Profile** page, go to the **Signature Settings** section and click **Allow List**.

4. In the **Allow List** section, set the following parameters:
 - a) Enabled. Select the checkbox to validate the allow list URLs as part of the detection process.
 - b) Configure Types. Configure an allow list URL. The URL is bypassed during bot detection. Click Add to add a URL to the bot allow list.
 - c) In the **Configure NetScaler Bot Management Profile allowlist Binding** page, set the following parameters:
 - i. Type. URL type can be an IPv4 address, subnet IP address, or an IP address matching a policy expression.
 - ii. Enabled. Select the checkbox to validate the URL.
 - iii. Value. URL address.
 - iv. Log. Select the checkbox to store log entries.
 - v. Log Message. Brief description of the log.
 - vi. Comments. Brief description about the allow list URL.
 - vii. Click **OK**.

Configure bot block list by using NetScaler GUI

This detection technique enables you to drop the URLs that you configure as blocked URLs. Complete the following step to configure a block list URL.

1. Navigate to **Security > NetScaler Bot Management** and **Profiles**.
2. On the **NetScaler Bot Management Profiles** page, select a signature file and click **Edit**.
3. On the **NetScaler Bot Management Profile** page, go to the **Signature Settings** section and click **Block List**.
4. In the **Block List** section, set the following parameters:
 - a) Enabled. Select the checkbox to validate block list URLs as part of the detection process.
 - b) Configure Types. Configure a URL to be part of the bot block list detection process. These URLs are dropped during bot detection. Click Add to add a URL to the bot block list
 - c) In the **Configure NetScaler Bot Management Profile Blocklist Binding** page, set the following parameters.
 - i. Type. URL type can be an IPv4 address, subnet IP address, or IP address.
 - ii. Enabled. Select the checkbox to validate the URL.
 - iii. Value. URL address.
 - iv. Log. Select the checkbox to store log entries.
 - v. Log Message. Brief description of the login.
 - vi. Comments. Brief description about the block list URL.

Configure CAPTCHA for IP reputation

CAPTCHA helps to block automated bots that cause security violations to web applications. In the NetScaler, CAPTCHA uses the challenge-response module to identify if the incoming traffic is from a human user and not an automated bot.

How CAPTCHA works in NetScaler bot management

In NetScaler bot management, CAPTCHA validation is configured as a policy action to be run after bot policy is evaluated. The CAPTCHA action is available only for IP reputation and device fingerprint detection techniques. Following are the steps to understand how CAPTCHA works:

1. If a security violation is observed during IP reputation or device fingerprint bot detection, the ADC appliance sends a CAPTCHA challenge.
2. The client sends the CAPTCHA response.

3. The appliance validates the CAPTCHA response and if the CAPTCHA is valid, the request is allowed and it is forwarded to the back-end server.
4. If the CAPTCHA response is invalid, the appliance sends a new CAPTCHA challenge until the maximum number of attempts is reached.
5. If the CAPTCHA response is invalid even after the maximum number of attempts, the appliance drops or redirects the request to the configured error URL.
6. If you have configured log action, then the appliance stores the request details in the ns.log file.

Configure CAPTCHA settings by using the NetScaler GUI

The bot management CAPTCHA action is supported only for IP reputation and device fingerprint detection techniques. Complete the following steps to configure the **CAPTCHA** settings.

1. Navigate to **Security > NetScaler Bot Management and Profiles**.
2. On the **NetScaler Bot Management Profiles** page, select a profile and click **Edit**.
3. On the **NetScaler Bot Management Profile** page, go to the **Signature Settings** section and click **CAPTCHA**.
4. In the **CAPTCHA Settings** section, click **Add to configure CAPTCHA** settings to the profile:
5. In the **Configure NetScaler Bot Management CAPTCHA** page, set the following parameters.
 - a) URL. Bot URL for which the CAPTCHA action is applied during IP reputation and device fingerprint detection techniques.
 - b) Enabled. Set this option to enable CAPTCHA support.
 - c) Grace time. Duration until when no new CAPTCHA challenge is sent after the current valid CAPTCHA response is received.
 - d) Wait time. Duration taken for the ADC appliance to wait until the client sends the CAPTCHA response.
 - e) Mute Period. Duration for which the client which sent an incorrect CAPTCHA response must wait until allowed to try next. During this mute period, the ADC appliance does not allow any requests. Range: 60–900 seconds, Recommended: 300 seconds
 - f) Request Length limit. Length of the request for which the CAPTCHA challenge is sent to the client. If the length is greater than the threshold value, the request is dropped. Default value is 10–3000 bytes.
 - g) Retry Attempts. Number of attempts the client is allowed to retry to solve the CAPTCHA challenge. Range: 1–10, Recommended: 5.
 - h) No Action/Drop/Redirect action to be taken if the client fails the CAPTCHA validation.

- i) Log. Set this option to store request information from the client when response CAPTCHA fails. The data is stored in `ns.log` file.
 - j) Comment. A brief description about the CAPTCHA configuration.
6. Click **OK** and **Done**.
 7. Navigate to **Security > NetScaler Bot Management > Signatures**.
 8. On the **NetScaler Bot Management Signatures** page, select a signature file and click **Edit**.
 9. On the **NetScaler Bot Management Signature** page, go to the **Signature Settings** section and click **Bot Signatures**.
 10. In the **Bot Signatures** section, set the following parameters:
 11. Configure **Static Signatures**. Select a bot static signature record and click Edit to assign a bot action to it.
 12. Click **OK**.
 13. Click **Update Signature**.
 14. Click **Done**.

Bot Transactions Per second (TPS)

The Transactions Per Second (TPS) bot technique detects incoming traffic as a bot if the number of requests per second (RPS) and percentage increase in RPS exceeds the configured threshold value. The detection technique protects your web applications from automated bots that can cause web scraping activities, brute forcing login, and other malicious attacks.

Note:

The bot technique detects an incoming traffic as bot only if both the parameters are configured and if both values increase beyond the threshold limit.

Let us consider a scenario, where the appliance receives many requests coming from a specific URL and you want the NetScaler bot management to detect if there is a bot attack. The TPS detection technique examines the number of requests (configured value) coming from the URL within 1 second and the percentage increase (configured value) in the number of requests received within 30 minutes. If the values exceed the threshold limit, the traffic is considered as bot and the appliance runs the configured action.

To configure TPS, you must complete the following steps:

1. Enable bot TPS
2. Bind TPS settings to bot management profile

Configure bot transactions per second (TPS) using CLI

Enable bot transaction per second (TPS) Before you can begin, you must ensure that the bot TPS feature is enabled on the appliance. At the command prompt, type:

```
set bot profile profile1 -enableTPS ON
```

Bind TPS settings to bot management profile Once you enable the bot TPS feature, you must bind the TPS settings to the bot management profile.

At the command prompt, type:

```
bind bot profile <name>... (-tps [-type ( SourceIP | GeoLocation | RequestURL | Host )] [-threshold <positive_integer>] [-percentage <positive_integer>] [-action ( none | log | drop | redirect | reset | mitigation )] [-logMessage <string>])
```

Example:

```
bind bot profile profile1 -tps -type RequestURL -threshold 1 -percentage 100000 -action drop -logMessage log
```

Configure bot transactions per second (TPS) by using the NetScaler GUI

Complete the following steps to configure bot transactions per second:

1. Navigate to **Security > NetScaler Bot Management > Profiles**.
2. In the **NetScaler Bot Management Profiles** page, select a profile and click **Edit**.
3. In the **Create NetScaler Bot Management Profile** page, click **TPS** under **Signature Settings** section.
4. In the **TPS** section, enable the feature and click **Add**.
5. In **Configure NetScaler bot Management Profile TPS Binding** page, set the following parameters.
 - a) Type - Input types allowed by the detection technique. Possible values: SOURCE IP, GEOLOCATION, HOST, URL.
 - SOURCE_IP –TPS based on client IP address.
 - GEOLOCATION –TPS based on the client’s geographic location.
 - HOST - TPS based on client requests forwarded to a specific back-end server IP address.
 - URL –TPS based on client requests coming from a specific URL.

- b) Fixed Threshold - Maximum number of requests allowed from a TPS input type within 1 second time interval.
 - c) Percentage Threshold - Maximum percentage increase in requests from a TPS input type within 30 minute time interval.
 - d) Action - Action to be taken for bot detected by TPS binding.
 - e) Log - Enable or disable logging for TPS binding.
 - f) Log Message. Message to log for bot detected by TPS binding. Maximum Length: 255.
 - g) Comments - A brief description about the TPS configuration. Maximum Length: 255
6. Click **OK** and then **Close**.

Bot signature auto update

January 3, 2024

The bot static signature technique uses a signature lookup table with a list of good and bad bots. The bots are categorized based on user-agent string and domain names. If the user-agent string and domain name in incoming bot traffic matches a value in the lookup table, the configured bot action is applied.

The bot signature updates are hosted on the AWS cloud and the signature lookup table communicates with the AWS database for signature updates. The auto signature update scheduler runs every 1-hour to check the **AWS database** and updates the signature table in the NetScaler appliance.

The signature auto update URL to configure is, <https://nsbotssignatures.s3.amazonaws.com/BotSignatureMapping.json>

Note:

You can also configure a proxy server and periodically update signatures from the AWS cloud to the appliance through the proxy. For proxy configuration, you must set the proxy IP address and port address in the bot settings.

How bot signature auto update works

The following diagram shows how the bot signatures are retrieved from the AWS cloud, updated on NetScaler, and viewed on NetScaler Console for signature update summary.

The bot signature auto-update scheduler does the following:

1. Retrieves the mapping file from the AWS URI.
2. Checks the latest signatures in the mapping file with the existing signatures in the ADC appliance.
3. Downloads the new signatures from AWS and verifies the signature integrity.
4. Updates the existing bot signatures with the new signatures in the bot signature file.
5. Generates an SNMP alert and sends the signature update summary to NetScaler Console.

Configure bot signature auto update

For configuring bot signature auto update, complete the following steps:

Enable bot signature auto update

You must enable the auto update option in the bot settings on the ADC appliance.

At the command prompt, type:

```
set bot settings -signatureAutoUpdate ON
```

Configure proxy server settings (optional)

If you are accessing the AWS signature database through a proxy server, you must configure the proxy server and port.

```
set bot settings -proxyserver -proxyport
```

Example:

```
set bot settings -proxy server 1.1.1.1 -proxyport 1356
```

Configure bot signature auto update using the NetScaler GUI

Complete the following steps to configure bot signature auto update:

1. Navigate to **Security > NetScaler Bot Management**.
2. In the details pane, under **Settings** click **Change NetScaler Bot Management Settings**.
3. In the **Configure NetScaler Bot Management Settings**, select the **Auto Update Signature** checkbox.
4. Click **OK** and **Close**.

```

```

Bot Management

May 2, 2023

Following are some of the troubleshooting scenarios covered in NetScaler bot management.

1. How to handle false positive cases?

You can use the bot allow list functionality to manage false positive cases and these transactions can be bypassed.

2. How to find more details about bad bot traffic?

You can use the audit logging functionality to get details about the traffic classified as bad bots.

3. Why should you change the default signature name?

You can change the default signature name if there are conflicts detected at the end point resources served by the NetScaler appliance.

Bot Management

May 2, 2023

1. What is NetScaler bot management?

NetScaler bot management detects and distinguishes traffic from good bots, bad bots, and human clients. The bot management functionality protects your web applications from bad bots by applying a configured action on incoming requests.

2. Why NetScaler must manage bots for your web application?

Malicious bots constitute 30% of your internet traffic. Malicious bots impact web applications in various ways such as initiating a DoS attack, spamming email addresses, slowing down the application using downloader programs, downloading the content from websites and so forth. In addition, bots can easily bypass some of the well known detection mechanisms leading to loss of data, revenue, and reputation to your organization.

3. What are the techniques used for detecting an incoming bot?

The appliance uses detection techniques such as IP reputation, rate limiting, device fingerprinting, TPS, and Bot trap detection techniques. In addition, you can configure a customized block list on the NetScaler GUI to categorize organization specific bad bots.

4. What is a bot signature file and its purpose?

The bot signature file contains the footprint of known good and bad bots. The signature file is updated periodically to include the latest bot signatures for better bot protection.

5. What type of NetScaler license must I purchase?

Bot management is available with the ADC Premium license.

6. Where can I find bot logs for troubleshooting?

NetScaler audit logs provide detected bot details. For more information, see [Audit Logging](#) topic.

7. Is there an auto update functionality for the bot signature files?

Yes, NetScaler bot management supports auto update functionality.

8. Is there a pre-requisite for using the bot IP reputation technique?

Enable the IP reputation feature before enabling and configuring the IP reputation in the bot profile.

Bot signature alert Articles

May 2, 2023

NetScaler bot management announces signature updates that you can download and apply on your appliance. When you detect a bot attack, you will receive an email notification about the new signature update. You can download the signature and apply it on your appliance.

To get updates about new bot signatures, you must configure the signature auto-update feature. For more information, see [Bot Signature Auto Update](#) topic.

Bot signature update for November 2020

May 2, 2023

New signature rules are generated for the bots identified in the week 2020-11-11. You can download and configure these signature rules to protect your appliance from bot attacks.

Bot signature version

Signature version 5 applicable for NetScaler 13.0 platform.

New Bot signatures

Following is a list of bot signature rules, category, and its type.

| Category | Bot Type | Signature Count |
|--------------------|----------|-----------------|

| Tool | Good Bot | 7 |

Bot signature update for January 2021

May 2, 2023

Some of existing bot signatures are updated. You can download and configure these signature rules to protect your appliance from bot attacks.

Bot signature version

Signature version 6 is applicable for NetScaler platforms with 13.0 61.x builds or later.

Updated bot signatures

Following is a list of bot signature rule IDs, category and its type.

| Bot signature ID | Bot Category | Bot Type |

Bot signature update for May 2023

March 14, 2024

New signatures rules are generated for the bots identified in the week 2023-05-15. You can download and configure these signature rules to protect your appliance from bot attacks.

Bot signature version

Signature version 15 applicable for Netscaler platforms with 13.0 76.31 or later builds.

New bot signatures in this version

Following is a list of bot signature rule IDs, category and its type.

| 628 | Search Engine | Good Bot |

Cache Redirection

May 2, 2023

In a typical deployment, different clients ask web servers for the same content repeatedly. To relieve the origin web server of processing each request, a NetScaler appliance with cache redirection enabled can serve this content from a cache server instead of from the origin server.

The NetScaler appliance analyzes incoming requests, sends requests for cacheable data to cache servers, and sends non-cacheable requests and dynamic HTTP requests to origin servers.

Cache redirection is a policy-based feature. By default, requests that match a policy are sent to the origin server, and all other requests are sent to a cache server. For testing or maintenance, you might want to skip policy evaluation and direct all requests to the cache or to the origin server.

You can combine content switching with cache redirection to cache selective content and serve content from specific cache servers for specific types of requested content.

A NetScaler appliance configured for cache redirection can be deployed at the edge of a network, in front of the origin server, or anywhere along the network backbone. In an edge deployment, commonly used by Internet Service Providers (ISPs), cable companies, content delivery distribution networks, and enterprise networks, the NetScaler appliance resides directly in front of the clients. In a server-side deployment, the NetScaler appliance is closer to the origin servers.

Cache redirection is used most commonly with the HTTP service type, but it also supports the secure HTTPS protocol.

Cache redirection policies

May 2, 2023

A cache redirection virtual server applies cache redirection policies to each incoming request. By default, if a request matches one of the configured policies, it is considered non-cacheable, and the NetScaler appliance sends it to the origin server. Other requests are sent to a cache server. This behavior can be reversed, so that requests that match configured cache redirection policies are sent to cache servers.

The appliance provides a set of policies for cache redirection. If these built-in policies are not adequate for your deployment, you can configure user-defined cache redirection policies.

Note: Once you have determined which built-in cache redirection policies to use, or have created user-defined policies, proceed with configuring cache redirection. To use this feature, you must configure at least one cache redirection virtual server, and, for normal operation, you must bind at least one cache redirection policy to that virtual server.

Built-in cache redirection policies

May 2, 2023

The NetScaler appliance provides built-in cache redirection policies that handle typical cache requests. These policies are based on HTTP methods, the URL or URL tokens of the incoming request, the HTTP version, or the HTTP headers and their values in the request.

Built-in cache redirection policies can be directly bound to a virtual server and do not need further configuration.

Cache redirection policies use two types of appliance expressions languages, classic and Advanced policy. For more information about these languages, see [Policies and expressions](#).

Built-in classic cache redirection policies

Built-in cache redirection policies based on classic expressions are called *classic cache redirection policies*. For a complete description of classic expressions and how to configure them, see [Policies and Expressions](#).

The classic cache redirection policies evaluate basic characteristics of traffic and other data. For example, classic cache redirection policies can determine whether an HTTP request or response contains a particular type of header or URL.

The NetScaler appliance provides the following built-in classic cache redirection policies:

| Built-In Policy Name | Description |
|----------------------|---|
| bypass-non-get | Bypass the cache if the request uses an HTTP method other than GET. |
| bypass-cache-control | Bypass the cache if the request header contains a Cache-Control: no-cache or Cache-Control: no-store header, or if the HTTP request contains a pragma header. |
| bypass-dynamic-url | Bypass the cache if the URL suggests that the content is dynamic, as indicated by the presence of any of the following extensions: cgi, asp, exe, cfm, ex, shtml, or htx. Also bypass the cache if the URL starts with any of the following: /cgi-bin/, /bin/, or /exec/. |
| bypass-urltokens | Bypass the cache because the request is dynamic, as indicated by one of the following tokens in the URL: ?, !, or =. |
| bypass-cookie | Bypass the cache for any URL that has a cookie header and an extension other than .png or .jpg. |

Built-in Advanced policy cache redirection policies

Built-in cache redirection policies based on Advanced policy expressions are called *Advanced policy cache redirection policies*. For a complete description of Advanced policy expressions and how to configure them, see [Policies and Expressions](#).

In addition to the same types of evaluations done by classic cache redirection policies, Advanced policy cache redirection policies enable you to analyze more data (for example, the body of an HTTP request) and to configure more operations in the policy rule (for example, directing the request to either cache or origin server).

NetScaler appliances provide the following two built-in actions for the Advanced policy cache redirection policies:

- CACHE
- ORIGIN

As implied by their names, they direct the request to the cache server or the origin server, respectively.

Note: If you are using the built-in Advanced policy cache redirection policy, you cannot modify the action.

The NetScaler appliance provides the following built-in Advanced policy cache redirection policies:

| Built-In Policy Name | Description |
|--------------------------|---|
| bypass-non-get_adv | Bypass the cache if the request uses an HTTP method other than GET. |
| bypass-cache-control_adv | Bypass the cache if the request header contains a Cache-Control: no-cache or Cache-Control: no-store header, or if the HTTP request contains a pragma header. |
| bypass-dynamic-url_adv | Bypass the cache if the URL suggests that the content is dynamic, as indicated by the presence of any of the following extensions: cgi, asp, exe, cfm, ex, shtml, or htx. Also bypass the cache if the URL starts with any of the following: /cgi-bin/, /bin/, or /exec/. |
| bypass-urltokens_adv | Bypass the cache because the request is dynamic, as indicated by one of the following tokens in the URL: ?, !, or =. |
| bypass-cookie_adv | Bypass the cache for any URL that has a cookie header and an extension other than .png or .jpg. |

Display the built-in cache redirection policies

You can display the available cache redirection policies by using the command line interface or the configuration utility.

Display the built-in cache redirection policies by using the CLI

At the command prompt, type:

```
show cr policy [<policyName>]
```

Example:

```
1 > show cr policy
2 1)      Cache-By-Pass RULE: NS_NON_GET          Policy:bypass-non-get
3 2)      Cache-By-Pass RULE: (NS_CACHECONTROL_NOSTORE ||
         NS_CACHECONTROL_NOCACHE || NS_HEADER_PRAGMA)    Policy:bypass-cache-
         control
4 3)      Cache-By-Pass RULE: (NS_EXT_CGI || NS_EXT_ASP || NS_EXT_EXE ||
         NS_EXT_CFM || NS_EXT_EX || NS_EXT_SHTML || NS_EXT_HTX) || (
         NS_URL_PATH_CGIBIN || NS_URL_PATH_EXEC || NS_URL_PATH_BIN)
         Policy:bypass-dynamic-url
5 4)      Cache-By-Pass RULE: NS_URL_TOKENS        Policy:bypass-
         urltokens
6 5)      Cache-By-Pass RULE: (NS_HEADER_COOKIE && NS_EXT_NOT_GIF &&
         NS_EXT_NOT_JPEG)      Policy:bypass-cookie
7 Done
8 <!--NeedCopy-->
```

Display the built-in cache redirection policies by using the GUI

1. Navigate to Traffic Management > Cache Redirection > Policies. The configured cache redirection policies appear in the details pane.
2. Select one of the configured policies to view details.

Configure a cache redirection policy

October 16, 2023

A cache redirection policy includes an expression (also called a *rule*). The expression represents a condition that is evaluated when the client request is compared to the policy.

You do not explicitly configure actions for cache redirection policies.

A cache redirection policy has a name and includes an Advanced policy expression, or a set of Advanced policy expression clauses that are combined by using logical operators, and the following built-in actions:

- CACHE
- ORIGIN

For more information about Advanced policy expressions, see [Policies and Expressions](#).

Add a cache redirection policy by using the CLI

At the command prompt, type the following commands to add a cache redirection policy and verify the configuration:

```
1 - add cr policy <policyName> **-rule** <expression> -action<string> [-logAction<string>]
2
3 - show cr policy [<policyName>]
4
5 <!--NeedCopy-->
```

Examples:

Policy with a simple expression:

```
1 > add cr policy crpol1 -rule !(HTTP.REQ.URL.ENDSWITH(".jpeg")) -action origin
2 Done
3 > show cr policy crpoll
4 Policy: crpol1 Rule: !(HTTP.REQ.URL.ENDSWITH(".jpeg")) Action: ORIGIN
5 Hits: 0
6 Done
7
8 <!--NeedCopy-->
```

Policy with a compound expression:

```
1 > add cr policy crpol11 -rule 'http.req.method.eq(post) && (HTTP.REQ.URL.ENDSWITH(".png") || HTTP.REQ.URL.ENDSWITH(".cgi"))' -action cache
2 Done
3 > show cr policy crpol11
4 Policy: crpol11 Rule: http.req.method.eq(post) && (HTTP.REQ.URL.ENDSWITH(".png") || HTTP.REQ.URL.ENDSWITH(".cgi")) Action: CACHE
5 Hits: 0
6 Done
7
8 <!--NeedCopy-->
```

Policy that evaluates a header:

```
1 > add cr policy crpol12 -rule http.req.header("If-Modified-Since").exists -action origin
2 Done
3 > show cr policy crpol12
4 Policy: crpol12 Rule: http.req.header("If-Modified-Since").exists Action: ORIGIN
5 Hits: 0
6 Done
7
```

Modify or remove a cache redirection policy by using the CLI

- To modify a cache redirection policy, use the `set cr policy` command, which is just like `add cr policy` command, except that you enter the name of an existing policy and you only have to provide the parameters that you want to modify.
- To remove a policy, use the `rm cr policy` command, which accepts only the `<name>` argument. If the policy is bound to a virtual server, you have to unbind the policy, before you can remove it.

For the details of unbinding a cache redirection policy, see [Unbind a policy from a cache redirection virtual server](#).

Configure a cache redirection policy with a simple expression by using the GUI

1. Navigate to **Traffic Management > Cache Redirection > Policies**.
2. In the details pane, click **Add**.
3. In the **Create Cache Redirection Policy** dialog box, in the **Name** text box, type the name of the policy.
4. Select the appropriate action **CACHE** or **ORIGIN** from the **Action** drop-down list.
5. In the **Log Action** area, click **Add**. Type a name in the **Create Audit Message Action** dialog box.
 - Configure **Log Level** by choosing the appropriate value from the drop-down list:
 - **EMERGENCY**
 - **ALERT**
 - **CRITICAL**
 - **ERROR**
 - **WARNING**
 - **NOTICE**
 - **INFORMATIONAL**
 - **DEBUG**
 - Enter the expression in the **Expression** area.
 - Expression Type-General
 - Flow Type -REQ
 - Protocol -HTTP
 - Qualifier -URL

- Operator - !=
- Value - /.jpeg

- Click **Create**.

6. To configure a simple expression, enter the expression. Following is an example of an expression that checks for a `.jpeg` extension in a URL:

- Expression Type-General
- Flow Type -REQ
- Protocol -HTTP
- Qualifier -URL
- Operator - !=
- Value - /.jpeg

The simple expression in the following example checks for an If-Modified-Since header in a request:

- Expression Type -General
- Flow Type -REQ
- Protocol -HTTP
- Qualifier -HEADER
- Operator -EXISTS
- Header Name -If-Modified-Since

7. When you are finished entering the expression, click **Create**.

The screenshot shows the 'Create Cache Redirection Policy' configuration page. The 'Name' field is set to 'example'. The 'Action' is set to 'CACHE'. The 'Log Action' is set to 'example', with 'Add' and 'Edit' buttons. The 'Expression' field is set to 'HTTP.REQ.URL_PATH_AND_QUERY.CONTAINS('.jpeg')'. There are 'Add' and 'Edit' buttons for the Log Action, and 'Evaluate' and 'Create' buttons at the bottom.

Configure a cache redirection policy with a compound expression by using the GUI

1. Navigate to **Traffic Management > Cache Redirection > Policies**.

2. In the details pane, click **Add**.

3. In the **Name** text box, enter a name for the policy.

The name can begin with a letter, number, or the underscore symbol, and can consist of from one to 127 letters, numbers, and the hyphen (-), period (.) pound (#), space (), at (@), equals (=), and underscore (_) symbols. You should choose a name that makes it easy for others to tell what type of content this policy was created to detect.

4. Select the appropriate action **CACHE** or **ORIGIN** from the **Action** drop-down list.

5. In the **Log Action** area, click **Add**. Type a name in the **Create Audit Message Action** dialog box.

- Configure **Log Level** by choosing the appropriate value from the drop-down list:

- **EMERGENCY**
- **ALERT**
- **CRITICAL**
- **ERROR**
- **WARNING**
- **NOTICE**
- **INFORMATIONAL**
- **DEBUG**

- Enter the expression in the **Expression** area.

- Expression Type-General
- Flow Type-REQ
- Protocol -HTTP
- Qualifier -URL
- Operator - !=
- Value - /.jpeg

- Click **Create**.

6. Choose the type of compound expression that you want to create. Your choices are:

- **Match Any Expression.** The policy matches the traffic if one or more individual expressions match the traffic.
- **Match All Expressions.** The policy matches the traffic only if every individual expression matches the traffic.
- **Tabular Expressions.** Switches the Expressions list to a tabular format with three columns. In the rightmost column, you place one of the following operators:

- The AND [&&] operator, to require that, to match the policy, a request must match both the current expression and the following expression.

The OR [

-

You can also group expressions in nested subgroups by selecting an existing expression and clicking one of the following operators:

- The BEGIN SUBGROUP [+ (] operator, which tells the NetScaler appliance to begin a nested subgroup with the selected expression. (To remove this operator from the expression, click -(.)
- The END SUBGROUP [+)] operator, which tells the NetScaler appliance to end the current nested subgroup with the selected expression. (To remove this operator from the expression, click -) .)
- **Advanced Free-Form.** Switches off the Expressions Editor entirely and turns the Expressions list into a text area in which you can type a compound expression. This is both the most powerful and the most difficult method of creating a policy expression, and is recommended only for those thoroughly familiar with the NetScaler classic expressions language.

For more information about creating classic expressions in the Advanced Free-Form text area, see [Configuring Classic Policies and Expressions](#).

Caution: If you switch to Advanced Free Form expression editing mode, you cannot switch back to any of the other modes. Do not choose this expression editing mode unless you are sure that you want to use it.

7. If you chose Match Any Expression, Match All Expressions, or Tabular Expressions, click **Add** to display the Add Expression dialog box.

You should leave the expression type set to General for cache redirection policies.

8. In the Flow Type drop-down list, choose a flow type for your expression.

The flow type determines whether the policy examines incoming or outgoing connections. You have two choices:

- **REQ.** Configures the NetScaler appliance to examine incoming connections, or requests.
- **RES.** Configures the appliance to examine outgoing connections, or responses.

9. In the Protocol drop-down list, choose a protocol for your expression.

The protocol determines the type of information that the policy examines in the request or response. Depending upon whether you chose REQ or RES in the previous drop-down list, either all four or only three of the following choices are available:

- **HTTP**. Configures the appliance to examine the HTTP header.
- **SSL**. Configures the appliance to examine the SSL client certificate. Available only if you chose REQ (requests) in the previous drop-down list.
- **TCP**. Configures the appliance to examine the TCP header.
- **IP**. Configures the appliance to examine the source or destination IP address.

10. Choose a qualifier for your expression from the Qualifier drop-down list.

The contents of the Qualifier drop-down list depend on which protocol you chose. The following table describes the choices available for each protocol.

Table 1. Cache Redirection Policy Qualifiers Available for Each Protocol

| Protocol | Qualifier | Definition |
|----------|---------------------|---|
| HTTP | METHOD | HTTP method used in the request. |
| - | URL | Contents of the URL header. |
| - | URLTOKENS | URL tokens in the HTTP header. |
| - | VERSION | HTTP version of the connection. |
| - | HEADER | Header portion of the HTTP request. |
| - | URLLEN | Length of the contents of the URL header. |
| - | URLQUERY | Query portion of the contents of the URL header. |
| - | URLQUERYLEN | Length of the query portion of the URL header. |
| SSL | CLIENT.CERT | SSL client certificate as a whole. |
| - | CLIENT.CERT.SUBJECT | Contents of the client certificate subject field. |
| - | CLIENT.CERT.ISSUER | Client certificate issuer. |
| - | CLIENT.CERT.SIGALGO | Signature algorithm used in the client certificate. |
| - | CLIENT.CERT.VERSION | Client certificate version. |

| Protocol | Qualifier | Definition |
|----------|--------------------------|---|
| - | CLIENT.CERT.VALIDFROM | Date from which the client certificate is valid. (The start date.) |
| - | CLIENT.CERT.VALIDTO | Date after which the client certificate is no longer valid. (The end date.) |
| - | CLIENT.CERT.SERIALNUMBER | Client certificate serial number. |
| - | CLIENT.CIPHER.TYPE | Encryption method used in the client certificate. |
| - | CLIENT.CIPHER.BITS | Number of significant bits in the encryption key. |
| - | CLIENT.SSL.VERSION | SSL version of the client certificate. |
| TCP | SOURCEPORT | Source port of the TCP connection. |
| - | DESTPORT | Destination port of the TCP connection. |
| - | MSS | Maximum segment size (MSS) of the TCP connection. |
| IP | SOURCEIP | Source IP address of the connection. |
| - | DESTIP | Destination IP address of the connection. |

11. Choose the operator for your expression from the Operator drop-down list.

Your choices depend on the qualifier you chose in the previous step. The complete list of operators that can appear in this drop-down list is:

- `==` . Matches the following text string exactly.
- `!=` . Does not match the following text string.
- `>` . Is greater than the following integer.
- `CONTAINS` . Contains the following text string.
- `CONTENTS` . The contents of the designated header, URL, or URL query.
- `EXISTS` . The specified header or query exists.
- `NOTCONTAINS` . Does not contain the following text string.
- `NOTEXISTS` . The specified header or query does not exist.

If you want this policy to operate on requests sent to a specific Host, you can leave the default,

the equals (==) sign.

12. If the Value text box is visible, type the appropriate string or number into the text box.

For example, if you want this policy to select requests sent to the host shopping.example.com, you would type that string in the Value text box.

13. If you chose HEADER as the qualifier, type the header you want in the Header Name text box.
14. Click **OK** to add your expression to the Expression list.
15. Repeat steps 4 through 11 to create more expressions.
16. Click **Close** to close the Add Expression dialog box and return to the **Create Cache Redirection Policy** dialog box.
17. When you are finished entering the expression, click **Create**.

Cache redirection configurations

May 2, 2023

Depending on your deployment and network topology, you can configure one of the following types of cache redirection:

- **Transparent.** A transparent cache can reside on a variety of points along a network backbone to alleviate traffic along the delivery route. In transparent mode, the cache redirection virtual server intercepts all traffic flowing to the NetScaler appliance and applies cache redirection policies to determine whether content should be served from the cache or from the origin server.
- **Forward proxy.** A forward proxy cache server resides on the edge of an enterprise LAN and faces the WAN. In the forward proxy mode, the cache redirection virtual server resolves the hostname of the incoming request by using a DNS server and forwards requests for non-cacheable content to the resolved origin servers. Cacheable requests are sent to the configured cache servers.
- **Reverse proxy.** Reverse proxy caches are configured for specific origin servers. Incoming traffic directed to the reverse proxy, can either be served from a cache server or be sent to the origin server with or without modification to the URL.

Configure transparent redirection

May 2, 2023

When you configure transparent cache redirection, the NetScaler appliance evaluates all traffic it receives, to determine whether it is cacheable. This mode alleviates traffic along the delivery route and is often used when the cache server resides on the backbone of an ISP or carrier.

By default, cacheable requests are sent to a cache server, and non-cacheable requests to the origin server. For example, when the NetScaler appliance receives a request that is directed to a web server, it compares the HTTP headers in the request with a set of policy expressions. If the request does not match the policy, the appliance forwards the request to a cache server. If the request does match a policy, the appliance forwards the request, unchanged, to the web server.

For details on how to modify this default behavior, see [Direct policy hits to the cache instead of the origin](#).

To configure transparent redirection, first enable cache redirection and load balancing, and configure edge mode. Then, create a cache redirection virtual server with a wildcard IP address (*), so that this virtual server can receive traffic coming to the appliance on any IP address the appliance owns. To this virtual server, bind cache redirection policies that describe the types of requests that should not be cached. Then, create a load balancing virtual server that will receive traffic from the cache redirection virtual server for cacheable requests. Finally, create a service that represents a physical cache server and bind it to the load balancing virtual server.

Enable cache redirection and load balancing

July 22, 2021

The appliance cache redirection and load balancing features are not enabled by default. They must be enabled before any cache redirection configuration can take effect.

Enable cache redirection and load balancing by using the CLI

At the command prompt, type the following command to enable cache redirection and load balancing and verify the settings:

```
1 - enable ns feature cr lb
2 - show ns feature
3 <!--NeedCopy-->
```

Example:

```
1 > enable ns feature cr lb
2   Done
3 > show ns feature
4
```

| 5 | Feature | Acronym | Status |
|----|----------------------|---------|--------|
| 6 | ----- | ----- | ----- |
| 7 | 1) Web Logging | WL | ON |
| 8 | 2) Surge Protection | SP | ON |
| 9 | 3) Load Balancing | LB | ON |
| 10 | 4) Content Switching | CS | ON |
| 11 | 5) Cache Redirection | CR | ON |
| 12 | ... | | |
| 13 | ... | | |
| 14 | ... | | |
| 15 | | | |
| 16 | 23) appliance Push | push | OFF |
| 17 | Done | | |
| 18 | <!--NeedCopy--> | | |

Enable cache redirection and load balancing by using the GUI

1. In the navigation pane, expand **System**, and then click **Settings**.
2. To enable cache redirection, in the details pane, under **Modes and Features**, click **Configure Advanced Features**.
 - a) In **Configure Advanced Features** dialog box, select the check box next to the **Cache Redirection**, and then click **OK**.
 - b) In Enable/Disable Features? dialog box, click Yes.
3. To enable load balancing, in the details pane, under **Modes and Features**, click **Configure Basic Features**.
 - a) In **Configure Basic Features** dialog box, select the check box next to the Load Balancing, and then click **OK**.
 - b) In Enable/Disable Features? dialog box, click Yes.

Configure edge mode

May 2, 2023

When deployed at the edge of a network, the NetScaler appliance dynamically learns about the servers on that network. Edge mode enables the appliance to dynamically learn about up to 40,000 HTTP servers and proxy TCP connections for these servers.

This mode turns on the collection of statistics for the dynamically learned services and is typically used in transparent deployments for cache redirection.

Enable edge mode by using the CLI

At the command prompt, type the following commands to enable edge mode and verify the setting:

```
1 - enable ns mode Edge
2 - show ns mode
3 <!--NeedCopy-->
```

Example:

```
1 > enable ns mode edge
2 Done
3
4 > show ns mode
5
6 Mode Acronym Status
7 -----
8 ...
9 ...
10 ...
11 6) MAC-based forwarding MBF ON
12 7) Edge configuration Edge ON
13 8) Use Subnet IP USNIP OFF
14 ...
15 ...
16 ...
17 16) Bridge BPDUs BridgeBPDUs OFF
18 Done
19 <!--NeedCopy-->
```

Enable edge mode by using the GUI

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Configure modes.
3. In Configure Modes dialog box, select the check box next to the Edge Configuration, and then click OK.
4. In Enable/Disable Feature(s)? dialog box, click Yes.

Configure a cache redirection virtual server

October 16, 2023

By default, a cache redirection virtual server forwards cacheable requests to the load balancing virtual server for the cache, and forwards non-cacheable requests to the origin server (except in a reverse proxy configuration, in which non-cacheable requests are sent to a load balancing virtual server).

There are three types of cache redirection virtual servers: transparent, forward proxy, and reverse proxy.

A transparent cache redirection virtual server uses an IP address of * and a port number, usually 80, that can accept HTTP traffic sent to any IP address that the appliance represents. As a result, you can configure only one transparent cache redirection virtual server. Any additional cache redirection virtual servers that you configure must be forward proxy or reverse proxy redirection servers.

Add a cache redirection virtual server in transparent mode by using the CLI

At the command prompt, type the following commands to add a cache redirection virtual server and verify the configuration:

```
1 - add cr vserver <name> <serviceType> [<IPAddress> <port> ] [-  
    cacheType <cacheType>] [-redirect <redirect>]  
2 - show cr vserver [<name>]  
3 <!--NeedCopy-->
```

Example:

```
1 add cr vserver Vserver-CRD-1 HTTP * 80 -cacheType TRANSPARENT -redirect  
    POLICY  
2 > show cr vserver Vserver-CRD-1  
3     Vserver-CRD-1 (*:80) - HTTP      Type: CONTENT  
4     State: UP  ARP:DISABLED  
5     Client Idle Timeout: 180 sec  
6     Down state flush: ENABLED  
7     Disable Primary Vserver On Down : DISABLED  
8     Default:          Content Precedence: RULE          Cache:  
        TRANSPARENT  
9     On Policy Match: ORIGIN L2Conn: OFF      OriginUSIP: OFF  
10    Redirect: POLICY      Reuse: ON      Via: ON ARP: OFF  
11 Done  
12 <!--NeedCopy-->
```

Modify or remove a cache redirection virtual server by using the CLI

- To modify a virtual server, use the `set cr vserver` command, which is like using the `add cr vserver` command, except that you enter the name of an existing virtual server.
- To remove a virtual server, use the `rm cr vserver` command, which accepts only the `<name>` argument.

Add a cache redirection virtual server in transparent mode by using the GUI

1. Navigate to **Traffic Management > Cache Redirection > Virtual Servers**.

2. In the details pane, click **A**dd**.
3. In **Create Virtual Server (Cache Redirection)**, specify the required parameter values.
4. In **Protocol**, select a supported protocol (for example, **HTTP**). If the virtual server is to receive traffic on a port other than the standard port for the selected protocol, enter a new value in the Port field.
5. Click the **Advanced** tab.
6. Verify that **Cache Type** is set to **TRANSPARENT** and **Redirect** is set to **POLICY**.
7. Click **Create**, and then click **Close**. The Cache Redirection Virtual Servers pane displays the new virtual server.
8. Select the new cache redirection virtual server to display the details of its configuration.

Bind policies to the cache redirection virtual server

September 21, 2020

Cache redirection policies are not automatically bound to the cache redirection virtual server. A policy based cache redirection virtual server cannot function unless you bind at least one policy to it.

Bind policies to a cache redirection virtual server by using the CLI

At the command prompt, type:

```
1 - bind cr vserver <name> -policyName <string>
2 - show cr vserver [<name>]
3 <!--NeedCopy-->
```

Example:

```
1 > bind cr vserver Vserver-CRD-1 -policyName bypass-cache-control
2 Done
3 > bind cr vserver Vserver-CRD-1 -policyName bypass-dynamic-url
4 Done
5 > bind cr vserver Vserver-CRD-1 -policyName bypass-urltokens
6 Done
7 > bind cr vserver Vserver-CRD-1 -policyName bypass-cookie
8 Done
9
10 > show cr vserver Vserver-CRD-1
11     Vserver-CRD-1 (*:80) - HTTP      Type: CONTENT
12     State: UP  ARP:DISABLED
13     Client Idle Timeout: 180 sec
```

```

14      Down state flush: ENABLED
15      Disable Primary Vserver On Down : DISABLED
16      Default:          Content Precedence: RULE          Cache:
          TRANSPARENT
17      On Policy Match: ORIGIN L2Conn: OFF          OriginUSIP: OFF
18      Redirect: POLICY          Reuse: ON          Via: ON ARP: OFF
19
20 1)      Cache bypass Policy: bypass-cache-control
21 2)      Cache bypass Policy: bypass-dynamic-url
22 3)      Cache bypass Policy: bypass-urltokens
23 4)      Cache bypass Policy: bypass-cookie
24 Done
25 <!--NeedCopy-->

```

Bind a user-defined policy to a cache redirection virtual server by using the GUI

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. Click the virtual server that you want to configure, and click Open.
3. On the Policies tab, select type of the policy and then click Insert Policy.
4. Under Policy Name column, select the policy that you want to bind.
5. Click OK.

Unbind a policy from a cache redirection virtual server

May 2, 2023

When you unbind a policy from the cache redirection virtual server, the NetScaler appliance no longer applies the policy when evaluating client requests.

Unbind a policy from a cache redirection virtual server by using the command CLI

At the command prompt, type:

```

1 - unbind cr vserver <name> -policyName <string>
2 - show cr vserver [<name>]
3 <!--NeedCopy-->

```

Example:

```

1 unbind cr vserver Vserver-CR-1 -policyName bypass-non-get
2 > show cr vserver Vserver-CRD-1
3      Vserver-CRD-1 (*:80) - HTTP          Type: CONTENT
4      State: UP ARP:DISABLED
5      Client Idle Timeout: 180 sec

```

```

6      Down state flush: ENABLED
7      Disable Primary Vserver On Down : DISABLED
8      Default:          Content Precedence: RULE          Cache:
          TRANSPARENT
9      On Policy Match: ORIGIN L2Conn: OFF          OriginUSIP: OFF
10     Redirect: POLICY          Reuse: ON          Via: ON ARP: OFF
11
12 1)    Cache bypass Policy: bypass-cache-control
13 Done
14 <!--NeedCopy-->

```

Unbind a user-defined policy from a cache redirection virtual server by using the GUI

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. Click the virtual server that you want to configure, and then click Open.
3. On the Policies tab, under Policy Name, select the policy that you want to unbind.
4. Click Unbind Policy, and then click OK.

Create a load balancing virtual server

May 2, 2023

The cache redirection virtual server on the NetScaler appliance can send requests to either a cache server farm, if the request is cacheable, or to the origin server farm if the request is not cacheable.

Each cache server is represented on the appliance by a service, which is bound to a load balancing virtual server that receives requests from the cache redirection virtual server and forwards those requests to the servers.

For details on configuring load balancing virtual servers and other configuration options, see [Load Balancing](#).

Create a load balancing virtual server by using the CLI

At the command prompt, type the following commands to create a load balancing virtual server and verify the configuration:

```

1 - add lb vserver <name> <serviceType> [<IPAddress>] [<port>]
2 - show lb vserver [<name>]
3 <!--NeedCopy-->

```

Example:

```
1 > add lb vserver Vserver-LB-CR HTTP 10.102.20.30 80
2 Done
3 > show lb vserver Vserver-LB-CR
4     Vserver-LB-CR (10.102.20.30:80) - HTTP Type: ADDRESS
5     State: DOWN
6     Last state change was at Fri Jul 2 08:47:52 2010
7     Time since last state change: 0 days, 00:00:08.470
8     Effective State: DOWN
9     Client Idle Timeout: 180 sec
10    Down state flush: ENABLED
11    Disable Primary Vserver On Down : DISABLED
12    Port Rewrite : DISABLED
13    No. of Bound Services : 0 (Total)          0 (Active)
14    Configured Method: LEASTCONNECTION
15    Mode: IP
16    Persistence: NONE
17    Vserver IP and Port insertion: OFF
18    Push: DISABLED Push VServer:
19    Push Multi Clients: NO
20    Push Label Rule: none
21 Done
22 <!--NeedCopy-->
```

Create a load balancing virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
 2. In the details pane, click Add.
 3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters as shown:
 - Name*-name
 - IP Address*- IPAddress
 - Port*-port
- *A required parameter
4. In the Protocol list, select a supported protocol (for example, **HTTP**). If the virtual server is to receive traffic on a port other than the well-known port for the selected protocol, enter a new value in the Port field.
 5. Click Create, and then click Close. The Load Balancing Virtual Servers pane displays the new virtual server.

Configure an HTTP service

May 2, 2023

On the NetScaler appliance, a service represents a physical server on the network. In the transparent cache redirection configuration, the service represents the cache server. Cacheable requests are sent by the cache redirection virtual server to the load balancing virtual server, which in turn forwards each request to the correct service, which passes it on to the cache server.

Configure an HTTP service by using the CLI

At the command prompt, type the following commands to create an HTTP service and verify the configuration:

```
1 - add service <name> <IP> <serviceType> <port> -cacheType <cacheType>
2 - show service [<name>]
3 <!--NeedCopy-->
```

Example:

```
1 > add service Service-HTTP-1 10.102.29.40 HTTP 80 -cacheType
   TRANSPARENT
2 Done
3 > show service Service-HTTP-1
4     Service-HTTP-1 (10.102.29.40:80) - HTTP
5     State: DOWN
6     Last state change was at Fri Jul  2 09:14:17 2010
7     Time since last state change: 0 days, 00:00:13.820
8     Server Name: 10.102.29.40
9     Server ID : 0   Monitor Threshold : 0
10    Max Conn: 0   Max Req: 0   Max Bandwidth: 0 kbits
11    Use Source IP: NO
12    Client Keepalive(CKA): NO
13    Access Down Service: NO
14    TCP Buffering(TCPB): NO
15    HTTP Compression(CMP): YES
16    Idle timeout: Client: 180 sec   Server: 360 sec
17    Client IP: DISABLED
18    Cache Type: TRANSPARENT Redirect Mode:
19    Cacheable: NO
20    SC: OFF
21    SP: ON
22    Down state flush: ENABLED
23
24 1) Monitor Name: tcp-default
25     State: DOWN   Weight: 1
26     Probes: 3     Failed [Total: 3 Current: 3]
27     Last response: Failure - Time out during TCP connection
                        establishment stage
```

```
28                                     Response Time: N/A
29   Done
30 <!--NeedCopy-->
```

Modify or remove a service by using the CLI

- To modify a service, use the `set service` command, which is just like using the `add service` command, except that you enter the name of an existing service.
- To remove a service, use the `rm service` command, which accepts only the `<name>` argument.

Add an HTTP service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services
 2. In the details pane, click Add.
 3. In the Create Service dialog box, specify values for the following parameters as shown:
 - Service Name*—name
 - Server*—IP
 - Port*—port
- *A required parameter
4. In the Protocol* drop-down list, select a supported protocol (for example, **HTTP**).
 5. Click Create, and then click Close.

Bind/unbind a service to/from a load balancing virtual server

September 21, 2020

You must bind a service to the load balancing virtual server. This enables the load balancer to forward the request to the server that the service represents. If your configuration changes, you can unbind a service from the load balancing virtual server.

Bind a service to a load balancing virtual server by using the CLI

At the command prompt, type:

```
1 - bind lb vserver <name> <serviceName>
2 - show lb vserver [<name>]
3 <!--NeedCopy-->
```

Example:

```
1 > bind lb vserver vserver-LB-CR service-HTTP-1
2 Done
3 > show lb vserver Vserver-LB-CR
4     Vserver-LB-CR (10.102.20.30:80) - HTTP Type: ADDRESS
5     State: DOWN
6     Last state change was at Fri Jul  2 08:47:52 2010
7     Time since last state change: 0 days, 00:42:25.610
8     Effective State: DOWN
9     Client Idle Timeout: 180 sec
10    Down state flush: ENABLED
11    Disable Primary Vserver On Down : DISABLED
12    Port Rewrite : DISABLED
13    No. of Bound Services : 1 (Total)          0 (Active)
14    Configured Method: LEASTCONNECTION
15    Mode: IP
16    Persistence: NONE
17    Vserver IP and Port insertion: OFF
18    Push: DISABLED Push VServer:
19    Push Multi Clients: NO
20    Push Label Rule: none
21
22 1) Service-HTTP-1 (10.102.29.40: 80) - HTTP State: DOWN Weight: 1
23 Done
24 <!--NeedCopy-->
```

Unbind a service from a load balancing virtual server by using the CLI

To unbind a service, use the `unbind lb vserver` command instead of `bind lb vserver`.

Bind/unbind a service from a load balancing virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers
2. In the details pane, select the virtual server from which you want to bind/unbind the service, and then click Open.
3. On the Services tab, in the Active column, select/clear the check box next to the Service Name.
4. Click OK.

Disable the use the proxy port setting for transparent caching

May 2, 2023

If the use source IP (USIP) option is disabled on a cache service configured on the NetScaler appliance, the appliance forwards client requests to the cache service by using a appliance-owned subnet IP (SNIP) address or mapped IP (MIP) address as the source IP address and a random port as the source port. The randomly selected port is called the proxy port.

However, if you want to configure a fully transparent cache (a cache configuration in which the cache service receives the client's IP address and port number), you must not only enable the USIP option, either globally or on the cache service, but also disable the Use Proxy Port setting, either globally or on the cache service. Disabling the Use Proxy Port setting enables the appliance to use the client's source port as the source port when it connects to the cache service, and ensures a fully transparent cache configuration.

For more information about configuring the Use Proxy Port option globally or on a service, see [Configuring the Source Port for Server-Side Connections](#).

Assign a port range to the NetScaler appliance

May 2, 2023

Sharing of the client IP address may create a conflict that makes network devices, such as routers, cache servers, origin servers, and other NetScaler appliances, unable to determine the appliance, and therefore the client, to which the response should be sent.

A method to solve this problem is to assign a source port range to the NetScaler appliance. This allotment enables network devices to unambiguously identify the NetScaler appliance that sent the request.

Assign a source port range to a NetScaler appliance by using the CLI

At the command prompt, type:

```
set ns param -crPortRange <startPortNumber-endPortNumber>
```

Assign a source port range to a NetScaler appliance by using the appliance GUI

1. In the navigation pane, click System, and then click Settings.

2. In the Settings group, click the Change global system settings link.
3. In the Cache Redirection Port Range group, specify the port range for the appliance by typing a port number for Start Port and a port number for End Port.
4. Click OK.

Enable load balancing virtual servers to redirect requests to cache

May 2, 2023

If a load balancing virtual server is configured to listen on a particular IP address and port combination, it takes precedence over the cache redirection virtual server for any requests destined for that address-port combination. Therefore, the cache redirection virtual server does not process those requests.

If you want to override this functionality and let the cache redirection virtual server decide whether the request should be served from the cache or not, configure the particular load balancing virtual server to be cacheable.

Such a configuration is typically used when an ISP uses a NetScaler appliance at the edge of its network and all traffic flows through the appliance.

Enable load balancing virtual servers to redirect requests to the cache by using the CLI

At the command prompt, type:

```
1 - set lb vserver <name> [-cacheable ( YES | NO)]
2 - show lb vserver [<name>]
3 <!--NeedCopy-->
```

Example:

```
1 set lb vserver Vserver-LB-CR - cacheable YES
2 > show lb vserver vserver-LB-CR
3      Vserver-LB-CR (10.102.20.30:80) - HTTP  Type: ADDRESS
4      State: DOWN
5      Last state change was at Fri Jul  2 08:47:52 2010
6      Time since last state change: 0 days, 01:05:51.510
7      Effective State: DOWN
8      Client Idle Timeout: 180 sec
9      Down state flush: ENABLED
10     Disable Primary Vserver On Down : DISABLED
11     Port Rewrite : DISABLED
12     No. of Bound Services : 1 (Total)          0 (Active)
13     Configured Method: LEASTCONNECTION
14     Mode: IP
15     Persistence: NONE
```

```
16      Cacheable: YES  PQ: OFF SC: OFF
17      Vserver IP and Port insertion: OFF
18      Push: DISABLED  Push VServer:
19      Push Multi Clients: NO
20      Push Label Rule: none
21
22  1) Service-HTTP-1 (10.102.29.40: 80) - HTTP State: DOWN Weight: 1
23      Done
24  <!--NeedCopy-->
```

For transparent cache redirection, the appliance intercepts all traffic and evaluates every request to determine whether it is cacheable. Non-cacheable requests are sent unchanged to the origin server.

When using transparent cache redirection, you may want to turn off cache redirection for load balancing virtual servers that always direct traffic to origin servers.

Turn off caching for a load balancing virtual server by using the CLI

To turn off caching for a load balancing virtual, use the `unset lb vserver` command instead of `set lb vserver`. Specify a value of `NO` value for the **cacheable** parameter.

Enable or disable load balancing virtual servers to redirect requests to the cache by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server from which you want to enable/disable the caching, and then click Open.
3. On the Advanced tab, select/clear Cache Redirection check box.
4. Click OK.

Configure forward proxy redirection

May 2, 2023

A forward proxy is a single point of contact for a client or group of clients. In this configuration, the NetScaler appliance redirects non-cacheable requests to an origin server and redirects cacheable requests to either a forward proxy cache or a transparent cache.

When the appliance is configured as a forward proxy, users must modify their browsers so that the browser sends requests to the forward proxy instead of the destination servers.

A forward proxy cache redirection virtual server on the appliance compares the request with a policy for caching. If the request is not cacheable, the appliance queries a DNS load balancing virtual server for resolution of the destination, and then sends the request to the origin server. If the request is cacheable, the appliance forwards the request to a load balancing virtual server for the cache.

The appliance relies on a host domain name or IP address in the request's HOST header to determine the requested destination. If there is no HOST header in the request, the appliance inserts a HOST header based on the destination IP address in the request.

Typically, the NetScaler appliance acts as a forward proxy in an enterprise LAN. In such a configuration, the appliance resides at the edge of an enterprise LAN and intercepts client requests before they are fanned out to the WAN. Configuring the appliance in the forward proxy mode reduces traffic on the WAN.

To configure forward proxy cache redirection, first enable load balancing and cache redirection on the appliance. Then, configure a DNS load balancing virtual server and associated services. Also configure a load balancing virtual server and bind to it appropriate services for the cache. Configure a forward proxy cache redirection virtual server and bind the DNS and load balancing virtual servers to it. You must also configure caching policies and bind them to the cache redirection virtual server. To complete the setup, configure the client browsers to use the forward proxy.

For details on how to enable cache redirection and load balancing on the appliance, see [Enable cache redirection and load balancing](#).

For details on how to create a load balancing virtual server, see [Create a load balancing virtual server](#).

For details on how to configure services that represent the cache server, see [Configure an HTTP service](#).

For details on how to bind the service to a virtual server, see [Bind/unbind a service to/from a load balancing virtual server](#).

For details on how to create a forward proxy cache redirection server, see [Configure a cache redirection virtual server](#), and create a virtual server of type TRANSPARENT or FORWARD.

For details on binding cache redirection policies to the cache redirection virtual server, see [Configure a cache redirection policy](#).

Create a DNS service

May 2, 2023

A DNS service is a representation, on the NetScaler appliance, of a physical DNS server in the network. A DNS load balancing virtual server sends DNS requests to the DNS server in the network through such a service.

Create a DNS service by using the CLI

At the command line, type the following commands to create a DNS service and verify the configuration:

```
1 - add service <name> <IP> <serviceType> <port>
2 - show service [<name>]
3 <!--NeedCopy-->
```

Example:

```
1 add service Service-DNS-1 10.102.29.41 DNS 53
2 show service Service-DNS-1
3     Service-DNS-1 (10.102.29.41:53) - DNS
4     State: DOWN
5     Last state change was at Fri Jul  2 10:14:32 2010
6     Time since last state change: 0 days, 00:00:13.550
7     Server Name: 10.102.29.41
8     Server ID : 0   Monitor Threshold : 0
9     Max Conn: 0   Max Req: 0   Max Bandwidth: 0 kbits
10    Use Source IP: NO
11    Client Keepalive(CKA): NO
12    Access Down Service: NO
13    TCP Buffering(TCPB): NO
14    HTTP Compression(CMP): NO
15    Idle timeout: Client: 120 sec   Server: 120 sec
16    Client IP: DISABLED
17    Cacheable: NO
18    SC: OFF
19    SP: OFF
20    Down state flush: ENABLED
21
22 1)    Monitor Name: ping-default
23         State: DOWN   Weight: 1
24         Probes: 3   Failed [Total: 3 Current: 3]
25         Last response: Failure - Probe timed out.
26         Response Time: 2000.0 millisec
27 Done
28 <!--NeedCopy-->
```

Add a DNS service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.

3. In the Create Service dialog box, specify values for the following parameters as shown:

- Service Name*—name
- Server*—IP
- Port*—port

*A required parameter

1. In the Protocol* drop down list, select a supported protocol (for example, **DNS**).
2. Click Create, and then click Close.

Create a DNS load balancing virtual server

September 21, 2020

The DNS virtual server enables the forward proxy to perform DNS resolution before forwarding a client request to an origin server. The DNS load balancing virtual server is associated with the DNS service that represents the physical DNS server on the network.

Create a DNS load balancing virtual server by using the CLI

At the command line, type the following commands to create a DNS load balancing virtual server and verify the configuration:

```
1 - add lb vserver <name> <serviceType>
2 - show lb vserver [<name>]
3 <!--NeedCopy-->
```

Example:

```
1 > add lb vserver Vserver-DNS-1 DNS
2 Done
3 > show lb vserver Vserver-DNS-1
4     Vserver-DNS-1 (0.0.0.0:0) - DNS Type: ADDRESS
5     State: DOWN
6     Last state change was at Fri Jul  2 10:32:28 2010
7     Time since last state change: 0 days, 00:00:08.10
8     Effective State: DOWN ARP:DISABLED
9     Client Idle Timeout: 120 sec
10    Down state flush: ENABLED
11    Disable Primary Vserver On Down : DISABLED
12    No. of Bound Services : 0 (Total)      0 (Active)
13    Configured Method: LEASTCONNECTION
14    Mode: IP
15    Persistence: NONE
```

```

16 Done
17 <!--NeedCopy-->

```

Create a DNS load balancing virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, in the Name box, type a name for the virtual server.
4. In the Protocol* drop down list, select a supported protocol (for example, **DNS**).
5. Click Create, and then click Close. The DNS Virtual Servers pane displays the new virtual server.

Bind the DNS service to the virtual server

September 21, 2020

For the DNS server to respond to DNS requests, the service representing the DNS server must be bound to the DNS virtual server.

Bind the DNS service to the load balancing virtual server by using the CLI

At the command prompt, type the following commands to bind the DNS service to the load balancing virtual server and verify the configuration:

```

1 - bind lb vserver <name> <serviceName>
2 - show lb vserver <name>
3 <!--NeedCopy-->

```

Example:

```

1 > bind lb vserver Vserver-DNS-1 Service-DNS-1
2 Done
3 > show lb vserver Vserver-DNS-1
4     Vserver-DNS-1 (0.0.0.0:0) - DNS Type: ADDRESS
5     State: DOWN
6     Last state change was at Fri Jul 2 10:32:28 2010
7     Time since last state change: 0 days, 00:12:16.80
8     Effective State: DOWN ARP:DISABLED
9     Client Idle Timeout: 120 sec
10    Down state flush: ENABLED
11    Disable Primary Vserver On Down : DISABLED
12    No. of Bound Services : 1 (Total)      0 (Active)
13    Configured Method: LEASTCONNECTION

```

```
14         Mode: IP
15         Persistence: NONE
16
17 1) Service-DNS-1 (10.102.29.41: 53) - DNS State: DOWN   Weight: 1
18   Done
19 >
20 <!--NeedCopy-->
```

Unbind a DNS service from the load balancing virtual server by using the CLI

Use the `unbind lb vserver` command instead of `bind lb vserver`.

Bind/Unbind a DNS service to/from a load balancing virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers
2. In the details pane, select the virtual server to/from which you want to bind/unbind the DNS service, and then click Open.
3. On the Services tab, in the Active column, select/clear the check box next to the Service Name.
4. Click OK.

Configure a client web browser to use a forward proxy

May 2, 2023

When you configure the NetScaler appliance as forward proxy cache redirection virtual server in the network, you must configure the client Web browser to send requests to the forward proxy. Typically, when you use a forward proxy, the only route to the servers in the network is through the forward proxy.

Refer the documentation for your browser to configure the browser to use a forward proxy. Specify the IP address and port number of the forward proxy cache redirection virtual server for this configuration.

Configure reverse proxy redirection

February 14, 2023

A reverse proxy resides in front of one or more web servers and shields the origin server from client requests. Often, a reverse proxy cache is a front-end for all client requests to a server. An administrator

assigns a reverse proxy cache to a specific origin server. The reverse proxy cache is unlike transparent and forward proxy caches, which cache frequently requested content for all requests to any origin server, and the choice of a server is based on the request.

Unlike a transparent proxy cache, the reverse proxy cache has its own IP address and can replace destination domains and URLs in a non-cacheable request with new destination domains and URLs.

You can deploy reverse proxy cache redirection at the origin-server side or at the edge of a network. When deployed at the origin server, the reverse proxy cache redirection virtual server is a front-end for all requests to the origin server.

In the reverse proxy mode, when the appliance receives a request, the cache redirection virtual server evaluates the request and forwards it to either a load balancing virtual server for the cache or a load balancing virtual server for the origin. The incoming request can be transformed by changing the host header or the host URL before it is sent to the back-end server.

To configure reverse proxy cache redirection, first enable cache redirection and load balancing. Then, configure a load balancing virtual server and services to send cacheable requests to the cache servers. Also configure a load balancing virtual server and associated services for the origin servers. Then, configure a reverse proxy cache redirection virtual server and bind relevant cache redirection policies to it. Finally, configure mapping policies and bind them to the reverse proxy cache redirection virtual server.

The mapping policies have an associated action that enables the cache redirection virtual server to forward any non-cacheable request to the load balancing virtual server for the origin.

Be sure to create the default cache server destination.

For details on how to enable cache redirection and load balancing on the appliance, see [Enable cache redirection and load balancing](#).

For details on how to create a load balancing virtual server, see [Create a load balancing virtual server](#).

For details on how to configure services that represent the cache server, see [Configure an HTTP service](#).

For details on how to bind the service to a virtual server, see [Bind/unbind a service to/from a load balancing virtual server](#).

For details on how to create a reverse proxy cache redirection server, see [Configure a cache redirection virtual server](#), and create a virtual server of type REVERSE.

For details on binding built-in cache redirection policies to the cache redirection virtual server, see [Bind policies to the cache redirection virtual server](#).

Configure mapping policies

If an incoming request is non-cacheable, the reverse-proxy cache redirection virtual server replaces the domain and URL in the request with the domain and URL of a target origin server and forwards the request to the load balancing virtual server for the origin.

A mapping policy enables the reverse proxy cache redirection virtual server to replace the destination domain and URL and forward the request to the load balancing virtual server for the origin.

A mapping policy must first translate the domain and the URL, and then pass the request on to the origin load balancing virtual server.

A mapping policy can map a domain, a URL prefix, and a URL suffix, as follows:

- **Domain mapping:** You can map a domain without a prefix or suffix. The domain mapping is the default mapping for the virtual server (for example, mapping `www.mycompany.com` to `www.myrealcompany.com`).
- **Prefix mapping:** You can replace a specified pattern prefixed as part of the URL (for example, mapping `www.mycompany.com/sports/index.html` to `www.mycompany.com/news/index.html`).
- **Suffix mapping:** You can replace the file suffix in the URL (for example, mapping `www.mycompany.com/sports/index.html` to `www.mycompany.com/sports/index.asp`).

The source and the destination strings being mapped must be similar. If you specify a source domain, you must specify a destination domain, and if you specify a source suffix, you must specify a destination suffix. Similarly, if you specify an exact URL from the source, the target URL must also be an exact URL.

Once you configure mapping policies for the reverse proxy mode, you must bind them to the cache redirection virtual server.

You can use combinations of the source URL, target URL, and source and target domains to configure all three types of domain mapping.

Configure a mapping policy for reverse proxy mode by using the CLI

At the command prompt, type the following command to add a policy map and verify the configuration:

```
1 - add policy map <mapPolicyName> -sd <string> [-su <string>] [-td <string>] [-tu <string>]
2 - show policy map [<mapPolicyName>]
3 <!--NeedCopy-->
```

Example:

The following command maps a domain in a client request to a target domain:

```
1 > add policy map myMappingPolicy -sd www.mycompany.com -td www.
  myrealcompany.com
2 Done
3 > show policy map myMappingPolicy
4 1) Name: myMappingPolicy
5 Source Domain: www.mycompany.com Source Url:
6 Target Domain: www.myrealcompany.com Target Url:
7 Done
8 <!--NeedCopy-->
```

Following is an example of mapping a URL suffix to a different URL suffix:

```
1 > add policy map myOtherMappingPolicy -sd www.mycompany.com -td www.
  myrealcompany.com -su /news.html -tu /realnews.html
2 Done
3 > show policy map myOtherMappingPolicy
4 1) Name: myOtherMappingPolicy
5 Source Domain: www.mycompany.com Source Url: /news.html
6 Target Domain: www.myrealcompany.com Target Url: /realnews.
  html
7 Done
8 <!--NeedCopy-->
```

Configure a mapping policy for reverse proxy mode by using the GUI

1. Navigate to **Traffic Management > Cache Redirection > Map Policies**.
2. In the details pane, click Add.
3. In the Create Map Policy dialog box, specify values for the following parameters as shown:
 - Name*- mapPolicyName
 - Source Domain*-sd
 - Target Domain*-td
 - Source URL-su
 - Target URL-tu

*A required parameter

4. Click Create, and then click Close. The Map pane displays the new mapping policy.

Bind the mapping policy to the cache redirection virtual server by using the CLI

At the command prompt, type the following commands to bind the mapping policy to the cache redirection virtual server and verify the configuration:

```
1 - bind cr vserver <name> -policyName <string> [<targetVserver>]
```

```

2 - show cr vserver <name>
3 <!--NeedCopy-->

```

Example:

```

1 > bind cr vserver Vserver-CRD-3 -policyName myMappingPolicy Vserver-LB-
  CR
2 Done
3 > show cr vserver Vserver-CRD-3
4     Vserver-CRD-3 (10.102.29.50:88) - HTTP Type: CONTENT
5     State: UP
6     Client Idle Timeout: 180 sec
7     Down state flush: ENABLED
8     Disable Primary Vserver On Down : DISABLED
9     Default: Vserver-LB-CR Content Precedence: RULE          Cache:
      REVERSE
10    On Policy Match: ORIGIN L2Conn: OFF      OriginUSIP: OFF
11    Redirect: POLICY          Reuse: ON      Via: ON ARP: OFF
12
13 1) Policy:          Target: Vserver-LB-CR Priority: 0      Hits: 0
14 1) Map: myMappingPolicy Target: Vserver-LB-CR
15 Done
16 <!--NeedCopy-->

```

Bind the mapping policy to the cache redirection virtual server by using the GUI

1. Navigate to **Traffic Management > Cache Redirection > Virtual Servers**.
2. In the details pane, select the virtual server from which you want to bind the mapping policy, and then click **Open**.
3. In the **Configure Virtual Server**(Cache Redirection), on the **Policies** tab, select **Map**, and then click **Insert Policy**.
4. In the **Policy Name** column, select the policy from the drop-down list.
5. In the **Target** column, click the down arrow, and then select the virtual server from the drop-down list.
6. Click **OK**.

Selective cache redirection

May 2, 2023

Selective cache redirection sends requests for particular types of content, for example, images, to one cache server or group of cache servers and sends other types of content to a different cache server or group of cache servers. You can configure advanced cache redirection in transparent, reverse proxy, or forward proxy modes.

In selective cache redirection, the NetScaler appliance intercepts a client request and forwards non-cacheable requests to the original destination in the client request. For cacheable requests, the appliance sends the requests to the destination cache server that can serve content of a specific content type.

Selective cache redirection involves configuring content switching policies in addition to cache redirection policies. The appliance first evaluates the cache redirection policies that are bound to the cache redirection virtual server. If a request matches a cache redirection policy, the cache redirection virtual server sends the request to the origin server or a load balancing virtual server for the origin. If no cache redirection policies match the request, the appliance evaluates the content switching policies bound to the cache redirection virtual server. If a content switching policy matches the request, the cache redirection virtual server redirects the request to a load balancing virtual server for the cache.

To configure selective cache redirection, first enable cache redirection, load balancing, and content switching on the NetScaler appliance. Then, configure a load balancing virtual server for the cache and an associated HTTP service. After this, configure a cache redirection virtual server and bind both the cache redirection and content switching policies to it. Once you have bound the policies, you can configure the virtual server to give precedence to either rule based or URL based content-switching policies.

When configured for transparent mode cache redirection in an edge deployment topology, the appliance sends all cacheable HTTP traffic to a transparent cache farm. Clients access the Internet through the appliance, which is configured as a Layer 4 switch that receives traffic on port 80.

The appliance can direct requests for images (for example, .png and .jpg files) to one server in the transparent cache farm, and all other requests for static content to other servers in the farm. For this configuration, you configure content switching policies to send images to the image cache and send all other cacheable content to a default cache.

Note: The configuration described here is for transparent selective cache redirection. Therefore, it does not require a load balancing virtual server for the origin, as would a reverse proxy configuration.

To configure this type of selective cache redirection, first enable cache redirection, load balancing, and content switching. Then, configure a load balancing virtual server for the cache and configure an associated HTTP service. Then, configure a cache redirection virtual server and create and bind both cache redirection and content switching policies to this virtual server.

For details on how to enable cache redirection and load balancing on the appliance, see [Enable cache redirection and load balancing](#).

Enable content switching

June 29, 2021

To configure selective cache redirection, after you enable both the load balancing and cache redirection features on the appliance, you must enable content switching.

Enable content switching by using the CLI

At the command prompt, type:

```
1 - enable ns feature CS
2
3 - show ns feature
4 <!--NeedCopy-->
```

Example:

```
1 > enable ns feature cs
2 Done
3 > show ns feature
4
5         Feature                               Acronym           Status
6         -----                               -

```

Enable cache redirection and load balancing by using the GUI

1. In the navigation pane, expand **System**, and then click **Settings**.
2. In the details pane, under Modes and Features, click **Configure Basic Features**.
3. In **Configure Basic Features** dialog box, select the check box next to the **Content Switching**, and then click **OK**.
4. In Enable/Disable Features? dialog box, click Yes.

Configure a load balancing virtual server for the cache

May 2, 2023

Create a load balancing virtual server and an HTTP service for each type of cache server that will be used. For example, if you want to serve JPEG files from one cache server and GIF files from another cache server, and use a third cache server for the rest of the content, create an HTTP service and virtual server for each of the three types of cache servers. Then bind each service to its respective virtual server.

For details on how to create a load balancing virtual server, see [Create a load balancing virtual server](#).

For details on how to configure services that represent the cache server, see [Configure an HTTP service](#).

For details on how to bind the service to a virtual server, see [Bind/unbind a service to/from a load balancing virtual server](#).

For details on how to create a transparent proxy cache redirection server, see [Configure a cache redirection virtual server](#), and create a virtual server of type TRANSPARENT.

For details on binding built-in cache redirection policies to the cache redirection virtual server, see [Bind policies to the cache redirection virtual server](#).

Configure a cache redirection policy for a specific type of content

To identify requests that contain a .png or .jpeg extension as cacheable, you configure a cache redirection policy and bind it to the cache redirection virtual server.

Note: If a request matches a policy, the NetScaler appliance forwards it to the origin server. As a result, in the following procedure, you configure policies to match requests that do *not* have “.png” or “.jpeg” extensions.

To configure cache redirection for a specific type of content, configure a policy that uses a simple expression, as described in [Configure a cache redirection policy](#).

Configure policies for content switching

October 16, 2023

You must create a content switching policy to identify specific types of content to be directed to one server or farm and identify other types of content to serve from another cache server or farm. For example, you can configure a policy to determine the location for image files with .png and .jpeg extensions.

Before creating the content switching policy you must define a content switching action to describe which load balancing virtual server to select. This action is used in the content switching policy.

After defining the content switching policy, you bind it to a content switching virtual server and specify a load balancing virtual server. Requests that match the policy are forwarded to the named load balancing virtual server. Requests that do not match the content switching policy are forwarded to the default load balancing virtual server for the cache.

For more details about the content switching feature and configuring content switching policies, see [Content switching](#).

You must first create the content switching policy and then bind it to the content switching virtual server.

Create a content switching policy by using the command CLI

At the command line, type:

```
1 - add cs action <name> [-targetLBVserver <string> | -targetVserver <
  string> | -targetVserverExpr <expression>]
2 - add cs policy <policyName> -rule <expression> [-action <string>]
3 - show cs policy [<policyName>]
4
5 <!--NeedCopy-->
```

Examples:

```
1 > add cs action action-CS-JPEG -targetLBVserver lbcachejpeg
2 Done
3 > show cs action action-CS-JPEG
4   Name: action-CS-JPEG
5   Target LB Vserver: lbcachejpeg
6   Hits: 0
7   Undef Hits: 0
8   Action Reference Count: 0
9 Done
10
11 > add cs policy policy-CS-JPEG -rule 'HTTP.REQ.URL.SUFFIX == "jpeg"' -
    action action-CS-JPEG
12 Done
13 > show cs policy policy-CS-JPEG
14   Policy: policy-CS-JPEG Rule: HTTP.REQ.URL.SUFFIX == "jpeg"
15   Action: action-CS-JPEG
16
```

```
17     HITS: 0
18 Done
19 >
20
21 > add cs action action-CS-GIF -targetLBVserver lbcachegif
22 Done
23 > show cs action action-CS-GIF
24     Name: action-CS-GIF
25     Target LB Vserver: lbcachegif
26     Hits: 0
27     Undef Hits: 0
28     Action Reference Count: 0
29
30 Done
31 >
32 > add cs policy policy-CS-GIF -rule 'HTTP.REQ.URL.SUFFIX == "gif" -
    action action-CS-GIF
33 Done
34 > show cs policy policy-CS-GIF
35     Policy: policy-CS-GIF Rule: HTTP.REQ.URL.SUFFIX == "gif"
36     Action: action-CS-GIF
37
38     Hits: 0
39 Done
40 <!--NeedCopy-->
```

Create a rule-based content switching policy by using the GUI

1. Navigate to **Traffic Management > Content Switching > Policies**.
2. In the details pane, click **Add**.
3. In the **Create Content Switching Policy** dialog box, in the **Name** text box, type a name for the policy.
4. Click **Add** in the **Action** tab to create a content switch action. Or select the available action from the drop-down list.
 - Type a name for the content switch action in the **Name** tab.
 - Choose the virtual server or Expression from the drop-down list:
 - **Loadbalancing Virtual Server**
 - **Global Server Loadbalancing Virtual Server**
 - **Authentication Virtual Server**
 - **NetScaler Gateway Virtual Server**
 - **Expression**
 - Click **Add** or **Edit** to configure the **Target Load Balancing Virtual Server**.

5. Click **Add** in the **Log Action** tab to create an audit message action. Or select the available audit message action from the drop-down list.
6. In the **Expression** area, select the required type of expression.
7. In the **Expression Editor** dialog box, choose the expression syntax that you want to use.

In the **Expression** area click **Evaluate** to evaluate an expression evaluator. The evaluator evaluates the expression that you entered, to verify that it is valid, and displays an analysis of the expression's effect in the **Result** area.

8. Enter your policy expressions.

For information about using the advanced syntax, see [Configure advanced policy expression: Get started](#).

9. Click **Create**. The policy you created appears in the **Content Switching Policies** pane.

Bind the content switching policy to a cache redirection virtual server by using the CLI

At the command prompt, type the following commands to bind the content switching policy to a cache redirection virtual server and verify the configuration:

```

1 - bind cs vserver <name> (-lbvserver <string> | -vServer <string> (-
  policyName <string> [-targetLBVserver <string>] [-priority<
  positive_integer>] [-gotoPriorityExpression <expression>] [-type <
  type>] [-invoke (<labelType> <labelName>)] )
2
3 - show cs vserver [<name>]
4 <!--NeedCopy-->

```

Example:

```

1 > bind cs vserver Vserver-CR-1 -policyName Policy-CS-JPEG -priority 100
2 Done
3 > bind cs vserver Vserver-CR-1 -policyName Policy-CS-GIF -priority 200
4 Done
5 > show cs vserver Vserver-CR-1

Bind the content switching policy to a cache redirection virtual server by using the GUI

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**.
2. In the details pane, select the virtual server for which you want to bind the policy (for example, **Vserver-CS-1**), and then click **Edit**.
3. In the **Content Switching Virtual Server** dialog box, on the **Policies** tab under **Advanced Settings**, click **Add** icon, and then choose policy and choose type from **Choose Policy** and **Choose Type** drop-down list.
4. Click **Continue**.
5. In the **Policy Binding** tab, select the available policies from the list and then click **Select** or click **Add** to create a new policy and then click **Create**.
6. Click **Bind** to bind the content switching policy to the virtual server.
7. Click **Done**

Configure precedence for policy evaluation

September 21, 2020

You can configure a content switching policy based on either a rule, which is a generic configuration to accommodate various content types, or a URL, which is more specific and defines exactly the type of

content that has to be sent to a particular cache server. Essentially, the same content can be defined by either a rule based policy or a URL based policy.

Once you bind content switching policies of either type to a cache redirection virtual server, you can configure the virtual server to give precedence to either rule based or URL based policies. This will, in turn, decide which servers the particular requests are directed to.

To configure precedence for policy evaluation, use the precedence parameter, which specifies the type of policy (URL or RULE) that takes precedence on the content redirection virtual server.

Possible values: RULE, URL

Default value: RULE

Configure precedence for policy evaluation by using the CLI

At the command prompt, type the following commands to configure precedence for policy evaluation and verify the configuration:

```
1 - set cr vserver <name> [-precedence (RULE | URL)]
2 - show cr vserver <name>
3 <!--NeedCopy-->
```

Example:

```
1 > set cr vserver Vserver-CRD-1 -precedence URL
2 Done
3 > show cr vserver Vserver-CRD-1
4 Vserver-CRD-1 (*:80) - HTTP Type: CONTENT
5 State: UP ARP:DISABLED
6 Client Idle Timeout: 180 sec
7 Down state flush: ENABLED
8 Disable Primary Vserver On Down : DISABLED
9 Default: Content Precedence: URL Cache: TRANSPARENT
10 On Policy Match: ORIGIN L2Conn: OFF OriginUSIP: OFF
11 Redirect: POLICY Reuse: ON Via: ON ARP: OFF
12
13 1) Cache bypass Policy: bypass-cache-control
14 2) Cache bypass Policy: Policy-CRD
15 Done
16 >
17 <!--NeedCopy-->
```

Configure precedence for policy evaluation by using the GUI

1. Navigate to Traffic Management > Content Switching > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure precedence, (for example, **Vserver-CS-1**), and then click Open.

3. In the Configure Virtual Server (Content Switching) dialog box, on the Advanced tab, next to Precedence, click Rule or URL, and then click OK.

Administer a cache redirection virtual server

September 21, 2020

To administer a cache redirection virtual server, you need to view cache redirection statistics. You might need to enable or disable cache redirection servers, or direct policy hits to the cache instead of the origin. Administrative tasks also include backing up a cache redirection virtual server and managing client connections.

View cache redirection virtual server statistics

September 21, 2020

You can view properties of a cache redirection virtual server and statistics on the traffic that has passed through a cache redirection virtual server. You can also view the cache redirection virtual servers and policies that you have bound to load balancing virtual servers.

To view statistics for a specific cache redirection virtual servers, use the name parameter to specify the name of the virtual server for which statistics will be displayed. Otherwise, statistics for all cache redirection virtual servers are displayed. Maximum Length: 127

View statistics for a cache redirection virtual server by using the CLI

At the command prompt, type:

```
stat cr vserver [<name>]
```

Example:

```
1 > stat cr vserver Vserver-CRD-1
2
3 Vserver Summary
4
5 Vser...CRD-1      IP port      Protocol      State
6                   0.0.0.0   80           HTTP          UP
7 VServer Stats:
8
9                               Rate (/s)
10                              Total
```

| | | | |
|----|-----------------|---|---|
| 9 | Requests | | 0 |
| 10 | Responses | 0 | 0 |
| 11 | Request bytes | 0 | 0 |
| 12 | Response bytes | 0 | 0 |
| 13 | | | |
| 14 | Done | | |
| 15 | > | | |
| 16 | <!--NeedCopy--> | | |

View statistics for a cache redirection virtual server by using the GUI

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers
2. In the details pane, select the virtual server for which you want to view statistics, (for example, **Vserver-CRD-1**), and then click Statistics.

Omit the server name to display basic statistics for all cache redirection virtual servers. Include the server name to display detailed statistics for that virtual server, including number and size of requests and responses that pass through the virtual server

View the statistics of a cache redirection virtual server by using the monitoring and dashboard utilities

1. To view the statistics by using the monitoring utilities, click the Monitoring tab.
2. In the Select Group drop-down menu, choose CR Virtual Servers. A list of cache redirection virtual servers appears.
3. To view the statistics by using the dashboard utilities, click the Dashboard tab.
4. Click Applet Client or Web Start Client next to Statistical Utility.
5. In the Select Group drop-down menu, choose CR Virtual Servers. The dashboard displays summary statistics for the cache redirection virtual servers.
6. To see a chart of virtual server activity, click Chart. A graphical representation of the virtual server statistics appears.

Enable or disable a cache redirection virtual server

May 2, 2023

When you create a cache redirection virtual server, it is enabled by default. If you disable a cache redirection virtual server, its state changes to OUT OF SERVICE and it stops redirecting cacheable client requests. However, the NetScaler appliance continues to respond to ARP and ping requests for the IP address of this virtual server.

Enable or disable a cache redirection virtual server by using the CLI

At the command line, type one of the following commands:

```

1 - enable cr vserver <name>
2 - show cr vserver <name>
3 - disable cr vserver <name>
4 - show cr vserver <name>
5 <!--NeedCopy-->

```

Examples:

```

1 > enable cr vserver Vserver-CRD-1
2 Done
3 > show cr vserver Vserver-CRD-1
4     Vserver-CRD-1 (*:80) - HTTP      Type: CONTENT
5     State: UP  ARP:DISABLED
6     Client Idle Timeout: 180 sec
7     Down state flush: ENABLED
8     Disable Primary Vserver On Down : DISABLED
9     Default:          Content Precedence: URL Cache: TRANSPARENT
10    On Policy Match: ORIGIN L2Conn: OFF      OriginUSIP: OFF
11    Redirect: POLICY      Reuse: ON          Via: ON ARP: OFF
12
13 1)    Cache bypass  Policy: bypass-cache-control
14 2)    Cache bypass  Policy: Policy-CRD
15 Done
16 >
17
18 > disable cr vserver Vserver-CRD-1
19 Done
20 > show cr vserver Vserver-CRD-1
21     Vserver-CRD-1 (*:80) - HTTP      Type: CONTENT
22     State: OUT OF SERVICE  ARP:DISABLED
23     Client Idle Timeout: 180 sec
24     Down state flush: ENABLED
25     Disable Primary Vserver On Down : DISABLED
26     Default:          Content Precedence: URL Cache: TRANSPARENT
27     On Policy Match: ORIGIN L2Conn: OFF      OriginUSIP: OFF
28     Redirect: POLICY      Reuse: ON          Via: ON ARP: OFF
29
30 1)    Cache bypass  Policy: bypass-cache-control
31 2)    Cache bypass  Policy: Policy-CRD
32 Done
33 >
34 <!--NeedCopy-->

```

Enable or disable a cache redirection virtual server by using the GUI

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. In the navigation pane, expand Cache Redirection, and then click Virtual Servers.
3. In the details pane, select the virtual server that you want to enable or disable, (for example, **Vserver-CRD-1**), and then click Statistics.
4. In the Proceed dialog box, click Yes.

Direct policy requests to cache instead of origin web server

May 2, 2023

By default, when a request matches a policy, the NetScaler appliance forwards the request either to the origin server directly, or to a load balancing virtual server for the origin, depending on how you have configured cache redirection.

You can change the default behavior so that when a request matches a policy, the request is forwarded to a load balancing virtual server for the cache.

To change the destination for a policy request to the origin or the cache, use the `onPolicyMatch` parameter, which specifies where to send requests that match the cache redirection policy.

The valid options are:

1. `CACHE` - Directs all matching requests to the cache.
2. `ORIGIN` - Directs all matching requests to the origin server.

Note:

For this option to work, you must select the cache redirection type as `POLICY`.

Possible values: `CACHE`, `ORIGIN`

Default value: `ORIGIN`

Change the destination for a policy request to the origin or the cache by using the CLI

At the command prompt, type the following commands to change the destination for a policy hit and verify the configuration:

```
1 set cr vserver <name> [-onPolicyMatch (ORIGIN | CACHE)]
2 <!--NeedCopy-->
```

```
1 show cr vserver <name>
2 <!--NeedCopy-->
```

Example:

```
1 > set cr vserver Vserver-CRD-1 -onPolicyMatch CACHE
2 Done
3 > show cr vserver Vserver-CRD-1
4     Vserver-CRD-1 (*:80) - HTTP      Type: CONTENT
5     State: UP  ARP:DISABLED
6     Client Idle Timeout: 180 sec
7     Down state flush: ENABLED
8     Disable Primary Vserver On Down : DISABLED
9     Default:          Content Precedence: URL Cache: TRANSPARENT
10    On Policy Match: CACHE L2Conn: OFF      OriginUSIP: OFF
11    Redirect: POLICY      Reuse: ON      Via: ON ARP: OFF
12
13 1)    Cache bypass  Policy: bypass-cache-control
14 2)    Cache bypass  Policy: Policy-CRD
15 Done
16 <!--NeedCopy-->
```

Change the destination for a policy hit to the origin or the cache by using the GUI

1. Navigate to **Traffic Management > Cache Redirection > Virtual Servers**.
2. In the details pane, select the virtual server for which you want to change the destination for a policy request, (for example, **Vserver-CRD-1**), and then click **Open**.
3. In the **Configure Virtual Server (Cache Redirection)** dialog box, click **Advanced**.
4. Select **CACHE** or **ORIGIN** from the **Redirect To** drop-down list.
5. Click **OK**.

Back up a cache redirection virtual server

March 1, 2021

Cache redirection can fail if the primary virtual server fails, or if it is unable to handle excessive traffic. You can specify a backup virtual server to take over the processing of traffic when the primary virtual server fails.

To specify a backup cache redirection virtual server, use the backupVServer parameter, which specifies Backup Virtual Server. Maximum Length: 127

Specify a backup cache redirection virtual server by using the CLI

At the command prompt, type the following commands to specify a backup cache redirection virtual server and verify the configuration:

```
1 - set cr vservice <name> [-backupVServer <string>]
2 - show cr vservice <name>
3 <!--NeedCopy-->
```

Example:

```
1 > set cr vservice Vserver-CRD-1 -backupVServer Vserver-CRD-2
2 Done
3 > show cr vservice Vserver-CRD-1
4 Vserver-CRD-1 (*:80) - HTTP Type: CONTENT
5 State: UP ARP:DISABLED
6 Client Idle Timeout: 180 sec
7 Down state flush: ENABLED
8 Disable Primary Vserver On Down : DISABLED
9 Default: Content Precedence: URL Cache: TRANSPARENT
10 On Policy Match: CACHE L2Conn: OFF OriginUSIP: OFF
11 Redirect: POLICY Reuse: ON Via: ON ARP: OFF
12 Backup: Vserver-CRD-2
13
14 1) Cache bypass Policy: bypass-cache-control
15 2) Cache bypass Policy: Policy-CRD
16 Done
17 <!--NeedCopy-->
```

Specify a backup cache redirection virtual server by using the GUI

1. Navigate to **Traffic Management > Cache Redirection > Virtual Servers**.
2. In the details pane, select the virtual server for which you want to change the destination for a policy request, (for example, **Vserver-CRD-1**), and then click Open.
3. In the Configure Virtual Server (Cache Redirection) dialog box, select the Advanced tab.
4. In the Backup Virtual Server drop-down list, select the virtual server.
5. Click OK.

Manage client connections for a virtual server

May 2, 2023

You can configure timeouts on a cache redirection virtual server so that client connections are not kept open indefinitely. You can also insert Via headers in requests. To possibly reduce network congestion,

you can reuse open TCP connections. You can enable or disable delayed cleanup of cache redirection virtual server connections.

You can configure the appliance to send ICMP responses to PING requests according to your settings. On the IP address corresponding to the virtual server, set the ICMP RESPONSE to VSVR_CNTRLD, and on the virtual server, set the ICMP VSERVER RESPONSE.

The following settings can be made on a virtual server:

- When you set ICMP VSERVER RESPONSE to PASSIVE on all virtual servers, appliance always responds.
- When you set ICMP VSERVER RESPONSE to ACTIVE on all virtual servers, appliance responds even if one virtual server is UP.
- When you set ICMP VSERVER RESPONSE to ACTIVE on some and PASSIVE on others, appliance responds even if one virtual server set to ACTIVE is UP.

This document includes the following information:

- Configure client timeout
- Insert Via headers in the requests
- Reuse TCP connections
- Configure delayed connection cleanup

Configure client timeout

You can specify expiration of client requests by setting a timeout value for the cache redirection virtual server. The timeout value is the number of seconds for which the cache redirection virtual server waits to receive a response for the client request.

To configure a time-out value, use the `cltTimeout` parameter, which specifies the time, in seconds, after which the NetScaler appliance closes any idle client connections. The default value is 180sec for HTTP/SSL-based services and 9000sec for TCP-based services.

Configure client timeout by using the CLI

At the command prompt, type the following commands to configure client timeout and verify the configuration:

```
1 - set cr vserver <name> [-cltTimeout <secs>]
2 - show cr vserver <name>
3 <!--NeedCopy-->
```

Example:

```
1 > set cr vserver Vserver-CRD-1 -cltTimeout 6000
2 Done
3 > show cr vserver Vserver-CRD-1
4     Vserver-CRD-1 (*:80) - HTTP      Type: CONTENT
5     State: UP  ARP:DISABLED
6     Client Idle Timeout: 6000 sec
7     Down state flush: ENABLED
8     Disable Primary Vserver On Down : DISABLED
9     Default:          Content Precedence: URL Cache: TRANSPARENT
10    On Policy Match: CACHE L2Conn: OFF      OriginUSIP: OFF
11    Redirect: POLICY      Reuse: ON        Via: ON ARP: OFF
12    Backup: Vserver-CRD-2
13
14 1)      Cache bypass Policy: bypass-cache-control
15 2)      Cache bypass Policy: Policy-CRD
16 Done
17 <!--NeedCopy-->
```

Configure client timeout by using the GUI

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure client timeout, (for example, **Vserver-CRD-1**), and then click Open.
3. In Configure Virtual Server (Cache Redirection) dialog box, select the Advanced tab.
4. In the Client Time-out(secs) text box, enter the time-out value in seconds.
5. Click OK.

Insert Via headers in the requests

A Via header lists the protocols and recipients between the start and end points for a request or a response and informs the server of proxies through which the request was sent. You can configure the cache redirection virtual server to insert a Via header in each HTTP request. The via parameter is enabled by default when you create a cache redirection virtual server.

To enable or disable Via-header insertion in client requests, use the via parameter, which specifies the state of the system in inserting a Via header in the HTTP requests.

Possible values: ON, OFF

Default value: ON

Enable or disable Via-header insertion in client requests by using the CLI

At the command prompt, type:

```

1 - set cr vserver <name> [-via (ON|OFF)]
2 - show cr vserver <name>
3 <!--NeedCopy-->

```

Example:

```

1 > set cr vserver Vserver-CRD-1 -via ON
2 Done
3 > show cr vserver Vserver-CRD-1
4     Vserver-CRD-1 (*:80) - HTTP      Type: CONTENT
5     State: UP  ARP:DISABLED
6     Client Idle Timeout: 6000 sec
7     Down state flush: ENABLED
8     Disable Primary Vserver On Down : DISABLED
9     Default:          Content Precedence: URL Cache: TRANSPARENT
10    On Policy Match: CACHE L2Conn: OFF      OriginUSIP: OFF
11    Redirect: POLICY      Reuse: ON        Via: ON ARP: OFF
12    Backup: Vserver-CRD-2
13
14 1)    Cache bypass  Policy: bypass-cache-control
15 2)    Cache bypass  Policy: Policy-CRD
16 Done
17 >
18 <!--NeedCopy-->

```

Enable or disable Via-header insertion in client requests by using the GUI

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure client timeout, (for example, **Vserver-CRD-1**), and then click Open.
3. In Configure Virtual Server (Cache Redirection) dialog box, select the Advanced tab.
4. Select the Via check box.
5. Click OK.

Reuse TCP connections

You can configure the NetScaler appliance to reuse TCP connections to the cache and origin servers across client connections. This can improve performance by saving the time required to establish a session between the server and the appliance. The reuse option is enabled by default when you create a cache redirection virtual server.

To enable or disable the reuse of TCP connections, use the reuse parameter, which specifies the state of reuse of TCP connections to the cache or origin servers across client connections.

Possible values: ON, OFF

Default value: ON

Enable or disable the reuse of TCP connections by using the CLI

At the command prompt, type:

```
1 - set cr vserver <name> [-reuse (ON|OFF)]
2 - show cr vserver <name>
3 <!--NeedCopy-->
```

Example:

```
1 > set cr vserver Vserver-CRD-1 -reuse ON
2 Done
3 > show cr vserver Vserver-CRD-1
4     Vserver-CRD-1 (*:80) - HTTP      Type: CONTENT
5     State: UP  ARP:DISABLED
6     Client Idle Timeout: 6000 sec
7     Down state flush: ENABLED
8     Disable Primary Vserver On Down : DISABLED
9     Default:          Content Precedence: URL Cache: TRANSPARENT
10    On Policy Match: CACHE L2Conn: OFF      OriginUSIP: OFF
11    Redirect: POLICY      Reuse: ON      Via: ON ARP: OFF
12    Backup: Vserver-CRD-2
13
14 1)      Cache bypass  Policy: bypass-cache-control
15 2)      Cache bypass  Policy: Policy-CRD
16 Done
17 <!--NeedCopy-->
```

Enable or disable the reuse of TCP connections by using the GUI

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure client timeout, (for example, **Vserver-CRD-1**), and then click Open.
3. In Configure Virtual Server (Cache Redirection) dialog box, select the Advanced tab.
4. Select the Reuse check box.
5. Click OK.

Configure delayed connection cleanup

The down state flush option performs delayed cleanup of connections on a cache redirection virtual server. The down state flush option is enabled by default when you create a cache redirection virtual server.

To enable or disable the down state flush option, set the downStateFlush parameter.

Possible values: ENABLED, DISABLED

Default value: ENABLED

Enable or disable the down state flush option by using the CLI

At the command prompt, type the following commands to configure delayed connection clean up and verify the configuration:

```
1 - set cr vserver <name> [-downStateFlush (ENABLED | DISABLED)]
2 - show cr vserver <name>
3 <!--NeedCopy-->
```

Example:

```
1 > set cr vserver Vserver-CRD-1 -downStateFlush ENABLED
2 Done
3 > show cr vserver Vserver-CRD-1
4     Vserver-CRD-1 (*:80) - HTTP      Type: CONTENT
5     State: UP  ARP:DISABLED
6     Client Idle Timeout: 6000 sec
7     Down state flush: ENABLED
8     Disable Primary Vserver On Down : DISABLED
9     Default:          Content Precedence: URL  Cache: TRANSPARENT
10    On Policy Match: CACHE  L2Conn: OFF      OriginUSIP: OFF
11    Redirect: POLICY      Reuse: ON      Via: ON ARP: OFF
12    Backup: Vserver-CRD-2
13
14 1)    Cache bypass  Policy: bypass-cache-control
15 2)    Cache bypass  Policy: Policy-CRD
16 Done
17 <!--NeedCopy-->
```

Enable or disable the reuse of TCP connections by using the GUI

1. Navigate to Traffic Management > Cache Redirection > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure client timeout, (for example, **Vserver-CRD-1**), and then click Open.
3. In Configure Virtual Server (Cache Redirection) dialog box, click Advanced tab.
4. Select the Down state flush check box.
5. Click OK.

Enable external health check for UDP and non-HTTP TCP virtual servers

September 6, 2023

In public clouds, you can use the NetScaler appliance as a second-tier load balancer when the native load balancer is used as a first tier. The native load balancer can be an application load balancer (ALB)

or a network load balancer (NLB). Most of the public clouds do not support UDP health probes in their native load balancers. Hence, if these servers are down their actual status might not be updated. As a result, traffic is sent unconditionally to NetScaler, even if the request cannot be serviced.

To monitor the health of such applications, NetScaler supports HTTP and TCP health checks.

An HTTP or TCP listener is created for a content switching virtual server when both the `probeProtocol` and `probePort` parameters are configured. The listener reflects the status of the virtual server. The `ProbeSuccessResponseCode` parameter applies only to HTTP and returns the configured string when the probe is successful.

To enable external health check for UDP and non-HTTP TCP virtual servers by using CLI

At the command prompt, type:

```
1 add cr vservice <name> <serviceType> -ProbeProtocol <Http/TCP> -
  ProbePort <port-num> -ProbeSuccessResponseCode<http-code>
2 <!--NeedCopy-->
```

Example:

```
1 add cr vservice Vserver-CR-1 HTTP -ProbeProtocol HTTP -probeport 5000 -
  probesuccessResponseCode 200OK
2 <!--NeedCopy-->
```

To enable external health check for UDP and non-HTTP TCP virtual servers by using GUI

1. Navigate to **Traffic Management > Cache Redirection > Virtual Servers**, and then create a virtual server.
2. Click **Add** to create a virtual server.
3. In the **Basic Settings** pane, update the following details:
 - a) Probe Protocol—Select the protocol (HTTP or TCP) of the probe for external health check of the virtual server.
 - b) Probe Success Response Code—Enter the response string for a successful probe. This parameter is applicable only for the HTTP protocol.
 - Default Value: 200ok
 - Maximum Length: 63
 - c) Probe Port—Enter the port number for HTTP or TCP monitoring.
4. Click **OK**.

N-Tier cache redirection

May 2, 2023

To efficiently handle large amounts of cached data, typically several gigabytes per second, an Internet Service Provider (ISP) deploys several dedicated cache servers. The cache redirection feature of the NetScaler appliance can help load balance the cache servers, but a single appliance or a couple of appliances might not efficiently handle the large volume of traffic.

You can solve the problem by deploying the NetScaler appliances in two tiers (layers), where the appliances in the upper tier load balance those in the lower tier and the appliances in the lower tier load balance the cache servers. This arrangement is called *n-tier cache redirection*.

For purposes such as auditing and security, an ISP has to track client details such as the IP address, information provided, and the time of the interaction. Therefore, client connections through a NetScaler appliance have to be fully transparent. However, if you configure transparent cache redirection, with the NetScaler appliances deployed in parallel, the IP address of the client has to be shared among all the appliances. Sharing of the client IP address creates a conflict that makes network devices, such as routers, cache servers, origin servers, and other NetScaler appliances, unable to determine the appliance, and therefore the client, to which the response should be sent.

How N-tier cache redirection is implemented

To solve the problem, appliance n-tier cache redirection splits the source port range among the appliances in the lower tier and includes the client IP address in the request sent to the cache servers. The upper-tier NetScaler appliances are configured to do sessionless load balancing in order to avoid unnecessary load on the appliances.

When the lower-tier NetScaler appliance communicates with a cache server, it uses a mapped IP address (MIP) to represent the source IP address. Therefore, the cache server can identify the appliance from which it received the request and send the response to the same appliance.

The lower-tier NetScaler appliance inserts the client IP address into the header of the request sent to the cache server. The client IP in the header helps the appliance to determine the client to which the packet should be forwarded when it receives the response from a cache server, or the origin server in case of a cache miss. The origin server determines the response to be sent according to the client IP inserted in the request header.

The origin server sends the response to an upper-tier appliance, including the source port number from which the origin server received the request. The entire source port range, 1024 to 65535, is distributed among the lower-tier NetScaler appliances. Each lower-tier appliance is exclusively assigned

a group of addresses within the range. This allotment enables the upper-tier appliance to unambiguously identify the lower-tier NetScaler appliance that sent the request to the origin server. The upper-tier appliance can therefore forward the response to the correct lower-tier appliance.

The upper-tier NetScaler appliances are configured to do policy-based routing, and the routing policies are defined to determine the IP address of the destination appliance from the source port range.

Setup necessary for configuring N-Tier CRD

The following setup is necessary for the functioning of n-tier cache redirection:

For each upper-tier NetScaler appliance:

- Enable Layer 3 mode.
- Define policies for policy-based routes (PBRs) so that traffic is forwarded according to the range of the destination port.
- Configure a load balancing virtual server.
- Configure the virtual server to listen to all the traffic coming from the client. Set the Service Type/Protocol to be ANY and IP Address as asterisk (*).
- Enable sessionless load balancing with MAC-based redirection mode to avoid unnecessary load on the upper-tier NetScaler appliances.
- Make sure that the Use Proxy Port option is enabled.
- Create a service for each lower-tier appliance and bind all the services to the virtual server.

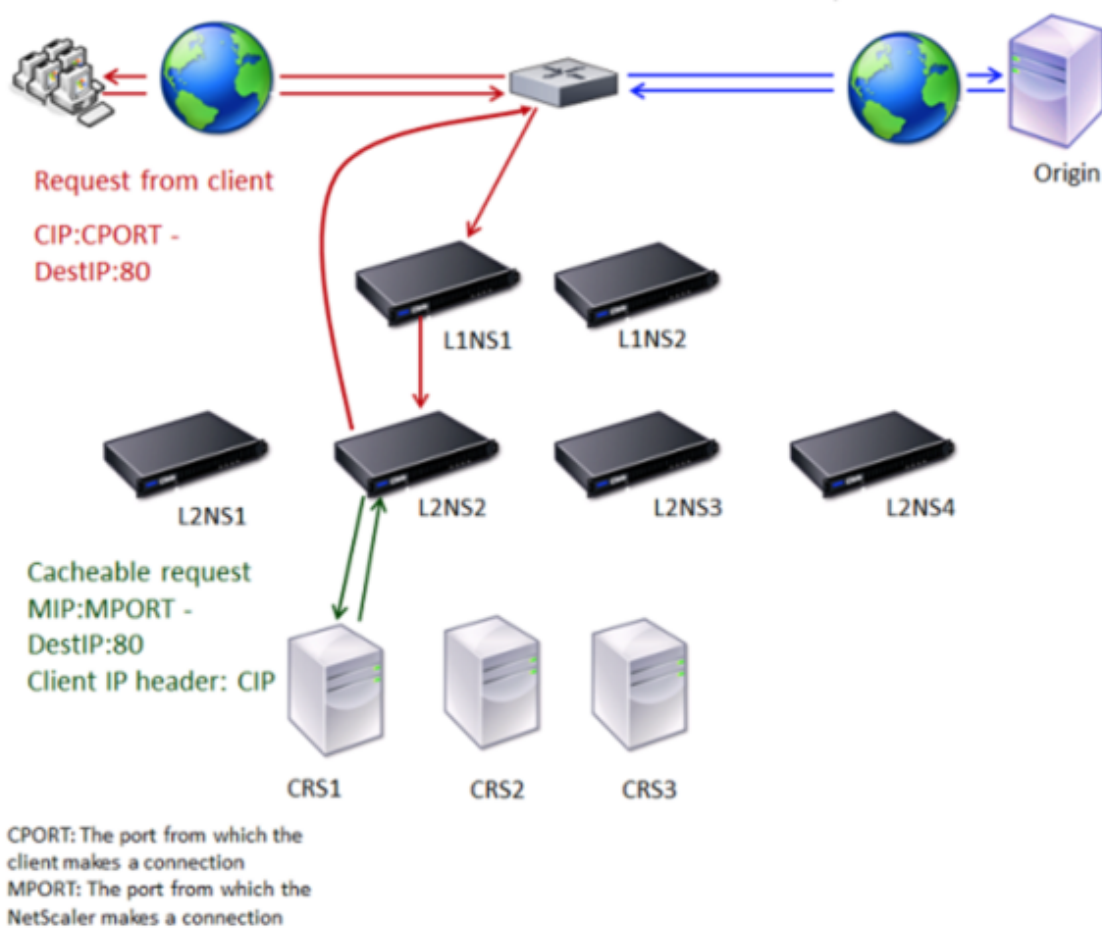

For each lower-tier NetScaler appliance,

- Configure the cache redirection port range on the appliance. Assign an exclusive range to each lower-tier appliance.
- Configure a load balancing virtual server and enable MAC-based redirection.
- Create a service for each cache server that is to be load balanced by this appliance. When creating the service, enable insertion of client IP in the header. Then, bind all the services to the load balancing virtual server.
- Configure a transparent mode cache redirection virtual server with the following settings:
 - Enable the Origin USIP option.
 - Add a source IP expression to include the client IP in the header.
 - Enable the Use Port Range option.

How N-tier cache redirection works during a cache hit

The following figure shows how cache redirection works when a client request is cacheable and the response is sent from a cache server.

Figure 1. Cache Redirection in Case of a Cache Hit

Two NetScaler appliances, L1NS1 and L1NS2, are deployed in the upper tier, and four NetScaler appliances, L2NS1, L2NS2, L2NS3, and L2NS4, are deployed in the lower tier. Client A sends a request, which is forwarded by the router. Cache servers CRS1, CRS2, and CRS3 service the cache requests. Origin Server O services the uncached requests.

Traffic flow

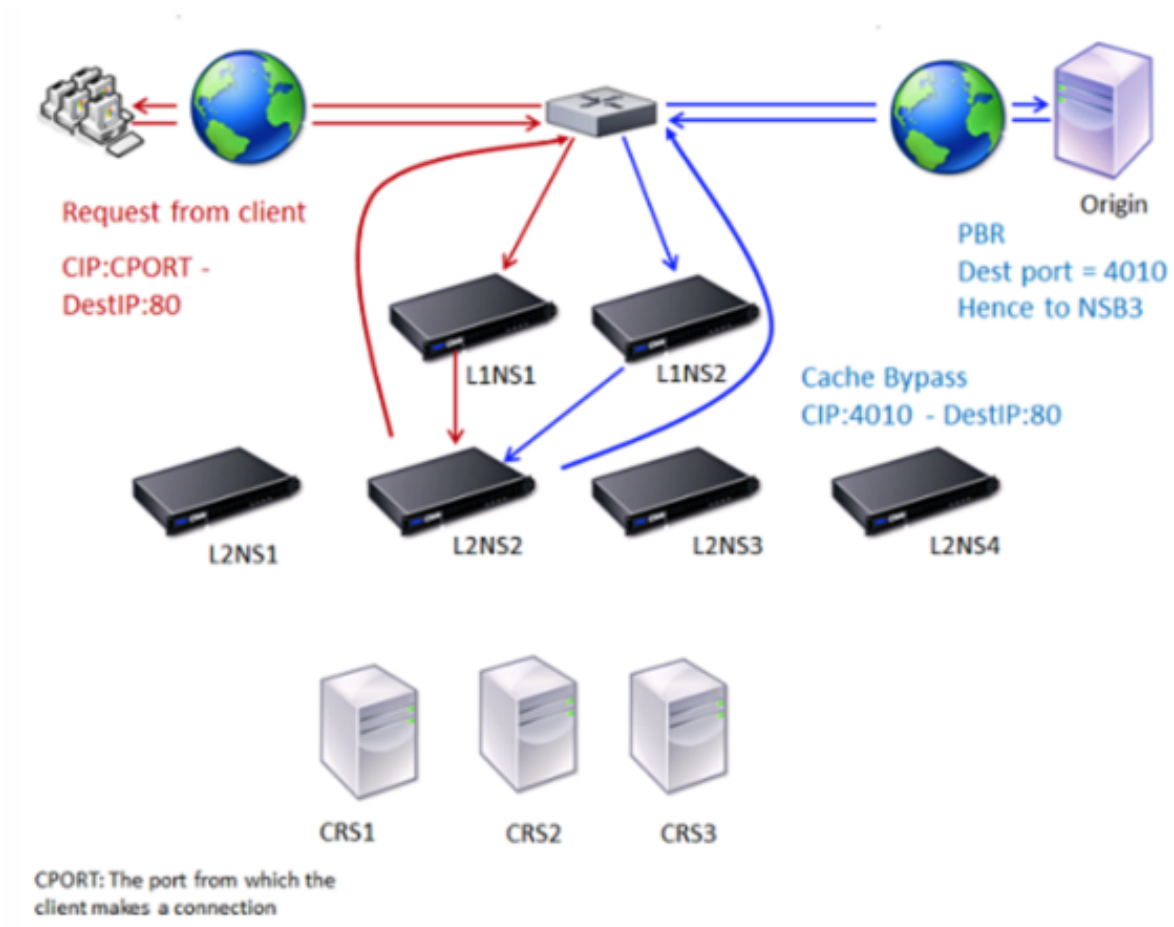

1. Client sends a request, and the router forwards it to L1NS1.
2. L1NS1 load balances the request to L2NS2.
3. L2NS2 load balances the request to the cache server CRS1, and the request is cacheable. L2NS2 includes the client IP in the request header.
4. CRS1 sends the response to L2NS2 because L2NS2 used its MIP as the source IP address when connecting to CRS1.
5. With the help of the client IP address in the request header, L2NS2 identifies the client from which the request came. L2NS2 directly sends the response to the router, avoiding unnecessary

- load on the appliance in the upper tier.
- 6. The router forwards the response to Client A.

How N-tier cache redirection works during a cache bypass

The following figure shows how cache redirection works when a client request is sent to an origin server for a response.

Figure 2. Cache Redirection in Case of a Cache Bypass

Two NetScaler appliances, L1NS1 and L1NS2, are deployed in the upper tier, and four NetScaler appliances, L2NS1, L2NS2, L2NS3, and L2NS4, are deployed in the lower tier. Client A sends a request, which is forwarded by the router. Cache servers CRS1, CRS2, and CRS3 service the cache requests. Origin Server O services the uncached requests.

Traffic flow

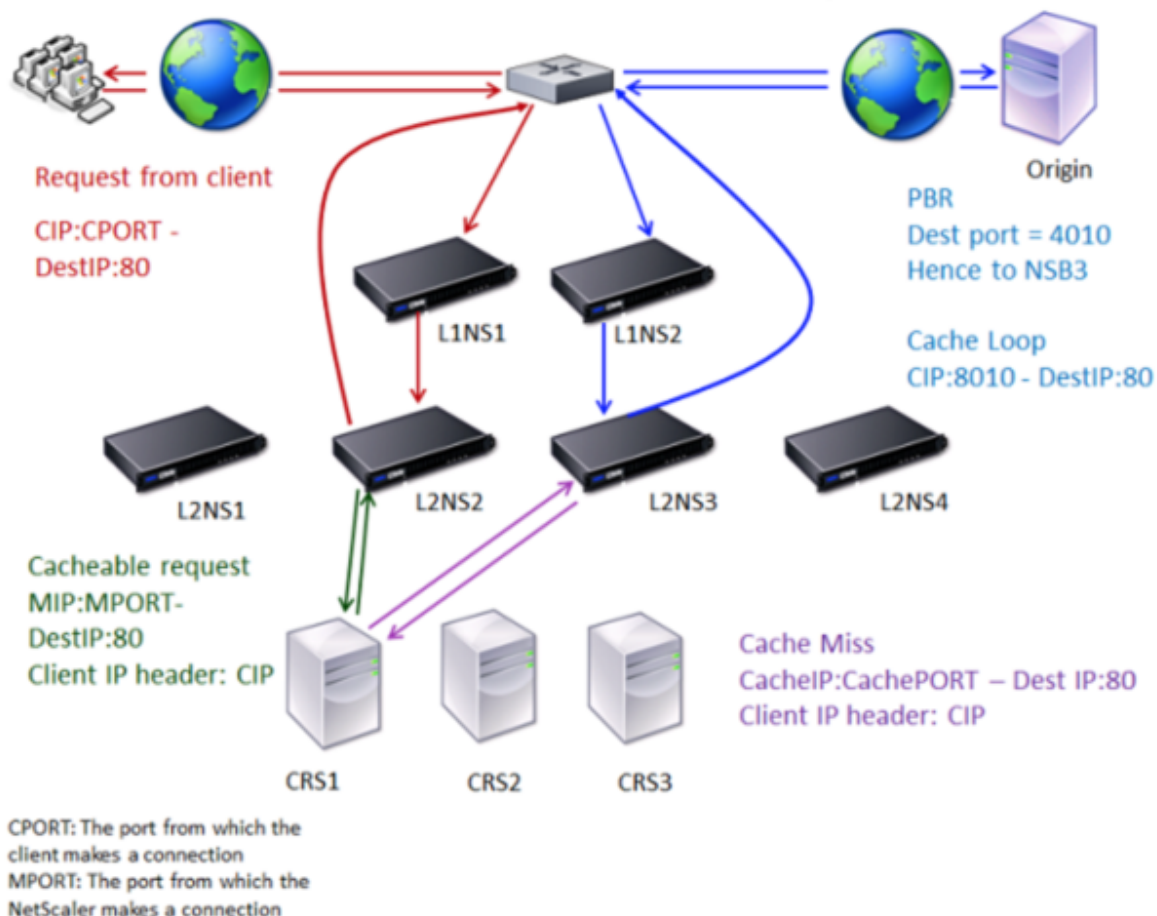

- 1. Client sends a request, and the router forwards it to L1NS1.

2. L1NS1 load balances the request to L2NS2.
3. The request is uncacheable (cache bypass). Therefore, L2NS2 sends the request to the origin server through the router.
4. The origin server sends the response to an upper-tier appliance, L1NS2.
5. According to the PBR policies, L1NS2 forwards the traffic to the appropriate appliance in the lower tier, L2NS2.
6. L2NS2 uses the client IP address in the request header to identify the client from which the request came and sends the response directly to the router, avoiding unnecessary load on the appliance in the upper tier.
7. The router forwards the response to Client A.

How N-tier cache redirection works during a cache miss

The following figure shows how cache redirection works when a client request is not cached.

Figure 3. Cache Redirection in Case of a Cache Miss

Two NetScaler appliances, L1NS1 and L1NS2, are deployed in the upper tier, and four NetScaler ap-

pliances, L2NS1, L2NS2, L2NS3, and L2NS4, are deployed in the lower tier. Client A sends a request, which is forwarded by the router. Cache servers CRS1, CRS2, and CRS3 service the cache requests. Origin Server O services the uncached requests.

Traffic flow

1. Client sends a request, and the router forwards it to L1NS1.
2. L1NS1 load balances the request to L2NS2.
3. L2NS2 load balances the request to the cache server CRS1 because the request is cacheable.
4. CRS1 does not have the response (cache miss). CRS1 forwards the request to the origin server through the appliance in the lower tier. L2NS3 intercepts the traffic.
5. L2NS3 takes the client IP from the header and forwards the request to the origin server. The source port included in the packet is the L2NS3 port from which the request is sent to the origin server.
6. The origin server sends the response to an upper-tier appliance, L1NS2.
7. According to the PBR policies, L1NS2 forwards the traffic to the appropriate appliance in the lower tier, L2NS3.
8. L2NS3 forwards the response to the router.
9. The router forwards the response to Client A.

Configure the upper-tier NetScaler appliances

October 16, 2023

Configure each of the upper-tier NetScaler appliances as follows.

Configure an upper-tier appliance for n-tier cache redirection by using the command CLI

At the command prompt, type the following commands:

- `add service <name>@ <serviceIP> <serviceType> <port>`

Run this command for each service to be added.

- `add lb vserver <name>@ ANY * <port> -persistenceType <persistenceMethod> -lbMethod <lbMethod> -m MAC -sessionless ENABLED -cltTimeout <client_Timeout_Value>`

- `bind lb vserver <name>@ <serviceName>`

Run this command for each service to be bound.

- `enable ns mode l3`
- `add ns pbr <name> <action> -srcPort <sourcePortNumber> -destPort <startPortNumber-endPortNumber> -nextHop <serviceIpAddress> -protocol TCP`
- `apply ns pbrs`

Run this command after adding all the necessary PBRs.

Configure an upper-tier appliance for n-tier cache redirection by using the GUI

1. Enable L3 mode:
 - a) In the navigation pane, click **System**, and then click **Settings**.
 - b) In **Settings**, click **Configure modes**.
 - c) Select **Layer 3 Mode (IP Forwarding)**.
 - d) Click **OK**.
2. Configure policy-based routing (PBR):
 - a) Navigate to **System > Network > PBRs**.
 - b) In the **Policy-Based Routing (PBRs)** pane, click **Add**.
 - c) Type a name for the PBR.
 - d) Select the action as **Allow**.
 - e) In **Next Hop**, type the IP address of the service, which represents a lower-tier appliance.
 - f) In **Protocol**, select **TCP**.
 - g) Type the source port and the range of the destination port corresponding to the lower-tier appliance being added.
 - h) Click **Create**.
 - i) In the details pane, select the PBR and click **Apply**.
 - j) Repeat these steps for each lower-tier appliance.
3. Create a service for each lower-tier appliance:
 - a) Navigate to **Traffic Management > Load Balancing > Services**.
 - b) In the details pane, click **Add**.
 - c) Specify the name, protocol, IP address, and port. The protocol should be **ANY**.
 - d) Click **Create**.
4. Configure a load balancing virtual server:
 - a) Navigate to **Traffic Management > Load Balancing > Virtual Servers**.

- b) In the details pane, click **Add**.
- c) Specify the name, protocol, IP address, and port. The protocol should be ANY and the IP address should be *.
- d) In **Services**, select the services that represent the lower-tier NetScaler appliances.
- e) In **Advanced**, select **Redirection Mode** as **MAC Based** and select **Sessionless**.
- f) Click **Create**.

Configure the lower-tier NetScaler appliances

May 2, 2023

Configure each of the lower-tier NetScaler appliances as follows.

Configure a lower-tier appliance for n-tier cache redirection by using the CLI

At the command prompt, type the following commands:

- `add service <name>@ <cacheServiceIP> <serviceType> <port> -cip ENABLED "ClientIP"-cachetype transparent`
Repeat for each cache server.
- `add lb vserver <name>@ <serviceType> -m MAC`
- `bind lb vserver <name>@ <cacheServiceName>`
Repeat for each cache server.
- `add cr vserver <name> <serviceType> * <port> -srcIPExpr "HTTP.REQ.HEADER("ClientIP")"-originusip ON -usePortRange ON`
- `set ns param-crPortRange <startPortNumber-endPortNumber>`

Configure a lower-tier appliance for n-tier cache redirection by using the GUI

1. Create a service for each cache server. To create a service:
 - a) Navigate to Traffic Management > Load Balancing > Services.
 - b) In the details pane, click Add, and specify the name and protocol. Clear the Directly Addressable check box.
 - c) In the Advanced tab, select the Override Global check box and the Client IP check box, and then in the Header box, type ClientIP.

- d) In the Cache Type box, select Transparent Cache.
 - e) Click Create.
2. Configure a load balancing virtual server:
 - a) Navigate to Traffic Management > Load Balancing > Virtual Services.
 - b) In the details pane, click Add and specify the name, protocol, IP address, and port. The IP address should be an asterisk (*).
 - c) In the Services tab, select the services that represent the cache servers.
 - d) In the Advanced tab, for Redirection Mode, select MAC Based.
 - e) Click Create.
 3. Configure a cache redirection virtual server:
 - a) Navigate to Traffic Management > Load Balancing > Virtual Services.
 - b) In the details pane, click Add and specify the name, protocol, IP address, and port. The IP address should be *.
 - c) For Cache Type, select Transparent.
 - d) On the Advanced tab, in the Cache Server box, select the new load balancing virtual server and check the Origin USIP and Use Port Range check boxes. In the Source IP Expression box, type HTTP.REQ.HEADER("ClientIP").
 - e) Click Create.
 4. Assign a source port range for the appliance:
 - a) In the navigation pane, click System, and then click Settings.
 - b) In the Settings group, click the Change global system settings link.
 - c) In the Cache Redirection Port Range group, specify the port range for the appliance by typing a port number for Start Port and a port number for End Port.
 - d) Click OK.

Translate destination IP address of a request to origin IP address

May 2, 2023

You can configure the forward proxy cache redirection virtual server on the NetScaler appliance to translate the destination IP address of the request landing on the cache redirection virtual server to the origin server IP address. This translation occurs irrespective of whether the request is sent to the cached servers or the origin server.

Previously, forward proxy cache redirection virtual server in service provider environment could not be effectively used to send traffic across firewall because of the limitations in cache redirection using content switching policies. The cache redirection virtual server did not translate the origin IP address

into the destination IP when the packet was sent to cache. The destination IP address was that of the origin server only when the requests were served from cached server.

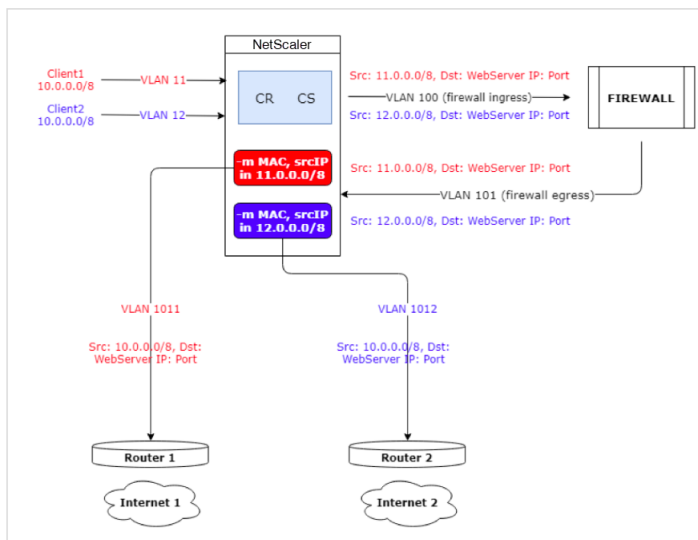

Note: Translation of destination IP address of a request to origin IP address is not supported for a transparent cache redirection virtual server. For a transparent cache redirection virtual server, this option must be set to OFF.

Use case

In a deployment that has NetScaler appliance configured for forward proxy cache redirection, firewall, and reused client IP addresses, firewall cannot distinguish/use the reused IP addresses. Therefore, these reused IP addresses must be translated to different IP addresses. To translate the reused IP addresses, the NetScaler appliance must perform the following:

1. Query a DNS load balancing virtual server for resolution of the destination.
2. Update the origin IP address and port number in the destination.
3. Send the request back to the firewall.

Consider the following deployment that has a NetScaler appliance configured for forward proxy cache redirection, firewall, two routers (Router 1 and Router 2). Network traffic flows to Internet 1 through Router 1 and to Internet 2 through Router 2 respectively.

In this example, input requests from clients come from two different VLANs, VLAN11 or VLAN12. The client IP address (10.0.0.0) is reused.

Based on the cache redirection and content switching policies, the request can go directly to the origin server or to the firewall.

- If the request has to bypass the firewall and go to the internet, then based on the input request VLAN, either Router 1 or Router 2 is selected and the request is sent to Internet 1 or Internet 2.

- If the request has to go through the firewall, then the source IP of the request must be translated to specific IP address. The translated IP address can be used to identify the VLAN through which request has come. For example, if the input request is coming from VLAN11, then the source IP address is translated to 11.x.x.x. If the request is coming from VLAN12, then the source IP address is translated to 12.x.x.x.

After the firewall processes the request, the request is sent back to the appliance. Using the combination of listen policy and net profiles, the appliance then translates the source IP address back to the original IP address and sends the request to Router 1 or Router 2 based on the input VLAN ID.

Note: The mode of the load balancing virtual server that is bound to the cache must always be set to MAC mode. Though IP mode for this feature is not blocked, setting to IP mode leads to unexpected behavior.

To translate the destination IP address and port number of the request to origin IP address by using the CLI

At the command prompt, type;

```
1 set cr vserver <vsname> -useoriginIpPortForCache <YES|NO>
2 <!--NeedCopy-->
```

Example:

```
1 set cr vserver cvsrv1 -useoriginIpPortForCache YES
2 <!--NeedCopy-->
```

When useoriginIpPortForCache is set to Yes and if the request must be served from the cached servers, then the request's destination IP is translated to the origin server IP address.

Note: If useoriginIpPortForCache is enabled, always set the load balancing virtual server that is bound to the cache to MAC mode.

To translate the destination IP address and port of the request to origin IP address by using the GUI

1. Navigate to **Traffic Management > Cache Redirection > Virtual Servers** and click **Add**.
2. Specify the details of the cache redirection virtual server.
3. Select **Use Origin IP Port** for cache to enable translation of the destination IP address of the request to origin IP address.
4. Click **OK**.

Clustering

May 2, 2023

Note

This feature is available with a NetScaler Advanced or Premium edition license.

A NetScaler cluster is a group of nCore appliances working together as a single system image. Each appliance of the cluster is called a node. The cluster can have one appliance or as many as 32 NetScaler nCore hardware or virtual appliances as nodes.

The client traffic is distributed between the nodes to provide high availability, high throughput, and scalability.

To create a cluster, you must perform the following steps:

- Add the appliances as cluster nodes.
- Set up communication between the nodes.
- Set up links to the client and server networks.
- Configure the appliances, and configure the distribution of client and server traffic.

Supportability matrix for NetScaler cluster

May 2, 2023

Clustering in the NetScaler appliance supports a wide-spread of features in NetScaler configurations.

The following table lists the NetScaler features and provides the supportability status across different NetScaler releases of cluster setups. The supportability status of some NetScaler features in a NetScaler BLX cluster is different than a NetScaler non-BLX (MPX, or VPX, SDX ADC) cluster.

Important

The “Node-level” entry in the table indicates that the feature is supported only on individual cluster nodes.

NetScaler 14.1

| NetScaler features | NetScaler 12.1 | NetScaler 13.0 | NetScaler BLX 13.0 | NetScaler 13.1 | NetScaler BLX 13.1 | NetScaler 14.1 | NetScaler BLX 14.1 |

Also, the following NetScaler configurations are supported:

Load balancing, load balancing persistency, DNS load balancing, SIP, maxClient, Spillover (connection and dynamic). Spillover based on bandwidth, DataStream, Compression control, Content filtering, TCP buffering, Cache redirection, distributed denial-of-service (DDoS). Client Keep-alive, Basic networking (IPv4 and IPv6), OSPF (IPv4 and IPv6), RIP (IPv4 and IPv6), RIP (IPv4 and IPv6). VLAN, ICMP, Fragmentation, MBF, ACL, Simple ACL, MSR, Path MTU discovery, IP-IP, SNMP, Policies (classic and advanced). Rewrite, Responder, HTTP callout, Web server logging, Audit logging (NSLOG and syslog). USIP, Location commands, NITRO API, AppExpert, KRPC.

Prerequisites

May 2, 2023

NetScaler appliances (MPX, VPX, SDX ADC, BLX) that are to be added to a cluster must meet the following prerequisites:

- All appliances must have the same software version and build.
- All appliances must be of the same platform type. This means that a cluster must have either all hardware appliances (NetScaler MPX) or all NetScaler VPX appliances, or all NetScaler BLX appliances, or all NetScaler SDX ADC instances.

Note:

- For a cluster of hardware appliances (MPX), the appliances must be of the same model type.
 - For the formation of the heterogeneous cluster, all appliances must be of MPX platform type.
 - For a cluster of virtual appliances (VPX), the appliances must be deployed on the following hypervisors: XenServer, Hyper-V, VMware ESX, and KVM.
 - For setting up a cluster of SDX NetScaler instances, see [Set up a cluster of NetScaler instances](#).
 - Jumbo frames are supported on a NetScaler cluster that is made up of NetScaler SDX instances.
 - You can create L3 clusters of SDX instances.
 - For information about setting up a NetScaler BLX cluster, see [NetScaler BLX cluster](#).
- Appliances can belong to different networks.
 - Be initially configured and connected to a common client-side and server-side network.
 - For a cluster of virtual appliances (NetScaler VPX, or NetScaler BLX, or NetScaler SDX ADC instance), that has large configurations, it is recommended to use 6 GB RAM for each node of the cluster.

Cluster overview

May 2, 2023

A NetScaler cluster is formed by grouping NetScaler appliances together. Based on the network location of the NetScaler appliances that you intend to add the cluster, you must be aware of the following cluster setups:

Note

Unless specified otherwise, cluster features and configurations are the same for L2 and L3 clusters.

- **L2 cluster:** In this cluster deployment, all cluster nodes belong to the same network.

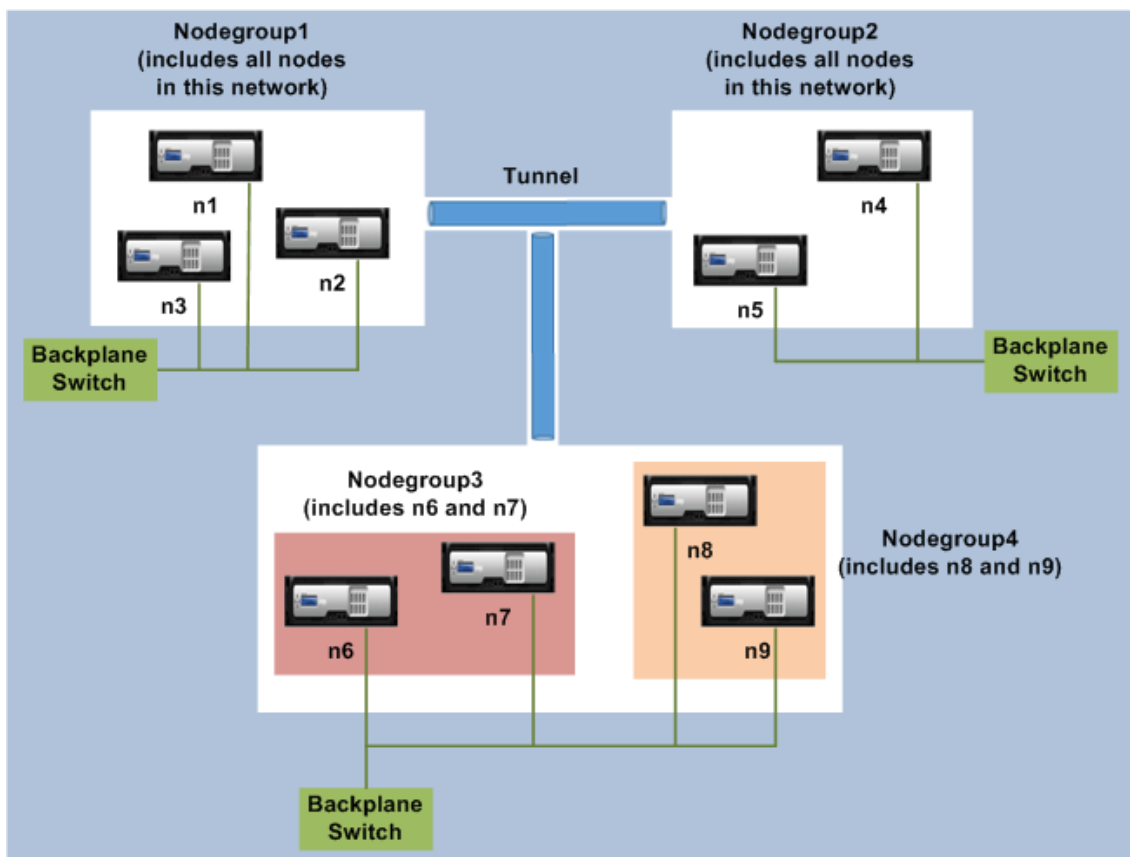

- **L3 cluster (also referred to as ‘cluster in INC mode’):** In this cluster deployment, cluster nodes can belong to different networks. The cluster nodes from a specific network must be grouped into node groups that include only nodes from that network. From the following figure, we see that nodes n1, n2, n3 are in the same network and are grouped into Nodegroup1.

Similarly, the case for nodes n4 and n5, that are grouped in Nodegroup2. In the third network, there are two node groups. Nodegroup3 includes n6 and n7 and Nodegroup4 includes n8 and n9.

Note

Supported from NetScaler 11.0 onwards.

- **Sync State:** The **show cluster** command displays the status of the cluster node. The following are the Sync States for the **show cluster node** command:
 - **Enable:** This state shows that the node has the capability to do a configuration sync from other nodes.
 - **In-progress:** This is a temporary state which is displayed when the node is syncing configurations from other nodes.
 - **Success:** This state represents the status of the last sync that has happened on this node.

Synchronization across cluster nodes

May 2, 2023

All configurations on a NetScaler cluster are performed on the cluster IP address, which is the management address of the cluster. The cluster node owns the cluster IP address that is referred to as the cluster configuration coordinator (CCO) as shown in the following figure:

The configurations that are available on the CCO are automatically propagated to the other cluster nodes and therefore all cluster nodes have the same configurations.

- NetScaler allows only a few configurations to be performed on individual cluster nodes through their NSIP address. In these cases, you must ensure configuration consistency manually across all nodes in the cluster. These configurations are not propagated across the other cluster nodes. For more information on operations supported on each cluster node, see [Operations Supported on Individual Cluster Nodes](#).
- The following commands when ran on the cluster IP address are not propagated to other cluster nodes:
 - **shutdown**. Shuts down only the configuration coordinator.
 - **reboot**. Reboots only the configuration coordinator.
 - **rm cluster instance**. Removes the cluster instance from the node that you are running the command on.
- For a command to propagate to other cluster nodes:
 - The quorum must be configured on the cluster instance.
 - Most the cluster quorum with $(n/2 + 1)$ of the cluster nodes must be active for the cluster to be operational.
 - A cluster can run with a minimum number of nodes when the majority rule $(n/2 + 1)$ is relaxed.

When a node is added to a cluster, the configurations and the files (SSL certificates, licenses, DNS, and so on) that are available on the CCO are synchronized to the newly added cluster node. When an existing cluster node, that was intentionally disabled or that had failed, is once again added, the cluster compares the configurations available on the node with the configurations available on the CCO. If there is a mismatch in configurations, the node is synchronized by using one of the following:

- **Full synchronization.** If the difference between configurations exceeds 255 commands, all the configurations of the CCO are applied to the node that is rejoining the cluster. The node remains operationally unavailable during the synchronization.
- **Incremental Synchronization.** If the difference between configurations is less than or equal to 255 commands, only the configurations that are not available are applied to the node that is rejoining the cluster. The operational state of the node remains unaffected.

Note

You can also manually synchronize the configurations and files. For more information, see [Synchronizing Cluster Configurations](#) and [Synchronizing Cluster Files](#).

Striped, partially striped, and spotted configurations

December 15, 2023

By virtue of command propagation, all nodes in a cluster have the same configurations. However, you might want some configurations to be available only on certain cluster nodes. While you cannot restrict the nodes on which the configurations are available, you can specify the nodes on which the configurations are active.

For example, you can:

- define a SNIP address to be active on only one node, or
- define a SNIP address to be active on all nodes, or
- define a VIP address to be active on only one node, or
- define a VIP address to be active on all nodes, or
- define a VIP address to be active only on two nodes of a 3-node cluster

Depending on the number of nodes the configurations are active on, cluster configurations are referred to as striped, partially striped, or spotted configurations.

Figure 1. Three-node cluster with striped, partially striped, and spotted configurations

NetScaler Cluster

The following table provides more details on the types of configurations:

| Configuration Type | Active on | Applicable to | Configurations |
|---------------------------------|---------------------------|---|--|
| Striped configuration | All the cluster nodes | All entries | No specific configuration required to make an entity striped. By default, all entities defined on a cluster IP address are striped on all the cluster nodes. |
| Partially striped configuration | A subset of cluster nodes | See Cluster Node groups | Bind the entities that you want to be partially striped, to a node group. The configuration is active only on the cluster nodes that belong to the node group. |

| Configuration Type | Active on | Applicable to | Configurations |
|-----------------------|---------------------|-----------------------------------|--|
| Spotted configuration | Single cluster node | See List of spotted configuration | <p>A spotted configuration can be defined using one of two approaches. SNIP address When creating the SNIP address, specify the node on which you want the SNIP address to be active, as the owner node. Example,
 <pre>add ns ip 10.102.29.106 255.255.255.0 - type SNIP - ownerNode 2</pre> (assuming node NS2 ID is 2). Note: You cannot change the ownership of a spotted SNIP address at run time. To change the ownership, you must first delete the SNIP address and add it again by specifying the new owner. Entities that can be bound to a node group. By binding the entity to a single-member node group.</p> |

Note

- When you disable USIP, we recommend you to use spotted SNIP addresses. You can use striped SNIP addresses only if there is a shortage of IP addresses. The use of striped IP

addresses can result in ARP flux issues if no spotted IP addresses are present in the same subnet for ARP resolution.

- When you enable USIP, we recommend you to use striped SNIP addresses as a gateway for server initiated traffic.

List of spotted configuration

- IPv4 addresses
- IPv6 addresses
- ARP entries
- Interface settings
- IPv6 Static Routes (Route6)
- IP tunnel
- IPv6 tunnel
- Reverse network address translation (RNAT)
- Policy-based routes for IPv4 (PBR)
- Policy-based routes for IPv6 (PBR6)
- Cluster LAG
- Neighbor discovery protocol (ND6) entries
- Failover interface set (FIS)
- Linksets
- SNMP MIB/engine ID
- Diameters
- NetScaler VPX param
- Hostname

ARP owner support for striped IP

In a cluster setup, you can configure a specific node to respond to the ARP request for a striped IP. The configured node responds to the ARP traffic.

A new parameter “arpOwner” is introduced in the “add, set, and unset IP” commands.

To enable the ARP owner on a node by using the CLI.

At the command prompt, type:

```
add ns ip <ip_address> -arpOwner <node_id>
```

Note

The ARP owner parameter is supported only in the L2 cluster.

Neighbor discovery owner support for striped IPv6 address

In a cluster setup, you can configure a specific node as neighbor discovery (ND) owner for the striped IPv6 address to determine the link-layer address. A client sends a Neighbor Solicitation (NS) message to all the nodes in the cluster setup. The ND owner responds with a Neighbor Advertisement (NA) message with the link-layer address for the striped IPv6 address, and serves traffic.

To enable ND owner on a node by using the CLI

At the command prompt, type:

```
1 add ns ip6 <IPv6Address> -ndOwner <node id>
2
3 set ns ip6 <IPv6Address> -ndOwner <node id>
4 <!--NeedCopy-->
```

Example:

```
1 add ns ip6 2001::21/64 -ndOwner 1
2
3 set ns ip6 2001::21/64 -ndOwner 1
4 <!--NeedCopy-->
```

To enable ND owner on a node by using the GUI

1. Navigate to **System > Network > IPs**.
2. In the **IPs** page, go to the **IPv6s** tab and click **Add**.
3. In the **Create IPv6** page, select one of the node IDs listed in the **NdOwner in Cluster** drop-down menu.

Note

The ND owner parameter is supported only in the L2 cluster.

Communication in a cluster setup

May 2, 2023

The interfaces of NetScaler appliances that are added to a cluster are prefixed with a node ID. It helps identify the cluster node to which the interface belongs. Therefore, the interface identifier c/u, where c is the controller number and u is the unit number, now becomes n/c/u, where n is the node ID. For

example, in the following figure, interface 1/2 of node n1 is represented as 0/1/2, interface 1/1 of node n2 is represented as 1/1/1, and interface 1/4 of node n3 is represented as 2/1/4.

Figure 1. Interface naming convention in a cluster

- **Server communication-**

The cluster communicates with the server through the physical connections between the cluster node and the server-side connecting device. The logical grouping of these physical connections is called the server data plane.

- **Client communication-** The cluster communicates with the client through the physical connections between the cluster node and the client-side connecting device. The logical grouping of these physical connections is called the client data plane.
- **Inter-node communication-** The cluster nodes can also communicate with each other. The manner in which they communicate depends on whether the node exists on the same network or across networks.

- Cluster nodes within the same network communicate with each other by using the cluster backplane. The backplane is a set of interfaces in which one interface of each node is connected to a common switch, which is called the cluster backplane switch. The different types of traffic that goes through the backplane, which is used by internode communication are:
 - * Node to Node Messaging (NNM)
 - * Steered traffic
 - * Configuration propagation and synchronization
- Each node of the cluster uses a special MAC cluster backplane switch address to communicate with other nodes through the backplane. The cluster special MAC is of the form: `0x02 0x00 0x6F <cluster_id> <node_id> <reserved>`), where `cluster_id` is the cluster instance ID, `node_id` is the node number of the NetScaler appliance that is added to a cluster.

The following figures shows the communication interfaces in L2 clusters and L3 clusters.

Figure 2. Cluster communication interfaces - L2 cluster

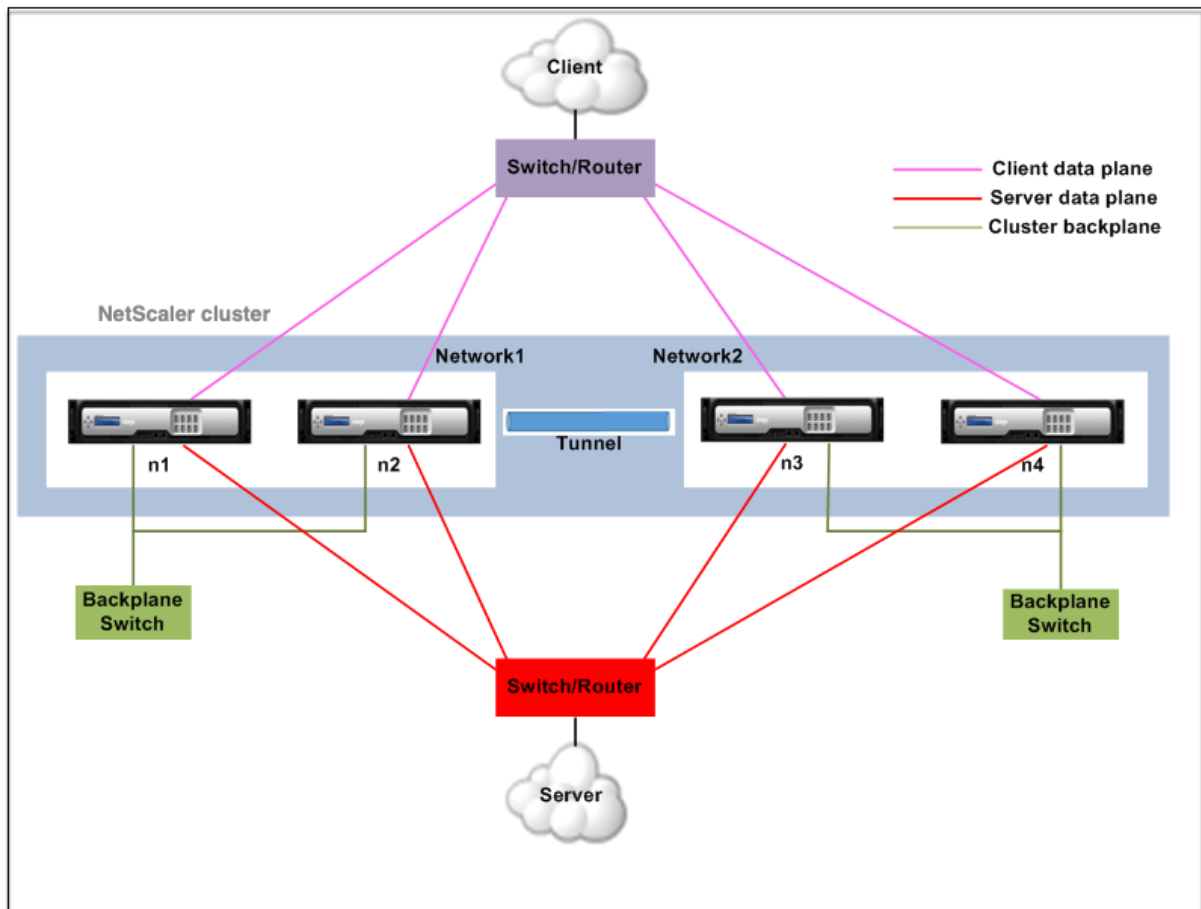

Figure 3. Cluster communication interfaces - L3 cluster

Traffic distribution in a cluster setup

March 26, 2024

In a cluster setup, external networks view the collection of NetScaler appliances as a single entity. So, the cluster must select a single node that must receive the traffic. The cluster does this selection by using the Equal Cost Multiple Path (ECMP) or cluster link aggregation traffic distribution mechanism. The selected node is called the flow receiver.

Note

For an L3 cluster (nodes across different networks), only the ECMP traffic distribution can be used.

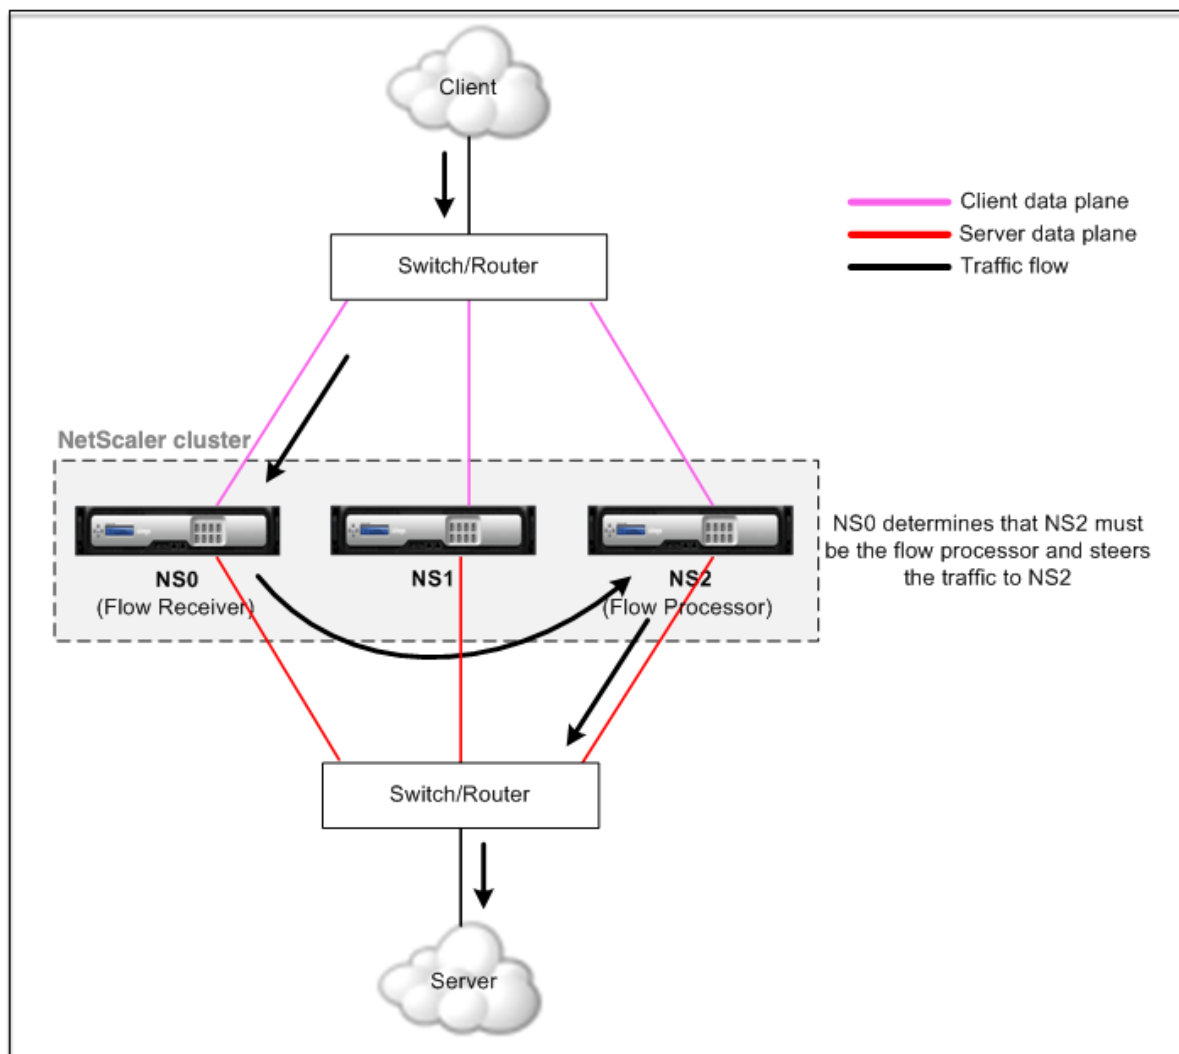

The flow receiver gets the traffic and then, using internal cluster logic determines the node that must process the traffic. This node is called the flow processor. The flow receiver steers the traffic to the flow processor over the backplane if the flow receiver and the flow processor are on the same network.

The traffic is steered through the tunnel if the flow receiver and the flow processor are on different networks.

Note

- The flow receiver and flow processor must be nodes capable of serving traffic.
- From NetScaler 11 onwards, you can disable steering on the cluster backplane. For more information, see [Disabling Steering on the Cluster Backplane](#).

Figure 1. Traffic distribution in a cluster

The preceding figure shows a client request flowing through the cluster. The client sends a request to a virtual IP (VIP) address. A traffic distribution mechanism configured on the client data plane selects one of the cluster nodes as the flow receiver. The flow receiver receives the traffic, determines the node that must process the traffic, and steers the request to that node (unless the flow receiver selects itself as the flow processor).

The flow processor establishes a connection with the server. The server processes the request and sends the response to the subnet IP (SNIP) address that sent the request to the server.

- If the SNIP address is a striped or partially striped IP address, the traffic distribution mechanism configured on the server data plane selects one of the cluster nodes as the flow receiver. The flow receiver receives the traffic, determines the flow processor, and steers the request to the flow processor through the cluster backplane.
- If the SNIP address is a spotted IP address, the node that owns the SNIP address receives the response from the server.

Cluster node groups

May 2, 2023

Note

Node groups are supported from NetScaler 10.1 onwards.

As the name indicates, a cluster node group is a group of cluster nodes.

Figure 1. NetScaler cluster with node groups

The preceding figure shows a cluster which has node groups NG1 and NG2 that include 3 cluster nodes each. The cluster also has 3 nodes that are not part of any node group.

A node group can be configured for the following:

- To define spotted and partially striped configurations. For more information, see [Node groups for Spotted and Partially Striped Configurations](#).
- To configure redundancy of node groups. For more information, see [Configuring Redundancy for Node groups](#).

Note: Supported from NetScaler 10.5 Build 52.1115.e onwards.

- To define an L3 cluster (also called a cluster in INC mode). In an L3 cluster, cluster nodes can be from different networks. You must group nodes that belong to a network in a single node group.

For example, if n1, n2, n3 are in network1 and n4, n5, n6 are in network2, then NG1 must include nodes of network1 and NG2 must include nodes of network2. For setting up an L3 cluster, see [Creating a NetScaler cluster](#).

Note

- Supported from NetScaler 11 onwards.
- The preceding functions of a node group are mutually exclusive. It means that a node group can provide only one of the preceding mentioned functionalities.

Cluster and node states

December 7, 2020

For a cluster to be functional, most of the nodes ($n/2 + 1$) must be operationally active (operational state is ACTIVE).

Important

From NetScaler release 10.5, you can configure the cluster to be functional even when the majority criteria is not satisfied. This configuration must be performed when creating a cluster.

For more information on states of a cluster node, refer to [States of a cluster node](#).

Routing in a cluster

May 2, 2023

Routing in a cluster works in much the same way as routing in a standalone system. A few points to note:

- All routing configurations must be performed from the cluster IP address and the configurations are propagated to the other cluster nodes.
- Routes are limited to the maximum number of ECMP routes supported by the upstream router.
- Node-specific routing configurations must be performed by using the owner-node argument as follows:

```
1  router ospf
2  owner-node 0
```

```
3     ospf router-id 97.131.0.1
4     exit-owner-node
5     !
6 <!--NeedCopy-->
```

The following command displays the consolidated cluster configuration for all nodes in VTYSH.

```
show cluster-config
```

The following command displays the cluster status on each node.

```
show cluser node
```

IPv4 routing in L2 cluster

The following section contains sample configurations that help you to configure IPv4 OSPF and BGP routing in the L2 cluster.

Adding spotted SNIP address and enabling dynamic routing

In the following configuration, OSPF, and BGP routing are enabled. Also, spotted SNIP addresses are added and dynamic routing is enabled on these SNIP addresses.

```
1 en ns fea ospf bgp
2 add vlan 10
3 add ns ip 10.10.10.1 255.255.255.0 -dynamicrouting enabled -ownernode 1
4 add ns ip 10.10.10.2 255.255.255.0 -dynamicrouting enabled -ownernode 2
5 add ns ip 10.10.10.3 255.255.255.0 -dynamicrouting enabled -ownernode 3
6 bind vlan 10 -ipaddress 10.10.10.1 255.255.255.0
7 <!--NeedCopy-->
```

VTYSH IPv4 OSPF configuration

For configuring IPv4 OSPF in the L2 cluster, you must:

- Set the priority to zero.
- Configure the Router-id as a spotted configuration.

Note

The OSPF configuration guidelines for the L2 cluster are applicable for OSPFv3 also.

In the following sample configuration IPv4 OSPF is configured.

```
1     interface vlan10
2     IP OSPF PRIORITY 0
```

```
3      !
4      router ospf
5          owner-node 1
6          ospf router-id 97.131.0.1
7          exit-owner-node
8          owner-node 2
9          ospf router-id 97.131.0.2
10         exit-owner-node
11         owner-node 3
12         ospf router-id 97.131.0.3
13         exit-owner-node
14         network 10.10.10.0/24 area 0
15         redistribute kernel
16         !
17 <!--NeedCopy-->
```

VTYSH IPv4 BGP configuration

In the following VTYSH sample configuration, IPv4 BGP is configured.

```
1      router bgp 100
2          neighbor 10.10.10.10 remote-as 200
3          owner-node 1
4          neighbor 10.10.10.10 update-source 10.10.10.1
5          exit-owner-node
6          owner-node 2
7          neighbor 10.10.10.10 update-source 10.10.10.2
8          exit-owner-node
9          owner-node 3
10         neighbor 10.10.10.10 update-source 10.10.10.3
11         exit-owner-node
12         redistribute kernel
13         !
14 <!--NeedCopy-->
```

Note

The update-source command is used for each neighbor with the owner-node argument in the following configuration to connect with proper source IP.

IPv6 routing in L2 cluster

The following section contains sample configurations that help you to configure IPv6 OSPF and BGP routing in the L2 cluster.

Enable IPv6 routing

Before configuring IPv6 routing in a L2 cluster, you must enable the IPv6 feature.

To enable IPv6 routing by using the CLI,

At the command prompt, type:

- `enable ns fea ipv6pt`

Adding spotted SNIP6 address and enabling dynamic routing

In the following configuration, OSPF, and BGP routing are enabled. Also, spotted SNIP6 addresses are added and dynamic routing is enabled on these SNIP6 addresses.

```
1 add ns ip6 3ffa::1/64 -dynamicrouting enabled -ownernode 1
2 add ns ip6 3ffa::2/64 -dynamicrouting enabled -ownernode 2
3 add ns ip6 3ffa::3/64 -dynamicrouting enabled -ownernode 3
4 add vlan 10
5 bind vlan 10 -ipaddress 3ffa::1/64
6 <!--NeedCopy-->
```

VTYSH IPv6 BGP configuration

In the following VTYSH sample configuration, IPv6 BGP is configured.

```
1 router bgp 100
2 neighbor 3ffa::10 remote-as 200
3 owner-node 1
4 neighbor 3ffa::10 update-source 3ffa::1
5 exit-owner-node
6 owner-node-2
7 neighbor 3ffa::10 update-source 3ffa::2
8 exit-owner-node
9 owner-node-3
10 neighbor 3ffa::10 update-source 3ffa::3
11 exit-owner-node
12 no neighbor 3ffa::10 activate
13 address-family ipv6
14 redistribute kernel
15 neighbor 3ffa::10 activate
16 exit-address-family
17 !
18 <!--NeedCopy-->
```

Install IPv6 learned routes

The NetScaler cluster can use routes learned by various routing protocols after you install the routes in the NetScaler cluster routing table.

To install IPv6 learned routes to the internal routing table by using the CLI:

At the command prompt, type:

- `ns route-install ipv6 bgp`
- `ns route-install ipv6 ospf`
- `ns route-install default`

Note

- If you have to exchange IPv4 routes on a IPv6 neighbor, you must remove the `no neighbor 3ffa::10 active` VTYSH command from the earlier configuration.
- The `update-source` VTYSH command must be used for each owner node to specify the right IPv6 source IP while connecting to the BGP peer as given in the BGP IPv4 configuration.

Routing in a L3 cluster

The routing in a L3 cluster works only when the following configurations are done on the NetScaler appliance.

- Enable the dynamic routing for a VLAN.

```
1 set vlan <id> -dynamicrouting enabled
2 <!--NeedCopy-->
```

- To reach all cluster nodes, the VIP, CLIP, and NetScaler IP (NSIP) must be advertised by routing protocols along with the `set vlan` command.

Deployment scenario for BGP in L3 cluster

Consider an example where all the cluster nodes are grouped in the AS 100 network, and the upstream routers are in a different AS 200.

The following figure depicts the AS 100 and AS 200 deployment in a cluster setup.

In this deployment, CLIP advertises CCO to upstream routers. Some cluster nodes drop the advertised traffic, as an AS loop is detected.

To overcome the issue, configure the following command in VTYSH BGP router mode for each neighbor.

At the VTYSH command prompt, type:

```
neighbor <peer_ip> allowas-in 1
```

As a best practice, Citrix recommends you to configure any one of the following:

- Configure route-maps to learn only desired networks such as; default route, NetScaler IP (NSIP), and NSIP subnets on cluster nodes.
- Configure upstream routes to advertise only desired networks such as; CLIP and NetScaler IP (NSIP) in cluster.

IP addressing for a cluster

May 2, 2023

In addition to the standard types of NetScaler-owned IP addresses—NetScaler NSIP, Virtual IP (VIP), and Subnet IP (SNIP)—a clustered NetScaler appliance can have a cluster management IP (CLIP) address. It can also have striped and spotted IP addresses.

- **CLIP address.** An IP address owned by the cluster coordinator node (CCO). The CLIP address can float between different nodes in a cluster setup. If the CLIP is moved to a different node of the cluster, that node becomes the CCO. The CCO is the NetScaler appliance that is responsible for management tasks in the cluster. A network administrator uses the CLIP address to connect to the cluster to perform configuration and management tasks, such as accessing the unified GUI, reporting, tracing packet flow, and collecting logs. You can add multiple CLIP addresses in a cluster on the same or different networks. Only configurations performed on the CCO through the cluster IP address are propagated to other nodes in the cluster.
- **Striped IP address.** A logical IP address available on all nodes of the cluster, it can be either a VIP or SNIP address.
- **Spotted IP address.** A logical IP (preferably SNIP address) is available only on one node. A spotted IP address has visibility on only that node. To minimize traffic-steering overhead, Citrix recommends that you use a spotted SNIP address for back-end communication with the server.

The following table provides the details of the configurations.

| IP Address | NSIP | VIP | SNIP |
|------------|------|-----|------|
| Spotted | Yes | Yes | Yes |
| Striped | No | Yes | Yes |

For example, in a four-node cluster group, you must configure each node with a spotted SNIP address. For more information on how to configure a spotted IP configuration, see [Striped, Partially Striped, and Spotted Configurations](#).

You can define a SNIP address to be active on only one node, or active on all nodes. If the virtual IP address and subnet IP address are available only on a specific node, it is of spotted configuration. The configuration is defined as striped if the subnet IP address and virtual server IP address are available on all nodes. Spotted SNIP addresses help in reducing the steering and backplane traffic.

Best practices for VLAN bindings and route configuration while joining a node to the cluster

VLAN IP bindings

When you bind a VLAN with the spotted IP address, the NetScaler cluster must be configured with the spotted IP addresses in the same subnet on all the nodes. For example, in a two-node cluster with Node 0 and Node 1, you can have the following configuration:

```
1 add ns ip 192.254.101.101 255.255.255.0 -vServer DISABLED -  
   dynamicRouting ENABLED -ownerNode 1  
2 add ns ip 192.254.101.102 255.255.255.0 -vServer DISABLED -  
   dynamicRouting ENABLED -ownerNode 0  
3 add vlan 100  
4 bind vlan 100 -IPAddress 192.254.101.101 255.255.255.0  
5 <!--NeedCopy-->
```

Routing configuration

When routing configuration is required with the spotted IP address as the default gateway, then the ADC cluster must be configured with the spotted IP addresses in the same subnet on all the nodes. For example, in a two-node cluster with Node 0 and Node 1, you can have the following configuration:

```
1 add ns ip 192.254.101.101 255.255.255.0 -vServer DISABLED -  
   dynamicRouting ENABLED -ownerNode 1  
2 add ns ip 192.254.101.102 255.255.255.0 -vServer DISABLED -  
   dynamicRouting ENABLED -ownerNode 0  
3  
4 add route 192.254.102.0 255.255.255.0 192.254.101.103  
5 <!--NeedCopy-->
```

Note

In an L3 cluster setup, only spotted SNIP configuration is supported.

Configuring layer 3 clustering

March 6, 2024

Understanding the L3 cluster

The demand to expand the high availability deployment and increase the scalability of the client traffic across different networks guided to establish the L3 cluster. The L3 cluster lets you group NetScaler appliances across individual subnets (L2 cluster).

L3 cluster is also referred to as “cluster in Independent Network Configuration (INC) mode”. In L3 cluster deployment, the cluster nodes in the same network are grouped to form a Node group. L3 cluster uses GRE tunneling to steer the packets across networks. The heartbeat messages across the L3 clusters are routed.

Architecture

The L3 cluster architecture comprises the following components:

- **Nodegroup** - The cluster nodes from each network (n1, n2) and (n3, n4), as shown in the following figure, are grouped to form a Node group. These Node groups are terminated to the layer 3 switch on either side of the network.
 - The cluster communicates with the client through the physical connections between the cluster node and the client-side connecting device. The logical grouping of these physical connections is called the client data plane.
 - The cluster communicates with the server through the physical connections between the cluster node and the server side connecting device. The logical grouping of these physical connections is called the server data plane.
- **Backplane Switch** - Cluster nodes within the same network communicate with each other by using the cluster backplane. The backplane is a set of interfaces in which one interface of each node is connected to a common switch, which is called the cluster backplane switch.
- **Tunnel** - By default, the packets between nodes in a L3 cluster are exchanged over an unencrypted GRE tunnel that uses the NSIP addresses of the source and destination nodes for routing. The steering mechanism changes for nodes belonging to the different network. The packets are steered through a GRE tunnel to the node on the other subnet, instead of rewriting the MAC.

Note:

For a new deployment, we recommend using the UDP tunnel to steer the packets across networks. The advantages of using a UDP tunnel are:

- The steering between the packet engines is based on 4-tuple, which provides better distribution.
- You can avoid the skewness in CPU utilization.

Refer to the following table to understand how packets are steered in different tunnel modes.

| Tunnel mode | Same network | Different network |
|-------------|--|--|
| None | Backplane is used to steer the packets. | GRE tunnel is used to steer the traffic. |
| GRE | GRE tunnel is used to steer the packets. | GRE tunnel is used to steer the packets. |
| UDP | UDP tunnel is used to steer the packets. | UDP tunnel is used to steer the packets. |

Example

Consider an example of an L3 cluster deployment consisting of the following:

- Three NetScaler appliances (n1, n2, and n3) nodes are grouped into Nodegroup1.
- Similarly, the nodes n4 and n5 are grouped in Nodegroup2. In the third network, there are two node groups. Nodegroup3 includes n6 and n7 and Nodegroup4 includes n8 and n9.
- The NetScaler appliances that belong to the same network are combined to form a node group.

Points to consider before configuring the L3 cluster

Consider the following points before configuring the L3 cluster on a NetScaler appliance:

- The backplane is not mandatory while configuring L3 subnets. If the backplane is not specified, the node does not go to the backplane fail state.

Note:

If you have more than one node in the same L2 network, it is mandatory to define the backplane interface. If the backplane interface is not mentioned, the nodes go to the backplane fail state.

- L2 features and striped SNIPs are not supported in the L3 cluster.
- The external traffic distribution in the L3 cluster supports only Equal Cost Multiple Path (ECMP).
- The ICMP errors and fragmentation are not processed when steering is disabled in an L3 cluster deployment:

- The networking entities (`route`, `route6`, `pbr`, and `pbr6`) must be bound to the configuration node group.
- VLAN, RNAT, and IP tunnel cannot be bound to a configuration node group.
- Configuration node group must always have property STRICT “YES.”
- The cluster nodes must not be added to a config node group via “add cluster node” command.
- The `add cluster instance -INC enabled` command clears the networking entities (`route`, `route6`, `PBR`, `pb6`, `RNAT`, `IP tunnel`, `ip6tunnel`).
- The `clear config extended+` command does not clear the entities (`route`, `route6`, `PBR`, `pb6`, `RNAT`, `IP tunnel`, `ip6tunnel`) in an L3 cluster.

Configuring the L3 cluster

In an L3 cluster configuration, the cluster command has different attributes to configure that is based on nodes, and node groups. The L3 cluster configuration also includes an IPv6 profile apart from IPv4 profiles.

Configuring an L3 cluster on a NetScaler appliance consists of the following tasks:

- Create a cluster instance
- Create a node group in L3 cluster
- Add a NetScaler appliance to the cluster and group with node group
- Add cluster IP address to the node
- Enable the cluster instance
- Save the configuration
- Add a node to an existing node group
- Create a node group in L3 cluster
- Group new nodes to the newly created node group
- Join the node to the cluster

Configuring the following by using the CLI

- **To create a cluster instance**

```
add cluster instance <clid> -inc <ENABLED|DISABLED> -processLocal  
<ENABLED|DISABLED>
```

Note:

The “inc” parameter must be ENABLED for an L3 cluster.

- **To create a nodegroup in L3 cluster**

```
add cluster nodegroup <name>
```

- **To add a NetScaler appliance to the cluster and to associate with nodegroup**

```
add cluster node <nodeid> <nodeip> -backplane <interface_name>  
nodegroup <ng> -tunnelmode UDP
```

- **To add the cluster IP address on this node**

```
add ns ip <IPAddress> <netmask> -type clip
```

- **Enable the cluster instance**

```
enable cluster instance <clId>
```

- **Save the configuration**

```
save ns config
```

- **Warm reboot the appliance**

```
reboot -warm
```

- **To add a new node to an existing nodegroup**

```
add cluster node <nodeid> <nodeip> -nodegroup <ng> -tunnelmode  
UDP
```

- **To create a new nodegroup in L3 cluster**

```
add cluster nodegroup <ng>
```

- **To group new nodes to the newly created nodegroup**

```
add cluster node <nodeid> <nodeip> -nodegroup <ng> -tunnelmode  
UDP
```

- **To join the node to the cluster**

```
join cluster -clip <ip_addr> -password <password>
```

```
1 Example: The following is an example configuration for nodegroup1 and  
2 nodegroup2.  
3 > add cluster instance 1 -inc ENABLED -processLocal ENABLED  
4  
5 Done  
6  
7 > add cluster nodegroup ng1  
8  
9 Done  
10  
11 > add cluster node 0 1.1.1.1 -state ACTIVE -backplane 0/1/1 -  
nodegroup ng1 -tunnelmode UDP
```

```
12
13     Done
14
15     > add ns ip 1.1.1.100 255.255.255.255 -type clip
16
17     Done
18
19     > enable cluster instance 1
20
21     Done
22
23     > save ns config
24
25     Done
26
27     > add cluster node 1 1.1.1.2 - state ACTIVE - nodegroup ng1 -
        tunnelmode UDP
28
29     Done
30
31     > add cluster nodegroup ng2
32
33     Done
34
35     > add cluster node 4 2.2.2.1 - state ACTIVE - nodegroup ng2 -
        tunnelmode UDP
36
37     Done
38
39     > add cluster node 5 2.2.2.2 - state ACTIVE - nodegroup ng2 -
        tunnelmode UDP
40
41     Done
42
43     > join cluster -clip 1.1.1.100 -password nsroot
44 <!--NeedCopy-->
```

Advertising cluster IP address of a L3 cluster

Configure the cluster IP address to be advertised to the upstream router to make the cluster configuration accessible from any subnet. The cluster IP address is advertised as a kernel route by the dynamic routing protocols configured on a node.

Advertising the cluster IP address consists of the following tasks:

- **Enable the host route option of the cluster IP address.** The host route option pushes the cluster IP address to a ZebOS routing table for kernel route redistribution through dynamic routing protocols.
- **Configuring a dynamic routing protocol on a node.** A dynamic routing protocol advertises

the cluster IP address to the upstream router. For more information on configuring a dynamic routing protocol, see [Configuring Dynamic Routes](#).

To enable the host route option of the cluster IP address by using the CLI

At the command prompt, type:

- `add nsip <IPAddress> <netmask> -hostRoute ENABLED`
- `show nsip <IPAddress>`

```
1      > add ns ip 10.102.29.60 255.255.255.255 -hostRoute ENABLED
2
3      > Done
4 <!--NeedCopy-->
```

Spotted, partially striped configurations on L3 cluster

The spotted and partially striped configurations on the L3 cluster slightly differ from the L2 cluster. The configuration might differ from node to node as the nodes reside on different subnets. The network configurations can be node specific in the L3 cluster, hence you have to configure the spotted or partially striped configurations based on the below-mentioned parameters.

To configure spotted, partially striped configurations on a NetScaler appliance over the L3 cluster, perform the following tasks:

- Add a cluster owner group to an IPv4 static routing table
- Add a cluster owner group to an IPv6 static routing table
- Add a cluster owner group to an IPv4 policy based routing (PBR)
- Add a cluster owner group to an IPv6 PBR
- Add a VLAN
- Bind a VLAN to a specific owner group of cluster node group

Configuring the following by using the CLI

- **To add a cluster ownergroup to an IPv4 static route table of the NetScaler appliance**

```
add route <network> <netmask> <gateway> -owner group <ng>
```

- **To add a cluster ownergroup to an IPv6 static route table of the NetScaler appliance**

```
add route6 <network> -owner group <ng>
```

- **To add a cluster ownergroup to an IPv4 PBR**

```
add pbr <name> <action> -owner group <ng>
```

- **To add a cluster ownergroup to an IPv6 PBR**

```
add pbr6 <name> <action> -owner group <ng>
```

- **To add a VLAN**

```
add vlan <id>
```

- **To bind a VLAN to a specific ownergroup of cluster nodegroup**

```
bind vlan <id> -ifnum - [IPAddress <ipv4_addr | ipv6_addr> [-  
owner group <ng>]
```

The following commands are sample examples of spotted and partially striped configurations which can be configured by using the CLI.

```
1 > add route 10.102.29.0 255.255.255.0 10.102.29.2 - ownergroup ng2
2
3 Done
4
5 > add route6 fe80::9404:60ff:fedd:a464/64 - ownergroup ng1
6
7 Done
8
9 > add pbr pbr1 allow - ownergroup ng1
10
11 Done
12
13 > add pbr6 pbr2 allow - ownergroup ng2
14
15 Done
16
17 > add vlan 2
18
19 Done
20
21 > bind vlan 2 -ifnum 1/2 - [IPAddress 10.102.29.80 | fe80::9404:60
22 ff:fedd:a464/64-ownergroup ng1
23
24 Done
24 <!--NeedCopy-->
```

Configure node group

In an L3 cluster, to replicate the same set of configurations on more than one node group, the following commands are used:

Configuring the following by using the CLI

- **To add an IPv4 static route to the routing table of the NetScaler appliance**

```
add route <network> <netmask> <gateway> -ownerGroup <ng>
```

Sample Configuration:

```
1 add route 0 0 10.102.53.1 - ownerGroup ng1
2
3 add route 0 0 10.102.53.1 - ownerGroup ng2
4 <!--NeedCopy-->
```

You define a new node group ‘all’ to support the preceding configuration, and have to configure the following commands:

Configuring the following by using the CLI

- **To add a new nodegroup to cluster with strict parameter**

```
add cluster node group <name> -strict <YES | NO>
```

- **To bind a cluster node or an entity to the given nodegroup**

```
bind cluster nodegroup <name> -node <nodeid>
```

- **To add IPv4 static route to all ownergroup**

```
add route <network> <netmask> <gateway> -ownerGroup <ng>
```

Sample configuration:

```
1 add cluster nodegroup all -strict YES
2
3 bind cluster nodegroup all -node 1
4
5 bind cluster nodegroup all -node 2
6
7 add route 0 0 10.102.53.1 - ownerGroup all
8 <!--NeedCopy-->
```

Traffic distribution in a L3 cluster

In a cluster setup, external networks view the collection of NetScaler appliances as a single entity. So, the cluster must select a single node that must receive the traffic. In the L3 cluster this selection is done using the ECMP. The selected node is called the flow receiver.

Note

For an L3 cluster (nodes across different networks), only the ECMP traffic distribution can be used.

The flow receiver gets the traffic and then, using internal cluster logic determines the node that must process the traffic. This node is called the flow processor. The flow receiver steers the traffic to the flow processor over the backplane if the flow receiver and the flow processor are on the same network. The traffic is steered through the tunnel if the flow receiver and the flow processor are on different networks.

Note

- The flow receiver and flow processor must be nodes capable of serving traffic.
- From NetScaler 11 onwards, you can disable steering on the cluster backplane. For more information, see [Disabling steering on the cluster backplane](#).

The preceding figure shows a client request flowing through the cluster. The client sends a request to a virtual IP (VIP) address. A traffic distribution mechanism configured on the client data plane selects one of the cluster nodes as the flow receiver. The flow receiver receives the traffic, determines the node that must process the traffic, and steers the request to that node (unless the flow receiver selects itself as the flow processor). If the flow processor and flow receiver are in the same node group, the packet is steered over the backplane. And if the flow processor and flow receiver are in different node groups, then the packet is steered through the tunnel over the routed path.

The flow processor establishes a connection with the server. The server processes the request and sends the response to the subnet IP (SNIP) address that sent the request to the server. Since in the L3 cluster the SNIP is always a spotted SNIP, the node that owns the SNIP address receives the response from the server.

Setting up a NetScaler cluster

May 2, 2023

NetScaler appliances that you want to add to the cluster must satisfy the criteria specified in [Prerequisites for Cluster Nodes](#). Before actually setting up a cluster, you must be aware of cluster basics. For information, see [Cluster Overview](#).

Forming a cluster requires you to set up inter-node communication, create the cluster (by adding the first NetScaler appliance), and then add the other cluster nodes. Each of these steps is explained with relevant details in subsequent topics.

Note

While there are some differences in setting up an L2 and L3 cluster, there are many similarities too. The subsequent topics explain the setup for both cluster types while highlighting the con-

figurations that are specific to L3 clusters.

Setting up inter-node communication

March 25, 2024

The nodes in a cluster setup communicate with one another using the following inter-node communication mechanisms:

- Nodes that are within the network (same subnet) communicate with each other through the cluster backplane. The backplane must be explicitly set up. The following are the detailed steps.
- Across networks, steering of packets is done through a GRE tunnel and other node-to-node communication is routed across nodes as required.

Important:

- From Release 11.0 all builds, a cluster can include nodes from different networks.
- From Release 13.0 build 58.3, GRE steering is supported on Fortville NICs in an L3 cluster.

To set up the cluster backplane, do the following for every node

1. Identify the network interface that you want to use for the backplane.
2. Connect an Ethernet or optical cable from the selected network interface to the cluster backplane switch.

For example, to use interface 1/2 as the backplane interface for node 4, connect a cable from the 1/2 interface of node 4 to the backplane switch.

Important points to note when setting up the cluster backplane

- Do not use the appliance's management interface (0/x) as the backplane interface. In a cluster, the interface 0/1/x is read as:
0 -> node ID 0
1/x -> NetScaler interface
- Do not use the backplane interfaces for the client or server data planes.
- Citrix recommends using the link aggregate (LA) channel for the cluster backplane.

Note:

After you unbind an interface from the LA channel, ensure that you set an appropriate MTU size for the unbound interface.

- In a two-node cluster, where the backplane is connected back-to-back, the cluster is operationally DOWN under any of the following conditions:
 - One of the nodes is rebooted.
 - Backplane interface of one of the nodes is disabled.

Therefore, Citrix recommends that you dedicate a separate switch for the backplane, so that the other cluster node and traffic are not impacted. You cannot scale out the cluster with a back-to-back link. You might encounter a downtime in the production environment when you scale out the cluster nodes.

- Backplane interfaces of all nodes of a cluster must be connected to the same switch and bound to the same L2 VLAN.
- If you have multiple clusters with the same cluster instance ID, make sure that the backplane interfaces of each cluster are bound to a different VLAN.
- The backplane interface is always monitored, regardless of the HA monitoring settings of that interface.
- The state of MAC spoofing on the different virtualization platforms can affect the steering mechanism on the cluster backplane. Therefore, make sure the appropriate state is configured:
 - XenServer - Disable MAC spoofing
 - Hyper-V - Enable MAC spoofing
 - VMware ESX - Enable MAC spoofing (also make sure “Forged Transmits” is enabled)
- The MTU for the cluster backplane is automatically updated. However, if jumbo frames are configured on the cluster, the MTU of the cluster backplane must be explicitly configured. The value must be set to $78 + X$, where X is the maximum MTU of the client and server data planes. For example, if the MTU of a server data plane is 7500 and of the client data plane is 8922. The MTU of a cluster backplane must be set to $78 + 8922 = 9000$. To set this MTU, use the following command:

```
> set interface <backplane_interface> -mtu <value>
```
- The MTU for the interfaces of the backplane switch must be specified to be greater than or equal to 1,578 bytes. It is applicable if the cluster has features like MBF, L2 policies, ACLs, routing in CLAG deployments, and vPath.

Note:

The default MTU size for a backplane interface is 1578. To reset the MTU size to the default value, you must use the `unset interface <backplane_interface> -mtu` command.

UDP based tunnel support for L2 and L3 cluster

Starting from NetScaler release 13.0 build 36.x, NetScaler L2 and L3 cluster can steer the traffic using UDP based tunneling. It is defined for the inter-node communications of two nodes in a cluster. By using the “tunnel mode” parameter, you can set GRE or UDP tunnel mode from the add and set cluster node command.

In an L3 cluster deployment, packets between NetScaler nodes are exchanged over an unencrypted GRE tunnel that uses the NSIP addresses of the source and destination nodes for routing. When this exchange occurs over the internet, in the absence of an IPsec tunnel, the NSIPs is exposed on the internet, and might result in security issues.

Important:

Citrix recommends customers to establish their own IPsec solution when using a L3 cluster.

The following table helps you to categorize the tunnel support based on different deployments.

| Steering Types | AWS | Microsoft Azure | On -premises |
|----------------|---------------|-----------------|--------------|
| MAC | Not supported | Not supported | Supported |
| GRE tunnel | Supported | Not supported | Supported |
| UDP tunnel | Supported | Supported | Supported |

Important:

In a L3 cluster, the tunnel mode is set to GRE by default.

Configuring UDP based tunnel

You can add a cluster node by setting the parameters of node ID and mention the state. Configure the backplane by providing the interface name, and select the tunnel mode of your choice (GRE or UDP).

Note:

You must configure the tunnel mode from the Cluster IP address.

CLI procedures To enable the UDP tunnel mode by using the CLI.

At the command prompt, type:

- `add cluster node <nodeId>@ [-state <state>] [-backplane <interface_name >] [-tunnelmode <tunnelmode>]`
- `set cluster node <nodeId>@ [-state <state>] [-tunnelmode <tunnelmode >]`

Note:

Possible values for tunnel mode are NONE, GRE, UDP.

Example

- `add cluster node 1 -state ACTIVE -backplane 1/1/1 -tunnelmode UDP`
- `set cluster node 1 -state ACTIVE -tunnelmode UDP`

GUI procedures To enable the UDP tunnel mode by using the GUI.

1. Navigate to **System > Cluster > Nodes**.
2. In the **Cluster Nodes** page, click **Add**.
3. In the **Create Cluster Node**, set the **Tunnel Mode** parameter to UDP and click **Create**.

← Create Cluster Node

| | |
|---|--|
| Node id | <input type="text" value="1"/> |
| NetScaler IP address | <input type="text" value="1 . 1 . 1 . 1"/> |
| Backplane interface | <input type="text" value="1/1/1"/> |
| State* | <input type="text" value="PASSIVE"/> ⓘ |
| Node Group | <input type="text" value="DEFAULT_NG"/> ⓘ |

| Tunnel Mode | <input type="text" value="UDP"/> ⓘ |
| <input checked="" type="checkbox"/> Execute join command and reboot the remote system | |

4. Click **Close**.

Creating a NetScaler cluster

May 2, 2023

To create a cluster, start by taking one of the NetScaler appliances that you want to add to the cluster. On this node, you must create the cluster instance and define the cluster IP address. This node is the first cluster node and is called the cluster configuration coordinator (CCO). All configurations that are performed on the cluster IP address are stored on this node and then propagated to the other cluster nodes.

The responsibility of CCO in a cluster is not fixed to a specific node. It can change over time depending on the following factors:

- The priority of the node. The node with the highest priority (lowest priority number) is made the CCO. Therefore, if a node with a priority number lower than the existing CCO is added, the

new node takes over as the CCO.

- If the current CCO goes down, the node with the next lowest priority number takes over as the CCO. If the priority is not set or if there are multiple nodes with the lowest priority number, the CCO is selected from one of the available nodes.

Note:

The configurations of the appliance (including SNIP addresses and VLANs) are cleared by implicitly running the `clear ns config extended` command. However, the default VLAN and NSVLAN are not cleared from the appliance. Therefore, if you want the NSVLAN on the cluster, make sure it is created before the appliance is added to the cluster. For an L3 cluster (cluster nodes on different networks), networking configurations are not cleared from the appliance.

Important:

HA Monitor (HAMON) on a cluster setup is used to monitor the health of an interface on each node. The HAMON parameter must be enabled on each node to monitor the state of the interface. If the operational state of the HAMON enabled interface goes down due to any reason, the respective cluster node is marked as unhealthy (NOT UP) and that node cannot serve traffic.

Create a cluster by using the command line interface

- Log on to a NetScaler appliance (for example, appliance with NSIP address 10.102.29.60) that you want to add to the cluster.
- Add a cluster instance.

```
1 add cluster instance <clId> -quorumType <NONE | MAJORITY> -inc <
  ENABLED | DISABLED> -backplanebasedview <ENABLED | DISABLED>
2 <!--NeedCopy-->
```

- The `-dfdretainl2params` option enables you to add the extended L2 headers for the backplane traffic.

At the command prompt, type:

```
add cluster instance 1 -dfdretainl2params <ENABLED|DISABLED>
```

The following command displays the status of the `-dfdretainl2params`:

```
show cluster instance <clusterid>
```

Use the following command to enable or disable the `-dfdretainl2params`:

```
set cluster instance 1 -dfdretainl2params <ENABLED|DISABLED>
```

- The `-proxyarpstatus` option enables or disables the proxy arp functionality for cluster.

At the command prompt, type:

```
add cluster instance 1 -proxyarpstatus <ENABLED|DISABLED>
```

The following command displays the status of the `proxyarpstatus`:

```
show cluster instance <clusterid>
```

You can use the following command to enable or disable the `proxyarpstatus`:

```
set cluster instance 1 -proxyarpstatus <ENABLED|DISABLED>
```

Note:

- The cluster instance ID must be unique within a LAN.
- The `-quorumType` parameter must be set to MAJORITY and not NONE in the following scenarios:
 - Topologies which do not have redundant links between cluster nodes. These topologies might be prone to network partition due to a single point of failure.
 - During any cluster operations such as node addition or removal.
- For an L3 cluster, make sure the `-inc` parameter is set to ENABLED. The `-inc` parameter must be disabled for an L2 cluster.
- When the `-backplanebasedview` parameter is enabled, the operational view (set of nodes that serve traffic) is decided based on heartbeats received only on the backplane interface. By default, this parameter is disabled. When this parameter is disabled, a node does not depend on the heartbeat reception only on the backplane.

1. [Only for an L3 cluster] Create a node group. In the next step, the newly added cluster node must be associated with this node group.

Note:

This node group includes all or a subset of the NetScaler appliances that belong to the same network.

```
1 add cluster nodegroup <name>
2 <!--NeedCopy-->
```

2. Add the NetScaler appliance to the cluster.

```
1 add cluster node <nodeId> <IPAddress> -state <state> -backplane <
  interface_name> -nodegroup <name>
2 <!--NeedCopy-->
```

Note:

For an L3 cluster:

- The node group parameter must be set to the name of the node group that is created.
- The backplane parameter is mandatory for nodes that are associated with a node

group that has more than one node, so that the nodes within the network can communicate with each other.

Example:

Adding a node for an L2 cluster (all cluster nodes are in the same network).

```
1 add cluster node 0 10.102.29.60 -state PASSIVE -backplane 0/1/1
2 <!--NeedCopy-->
```

Adding a node for an L3 cluster which includes a single node from each network. Here, you do not have to set the backplane.

```
1 add cluster node 0 10.102.29.60 -state PASSIVE -nodegroup ng1
2 <!--NeedCopy-->
```

Adding a node for an L3 cluster which includes multiple nodes from each network. Here, you have to set the backplane so that nodes within a network can communicate with each other.

```
1 add cluster node 0 10.102.29.60 -state PASSIVE -backplane 0/1/1
   -nodegroup ng1
2 <!--NeedCopy-->
```

3. Add the cluster IP address (for example, 10.102.29.61) on this node.

```
1 add ns ip <IPAddress> <netmask> -type clip
2 <!--NeedCopy-->
```

Example

```
1 add ns ip 10.102.29.61 255.255.255.255 -type clip
2 <!--NeedCopy-->
```

4. Enable the cluster instance.

```
1 enable cluster instance <clId>
2 <!--NeedCopy-->
```

5. Save the configuration.

```
1 save ns config
2 <!--NeedCopy-->
```

6. Warm reboot the appliance.

```
1 reboot -warm
2 <!--NeedCopy-->
```

Verify the cluster configurations by using the show cluster instance command. Verify that the output of the command displays the NSIP address of the appliance as a node of the cluster.

7. After the node is UP, login to the CLIP and change RPC credentials for both cluster IP address and Node IP address. For more information about changing an RPC node password, see [Change an RPC node password](#).

To create a cluster by using the GUI

1. Log on to an appliance (for example, an appliance with NSIP address 10.102.29.60) that you intend to add to the cluster.
2. Navigate to **System > Cluster**.
3. In the details pane, click the **Manage Cluster** link.
4. In the Cluster Configuration dialog box, set the parameters required to create a cluster. For a description of a parameter, hover the mouse cursor over the corresponding text box.
5. Click **Create**.
6. In the Configure cluster instance dialog box, select the Enable cluster instance check box.
7. In the Cluster Nodes pane, select the node and click **Open**.
8. In the Configure Cluster Node dialog box, set the State.
9. Click **OK**, and then click **Save**.
10. Warm reboot the appliance.
11. After the node is UP, login to the CLIP and change RPC credentials for both cluster IP address and Node IP address. For more information about changing an RPC node password, see [Change an RPC node password](#).

Strict mode support for sync status of the cluster

You can now configure a cluster node to view errors when applying the configuration. A new parameter, “syncStatusStrictMode” is introduced in both the add and set cluster instance command to track the status of each node in a cluster. By default, the `syncStatusStrictMode` parameter is disabled.

To enable the strict mode by using the CLI

At the command prompt, type:

```
1 set cluster instance <clID> [-syncStatusStrictMode (ENABLED | DISABLED)
  ]
2 <!--NeedCopy-->
```

Example:

```
1 set cluster instance 1 - syncStatusStrictMode ENABLED
2 <!--NeedCopy-->
```

To view the status of strict mode by using the CLI

```

1  >show cluster instance
2  1) Cluster ID: 1
3     Dead Interval: 3 secs
4     Hello Interval: 200 msec
5     Preemption: DISABLED
6     Propagation: ENABLED
7     Quorum Type: MAJORITY
8     INC State: DISABLED
9     Process Local: DISABLED
10    Retain Connections: NO
11    Heterogeneous: NO
12    Backplane based view: DISABLED
13    Cluster sync strict mode: ENABLED
14    Cluster Status: ENABLED(admin), ENABLED(operational), UP
15
16    WARNING(s):
17    (1) - There are no spotted SNIPs configured on the cluster.
18         Spotted SNIPs can help improve cluster performance
19
20    Member Nodes:
21    Node ID      Node IP      Health      Admin State  Operational
22    State
23    -----
24    1)          1           192.0.2.20  UP           ACTIVE       ACTIVE (
25    Configuration Coordinator)
26    2)          2           192.0.2.21  UP           ACTIVE       ACTIVE
27    3)          3           192.0.2.19* UP           ACTIVE       ACTIVE
28 <!--NeedCopy-->

```

To view the sync failure reason of a cluster node by using the GUI

1. Navigate to **System > Cluster > Cluster Nodes**.
2. In the **Cluster Nodes** page, scroll to the extreme right to view the details of the synchronization failure reason of the cluster nodes.

Adding a node to the cluster

October 13, 2023

You can seamlessly scale the size of a cluster to include a maximum of 32 nodes. When a NetScaler appliance is added to the cluster, the configurations from that appliance are cleared (by internally running the `clear ns config -extended` command). The SNIP addresses, **MTU** settings of the backplane

interface, and all VLAN configurations (except the default VLAN and NSVLAN) are also cleared from the appliance.

The cluster configurations are then synchronized on this node. There can be an intermittent drop in traffic while the synchronization is in progress.

Important:

Before you add a NetScaler appliance to a cluster:

- Set up the backplane interface for the node. Check the preceding topic.
- Check if the licenses that are available on the appliance match that are available on the configuration coordinator. The appliance is added only if the licenses match.
- If you want the NSVLAN on the cluster, make sure that the NSVLAN is created on the appliance before it is added to the cluster.
- Citrix recommends that you add the node as a passive node. Then, after joining the node to the cluster, complete the node specific configuration from the cluster IP address. Run the force cluster sync command if the cluster has only spotted IP addresses. And which has L3 VLAN binding, or has static routes.
- When an appliance with a preconfigured link aggregate (LA) channel is added to a cluster, the LA channel continues to exist in the cluster environment. The LA channel is renamed from LA/x to nodeId/LA/x, where LA/x is the LA channel identifier.

To add a node to the cluster by using the CLI

Note:

When you add a node to a cluster setup, make sure that the default static route configured in the node is present in the cluster coordinator node (CCO). If the node has a static route not present in the CCO, the command fails with the following error.

Node cannot join cluster as **static default** gateway route is not present in CCO

1. Log on to the cluster IP address, at the command prompt, do the following:

- Add the appliance (for example, 10.102.29.70) to the cluster.

Note:

For an L3 cluster:

- The node group parameter must be set to a node group that has nodes of the same network.
- If this node belongs to the same network as the first node that was added, then con-

figure the node group that was used for that node.

- If this node belongs to a different network, then create a node group and bind this node to the node group.
- The backplane parameter is mandatory for nodes that are associated with a node group that has more than one node, so that the nodes within the network can communicate with each other.

```

1 add cluster node <nodeId> <IPAddress> -state <state> -backplane <
  interface_name> -nodegroup <name>
2
3 Example:
4
5 add cluster node 1 10.102.29.70 -state PASSIVE -backplane 1/1/1
6 Warning: Add spotted configurations using the cluster IP for this
  node. Spotted configurations include: IPv4 addresses, IPv6
  addresses, ARP entries, interface settings, route6s, IP tunnel,
  IPv6 tunnels, RNATs, PBRs, PBR6, Cluster LAGs, ND6s entries,
  FISs, linksets, SNMP MIB / engine ID, diameters, Citrix ADC VPX
  param, and hostname. If a backup is taken using the
  spottedconfig script for this node, apply it using the cluster
  IP after the node has joined the setup.
7 Done
8 <!--NeedCopy-->

```

- Save the configuration.

```

1 save ns config
2 <!--NeedCopy-->

```

2. Log on to the newly added node (for example, 10.102.29.70) and join the node to the cluster.

```

1 join cluster -clip <ip_addr> -password <password>
2
3 Example:
4
5 join cluster -clip 10.102.29.61 -password nsroot
6 <!--NeedCopy-->

```

3. Configure the following commands on the CLIP.

- Bind VLAN to an interface

```

1 bind vlan <id> -ifnum <interface_name>
2 <!--NeedCopy-->

```

Example:

```

1 bind vlan 1 -ifnum 2/1/2
2 <!--NeedCopy-->

```

- Add spotted IP address to the newly added node

```
1 add ns ip <IpAddress> <netmask> -ownerNode <positive_integer>
2 <!--NeedCopy-->
```

Example:

```
1 add ns ip 97.131.0.3 255.0.0.0 -ownerNode 2
2 <!--NeedCopy-->
```

- Verify VLAN on NSIP

```
1 show vlan <id>
2 <!--NeedCopy-->
```

Example:

```
1 show vlan 1
2 <!--NeedCopy-->
```

4. Perform the following configurations:

- If the node is added to a cluster that has only spotted IPs, the configurations are synchronized before the spotted IP addresses are assigned to that node. In such cases, L3 VLAN bindings can be lost. To avoid this loss, either add a striped IP or add the L3 VLAN bindings.
- Define the required spotted configurations.
- Set the MTU for the backplane interface.

5. Save the configuration.

```
1 save ns config
2 <!--NeedCopy-->
```

6. Warm reboot the appliance.

```
1 reboot -warm
2 <!--NeedCopy-->
```

- #### 7. After the node is UP and sync is successful, change the RPC credentials for the node from the cluster IP address. For more information about changing an RPC node password, see [Change an RPC node password](#).

```
1 set rpcNode <node-NSIP> -password <passwd>
2
3 Example:
4
5 set rpcNode 192.0.2.4 -password mypassword
6 <!--NeedCopy-->
```

8. Set the cluster node to Active.

```
1 set cluster node <nodeID> -state active.  
2  
3 Example:  
4  
5 set cluster node 1 -state active  
6 <!--NeedCopy-->
```

To add a node to the cluster by using the GUI

1. Log on to the cluster IP address.
2. Navigate to **System > Cluster > Nodes**.
3. In the details pane, click **Add** to add the new node (for example, 10.102.29.70).
4. In the **Create Cluster Node** dialog box, configure the new node. For a description of a parameter, hover the mouse cursor over the corresponding text box.
5. Click **Create**. When prompted to perform a warm reboot, click **Yes**.
6. After the node is UP and sync is successful, change the RPC credentials for the node from the cluster IP address. For more information about changing an RPC node password, see [Change an RPC node password](#).
7. Navigate to **System > Cluster > Nodes > Edit**.
8. Modify the State to **ACTIVE** and confirm.

To join a previously added node to the cluster by using the GUI

If you have used the CLI to add a node to the cluster, but have not joined the node to the cluster, you can use the following procedure.

Note:

When a node joins the cluster, it takes over its share of traffic from the cluster and hence an existing connection can get terminated.

1. Log on to the node that you want to join to the cluster (for example, 10.102.29.70).
2. Navigate to **System > Cluster**.
3. In the details pane, under Get Started, click the Join Cluster link.
4. In the Join to existing cluster dialog box, set the cluster IP address and the `nsroot` password of the configuration coordinator. For a description of a parameter, hover the mouse cursor over the corresponding text box.
5. Click **OK**.

Viewing the details of a cluster

December 21, 2020

You can view the details of the cluster instance and the cluster nodes by logging on to the cluster IP address.

To view details of a cluster instance by using the CLI

Log on to the cluster IP address and, at the command prompt, type:

```
1 show cluster instance <clId>
```

Note

When the preceding command is run from the NSIP address of the non-CCO node, the command displays the status of the cluster on this node.

To view details of a cluster node by using the CLI

Log on to the cluster IP address and, at the command prompt, type:

```
1 show cluster node <nodeId>
```

To view details of a cluster instance by using the GUI

1. Log on to the cluster IP address.
2. Navigate to **System > Cluster**.
3. In the details pane, under **Get Started**, click the **Manage Cluster** link to view the details of the cluster.

To view details of a cluster node by using the GUI

1. Log on to the cluster IP address.
2. Navigate to **System > Cluster > Nodes**.
3. In the details pane, click the node for which you want to view the details.

Distributing traffic across cluster nodes

May 2, 2023

After you have created the NetScaler cluster and performed the required configurations, you must deploy Equal Cost Multiple Path (ECMP) or cluster Link Aggregation (LA) on the client data plane (for client traffic) or server data plane (for server traffic). These mechanisms distribute external traffic across the cluster nodes.

Policy-based backplane steering

The policy-based backplane steering (PBS) is a mechanism in cluster deployment, which steers the traffic across cluster nodes based on the hash method defined for the flow. The flow is defined by a combination of L2 and L3 parameters similar to the Access Control List (ACL).

The PBS supports both IPv4 and IPv6 traffic. In the case of IPv6 deployments, the steering supports an extra option [`dfdprefix <positive_integer>`]. It provides the flexibility to choose the same flow processor for the same IP prefix. The prefix option is supported for source IP or destination IP hash methods only.

Note

If the PBS mechanism is not used to steer the traffic, the traffic is steered through the default method.

To configure the new ACL attributes, at the CLI, type the following commands:

CLI commands for IPv4

- `add ns acl <aclname> <aclaction> [-type (classic | dfd)] [-dfdhash <dfdhash>]`
- `set ns acl <aclname> <aclaction> [-dfdhash <dfdhash>]`
- `show ns acl [<aclname>][-type (classic | DFD)]`
- `apply ns acls [-type (classic | DFD)]`
- `clear ns acls [-type (classic | DFD)]`
- `renumber ns acls [-type (classic | DFD)]`

CLI commands for IPv6

- `add ns acl6 <acl6name> <acl6action> [-type (classic | dfd)][-dfdhash <dfdhash>][-dfdprefix <positive_integer>]`

- `set ns acl6 <acl6name> <acl6action> [-dfdhash <dfdhash>][-dfdprefix <positive_integer>]`
- `show ns acl6 [<acl6name>][-type (classic | DFD)]`
- `apply ns acls6 [-type (classic | DFD)]`
- `clear ns acls6 [-type (classic | DFD)]`
- `renumber ns acls6 [-type (classic | DFD)]`

The following are the different types of hash methods that you can specify to steer the packet to the flow processor:

- SIP-SPORT-DIP-DPORT
- SIP
- DIP
- SIP-DIP
- SIP-SPORT

Limitations

1. The traffic flow distribution across the cluster nodes is not ensured, as the flow processor is decided by the admin configured rules.
2. L2 mode is not supported.
3. The node groups and striped SNIPs are not supported, as there is no deployment scenarios.
4. MPTCP is not supported.
5. Support only for TCP, UDP, and ICMP traffic.
6. Cluster over L3 mode is not supported.
7. Process local at service level is not supported.

Using the Equal Cost Multiple Path (ECMP)

December 21, 2020

By using the Equal Cost Multiple Path (ECMP) mechanism on a cluster deployment, active cluster nodes advertise the virtual server IP addresses. The cluster node which receives the advertised traffic steers the traffic to the node that must process the traffic. There can be redundant steering in spotted and partially striped virtual servers. Therefore, from NetScaler 11 onwards, spotted and partially striped virtual server IP addresses advertise the owner nodes, which reduce the redundant steering.

You must have detailed knowledge of routing protocols to use ECMP. For more information, see [Configuring Dynamic Routes](#). For more information on routing in a cluster, see [Routing in a Cluster](#).

To use ECMP, you must first perform the following:

- Enable the required routing protocol (OSPF, RIP, BGP, or ISIS) on the cluster IP address.
- Bind the interfaces and the spotted IP address (with dynamic routing enabled) to a VLAN.
- Configure the selected routing protocol and redistribute the kernel routes on the ZebOS by using the VTYSH shell.

Perform similar configurations on the cluster IP address and on the external connecting device.

Note

- Make sure that the licenses on the cluster support dynamic routing, otherwise ECMP does not work.
- ECMP is not supported for wildcard virtual servers since RHI needs a VIP address to advertise to a router and wildcard virtual servers. As they do not have associated VIP addresses.

Figure 1. ECMP topology

When you use the ECMP mechanism for traffic distribution on a cluster deployment, the active cluster nodes advertise the virtual server IP addresses to the upstream router. The ECMP router can reach the VIP address via SNIP0, SNIP1, or SNIP2. The traffic flow in the Figure 1 is described as follows:

1. The client sends a request to the VIP hosted on the cluster.
2. The upstream router, based on the learned routes of the VIP, forwards the packet to any one of the nodes. Let's say NS1. The node NS1 is the flow receiver.
3. The flow receiver (NS1) determines the node that must process the traffic, which is called the flow processor. For example, Node NS2 is the flow processor.
4. The flow receiver (NS1) with SNIP1 (97.131.0.2) steers the request to the flow processor (NS2) with SNIP2 (97.131.0.3).
5. The flow processor (NS2) establishes a connection with the server.

6. The server processes the request and sends the response to the SNIP address that sent the request to the server.

Notes:

- Only ACTIVE nodes advertise VIP routes.
- INACTIVE nodes do not advertise VIP routes.
- All ACTIVE nodes advertise striped VIPs.
- Only ACTIVE owner nodes advertise spotted or partially striped VIPs.

To configure ECMP on the cluster by using the command line interface

1. Log on to the cluster IP address.
2. Enable the routing protocol.

```
1 enable ns feature <feature>
```

Example: To enable the OSPF routing protocol.

```
1 enable ns feature ospf
```

3. Add a VLAN.

```
1 add vlan <id>
```

Example

```
1 add vlan 97
```

4. Bind the interfaces of the cluster nodes to the VLAN.

```
1 bind vlan <id> -ifnum <interface_name>
```

Example

```
1 bind vlan 97 -ifnum 0/1/2 1/1/2 2/1/2
```

5. Add a spotted SNIP address for each node and enable dynamic routing on it.

```
1 add ns ip <SNIP> <netmask> -ownerNode <positive_integer> -  
dynamicRouting ENABLED
```

Example

```
1 add ns ip 97.131.0.1 255.0.0.0 -ownerNode 0 -dynamicRouting  
ENABLED -type SNIP  
2 add ns ip 97.131.0.2 255.0.0.0 -ownerNode 1 -dynamicRouting  
ENABLED -type SNIP
```

```
3 add ns ip 97.131.0.3 255.0.0.0 -ownerNode 2 -dynamicRouting
   ENABLED -type SNIP
```

- Bind one of the spotted SNIP addresses to the VLAN. When you bind one spotted SNIP address to a VLAN, all other spotted SNIP addresses defined on the cluster in that subnet are automatically bound to the VLAN.

```
1 bind vlan <id> -IPAddress <SNIP> <netmask>
```

Example

```
1 bind vlan 97 -ipAddress 97.131.0.1 255.0.0.0
```

Note

You can use NSIP addresses of the cluster nodes instead of adding SNIP addresses. If so, you do not have to perform steps 3–6.

- Configure the routing protocol on ZebOS using the VTYSH shell.

Example:

To configure an OSPF routing protocol on node IDs 0, 1, and 2.

```
1 vtysh
2 ! interface vlan97 !
3 router ospf owner-node 0
4 ospf router-id 97.131.0.1 exit-owner-node
5 owner-node 1 ospf router-id 97.131.0.2
6 exit-owner-node
7 owner-node 2
8 ospf router-id 97.131.0.3 exit-owner-node redistribute kernel
   network 97.0.0.0/8 area 0 !
```

Note

For VIP addresses to be advertised, RHI setting is done by using the vserverRHILevel parameter as follows:

```
1 add ns ip <IPAddress> <netmask> -type VIP -vserverRHILevel <
   vserverRHILevel>
```

For OSPF specific RHI settings, there are more settings that can be done as follows:

```
1 add ns ip <IPAddress> <netmask> -type VIP -ospfLSAType \( TYPE1 |
   TYPE5 ) -ospfArea <positive\_integer>
```

Use the add ns ip6 command to perform the preceding commands on IPv6 addresses.

- Configure ECMP on the external switch. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1) switch. Similar configurations must be performed

on other switches.

```

1 //For OSPF (IPv4 addresses) Global config: Configure terminal
  feature ospf      Interface config: Configure terminal
  interface Vlan10      no shutdown      ip address 97.131.0.5/8
  Configure terminal  router ospf 1  network 97.0.0.0/8 area
  0.0.0.0 -----
2
3 //For OSPFv3 (IPv6 addresses) Global config: Configure terminal
  feature ospfv3      Configure terminal interface Vlan10      no
  shutdown      ipv6 address use-link-local-only      ipv6 router
  ospfv3 1 area 0.0.0.0      Configure terminal  router ospfv3 1

```

Router monitoring cluster nodes in ECMP deployment

In a cluster setup, on an owner node that has a spotted SNIP address configuration, you can now disable the ownerDownResponse option. By default, the option is enabled, allowing the node to respond to an ICMP/ARP/ICMP6/ND6 request coming from the upstream router. You can now disable this option to allow the router to monitor if a cluster node is active or inactive. When the router sends a request, if the option is disabled, it identifies the owner node to be inactive and unavailable for traffic distribution.

To configure ECMP for static routes traffic distribution by using the command line interface

```

1 add ns ip <ipaddress> <netmask> -ownernode <node-id> - ownerDownResponse
  disable

```

Use Case: ECMP with BGP routing

December 21, 2020

To configure ECMP with BGP routing protocol, perform the following steps:

1. Log on to the cluster IP address.
2. Enable BGP routing protocol.

```

1 > enable ns feature bgp

```

3. Add VLAN and bind the required interfaces.

```

1 > add vlan 985
2 > bind vlan 985 -ifnum 0/0/1 1/0/1

```

4. Add the spotted IP address and bind them to the VLAN.

```
1 > add ns ip 10.100.26.14 255.255.255.0 -ownerNode 1 -  
    dynamicRouting ENABLED  
2 > add ns ip 10.100.26.15 255.255.255.0 -ownerNode 2 -  
    dynamicRouting ENABLED  
3 > bind vlan 985 -ipAddress 10.100.26.10 255.255.255.0
```

5. Configure BGP routing protocol on ZebOS using the VTYSH shell.

```
1 > vtysh conf t router bgp 65535 neighbor 10.100.26.1 remote-as  
    65535
```

6. Configure BGP on the external switch. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1) switch. Similar configurations must be performed on other switches.

```
1 > router bgp 65535 no synchronization  
2   bgp log-neighbor-changes neighbor 10.100.26.14 remote-as 65535  
    neighbor 10.100.26.15 remote-as 65535 no auto-summary  
3   dont-capability-negotiate  
4   dont-capability-negotiate  
5   no dynamic-capability
```

Configuration of cluster ECMP by using Cisco Nexus 7000 switch with routing Protocol

May 2, 2023

With ECMP over a cluster setup, a NetScaler appliance is able to handle the traffic through a routing protocol. The ECMP mechanism helps in advertising the virtual server IP addresses through all active cluster nodes.

To use ECMP, you must first enable the BGP protocol on the cluster IP address. Bind the interfaces and the spotted IP address (with dynamic routing enabled) to a VLAN. Configure the selected routing protocol and redistribute the kernel routes on the ZebOS by using the VTYSH shell.

Use Case: Cluster ECMP by using Cisco Nexus 7000 switch with routing Protocol

Consider an example of a cluster deployment with a Cisco Nexus 7000 switch:

- Two NetScaler appliances (Node 1 and Node 2), connected to the Nexus switch (upstream).
- Two Cisco Nexus 7000 switch.
- Client and server (drawing HTTP traffic through the Nexus switch). With Hot Standby Router Protocol (HSRP) enabled on the client-side.

Prerequisites

Consider the following points before configuring cluster nodes on a NetScaler appliance.

1. All appliances must be of the same platform type.
2. Border Gateway Protocol (BGP) must be enabled on the cluster nodes.

Configuring by using the CLI on a NetScaler appliance

1. Log on to an appliance (for example, appliance with NSIP address 1.1.1.1)
2. To add a cluster node.

```
1 add cluster node 0 1.1.1.2 - state ACTIVE - backplane 0/10/8
```

3. To add the cluster IP address

```
1 add ns ip 1.1.1.10 255.255.255.254 - type clip
```

4. Save the configuration

```
1 save ns config
```

5. Warm reboot the appliance

```
1 reboot -warm
```

6. To add node 1 using CLIP

```
1 add cluster node 1 2.2.2.2 -state ACTIVE -backplane 1/10/8
```

7. To join a node to the cluster

```
1 join cluster -clip 1.1.1.10 -password nsroot
```

8. Perform the following configuration on CLIP

- `enable ns feature bgp ospf DYNAMICROUTING`
- `add ns ip 11.1.1.3 255.255.255.254 -dynamicRouting ENABLED -ownerNode 0`
- `add ns ip 11.1.1.7 255.255.255.254 -dynamicRouting ENABLED -ownerNode 0`
- `add ns ip 11.1.1.5 255.255.255.254 -dynamicRouting ENABLED -ownerNode 1`
- `add ns ip 11.1.1.9 255.255.255.254 -dynamicRouting ENABLED -ownerNode 1`

On the Cisco Nexus router (11.1.1.2/31 and 11.1.1.4/31), you must perform the following configurations by using the command line:

- `feature ospf`
- `feature bgp`
- `feature interface-vlan`
- `feature hsrp`

```
1 > interface vlan100
2   no shutdown
3   ip address 50.1.1.1/8
4   hsrp 50
5     ip 50.50.50.50
6
7 > interface Ethernet 4/15
8   ip address 11.1.1.2/31
9   no shutdown
10
```

```
11 > interface Ethernet 4/19
12     ip address 11.1.1.4/31
13     no shutdown
14
15 > interface Ethernet 4/22
16     switchport
17     switchport access vlan 100
```

On the Cisco Nexus router (11.1.1.6/31 and 11.1.1.8/31), you must perform the following configurations by using the command line:

- feature ospf
- feature bgp
- feature **interface-vlan**
- feature hsrp

```
1 > interface vlan100
2     no shutdown
3     no ip redirects
4     ip address 50.1.1.2/8
5     hsrp 50
6     ip 50.50.50.50
7
8 > interface Ethernet 4/13
9     ip address 11.1.1.6/31
10    no shutdown
11
12 > interface Ethernet 4/15
13    ip address 11.1.1.8/31
14    no shutdown
15
16 > interface Ethernet 4/22
17    switchport
18    switchport access vlan 100
```

For the BGP protocol, you must perform the following configurations on CLIP of the NetScaler appliance:

```
1 > vtysh
2 ns# router bgp 1
3 redistribute kernel
4 owner-node 0
5 neighbor 11.1.1.2 remote-as 2
6 neighbor 11.1.1.2 as-origination-interval 1
7 neighbor 11.1.1.2 advertisement-interval 0
8 neighbor 11.1.1.6 remote-as 2
9 neighbor 11.1.1.6 as-origination-interval 1
10 neighbor 11.1.1.6 advertisement-interval 0
11 owner-node 1
12 neighbor 11.1.1.4 remote-as 2
```

```
13 neighbor 11.1.1.4 as-origination-interval 1
14 neighbor 11.1.1.4 advertisement-interval 0
15 neighbor 11.1.1.8 remote-as 2
16 neighbor 11.1.1.8 as-origination-interval 1
17 neighbor 11.1.1.8 advertisement-interval 0
18 exit-owner-node
```

Perform the following configurations on the Cisco Nexus router (11.1.1.3 and 11.1.1.5)

```
1 > ip access-list acl1
2 10 permit ip 50.0.0.0/8 any
3 route-map test permit
4 match ip address acl1
5 router bgp 2
6 address-family ipv4 unicast
7 redistribute direct route-map test
8 maximum-paths 2
9 neighbor 11.1.1.3 remote-as 1
10 address-family ipv4 unicast
11 neighbor 11.1.1.5 remote-as 1
12 address-family ipv4 unicast
```

Perform the following configurations on the Cisco Nexus router (11.1.1.7 and 11.1.1.9)

```
1 > ip access-list acl1
2 10 permit ip 50.0.0.0/8 any
3 route-map test permit 1
4 match ip address acl1
5 router bgp 2
6 address-family ipv4 unicast
7 redistribute direct route-map test
8 maximum-paths 2
9 neighbor 11.1.1.7 remote-as 1
10 address-family ipv4 unicast
11 neighbor 11.1.1.9 remote-as 1
12 address-family ipv4 unicast
```

For the OSPF protocol, you must perform the following configurations on CLIP of the NetScaler appliance:

```
1 > vtysh
2 ns# router ospf 1
3 redistribute kernel
4 owner-node 0
5 network 15.1.1.2/31 area 0
6 network 15.1.1.6/31 area 0
7 exit-owner-node
8
9 owner-node 1
10 network 15.1.1.4/31 area 0
11 network 15.1.1.8/31 area 0
12 exit-owner-node
13
```

```
14 route-map map2 permit 1
15 set metric 10
```

On the Cisco Nexus router (11.1.1.2/31 and 11.1.1.4/31), you must perform the following configurations by using the command line:

```
1 > route-map- map2 permit 1
2   set metric 10
3
4 interface Ethernet4/15
5   ip address 15.1.1.2/31
6   ip router ospf 1 area 0.0.0.0
7   no shutdown
8
9 interface Ethernet4/19
10  ip address 15.1.1.4/31
11  ip router ospf 1 area 0.0.0.0
12  no shutdown
13
14  router ospf 1
15  router-id 1.1.1.1
16  redistribute direct route-map map2
```

On the Cisco Nexus router (11.1.1.7/31 and 11.1.1.9/31), you must perform the following configurations by using the command line:

```
1 > route-map- map2 permit 1
2   set metric 10
3
4 interface Ethernet4/13
5   ip address 15.1.1.6/31
6   ip router ospf 1 area 0.0.0.0
7   no shutdown
8
9 interface Ethernet4/15
10  ip address 15.1.1.8/31
11  ip router ospf 1 area 0.0.0.0
12  no shutdown
13
14  router ospf 1
15  router-id 1.1.1.2
16  redistribute direct route-map map2
```

Using cluster link aggregation

May 2, 2023

Cluster link aggregation is a group of interfaces of cluster nodes. It is an extension of NetScaler link

aggregation. The only difference is that, while link aggregation requires the interfaces to be from the same device, in cluster link aggregation, the interfaces are from different nodes of the cluster. For more information about link aggregation, see [Configuring Link Aggregation](#).

Important

- Cluster link aggregation is supported for a cluster of hardware (MPX) appliances.
- Cluster link aggregation is supported for a cluster of virtual (VPX) appliances that are deployed on ESX and KVM hypervisors, with the following restrictions:
- Dedicated interfaces must be used. It means that the interfaces must not be shared with other virtual machines.
- When a node becomes INACTIVE, the corresponding cluster LA interface is marked as power DOWN, so that the data traffic is not sent to an INACTIVE node.
- When a node becomes ACTIVE, the corresponding cluster LA interface is marked as power ON.
- If the cluster link aggregation member interfaces are manually disabled or if cluster link aggregation itself is manually disabled, then interface power down capability is achieved only by the LACP timeout mechanism.
- Jumbo MTU is not supported on LACP cluster link aggregation.

Note: Cluster link aggregation is not supported on VPX appliances that are deployed on XenServer, AWS, and Hyper-V.

- Starting from 12.0 release, cluster link aggregation is supported on NetScaler SDX appliances.
- The number of interfaces that can be bound to cluster LA is 16 (from each node). The maximum number of interfaces in cluster LA can be $(16 * n)$, where n is the number of nodes in a cluster. The total number of interfaces in cluster LA depends on the number of interfaces for every port channel on the upstream switch.
- If a NetScaler appliance uses Intel Fortville interfaces, the switchover of a cluster node to passive mode might cause a few seconds of outage with CLAG. The issue occurs because LACP is enabled for CLAG to function properly, and the outage time depends on NIC LACP timers.

For example, consider a three-node cluster where all three nodes are connected to the upstream switch. A cluster LA channel (CLA/1) is formed by binding interfaces 0/1/2, 1/1/2, and 2/1/2.

Figure 1. Cluster Link Aggregation topology

A cluster LA channel has the following attributes:

- Each channel has a unique MAC agreed upon by cluster nodes.
- The channel can bind both local and remote nodes' interfaces.
- A maximum of four cluster LA channels are supported in a cluster.
- Backplane interfaces cannot be part of a cluster LA channel.
- When an interface is bound to a cluster LA channel, the channel parameters have precedence over the network interface parameters. A network interface can be bound to one channel only.
- Management access to a cluster node, must not be configured on a cluster LA channel (for example, CLA/1) or its member interfaces. This is because when the node is INACTIVE, the corresponding cluster LA interface is marked as power down, and therefore loses management access.

Figure 2. Traffic distribution flow using cluster LA

Backup and restore support of cluster LA on NetScaler MPX

You can backup and restore the cluster setup of LA on NetScaler MPX. The cluster LA MAC address is independent of the physical interface MAC address of the cluster nodes, and can change after the backup and restore process. The cluster LA can serve the traffic after a cluster restore process is complete. For more information about backup and restore, see [Backup and restore of cluster setup](#)

Static cluster link aggregation

December 7, 2020

You must configure a static cluster LA channel on the cluster IP address and on the external connecting device. If possible, configure the upstream switch to distribute traffic based on IP address or port instead of MAC address.

To configure a static cluster LA channel by using the CLI

1. Log on to the cluster IP address.

Note

Make sure that you configure the cluster LA channel on the cluster IP address before configuring link aggregation on the external switch. Otherwise, the switch forwards traffic to the cluster even though the cluster LA channel is not configured. It can lead to loss of traffic.

2. Create a cluster LA channel.

```
1 add channel <id> -speed <speed>
```

Example

```
1 add channel CLA/1 -speed 1000
```

Note

You must not specify the speed as AUTO. Rather, you must explicitly specify the speed as 10, 100, 1000, or 10000. Only interfaces that have the speed matching the <speed> attribute in the cluster LA channel are added to the active distribution list.

3. Bind the required interfaces to the cluster LA channel. Make sure that the interfaces are not used for the cluster backplane.

```
1 bind channel <id> <ifnum>
```

Example

```
1 bind channel CLA/1 0/1/2 1/1/2 2/1/2
```

4. Verify the configurations.

```
1 show channel <id>
```

Example

```
1 show channel CLA/1
```

Note

You can bind the cluster LA channel to a VLAN by using the `bind vlan` command. The interfaces of the channel are automatically bound to the VLAN.

5. Configure static LA on the external switch. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1). Similar configurations must be performed on other switches.

```
1 Global config:
2 Configure terminal
3
4 Interface level config:
5
6 interface Ethernet2/47
7 switchport
8 switchport access vlan 10
9 channel-group 7 mode on
10 no shutdown
11
12 interface Ethernet2/48
13 switchport
14 switchport access vlan 10
15 channel-group 7 mode on
16 no shutdown
```

Dynamic cluster link aggregation

May 2, 2023

Dynamic cluster LA channel uses the Link Aggregation Control Protocol (LACP).

You must perform similar configurations on the cluster IP address and on the external connecting device. If possible, configure the upstream switch to distribute traffic based on IP address or port instead of MAC address.

Points to remember

- Enable LACP (by specifying the LACP mode as either ACTIVE or PASSIVE).

```

1 >***Note**
2 >
3 > Make sure the LACP mode is not set as PASSIVE on both the NetScaler
   cluster and the external connecting device.

```

- Specify the same LACP key on each interface that you want to be the part of the channel. For creating a cluster LA channel, the LACP key can have a value from 5 through 8. For example, if you set the LACP key on interfaces 0/1/2, 1/1/2, and 2/1/2 to 5, CLA/1 is created. The interfaces 0/1/2, 1/1/2, and 2/1/2 are automatically bound to CLA/1. Similarly, if you set the LACP key to 6, the CLA/2 channel is created.
- Specify the LAG type as Cluster.

To configure a dynamic cluster LA channel by using the CLI

On the cluster IP address, for each interface that you want to add to the cluster LA channel, type:

```
set interface <id> -lacpMode <lacpMode> -lacpKey <positive_integer> -
lagType CLUSTER<!--NeedCopy-->
```

Example:

To configure a cluster LA channel CLA/1 of 3 interfaces.

```

1 > set interface 0/1/2 -lacpMode active -lacpKey 5 -lagType Cluster
2 > set interface 1/1/2 -lacpMode active -lacpKey 5 -lagType Cluster
3 > set interface 2/1/2 -lacpMode active -lacpKey 5 -lagType Cluster

```

Note

Optionally, you can enable [Link Redundancy in a Cluster with LACP](#).

Similarly, configure dynamic LA on the external switch. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1). Similar configurations must be performed on other switches.

```

1 Global config:
2 Configure terminal
3 feature lacp
4 Interface level config:
5
6 interface Ethernet2/47
7 switchport
8 switchport access vlan 10

```

```
9 channel-group 7 mode active
10 no shutdown
11
12 interface Ethernet2/48
13 switchport
14 switchport access vlan 10
15 channel-group 7 mode active
16 no shutdown
```

Link redundancy in a cluster with LACP

May 2, 2023

A NetScaler cluster provides link redundancy for LACP to ensure that all nodes have the same partner key.

To understand the need for link redundancy, let us consider the example of the following cluster setup along with the accompanying cases (with attention to case 3):

In this setup, interfaces I1, I2, I3, and I4 are bound to the LACP channel with KEY 5. On the partner side, I1 and I2 are connected to Switch 1 to form a single LA channel with KEY 1. Similarly, I3 and I4 are connected to Switch 2 to form a single LA channel with KEY 2.

Now let us consider the following cases to understand the need for link redundancy:

- **Case 1: Switch 1 is up and Switch 2 is down**

In this case, cluster LA on both the nodes would stop receiving LACPDU from Key2 and would start receiving LACPDU from Key1. On both the nodes, cluster LA is connected to KEY 1 and I1

and I2 is UP and the channel on both the nodes would be UP.

- **Case 2: Switch1 goes down and Switch2 becomes UP**

In this case, cluster LA on both the nodes would stop receiving LACPDUs from Key1 and would start receiving LACPDUs from Key2. On both the nodes, cluster LA is connected to Key2 and I3 and I4 is UP and the channel on both the nodes would be UP.

- **Case 3: Both Switch1 and Switch2 are UP**

In this case, it is possible that cluster LA on node1 chooses Key1 as its partner and cluster LA on node2 chooses Key2 as its partner. It means that I1 on node1 and I4 on node2 are receiving traffic which is undesirable. It can happen because the LACP state machine is node-level and chooses its partners on first-come first-serve basis.

To solve these concerns, link redundancy of dynamic cluster LA is supported. To configure link redundancy on a channel or interface, you must enable it and optionally specify the threshold throughput as follows:

```
set channel CLA/1 -linkRedundancy ON -lrMinThroughput <positive_integer>
```

The throughput of the partner channels is checked against the configured threshold throughput. The partner channel that satisfies the threshold throughput is selected in a first-in-first-out (FIFO) manner. If none of the partner channel meets the threshold, or if threshold throughput is not configured, the partner channel with the maximum number of links is selected.

Note

The threshold throughput can be configured from NetScaler 11 onwards.

Using USIP mode in cluster

May 2, 2023

In use source IP (USIP) mode, the cluster, or NetScaler appliance forwards each packet to the appropriate back-end server with the client IP address.

USIP mode traffic distribution

The USIP mode behavior differs traffic distribution across client data plane and server data plane in ECMP and CLAG deployment. The following section provides more information about USIP mode behavior. For more information related to CLAG on USIP mode, see [Using cluster link aggregation](#).

USIP mode

The cluster uses the client IP to open the server-side connection. The source port may or might not be preserved based on the `useproxyport` setting.

USIP useproxyport scenarios

The USIP `useproxyport` is ON for the traffic flow, the source port is selected in a way that the reverse traffic hashes to the flow processor. It ensures single steering on the server side.

The USIP `useproxyport` is OFF for the traffic flow, the source port is preserved and hence there is double steering on the server side.

Important

- When USIP is ON, the client IP is used in back end server connection, and traffic distribution for response is needed across cluster nodes. You can use ECMP or CLAG deployment for traffic distribution on the server side. In the absence of traffic distribution on the server side, the whole return traffic might land on a single cluster node, resulting in congestion.
- The `set rsskeytype -rsskey symmetric` command is used to reduce double steering to single steering of traffic in the `useproxyport` off deployments. Where the 4-tuple for the connection remains the same for the server and client side. For example, wildcard MAC mode virtual server.

Limitations

The USIP does not work when the process local is disabled.

USIP mode deployment

The following figure depicts a USIP mode deployment in a cluster setup.

Configure the following using CLI

1. Enable the routing protocol.

```
1 enable ns feature <feature>
```

Example:

```
1 enable ns feature ospf
```

2. Add a spotted SNIP address for each node and enable dynamic routing on it.

```
1 add ns ip <SNIP> <netmask> -dynamicRouting \( ENABLED | DISABLED )
   - ownerNode <positive\_interger> - ownerdownResponse \( YES |
   NO )
```

Example

```
1 - add ns ip 192.0.2.1 255.255.255.0 -dynamicRouting ENABLED -
   ownerNode 0 - ownerDownResponse NO
2 - add ns ip 192.0.2.2 255.255.255.0 -dynamicRouting ENABLED -
   ownerNode 1 - ownerDownResponse NO
3 - add ns ip 192.0.2.3 255.255.255.0 -dynamicRouting ENABLED -
   ownerNode 2 - ownerDownResponse NO
```

3. Add a VLAN.

```
1 add vlan <id>
```

Example

```
1 add vlan 300
```

4. Bind the interfaces of the cluster nodes to the VLAN.

```
1 bind vlan <id> -ifnum <interface_name>
```

Example

```
1 bind vlan 300 -ifnum 0/1/2 1/1/2 2/1/2
```

5. Bind one of the spotted SNIP addresses to the VLAN. When you bind one spotted SNIP address to a VLAN, all other spotted SNIP addresses defined on the cluster in that subnet are automatically bound to the VLAN.

```
1 bind vlan <id> -IPAddress <ip\_addr | ipv6\_addr> -netmask
```

Example

```
1 bind vlan 300 -IPAddress 192.0.2.1 255.255.255.0
```

6. Configure the routing protocol on ZebOS using the VTYSH shell. Configure OSPF routing protocol on node IDs 0, 1, and 2.

```
1 vtysh
2 configure terminal
3 ns block-sec-rtadv
4 router ospf
5 owner -node 0
6 router-id 192.0.2.1
7 exit-owner-node
8 owner-node 1
```

```
9  router-id 192.0.2.2
10 exit-owner-node
11 owner-node 2
12 router-id 192.0.2.3
13 exit-owner-node
14 network 192.0.2.0/24 area 0
15
16 default-information originate always
```

7. Perform the following configurations on the Cisco 3750 router by using the CLI.

```
1  Configure terminal
2  feature ospf
3  interface vlan300
4  no shutdown
5  ip address 192.0.2.100/24
6  Configure terminal
7  router ospf 1
8  router-id 192.0.2.100
9  network 192.0.2.0 0.0.0.255 area 0
```

Notes

- Traffic distribution on client and server need not be the same. For example, you can configure ECMP on the client side and CLAG on the server side or the opposite way.
- Plan for extra capacity of the backplane as there is more steering overhead in the USIP deployment.
- The Configuration related to CLAG and Monitor Static Route (MSR) must remain the same on the server side.
- Traffic steering is more in the USIP mode deployments.

Managing the NetScaler cluster

May 2, 2023

After you have created a cluster and configured the required traffic distribution mechanism, the cluster is able to serve traffic. During the lifetime of the cluster, you can perform the following cluster tasks:

- Configuring node groups
- Disabling nodes of a cluster
- Discovering NetScaler appliances
- Viewing statistics
- Synchronizing cluster configurations, and cluster files

- Synchronizing the time across the nodes
- Upgrading or downgrading the software of cluster nodes

Configuring linksets

December 24, 2020

Linkset is a group of interfaces of cluster nodes that belong to the same broadcast domain. In linksets, each node has the information about which interfaces of other nodes are connected to the same broadcast domain.

Note

Linksets are a mandatory configuration in the following scenarios:

- For deployments that require MAC-Based Forwarding (MBF).
- For “-m MAC” mode that is enabled at the virtual server along with MBF mode enabled globally.
- To improve the manageability of ACL and L2 policies involving interfaces. You define a linkset of the interfaces and add ACL and L2 policies based on linksets.

In a cluster setup, the following features use MBF internally.

- Forwarding session
- L2Conn
- MAC mode virtual server
- Transparent monitor
- LLB

Linksets must be configured only through the cluster IP address.

Consider an example with a three node cluster. In the following figure, the interfaces 0/1/2, 1/1/2, and 2/1/2 are in the same broadcast domain and therefore can be configured as linkset (LS/1).

Figure 1. Linksets topology

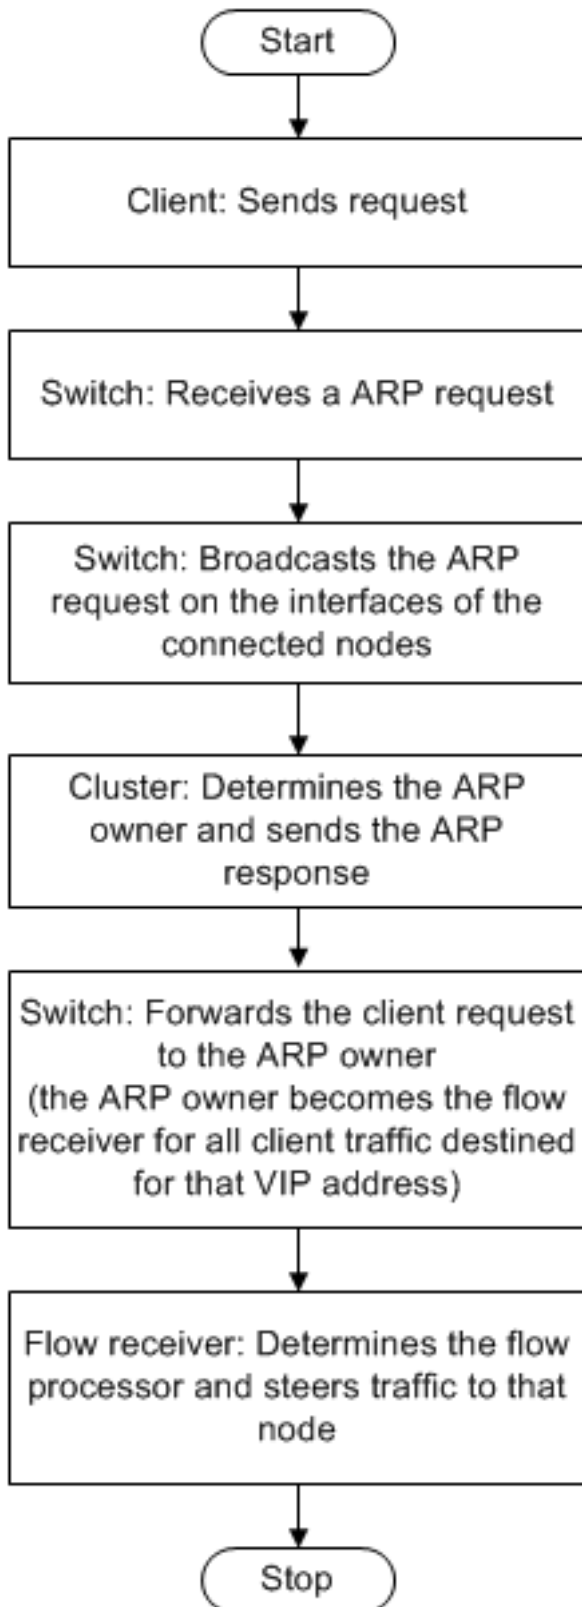

Figure 2. Traffic distribution flow using linksets

To configure a linkset by using the CLI

1. Log on to the cluster IP address.
2. Create a linkset.

“add linkset

```
1  **Example**
2
3  ``add linkset LS/1<!--NeedCopy-->
```

3. Bind the required interfaces to the linkset. Make sure the interfaces are not used for the cluster backplane.

“bind linkset -ifnum ...

```
1  **Example**
2
3  ``bind linkset LS/1 -ifnum 0/1/2 1/1/2 2/1/2<!--NeedCopy-->
```

4. Verify the linkset configurations.

“show linkset

```
1  **Example**
2
3  ``show linkset LS/1<!--NeedCopy-->
```

Note

You can bind the linkset to a VLAN by using the `bind vlan` command. The interfaces of the linkset are automatically bound to the VLAN.

To configure a linkset by using the GUI

1. Log on to the cluster IP address.
2. Navigate to **System > Network > Linksets**.
3. In the details pane, click **Add**.
4. In the **Create Linkset** dialog box:
 - Specify the name of the linkset by setting the Linkset parameter.
 - Specify the Interfaces to be added to the linkset and click Add. Repeat this step for each interface you want to add to the linkset.
5. Click **Create**, and then click **Close**.

Node groups for spotted and partially striped configurations

May 2, 2023

By virtue of the default cluster behavior, all configurations performed on the cluster IP address are available on all nodes of the cluster. However, there might be cases where you need some configurations to be available only on specific cluster nodes.

You can achieve this requirement by defining a node group that includes the specific cluster nodes, and then binding the configuration to that node group. It ensures that the configuration is active only on those cluster nodes. These configurations are called partially striped or spotted (if active only on a single node). For more information, see [Striped, Partially Striped, and Spotted Configurations](#).

For example, consider a cluster with three nodes. You create a node group NG0 that includes node n1 and another node group NG1 that includes n2 and n3. Bind load balancing virtual servers 0.77 to NG0 and load balancing virtual server 0.69 to NG1.

It means that virtual server 0.77 is active only on n1 and therefore only n1 receives the traffic that is directed to 0.77. Similarly, virtual server 0.69 is active only on nodes n2 and n3 and therefore only n2 and n3 receives traffic that is directed to 0.69.

Figure 1. NetScaler cluster with node groups configured for spotted and partial-striped configurations

The entities or configurations that you can bind to a node group are:

- Load balancing, content switching, cache redirection, authentication, authorization, and auditing virtual servers

Note

FTP load balancing virtual servers cannot be bound to node groups.

- VPN virtual server (Supported from NetScaler 10.5 Build 50.10 onwards)
- Global Server Load Balancing (GSLB) sites and other GSLB entities (Supported from NetScaler 10.5 Build 52.11 onwards)
- Limit identifiers and stream identifiers

Behavior of node groups

May 2, 2023

Due to the interoperability of node groups with different NetScaler features and entities, there are some behavioral aspects to be noted. Nodes in a node group can also be backed up. Read on for more information.

General behavior of a cluster node group

- A node group that has entities bound to it cannot be removed.
- A cluster node that belongs to a node group with entities bound to it, cannot be removed.
- A cluster instance that has node groups with entities bound to it, cannot be removed.
- You cannot add an entity that has a dependency on another entity. It must not be a part of the node group. If you must do so, first remove the dependency. Then, add both the entities to the node group and reassociate the entities.

Examples:

- Assume you have a virtual server, VS1, whose backup is virtual server VS2. To add VS1 to a node group, first make sure that VS2 is removed as the backup server of VS1. Then, bind each server individually to the node group, and then configure VS2 as the backup for VS1.
 - Assume you have a content switching virtual server, CSVS1, whose target load balancing virtual server is LBVS1. To add CSVS1 to a node group, first remove LBVS1 as the target. Then, bind each server individually to the node group, and then configure LBVS1 as the target.
 - Assume you have a load balancing virtual server, LBVS1, that has a policy which invokes another load balancing virtual server, LBVS2. To add either one of the virtual servers, first remove the association. Then, bind each server individually to the node group, and then reassociate the virtual servers.
- You cannot bind an entity to a node group. It has no nodes and that has the strict option enabled. Therefore, you cannot unbind the last node of a node group that has entities bound to it and that has the strict option enabled.
 - The strict option cannot be modified for a node group that has no nodes but has entities bound to it.

Backing up nodes in a node group

By default, a node group is designed to provide back up nodes for members of a node group. If a node group member goes down, a cluster node that is not a member of the node group dynamically replaces the failed node. This node is called the replacement node.

Note

For a single-member node group, a backup node is automatically preselected when an entity is bound to the node group.

When the original member of the node group comes up, the replacement node, by default, is replaced by the original member node.

From NetScaler 10.5 Build 50.10 onwards, however, the NetScaler allows you to change this replacement behavior. When you enable the sticky option, the replacement node is retained even after the original member node comes up. The original node takes over only when the replacement node goes down.

You can also disable the backup functionality. To do it, you must enable the strict option. In this scenario, when a node group member goes down, no other cluster node is picked up as a backup node. The original node continues being part of the node group when it comes up. This option ensures that entities bound to a node group are active only on node group members.

Note

The strict and sticky option can be set only when creating a node group.

Configuring node groups for spotted and partially striped configurations

May 2, 2023

To configure a node group for spotted and partially striped configurations you must first create a node group and then bind the required nodes to the node group. You then associate the required entities to that node group. The entities that are bound to the node group are of the following:

- **Spotted** - If bound to a node group that has a single node.
- **Partially Striped** - If bound to a node group that has more than one node.

Some points to remember:

- GSLB is supported on a cluster only when GSLB sites are bound to node groups that have a single cluster node. For more information, see [Setting Up GSLB in a Cluster](#).
- NetScaler Gateway is supported on a cluster only when the VPN virtual servers are bound to node groups that have a single cluster node. The sticky option must be enabled on the node group.
- For versions prior to NetScaler 11, the application firewall is supported only on individual cluster nodes (spotted configuration). Application firewall profiles can be associated only with virtual servers that are bound to node groups that have a single cluster node. It means that application you are not allowed to do the following:
 - Bind application firewall profiles to striped or partially striped virtual servers.
 - Bind the policy to a global bind point or to user-defined policy labels.
 - Unbind, from a node group, a virtual server that has application firewall profiles.
- NetScaler 11 introduced application firewall support for striped and partially striped configurations. For more information, see [Application Firewall Support for Cluster Configurations](#).

Check [NetScaler Features Supported in a Cluster](#) to see the NetScaler versions from which GSLB, NetScaler Gateway, and application firewall are supported in a cluster.

To configure a node group by using the command line interface

1. Log on to the cluster IP address.
2. Create a node group. Type:

```
add cluster nodegroup <name> -strict (YES | NO)<!--NeedCopy-->
```

Example

```
1 add cluster nodegroup NG0 -strict YES
```

3. Bind the required nodes to the node group. Type the following command for each member of the node group:

```
bind cluster nodegroup <name> -node <nodeId><!--NeedCopy-->
```

Example

To bind nodes with IDs 1, 5, and 6.

```
1 > bind cluster nodegroup NG0 -node 1
2 > bind cluster nodegroup NG0 -node 5
3 > bind cluster nodegroup NG0 -node 6
```

4. Bind the entity to the node group. Type the following command once for every entity that you want to bind:

```
bind cluster nodegroup <name> (-vServer <string> | -identifierName
  <string> | -gslbSite <string> -service <string>)<!--NeedCopy-->
```

Note

The gslbSite and service parameters are available from NetScaler 10.5 onwards.

Example

To bind virtual servers VS1 and VS2 and rate limit identifier named identifier1.

```
1 > bind cluster nodegroup NG0 -vServer VS1
2 > bind cluster nodegroup NG0 -vServer VS2
3 > bind cluster nodegroup NG0 -identifierName identifier1
```

5. Verify the configurations by viewing the details of the node group. Type:

```
show cluster nodegroup <name><!--NeedCopy-->
```

Example

```
1 > show cluster nodegroup NG0
```

To configure a node group by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to **System > Cluster > Node Groups**.
3. In the details pane, click **Add**.
4. In the **Create Node Group** dialog box, configure the node group:
 - a) Under **Cluster Nodes**, click the **Add** button.
 - The Available list displays the nodes that you can bind to the node group and the Configured list displays the nodes that are bound to the node group.
 - Click the + sign in the Available list to bind the node. Similarly, click the - sign in the Configured list to unbind the node.
 - b) Under **Virtual Servers**, select the tab corresponding to the type of virtual server that you want to bind to the node group. Click the **Add** button.
 - The Available list displays the virtual servers that you can bind to the node group and the Configured list displays the virtual servers that are bound to the node group.
 - Click the + sign in the Available list to bind the virtual server. Similarly, click the - sign in the Configured list to unbind the virtual server.

Configuring redundancy for node groups

May 2, 2023

Note

Supported from NetScaler 10.5 Build 52.1115.e onwards.

Node groups can be configured such that when one node group goes down, another node group can take over and process traffic. For example, when a node group NG1 goes down, NG2 takes over.

Note

This functionality can be used to configure data center redundancy where each node group is configured as a data center.

To achieve this use case, cluster nodes must be logically grouped into node groups, where some node groups must be configured as ACTIVE and others as SPARE. The active node group with the highest priority (that is, the lowest priority number) is made operationally active and therefore serves traffic. When a node from this operationally active node group goes down, the node count of this node group is compared with the node count of the other active node groups in order of their priority. If a node group has a higher or equal node count, that node group is made operationally active. Else, the spare node groups are checked.

Note

- Only one state-specific node group can be active at a given point in time.
- A cluster node inherits the state of the node group. So, if a node with “SPARE” state is added to the node group with state as “ACTIVE”, the node automatically behaves as an active node.
- The pre-emption parameter that is defined for the cluster instance decides whether the initial active node group takes the control when it comes up again.
- A spare node group can take up a node group and host active traffic when an active node group goes down.

The following figure shows a node group setup that has node group redundancy defined. NG1 is initially the active node group. When it loses one of the nodes, the spare node group (NG3) with the highest priority starts serving traffic.

Figure 1. NetScaler cluster with node group redundancy configured.

Configuring redundancy for node groups

1. Log on to the cluster IP address.
2. Create the active node group and bind the required cluster nodes.

```

1 > add cluster nodegroup NG1 -state ACTIVE
2 > bind cluster nodegroup NG1 -node n1
3 > bind cluster nodegroup NG1 -node n2
4 > bind cluster nodegroup NG1 -node n3
    
```

3. Create the spare node group and bind the requisite nodes.

```

1 > add cluster nodegroup NG2 -state SPARE -priority 20
2 > bind cluster nodegroup NG2 -node n4
3 > bind cluster nodegroup NG2 -node n5
4 > bind cluster nodegroup NG2 -node n6
    
```

4. Create another spare node group and bind the requisite nodes.

```

1 > add cluster nodegroup NG3 -state SPARE -priority 10
2 > bind cluster nodegroup NG3 -node n7
3 > bind cluster nodegroup NG3 -node n8
4 > bind cluster nodegroup NG3 -node n9
    
```

Disabling steering on the cluster backplane

May 2, 2023

Note

Supported from NetScaler 11 onwards.

The default behavior of a NetScaler cluster is to direct the traffic that it receives (flow receiver) to another node (flow processor). The flow processor must then process the traffic. This process of directing the traffic from flow receiver to flow processor occurs over the cluster backplane and is called steering.

If necessary, you can disable steering so that the process becomes local to the flow receiver and therefore makes the flow receiver as the flow processor. Such a configuration setup can come handy when you have a high latency link.

Note

This configuration is applicable only for striped virtual servers.

- For partially striped virtual servers, if the flow receiver is a non-owner node, the traffic is steered to an owner node. If however, the flow receiver is an owner node, then steering is disabled.
- For spotted virtual servers, the flow receiver is the flow processor, and hence there is no need for steering.

Some points to remember when disabling the steering mechanism:

- Striped SNIPs are not supported as steering is disabled.
- MPTCP and FTP do not work.
- L2 mode must be disabled.
- If USIP is enabled, traffic might not reach back to the same node as the steering is disabled.
- Traffic that is directed to the cluster IP address is steered to the configuration coordinator.
- When a node joins or leaves a cluster, it is possible that more than 1/N connections are affected. It is because a change in the nodes available, might cause the routes to be reshaped. As a result, the traffic is routed to another node and due to the non-availability of steering, the traffic is not processed.

Steering can be disabled at the individual virtual server level or at the global level. The global configuration takes precedence over the virtual server setting.

- Disabling backplane steering for all striped virtual servers

Configured at cluster instance level. Traffic meant for any striped virtual server is not steered on the cluster backplane.

```
add cluster instance \<clId\> -processLocal ENABLED<!--NeedCopy
-->
```

- Disabling backplane steering for a specific striped virtual server

Configured on a striped virtual server. Traffic meant for the virtual server is not steered on the cluster backplane.

```
add lb vserver <name> <serviceType> -processLocal ENABLED<!--
NeedCopy-->
```

Synchronizing cluster configurations

May 2, 2023

NetScaler configurations that are available on the configuration coordinator are synchronized to the other nodes of the cluster when:

- A node joins the cluster
- A node rejoins the cluster
- A new command is run through the cluster IP address

Also, you can forcefully synchronize the configurations that are available on the configuration coordinator (full synchronization) to a specific cluster node. Make sure you synchronize one cluster node at a time, otherwise the cluster can get affected.

To synchronize cluster configurations by using the CLI:

At the command prompt of the appliance on which you want to synchronize the configurations, type:

```
1 force cluster sync
```

To synchronize cluster configurations by using the GUI:

1. Log on to the appliance on which you want to synchronize the configurations.
2. Navigate to **System > Cluster**.
3. In the details pane, under **Utilities**, click Force cluster sync.
4. Click **OK**.

Display list of commands failed during cluster config synchronization

In a cluster setup, with sync status strict mode `syncStatusStrictMode` enabled, you can display the list of commands failed during a cluster synchronization on a non-CCO node.

You can determine the cluster synchronization state of a non-CCO node by running the `show node` operation. `PARTIAL SUCCESS` Synchronization state indicates that some commands failed on the non-CCO node during the cluster synchronization.

To view the list of commands failed on a node during the cluster synchronization by using CLI:

- `show cluster syncFailures`

Sample configuration

```
1 > show cluster node
2
3 1) Node ID: 1
4     IP: 10.102.201.24
5     Backplane: 1/1/1
6     Health: UP
7     Admin State: ACTIVE
8     Operational State: ACTIVE(Configuration Coordinator)
9     Sync State: ENABLED
10    Priority: 31
11    Tunnel Mode: NONE
12    Node Group: DEFAULT_NG
13 2) Node ID: 2
14     IP: 10.102.201.62*
15     Backplane: 2/1/1
16     Health: UP
17     Admin State: ACTIVE
18     Operational State: ACTIVE
19     Sync State: PARTIAL SUCCESS
20    (Refer the files clus_sync_batch_status.log, sync_route_status.log
21     and sync_clusdiff_status.log in /var/nssynclog directory for
22     list of commands failed)
23     Priority: 31
24     Tunnel Mode: NONE
25     Node Group: DEFAULT_NG
26 3) Node ID: 3
27     IP: 10.102.201.64
28     Backplane: 3/1/1
29     Health: UP
30     Admin State: ACTIVE
31     Operational State: ACTIVE
32     Sync State: PARTIAL SUCCESS
33    (Refer the files clus_sync_batch_status.log, sync_route_status.log
34     and sync_clusdiff_status.log in /var/nssynclog directory for
35     list of commands failed)
36     Priority: 31
37     Tunnel Mode: NONE
38     Node Group: DEFAULT_NG
39 Done
40 > show cluster syncFailures
```

```
38
39   exec: add system user nsroot "*****" -encrypted -externalAuth
      ENABLED -timeout 900 -logging ENABLED -maxsession 20 -
      allowedManagementInterface CLI API -devno 32768
40   ERROR: Resource already exists
41   --
42   exec: set interface 2/LO/1 -autoneg ENABLED -haMonitor OFF -
      haHeartbeat OFF -mtu 1500 -ringtype Elastic -tagall OFF -

43   ERROR: Operation not allowed on loopback interface.
```

Synchronizing time across cluster nodes

December 21, 2020

The cluster uses a Precision Time Protocol (PTP) to synchronize the time across cluster nodes. PTP uses multicast packets to synchronize the time. If there are some issues in time synchronization, you must disable PTP and configure Network Time Protocol (NTP) on the cluster.

To enable/disable PTP by using the command line interface

At the command prompt of the cluster IP address, type:

```
1 set ptp -state disable
```

To enable/disable PTP by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to **System > Cluster**.
3. In the details pane, under **Utilities**, click **Configure PTP Settings**.
4. In the **Enable/Disable PTP** dialog box, select whether you want to enable or disable PTP.
5. Click **OK**.

Synchronizing cluster files

June 29, 2021

The files available on the configuration coordinator are called cluster files. These files are automatically synchronized on the other cluster nodes when the node is added to the cluster and periodically, during the lifetime of the cluster. Also, you can manually synchronize the cluster files.

Important: Removing any certificate or key files in a cluster environment restricts further configuration on the ADC appliance. Add the files back at the same location to make any configuration changes.

The directories and files from the configuration coordinator that are synchronized are:

- /nsconfig/ssl/
- /var/netscaler/ssl/
- /var/vpn/bookmark/
- /nsconfig/dns/
- /nsconfig/monitors/
- /nsconfig/nstemplates/
- /nsconfig/ssh/
- /nsconfig/rc.netscaler
- /nsconfig/resolv.conf
- /nsconfig/inetd.conf
- /nsconfig/syslog.conf
- /nsconfig/snmpd.conf
- /nsconfig/ntp.conf
- /nsconfig/httpd.conf
- /nsconfig/sshd_config
- /nsconfig/hosts
- /nsconfig/enckey
- /var/nslw.bin/etc/krb5.conf
- /var/nslw.bin/etc/krb5.keytab
- /var/lib/likewise/db/
- /var/download/
- /var/wi/tomcat/webapps/
- /var/wi/tomcat/conf/Catalina/localhost/
- /var/wi/java_home/lib/security/cacerts
- /var/wi/java_home/jre/lib/security/cacerts
- /nsconfig/license/
- /nsconfig/rc.conf

Tip

Files (certificates and key files) that are copied to the cluster configuration coordinator manually (or through the shell) are not automatically available on the other cluster nodes. Run the “sync

cluster files”command from the cluster IP address before running a command that depends on these files.

To synchronize cluster files by using the command line interface

At the command prompt of the cluster IP address, type:

```
1 sync cluster files <mode>
```

To synchronize cluster files by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to **System > Cluster**.
3. In the details pane, under **Utilities**, click Synchronize cluster files.
4. In the **Synchronize** cluster files dialog box, select the files to be synchronized in the Mode drop-down list.
5. Click **OK**.

Viewing the statistics of a cluster

December 21, 2020

You can view the statistics of a cluster instance and cluster nodes to evaluate the performance or to troubleshoot the operation of the cluster.

To view the statistics of a cluster instance by using the command line interface

At the command prompt of the cluster IP address, type:

```
1 stat cluster instance <clId>
```

To view the statistics of a cluster node by using the command line interface

At the command prompt of the cluster IP address, type:

```
1 stat cluster node <nodeid>
```

Note

The `stat cluster node <nodeid>` command displays the cluster level statistics when you run the command from the cluster IP address. However, when you run from the NSIP address of a cluster node, the command displays node level statistics.

To view the statistics of a cluster instance by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to **System > Cluster**.
3. In the details pane, in the center of the page, click **Statistics**.

To view the statistics of a cluster node by using the configuration utility

1. Log on to the cluster IP address.
2. Navigate to **System > Cluster > Nodes**.
3. In the details pane, select a node and click **Statistics** to view the statistics of the node. To view the statistics of all the nodes, click **Statistics** without selecting a specific node.

Discovering NetScaler appliances

May 2, 2023

You can discover the appliances present in the same subnet as the current node. The required discovered appliances can then be selectively added to the cluster. This operation can be performed to either create a cluster or to add nodes to an existing cluster.

Note

- The discover operation can be performed only through the configuration utility.
- This operation cannot discover NetScaler appliances from different networks.
- When performing this operation to add nodes to an existing cluster, the L3 VLAN configurations are cleared from the node. You make sure to define these configurations once the appliance is added to the cluster.

To discover appliances by using the GUI

1. Log on to the cluster IP address.
2. Navigate to **System > Cluster > Nodes**.

3. In the details pane, at the bottom of the page, click **Discover NetScalers**.
4. In the **Discover NetScalers** dialog box, set the following parameters:
 - **IP address range** - Specify the range of IP addresses within which you want to discover appliances. For example, you can search for all NSIP addresses between 10.102.29.4 to 10.102.29.15 by specifying this option as 10.102.29.4 - 15.
 - **Backplane interface** - Specify the interfaces to be used as the backplane interface. It is an optional parameter. If you do not specify this parameter, you must update it after the node is added to the cluster.
5. Click **OK**.
6. Select the appliances that you want to add to the cluster.
7. Click **OK**.

Disabling a cluster node

December 21, 2020

You can temporarily remove a node from a cluster by disabling the cluster instance on that node. A disabled node is not synchronized with the cluster configurations. When the node is enabled again, the cluster configurations are automatically synchronized on it. For more information, see [Synchronization across cluster nodes](#).

A disabled node cannot serve traffic and all existing connections on this node are terminated.

Note

If the configurations of a disabled non-configuration coordinator node are modified (through the NSIP address of the node), the configurations are not automatically synchronized on that node. You can manually synchronize the configurations as described in [Synchronizing Cluster Configurations](#).

To disable a cluster node by using the command line interface

At the command prompt of the node that you want to disable, type:

```
1 disable cluster instance <clId>
```

Note

To disable the cluster, run the `disable cluster instance` command on the cluster IP address.

To disable a cluster node by using the configuration utility

1. On the node that you want to disable, navigate to **System > Cluster**, and click **Manage Cluster**.
2. In the **Configure** cluster instance dialog box, unselect the **Enable** cluster instance check box.

Note

To disable the cluster instance on all the nodes, perform the preceding procedure on the cluster IP address.

Removing a cluster node

September 26, 2023

When a node is removed from the cluster, the cluster configurations are cleared from the node (by internally running the `clear ns config -extended` command). The SNIP addresses, **MTU** settings of the backplane interface, and all VLAN configurations (except the default VLAN and NSVLAN) are also cleared from the appliance.

Note:

- If the deleted node was the cluster configuration coordinator (CCO), another node is automatically selected as the CCO, and the cluster IP address is assigned to that node. All the current cluster IP address sessions are invalid and you have to start a new session.
- To delete the whole cluster, you must remove each node individually. When you remove the last node, the cluster IP addresses are deleted.
- When an active node is removed, the traffic serving capability of the cluster is reduced by one node. Existing connections on this node are terminated.
- You can list the spotted configuration of a cluster node using the `shell spottedconfig <nodeID>` command and take a backup before removing the node from the cluster.

To remove a cluster node by using the CLI

1. Log on to the cluster IP address and at the command prompt, type:

```
1 rm cluster node <nodeId>
2
3 Example:
4
5 rm cluster node 1
```

```
6 All spotted configurations will be lost. Take a backup of the
   spotted configurations for node ID 1 using the command `shell
   spottedconfig 1`.
7 Are you sure you want to remove the cluster node (Y/N)? [N]:Y
8 Done
9
10 save ns config
```

2. Log on to the removed node, NSIP address, and at the command prompt, type:

```
1 save ns config
```

Note:

If the cluster IP address is unreachable from the node, run the `rm cluster instance` command on the NSIP address of that node itself.

To remove a cluster node by using the GUI

On the cluster IP address, navigate to **System > Cluster > Nodes**, select the node you want to remove and click **Remove**.

Removing a node from a cluster deployed using cluster link aggregation

September 20, 2023

To remove a node from a cluster that uses cluster link aggregation as the traffic distribution mechanism, you must make sure that the node is made passive so that it does not receive any traffic and then, on the upstream switch, remove the corresponding interface from the channel.

For detailed information on cluster link aggregation, see [Using Cluster Link Aggregation](#).

To remove a node from a cluster that uses cluster link aggregation as the traffic distribution mechanism

1. Log on to the cluster IP address.
2. Set the state of the cluster node that you want to remove to `PASSIVE`.

```
1 set cluster node <nodeId> -state PASSIVE
```

3. On the upstream switch, remove the corresponding interface from the channel by using switch-specific commands.

Note:

You do not have to manually remove the nodes interface on the cluster link aggregation channel. It is automatically removed when the node is deleted in the next step.

4. Remove the node from the cluster.**Note:**

You can list the spotted configuration of a cluster node using the `shell spottedconfig <nodeID>` command and take a backup before removing the node from the cluster.

```
1  rm cluster node <nodeId>
2
3  Example:
4
5  rm cluster node 1
6  All spotted configurations will be lost. Take a backup of the
   spotted configurations for node ID 1 using the command `shell
   spottedconfig 1`.
7  Are you sure you want to remove the cluster node (Y/N)? [N]:Y
8  Done
```

Detecting jumbo probe on a cluster

December 21, 2020

If a Jumbo frame is enabled on a cluster interface, the backplane interface must be large enough to support the all packets in the Jumbo frame. It is achieved by setting the Maximum Transmission Unit (MTU) of the backplane as:

$\text{Backplane_MTU} = \text{maximum (all cluster interface MTUs)} + 78$

To verify the preceding configuration, you must send a jumbo probe (of the preceding computational size) to all the peer nodes of a Cluster setup. If the probe does not succeed, the appliance displays a warning message in the output of the “show cluster instance” command.

In the command interface mode, type the following command:

```
1  > show cluster instance
2  Cluster ID: 1
3  Dead Interval: 3 secs
4  Hello Interval: 200 msec
5  Preemption: DISABLED
6  Propagation: ENABLED
7  Quorum Type: MAJORITY
```

```

8      INC State: DISABLED
9      Process Local: DISABLED
10     Cluster Status: ENABLED(admin),    ENABLED(operational), UP

```

Warning

The MTU for a backplane interface must be large enough to handle all packets in the frame. It must be equal to <MTU_VAL>. If the recommended value is not user configurable, you must review the MTU value of jumbo interfaces.

| Sl. no | Member Nodes | Health | Admin State | Operation State |
|--------|---------------------------------------|--------|-------------|--|
| 1 | Node ID: 1; Node
IP: 10.102.53.167 | UP | Active | ACTIVE
(Configuration
Coordinator) |
| 2 | Node ID: 2; Node
IP: 10.102.53.168 | UP | Active | Active |

Route monitoring for dynamic routes in cluster

December 21, 2020

You can use a route monitor to make a cluster node dependent on the internal routing table whether it contains or does not contain a dynamically learned route. A route monitor on each node checks the internal routing table to ensure there is a route entry for reaching a particular network is always present. If the route entry is not present, the state of the route monitor changes to DOWN.

In a cluster deployment, if the client-side or server side-link of a node goes down, traffic is steered to this node through the peer nodes for processing. The steering of traffic is implemented by configuring dynamic routing and adding static ARP entries, pointing to the special MAC address of each node, on all the nodes. If there are many nodes in a cluster deployment, adding and managing static ARP entries with special MAC addresses on all the nodes is a cumbersome task. Now, nodes implicitly use special MAC addresses for steering packets. Therefore, static ARP entries pointing to special MAC addresses are no longer required to be added to the cluster nodes.

To bind a cluster node using the CLI

At the command prompt, type:

```

1 bind cluster node <nodeId> \(-routeMonitor <ip\_addr|ipv6\_addr|\*> \[<
  netmask>])
2 unbind cluster node <nodeId> \(-routeMonitor <ip\_addr|ipv6\_addr|\*>
  \[<netmask>])

```

Consider a scenario where Node 1 is bound to route monitor 1.1.1.0 255.255.255.0. When a dynamic route fails, Node 1 become INACTIVE. The health status is available in the `show cluster node` command by node id as per following.

```

1 Node ID: 1
2 IP: 10.102.169.96
3 Backplane: 1/1/2
4 Health: NOT UP
5 Reason(s): Route Monitor(s) of the node have failed
6 Route Monitor - Network: 1.1.1.0 Netmask: 255.255.255.0 State:
  DOWN

```

Monitoring cluster setup using SNMP MIB with SNMP link

May 2, 2023

SNMP MIB is device specific information that is configured on the SNMP agent for identifying a NetScaler appliance. It can identify information such as, appliance name, administrator, and location. In a cluster setup, you can now configure the SNMP MIB in any node by including the “ownerNode” parameter in the set SNMP MIB command. Without this parameter, the set SNMP MIB command applies only to the Cluster Coordinator (CCO) node.

To display the MIB configuration for a cluster node other than the CCO, include the “ownerNode” parameter in the show SNMP MIB command.

Configuring SNMP MIB on CLIP

To configure and view MIB configuration on CLIP by using the command line interface.

```

1 set snmp mib [-contact <string>] [-name <string>] [-location <string>]
2   [-customID <string>] [-ownerNode <positive_integer>]
3 Done
4 show snmp mib [-ownerNode <positive_integer>]
5

Cluster SNMP trap messages

In cluster setup, the SNMP trap alarm configurations must be done from the CLIP. The commands are propagated to each of the nodes.

For more information on configuring SNMP, see [Configuring the NetScaler to generate SNMP traps](#).

The following are the cluster specific traps that are available:

```

1      >sh snmp alarm | grep cluster
2      CLUSTER-BACKPLANE-HB-MISSING N/A N/A 86400  ENABLED - ENABLED
3      CLUSTER-CCO-CHANGE N/A N/A N/A  ENABLED - ENABLED
4      CLUSTER-NODE-HEALTH N/A N/A 86400  ENABLED - ENABLED
5      CLUSTER-NODE-QUORUM N/A N/A 86400  ENABLED - ENABLED
6      CLUSTER-OVS-CHANGE N/A N/A N/A  ENABLED - ENABLED
7      CLUSTER-PROP-FAILURE N/A N/A N/A  ENABLED - ENABLED
8      CLUSTER-SYNC-FAILURE N/A N/A N/A  ENABLED - ENABLED
9      CLUSTER-SYNC-PARTIAL-SUCCESS N/A N/A N/A  ENABLED - ENABLED
10     CLUSTER-VERSION-MISMATCH N/A N/A 86400  ENABLED - ENABLED

```

Monitoring command propagation failures in a cluster deployment

May 2, 2023

In a cluster deployment, you can use the new command “show prop status” for faster monitoring and troubleshooting of issues. The issues related to command-propagation failure on non-CCO nodes. This command displays up to 20 of the most recent command propagation failures on all non-CCO nodes. You can use either the NetScaler appliance CLI or GUI to perform this operation. You can access them through the CLIP address or through the NSIP address of any node in the cluster deployment.

Graceful shutdown of nodes

March 25, 2024

In a cluster setup, some of the existing connections (1/Nth connections, where N is the cluster size) at the cluster level or specific virtual server level are lost. This behavior is observed if a node leaves or joins the system. To address the loss, you must gracefully handle the existing connections. Graceful handling is done by configuring the “retain connections on cluster” option in the CLIP address and specifying a timeout interval in the node’s NSIP.

Graceful handling of connections is applicable in two scenarios:

1. Cluster upgrade
2. New node addition

Graceful handling of Nodes in cluster upgrade

To upgrade a cluster, you must upgrade one node at a time. Before upgrading a node, you must set it to passive state and then set it to active state after the upgrade. To avoid terminating existing connections when upgrading the node, shut it down gracefully with a configured timeout interval. Otherwise, 1/Nth (where N is the cluster size) of the cluster’s connections are terminated.

Note

- If existing sessions are not completed within the configured timeout interval, they get terminated after the grace time.
- To check the timeout interval, you must use the CLIP or NSIP address of the node, which is set to passive.

Following are the steps to gracefully handle nodes in a cluster upgrade scenario:

1. Consider a cluster setup of five nodes (n0, n1, n2, n3, n4).
2. Before you shut down a node, you must configure the “retainConnectionsOnCluster” option. It helps to retain all existing connections of this node at the cluster level or virtual server level for a specific time interval.

Example

On CLIP

```
“set cluster instance –retainConnectionsOnCluster YES
```

```
1 OR
2
3 `` `set lb vserver <vserver name> –retainConnectionsOnCluster Yes
  <!--NeedCopy-->
```

3. Now, log on to the NSIP address of node n3 and set the node n3 to PASSIVE with a timeout interval.

Example

```
“set cluster node n3 –state PASSIVE –delay 60
```

```
1 `` `saveconfig<!--NeedCopy-->
```

4. After the grace period expires, close all connections, shut down n3 and reboot the NetScaler appliance.
5. Upgrade the appliance. Then, with the CLI connected to the appliance’s NSIP address, set the node to ACTIVE.

Example

```
“set cluster node n3 –state ACTIVE
```

```
1 `` `saveconfig<!--NeedCopy-->
```

6. Repeat steps 4–6 for all nodes in the cluster.
7. After all nodes are upgraded and set to ACTIVE, reset the retainConnectionsOnCluster option from the CLIP address.

Example

```
“set cluster instance –retainConnectionsOnCluster NO
```

```
1 OR
2
3 `` `set lb vserver <vserver name> –retainConnectionsOnCluster NO
  <!--NeedCopy-->
```

Note

If there is a version mismatch when upgrading a cluster, cluster propagation is automatically disabled and no commands are allowed on the CLIP.

Graceful handling of nodes during a new node addition

The graceful handling of nodes describes how a new node can be added to the existing NetScaler cluster. Consider you have a NetScaler cluster that is already serving traffic. And you want to add an extra appliance as a node to the cluster without terminating its existing connections. To accomplish the preceding scenario, set the option to retain existing connections either at a Global level or at a specific virtual server level. Once done, save the configuration. Now set the option to retain connections to NO, to allow existing connections from other nodes to be reassigned to the new node.

Following are the steps to gracefully handle nodes if a node newly added:

1. You save the existing configuration that has the “retainConnectionsOnCluster” option enabled. By doing so, you can retain all existing connections of this node at the cluster level or virtual server level for a specific time interval.

On CLIP

```
1 set cluster instance x - retainConnectionsOnCluster YES
```

OR

```
1 set lb vserver xxxx - retainConnectionsOnCluster Yes
```

2. Add a node ‘n5’ to the cluster setup.
3. Disable “the retainConnectionOnCluster” option to “NO” for distributing existing connections from other nodes to the newly added node n5.

On CLIP

```
1 set cluster instance x - retainConnectionsOnCluster NO
```

OR

```
1 set lb vserver xxxx - retainConnectionsOnCluster NO
```

Note

The backplane steering depends on the type of traffic distribution mechanism (ECMP, CLAG, and USIP) on a cluster setup. The increase in backplane steering is based on the traffic type.

Configuring graceful shutdown of nodes in a cluster

To configure graceful shutdown of nodes in a cluster, do the following:

1. Configure the “retainConnectionsOnCluster” option at Global (cluster) level.
2. Configure the “retainConnectionsOnCluster” option at the virtual server level.
3. Set the node (leaving the system) to the passive state with a graceful timeout interval specified in the node’s NSIP address.
4. Monitor the existing connections to make sure all transactions are completed within the grace period.

To retain existing connections at the global (cluster) level by using the CLI

You can retain existing connections either at a global level or at a specific virtual server level. This option is configured to retain all existing connections at the global level. By default, this option is disabled.

At the command prompt type:

```
1 - set cluster instance <clusterID> -retainConnectionsOnCluster YES
2
3 - set cluster instance 60 - retainConnectionsOnCluster YES
```

To retain existing connections of a specific virtual server in the cluster by using the CLI

This option is configured to retain existing connections specific to a load balancing virtual server. To retain those connections, we enable this option at the virtual server level. By default, this option is disabled.

At the command prompt, type:

```
1 - set lb vserver <clusterID> -retainConnectionsOnCluster Yes
2
3 - set lb vserver v1 -retainConnectionsOnCluster Yes
```

To set a cluster node to passive state by using the CLI

To set a cluster node to passive state with a graceful timeout interval. This setting is performed in the node’s NSIP as propagation is disabled during cluster upgrade.

At the command prompt, type:

```
1 - set cluster node <clusterID> -state passive
2 -backplane <interface_name>@
```

```
3 -priority <positive_integer>
4 -delay <mins>
5
6 - set cluster node 4 - state PASSIVE -delay 60
7
8 - set cluster instance 60 - retainConnectionsOnCluster YES
9 - set lb vserver v1 - retainConnectionsOnCluster Yes
10 - set cluster node 4 - state PASSIVE -delay 60
```

Note

You might observe the following behavior on a cluster node when it is set to passive with a delay option configured from a CLIP:

- After the timeout, the node shows as passive from the NSIP of the node.
- The **show cluster instance** command on CLIP displays the node as active from the CLIP. Whereas the **show cluster node** command on the CLIP displays the node as passive.

To configure graceful shutdown of nodes by using the GUI

1. Navigate to **Configuration > System > Cluster** and click **Manage Cluster**.
2. On the **Manage Cluster** page, select **Retain Connections on Cluster** option.
3. Click **OK**, and then click **Done**.

Graceful shutdown of services

May 2, 2023

Starting with NetScaler 12.1 build 49.xx, NetScaler clusters support graceful shutdown of services. To gracefully shut down the services, you can perform one of the following tasks.

- Explicitly disable the service, and
 - Set a delay (in seconds).
 - Enable graceful shutdown.
- Add a TROFS code or string to the monitor.

For more details, see [Graceful shutdown of services](#).

To configure graceful shutdown for a service by using the CLI**Disable with graceful option only:**

At the command prompt, type:

```
1 disable service <name> [-graceFul (YES|NO)]
2
3 show service <name>
4 <!--NeedCopy-->
```

Example

```
1 disable service svc1 -graceFul YES
2 Done
3 sh service svc1
4          svc1 (10.102.225.11:80) - HTTP
5          State: GOING OUT OF SERVICE   Graceful (number of
6          active clients: 1)
7          Last state change was at Wed Jul 25 10:46:29 2018
8          Time since last state change: 0 days, 00:00:02.680
9          .....
10         Traffic Domain: 0
11
12 1)          Monitor Name: tcp-default
13           State: UP                               Weight: 1
14           Passive: 0
15           Probes: 26                               Failed [Total: 0
16           Current: 0]
17           Last response: Success - TCP syn+ack
18           received.
19           Response Time: 0.0 millisec
20 <!--NeedCopy-->
```

Disable with timeout and graceful option:

At the command prompt, type:

```
1 disable service <name> [<delay>] [-graceFul (YES|NO)]
2
3 show service <name>
4 <!--NeedCopy-->
```

Example

```
1 disable service svc1 2000 -graceFul YES
2
3 Done
4 > sh service svc1
5          svc1 (10.102.225.11:80) - HTTP
6          State: GOING OUT OF SERVICE (Graceful (number of active
7          clients: 1), Out Of Service in 1998 seconds)
8          Last state change was at Wed Jul 25 10:49:08 2018
9          Time since last state change: 0 days, 00:00:01.710
10         .....
11         Traffic Domain: 0
```

```

12
13 1)          Monitor Name: tcp-default
14                               State: UP           Weight: 1
15                               Passive: 0
16                               Probes: 57          Failed [Total: 0
17                               Current: 0]
18                               Last response: Success - TCP syn+ack
19                               received.
                               Response Time: 0.0 millisec
18 Done
19 <!--NeedCopy-->

```

Disable service group with timeout and graceful option:

At the command prompt, type:

```

1 disable serviceGroup <serviceName>@ [<serverName>@ <port>] [-delay
2 <secs>] [-graceful ( YES | NO )]
3 Show service group <serviceName>
4 <!--NeedCopy-->

```

Example:

```

1 disable servicegroup sg -delay 2000 -graceful yes
2 sh servicegroup sg
3     sg - HTTP
4     State: DISABLED           Effective State: OUT OF
5     SERVICE Monitor Threshold : 0
6     Max Conn: 0             Max Req: 0             Max Bandwidth: 0
7     kbits
8     Use Source IP: NO
9     Client Keepalive(CKA): NO
10     .....
11
12     1) 200.200.10.21:80      Server Name: server3
13         Server ID: None Weight: 1
14         State: GOING OUT OF SERVICE (learnt
15         from node:2 ) Graceful (number
16         of active clients: 6), Out Of
17         Service in 1993 seconds
18         Last state change was at Mon Aug 13
19         15:15:11 2018
20         .....
21
22     2) 200.200.10.22:80      Server Name: server4
23         Server ID: None Weight: 1
24         State: GOING OUT OF SERVICE (learnt
25         from node:2 ) Graceful (number
26         of active clients: 7), Out Of
27         Service in 1993 seconds
28         Last state change was at Mon Aug 13
29         15:15:11 2018

```

```
20 <!--NeedCopy-->
```

Note

CLIP displays the aggregated value of all active clients connections from all cluster nodes.

To configure graceful shutdown for a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Open the service, and from the Action list, click **Disable**. Enter a wait time, and select Graceful.

To configure a TROFS code or string in a monitor by using the CLI

At the command prompt, type one of the following commands:

```
1 add lb monitor <monitor-name> HTTP -trofsCode <respcode>
2 add lb monitor <monitor-name> HTTP-ECV -trofsString <resp string>
3 add lb monitor <monitor-name> TCP-ECV -trofsString <resp string>
4 <!--NeedCopy-->
```

To configure a TROFS code or string in a monitor by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. On the Monitors pane, click Add, and do one of the following steps:
 - Select Type as HTTP, and specify a TROFS Code.
 - Select Type as HTTP-ECV or TCP-ECV, and specify a TROFS String.

IPv6 ready logo support for clusters

December 21, 2020

You can test clustered appliances for IPv6 Ready Logo certification. Modified commands for testing IPv6 core protocols, such as for ND test cases, Router Solicitation processing, and sending route advertisement and router redirection messages are available in a clustered setup. Following are the IPv6 functionalities available for testing the IPv6 core protocols.

Following are the modified functionalities available to pass IPv6 core protocols, such as ND test cases, Router Solicitation processing and sending Route advertisement and router redirection messaging in the IPv6readylogo phase2 test suite.

- Link Local SNIPs
- Address Resolution and Neighbor Unreachability
- Router and Prefix Discovery
- Router Redirection
- DoDAD

With these modified commands, the following configurations are supported in a clustered appliance.

Supportable configurations for testing IPv6 core protocols

For a clustered setup to pass IPv6 Ready Logo test cases, you can run the following configurations on the Cluster Management IP address (CLIP).

- global IPv6 configuration
- basic IPv6 configuration
- more IPv6 configurations

Global configuration

A global IPv6 configuration enables you to set the global IPv6 parameters (such as relearning, routeRedirection, ndBasereachTime, nRetransmissionTime, `natprefix`, `td`, and `doodad`) to run the basic IPv6 configuration.

At the command prompt, type the following:

```
1 set ipv6 \[-relearning \(( ENABLED | DISABLED )\)] \[-routerRedirection \((
  ENABLED | DISABLED )\)] \[-ndBasereachTime<positive\_integer>\]\[-
  ndRetransmissionTime <positive\_integer>\] \[-natprefix <ipv6\_addr
  | \* >\]\[-td<positive\_integer>\]\]\[-doDAD \(( ENABLED | DISABLED )\)]
```

Basic IPv6 configuration

The basic IPv6 configuration enables you to create an IPv6 address and bind to a VLAN interface. You can perform the following configurations to test the IPv6 core protocols.

To add a VLAN to the clustered setup by using the CLI

At the command prompt, type:

```
1 add vlan <id>
```

To add another VLAN to the clustered setup by using the CLI

At the command prompt, type:

```
1 add vlan <id>
```

To bind an interface to a VLAN by using the CLI

At the command prompt, type:

```
1 bind vlan <id> -ifnum <interface_name>
```

To bind an interface to a VLAN by using the CLI

This command adds the global prefix as on-link prefix into RA information for subsequent Router Advertisements. At the command prompt, type:

```
1 bind vlan <id> -ifnum <interface_name>
```

To add the IPv6 SNIP address on a VLAN by using the CLI

At the command prompt, type the following:

```
1 add ns ip6 <IPv6Address>@ \[-scope \( global | link-local )\]\[-type <
  type>
```

To add the IPv6 address on VLAN by using the CLI

At the command prompt, type the following:

```
1 add ns ip6 <IPv6Address>@ \[-scope \( global | link-local )\]\[-type <
  type>
```

To bind IPv6 address to VLAN by using the CLI

At the command prompt, type the following:

```
1 bind vlan <id> \[-ifnum <interface\_name> \[-tagged]]\[-IPAddress <ip\
  _addr|ipv6\_addr|
```

To bind the IPv6 address to VLAN by using the CLI

At the command prompt, type the following:

```
1 bind vlan <id> \[-ifnum <interface\_name> \[-tagged]]\[-IPAddress <ip\
  _addr|ipv6\_addr|
```

To display the link local IPv6 address attached to VLAN by using the CLI

At the command prompt, type the following:

```
1 sh VLAN
```

Example 1

```

1 add vlan 2
2 add vlan 3
3 bind vlan 2 -ifnum 1/2
4 bind vlan 3 -ifnum 1/3
5 add ip6 fe80::9404:60ff:fedd:a464/64 -vlan 2 -scope link-local -type
  SNIP
6 add ip6 fe80::c0ee:7bff:fede:263f/64 -vlan 3 -scope link-local -type
  SNIP
7 add ip6 3ffe:501:ffff:100:9404:60ff:fedd:a464/64 -vlan 2
8 add ip6 3ffe:501:ffff:101:c0ee:7bff:fede:263f/64 -vlan 3
9 bind vlan 2 -ipAddress 3ffe:501:ffff:100:9404:60ff:fedd:a464/64
10 bind vlan 3 -ipAddress 3ffe:501:ffff:101:c0ee:7bff:fede:263f/64

```

Example 2

```

1 sh vlan
2 1)      VLAN ID: 2      VLAN Alias Name:
3          Interfaces : 1/6
4          IPs :
5              3ffe:501:ffff:100:2e0:edff:fe15:ea2a/64
6 3)      VLAN ID: 3      VLAN Alias Name:
7          Link-local IPv6 addr: fe80::9404:60ff:fedd:a464/64
8          Interfaces : 1/5
9          IPs :
10             3ffe:501:ffff:101:2e0:edff:fe15:ea2b/64
11 Done

```

More IPv6 cluster configuration

To test IPv6 core protocols, you can use the following new or modified IPv6 configurations.

To set VLAN specific Router Advertisement parameters by using the CLI

At the command prompt, type:

```

1 set nd6RAvariables -vlan <positive\_integer> \[-ceaseRouterAdv \{ YES |
  NO\}\ \[-sendRouterAdv \{ YES | NO \}\ \[-srcLinkLayerAddrOption \{
  YES | NO \}\ \[-onlyUnicastRtAdvResponse \{ YES | NO \}\ \[-
  managedAddrConfig \{ YES | NO\}\ \[-otherAddrConfig \{ YES | NO \}\
  \[-currHopLimit <positive\_integer>\]\ \[-maxRtAdvInterval <positive\_
  integer>\] \[-minRtAdvInterval<positive\_integer>\] \[-linkMTU <
  positive\_integer>\] \[-reachableTime<positive\_integer>\] \[-
  retransTime <positive\_integer>\] \[-defaultLifeTime<integer>]

```

To set an on-link global prefix's configurable parameters by using the CLI

At the command prompt, type:

```
1 set onLinkIPv6Prefix <ipv6Prefix> \[-onlinkPrefix \(\ YES | NO \)\]\[-
  autonomusPrefix \(\ YES | NO \)\] \[-depricatePrefix \(\ YES | NO \)\]\[-
  decrementPrefixLifeTimes \(\ YES | NO \)\] \[-prefixValideLifeTime <
  positive\_integer>] \[-prefixPreferredLifeTime <positive\_integer>]
```

To add configurable parameters to an on-link global prefix by using the CLI

At the command prompt, type:

```
1 add onLinkIPv6Prefix <ipv6Prefix> \[-onlinkPrefix \(\ YES | NO \)\]\[-
  autonomusPrefix \(\ YES | NO \)\] \[-depricatePrefix \(\ YES | NO \)\]\[-
  decrementPrefixLifeTimes \(\ YES | NO \)\]-prefixValideLifeTime <
  positive\_integer>]\[-prefixPreferredLifeTime <positive\_integer>]
```

To set an on-link link to the IPv6 prefix's configurable parameters by using the CLI

At the command prompt, type the following:

```
1 help set onLinkIPv6Prefix
```

To bind an on-link link to the IPv6 prefix's configurable parameters by using the CLI

At the command prompt, type:

```
1 help bind nd6RAvariables
```

To show nd6RAvariables by using the CLI

At the command prompt, type:

```
1 help sh nd6RAvariables
```

Example

```
1 > sh nd6RAvariables
2 1) Vlan : 1
3   SendAdvert      : NO   CeaseAdv      : NO   SourceLLAddress:
4     YES
5   UnicastOnly    : NO   ManagedFlag   : NO   OtherConfigFlag:

Managing cluster heartbeat messages

May 2, 2023

Managing heartbeat messages in a cluster is similar to managing them in a high availability (HA) configuration. Nodes can send and receive heartbeat messages to and from each other on all interfaces that are enabled. To avoid increased traffic resulting from heartbeat messages, you can now disable the heartbeat option on node interfaces. However, the heartbeat option on the backplane interface cannot be disabled, because it is required for maintaining connectivity among the cluster nodes.

For more information about managing heart messages, see [Managing High Availability Heartbeat Messages on a NetScaler Appliance](#).

To manage heartbeat messages on a node interface by using the NetScaler CLI

At the command prompt, type:

```

1 set interface <ID> \[-HAHeartBeat \{ON | OFF\}]
2 Show interface <ID>

```

Configure secure heartbeats

November 28, 2023

The secure heartbeats feature provides protection against network attacks such as tampering and replay attacks. When you enable the secure heartbeats in a cluster setup, NetScaler authenticates the heartbeat packets and checks for packet integrity to protect against network attacks. If the authentication or packet integrity check fails, NetScaler drops the heartbeat packets.

You can enable or disable the secure heartbeats using the `secureHeartbeats` parameter of the `set cluster` command.

Note:

- Secure heartbeats must be configured from the cluster IP address.
- Ensure that all the cluster nodes are running release 14.1 build 12.30 or later.

Configure secure heartbeats using the CLI

Log in to the cluster IP address and perform the following steps to enable or disable secure heartbeats.

To enable the secure heartbeats:

1. Enable the secure heartbeats.

```
set cluster instance <clId> secureHeartbeats ENABLED
```

2. Save the configuration.

```
save ns config
```

3. Verify the configuration.

```
sh cluster instance <clid>
```

Example configuration:

```
1 > set cluster instance 1 secureHeartbeats ENABLED
2 Warning: [The Secure Heartbeats feature must be set in the cluster IP (
  CLIP) address.]
3 Done
4 > save ns config
5 Done
6 > sh cluster instance 1
7 1) Cluster ID: 1
8     Dead Interval: 3 secs
9     Hello Interval: 200 msec
10    Preemption: DISABLED
```

```

11      Propagation: ENABLED
12      Quorum Type: MAJORITY
13      INC State: DISABLED
14      Process Local: DISABLED
15      Retain Connections: NO
16      Heterogeneous: NO
17      Backplane based view: DISABLED
18      Cluster sync strict mode: DISABLED
19      DFD Retain L2 Params: DISABLED
20      Cluster Proxy Arp Status: ENABLED
21      Secure Heartbeats: ENABLED
22      Cluster Status: ENABLED(admin), ENABLED(operational), UP
23
24      WARNING(s):
25          (1) - There are no spotted SNIPs configured on the
                cluster. Spotted SNIPs can help improve cluster
                performance.
26
27      Member Nodes:
28      Node ID      Node IP          Health      Admin State
                Operational State
29      -----
30  1)      1          10.102.58.124      UP          ACTIVE      ACTIVE

32  3)      0          10.102.58.123*    UP          ACTIVE      ACTIVE (
                Configuration Coordinator)
33
34      Done
35      <!--NeedCopy-->

```

To disable the secure heartbeats:

Run the following commands to disable secure heartbeats.

1. `set cluster instance <clId> secureHeartbeats DISABLED`
2. `save ns config`

Configure secure heartbeats using the GUI

Log in to the cluster IP address and perform the following steps to enable or disable secure heartbeats.

To enable the secure heartbeats:

1. Navigate to **System > Cluster**.
2. In the details pane, click the **Manage Cluster** link.
3. In the **Configure cluster instance** page, select the **Secure Heartbeats** checkbox.
4. Click **Save**, and then click **Yes**.

To disable the secure heartbeats:

In the **Configure cluster instance** page, clear the **Secure Heartbeats** checkbox.

Configuring owner node response status

May 2, 2023

You can configure the `ownerDownResponse` option on a node which has a spotted SNIP address. By default, the option is enabled. It allows the spotted IP address to respond to PING or ARP requests (coming from the upstream router) when the node is inactive. If you disable the option, the IP address cannot respond to the router requests when the owner node is inactive.

To know how this feature is used for monitoring static routes in ECMP deployment, see [Using Equal Cost Multiple Path \(ECMP\)](#) topic.

To set owner node response status by using the NetScaler CLI

At the command prompt, type:

```
1 add ns ip <IPAddress> \[-ownerNode <positive\_integer>] \[-ownerDownResponse \ (YES | NO )] \[-td <positive\_integer>]
```

Example

```
1 add ns ip 2.2.2.2 255.255.255.0 -ownernode 6 -ownerdownResponse YES
```

To set owner node response status by using the NetScaler GUI

1. Navigate to **System > Network > IPs** and click **Add** to create a spotted SNIP address.
2. On the **Create IP Address** page, select, or clear the **ownerDownResponse** check box.

To edit owner node response status by using the NetScaler GUI

Navigate to **System > Network > IPs**, select an IP address, and click **Edit** to select or clear the **ownerDownResponse** check box.

Monitor static route (MSR) support for inactive nodes in a spotted cluster configuration

December 21, 2020

In a cluster set up with the MSR option enabled on the route, only active nodes can probe to a static route. It can reach a network while inactive and spare nodes have no link to the route and cannot probe to it. You can now configure an inactive or spare node to send PING and ARP probe to IPv4 route and send ping6 and nd6 probe to IPv6 route. You can perform this only in a spotted cluster configuration in which the SNIP address is active and owned exclusively only by one node.

VRRP interface binding in a single node active cluster

May 2, 2023

When you migrate a high availability (HA) setup to a cluster setup, all configurations must be compatible and must be supportable in the cluster. To achieve this, you can now configure virtual router IDs (VRIDs and VRID6s) on a node interface.

Important

Currently, only a single-node active cluster system supports VRIDs and VRID6s.

For instructions for configuring VRIDs and VRID6s, see [Configuring Virtual MAC Addresses](#).

To configure a virtual router ID on a single-node active cluster, add the VRID or VRID6 and bind it to the cluster-node interface.

To add a VRID by using the NetScaler CLI

At the command prompt, type:

```
1 add vrid <ID>
```

To bind a VRID to the cluster-node interface by using the NetScaler CLI

At the command prompt, type:

```
1 Bind vrid <ID> -ifnum <interface\_name> | -trackifNum <interface\_name>
2
3 Add vrid 100
4 Bind vrid 100 -ifnum 1/1 1/2
5 done
```

To add a VRID6 by using the NetScaler CLI

At the command prompt, type:

```
1 add vrID6 <ID>
```

To bind a VRID6 to a cluster node interface by using the CLI

At the command prompt, type:

```
1 bind vrid6 <ID> -ifnum <interface\_name> | -trackifNum <interface\_name
  >
2
3 Add vrID6 100
4 Bind vrid6 100 -ifnum 1/1 1/2
5 Done
```

Cluster setup and usage scenarios

May 2, 2023

This section explains some scenarios in which the NetScaler cluster can be set up, and configured for different features and network topologies. Provide feedback if you want any other scenarios to be documented.

Creating a two-node cluster

December 21, 2020

A two-node cluster is an exception to the rule that a cluster is functional only when a minimum of $(n/2 + 1)$ nodes, where n is the number of cluster nodes, are able to serve traffic. If the same formula is applied to a two-node cluster, the cluster would fail if one node went down ($n/2 + 1 = 2$).

A two-node cluster is functional even if only one node is able to serve traffic.

Creating a two node cluster is the same as creating any other cluster. You add a one node as the configuration coordinator and the other node as the other cluster node.

Note

Incremental configuration synchronization is not supported in a two-node cluster. Only full synchronization is supported.

Migrating an HA setup to a cluster setup

January 5, 2024

Migrating an existing high availability (HA) setup to a cluster setup requires you to first remove the two NetScaler instances from the HA setup and create a backup of the HA configuration file. You can then use these instances to create a cluster and apply the backed-up configuration to the cluster.

Note

- Before applying the configuration from the backed-up HA configuration file to the cluster, you must modify it to make it cluster compatible.

The preceding approach is a basic migration solution which results in downtime for the deployed application. As such, it must be used only in deployments where there is no consideration of application availability.

However, in most deployments, the availability of the application is of paramount importance. For such cases, you must use the approach where an HA setup can be migrated to a cluster setup with minimal downtime. In this approach, an existing HA setup is migrated to a cluster setup by first removing the secondary instance and using that instance to create a single-node cluster. After the cluster becomes operational and serves traffic, the primary instance of the HA setup is added to the cluster.

To convert an HA setup to a cluster setup by using the CLI

Let us consider the example of a HA setup with primary instance (NS1) - 198.51.100.131 and secondary instance (NS2) - 198.51.100.132.

1. Make sure that the configuration of the HA pair is stable.
2. Log on to the secondary instance, go to the shell, and create a copy of the ns.conf file (for example, `/nsconfig/ns_backup.conf`). For the list of backup files supported in cluster, see [Back up a cluster setup](#)
3. Log on to the secondary instance, NS2, and clear the configuration. This operation removes NS2 from the HA setup and makes it a standalone instance.

```
1 > clear ns config full
```

Note

- This step is required to make sure that NS2 does not start owning VIP addresses, now

that it is a standalone instance.

- At this stage, the primary instance, NS1, is still active and continues to serve traffic.

4. Create a cluster on NS2 (now no longer a secondary instance) and configure it as a PASSIVE node.

```
1 > add cluster instance 1
2
3 > add cluster node 0 198.51.100.132 -state PASSIVE -backplane
  0/1/1
4
5 > add ns ip 198.51.100.133 255.255.255.255 -type CLIP
6
7 > enable cluster instance 1
8
9 > save ns config
10
11 > reboot -warm
```

5. Modify the backed-up configuration file as follows:

- (Optional) Remove the features that are not supported on a cluster. For the list of unsupported features, see [NetScaler Features Supported by a Cluster](#). If you do not perform this step, the unsupported commands might fail when you apply the configuration from the backed-up file.
- Remove the configuration that have interfaces, or update the interface names from the c/u convention to the n/c/u convention.

Example

```
1 > add vlan 10 -ifnum 0/1
```

must be changed to

```
1 > add vlan 10 -ifnum 0/0/1 1/0/1
```

- The backup configuration file can have SNIP addresses. These addresses are striped on all the cluster nodes. It is recommended that you add spotted IP addresses for each node.

Example

```
1 > add ns ip 1.1.1.1 255.255.255.0 -ownerNode 0
2
3 > add ns ip 1.1.1.2 255.255.255.0 -ownerNode 1
```

- Update the host name to specify the owner node.

Example

```
1 > set ns hostname ns0 -ownerNode 0
2
```

```
3 > set ns hostname ns1 -ownerNode 1
```

- e) Change all other relevant networking configuration that depends on spotted IP addresses. For example, L3 VLAN, RNAT configuration which uses SNIPs as NATIP, INAT rules that refers to SNIPs/MIPs).

6. On the cluster, do the following:

- a) Make the topological changes to the cluster by connecting the cluster backplane, the cluster link aggregation channel, and so on.
- b) Apply configuration from the modified file to the configuration coordinator through the cluster IP address.

```
1 > batch -f /nsconfig/ns_backup.conf -o /nsconfig/batch_output  
> **Note:** > > The output of the commands is saved in the  
> `batch_output` file. You must review the output file to  
> ensure that the necessary commands are run without errors.
```

- c) Configure external traffic distribution mechanisms like ECMP or cluster link aggregation.

Note:

Ensure that you configure the necessary spotted configuration on the cluster nodes. For more information on the list of spotted configuration, see [List of spotted configuration](#) and [Supportability matrix for NetScaler cluster](#).

7. Switch the traffic from the HA setup to the cluster.

- a) Log on to the primary instance, NS1, and disable all the data interfaces on it.

```
1 > disable interface <interface_id>
```

- b) Log on to the cluster IP address and configure NS2 as an ACTIVE node.

```
1 > set cluster node 0 -state ACTIVE
```

Note

There might be a minimal downtime between disabling the interfaces and making the cluster node active.

8. Ensure that the cluster and all the services are up.

9. Log on to the primary instance, NS1, and remove it from the HA setup.

- a) Clear the configuration. This operation removes NS1 from the HA setup and makes it a standalone instance.

```
1 > clear ns config full
```

- b) Enable all the data interfaces.

```
1 > enable interface <interface_id>
```

10. Add NS1 to the cluster.

- a) Log on to the cluster IP address and add NS1 to the cluster.

```
1 > add cluster node 1 198.51.100.131 -state PASSIVE -backplane  
1/1/1
```

- b) Log on to NS1 and join it to the cluster by sequentially running the following commands:

```
1 > join cluster -clip 198.51.100.133 -password nsroot  
2  
3 > save ns config  
4  
5 > reboot -warm
```

11. Log on to NS1 and perform the required topological and configuration changes.

Note:

Ensure that you configure the necessary spotted configuration on the cluster nodes. For more information on the list of spotted configuration, see [List of spotted configuration](#) and [Supportability matrix for NetScaler cluster](#).

12. Log on to the cluster IP address and set NS1 as an ACTIVE node.

```
1 > set cluster node 1 -state ACTIVE
```

Transitioning between a L2 and L3 Cluster

May 2, 2023

Note

Supported from NetScaler 11 onwards.

An L2 cluster is one where all the nodes are from the same network and an L3 cluster is one that can include nodes from different networks. You can seamlessly transition from one type of cluster to the other without any downtime for the applications that are deployed on the NetScaler.

Transitioning a cluster from L2 to L3

You can transition to an L3 cluster when you want the cluster to include nodes from other networks.

On the cluster IP address, do the following:

1. Create a node group.

Example

```
1 > add cluster nodegroup NG0
```

This node group is used in the next step to group all the nodes from the existing L2 cluster.

2. Transition the L2 cluster to an L3 cluster.

Example

```
1 > set cluster instance 1 -inc ENABLED -nodegroup NG0
```

This command achieves the dual purpose of transitioning to the L3 cluster and also adding all the nodes of the L2 cluster to the node group.

3. Now, you can add more nodes to the cluster as explained in [Adding a Node to the Cluster](#).

Transitioning a cluster from L3 to L2

You can transition to an L2 cluster when you want to retain nodes that belong to a single network.

On the cluster IP address, do the following:

1. Remove the cluster nodes from the networks that you do not want to retain.

Example

```
1 > rm cluster node <nodeId>
```

2. Transition the L3 cluster to a L2 cluster.

Example

```
1 > set cluster instance 1 -inc DISABLED
```

The cluster now includes nodes only of a single network.

Setting up GSLB in a cluster

December 21, 2020

Note

Supported from NetScaler 10.5 Build 52.11 onwards.

To set up GSLB in a cluster you must bind the different GSLB entities to a node group. The node group must have a single member node.

Notes

- If you have configured the static proximity GSLB method, make sure that the static proximity database is present on all the cluster nodes. It happens by default if the database file is available at the default location. However, if the database file is maintained in a directory other than `/var/netscaler/locdb/`, you must manually sync the file to all the cluster nodes.
- The `show gslb domain` command is not supported in a cluster setup.

To set up GSLB in a cluster by using the CLI:

Log on to the cluster IP address and perform the following operations at the command prompt:

1. Configure the different GSLB entities. For information, see [GSLB Configuration Entities](#).

Note

When creating the GSLB site, make sure that you specify the cluster IP address and public cluster IP address. The public cluster IP address is needed only when the cluster is deployed behind a NAT device. While configuring a GSLB site, you must use the cluster IP address of the same site. These parameters are required to ensure the availability of the GSLB auto-sync functionality.

```
add gslb site <siteName> <siteType> <siteIPAddress> -publicIP <ip_addr> -clip <ip_addr> <publicCLIP><!--NeedCopy-->
```

2. Create a cluster node group.

```
add cluster nodegroup <name> <name>@ [-strict ( YES | NO )] [-sticky ( YES | NO )] [-state <state>] [-priority <positive_integer>]<!--NeedCopy-->
```

Note

Enable the sticky option if you want to set up GSLB based for VPN users.

3. Bind a single cluster node to the node group.

```
bind cluster nodegroup <name> -node <nodeId><!--NeedCopy-->
```

4. Bind the local GSLB site to the node group.

```
bind cluster nodegroup <name> -gslbSite <string><!--NeedCopy-->
```

Note

Make sure that the IP address of the local GSLB site IP address is striped (available across all cluster nodes).

5. Bind the ADNS (or ADNS-TCP) service or the DNS (or DNS-TCP) load balancing virtual server to the node group.

To bind the ADNS service:

```
bind cluster nodegroup -service
```

```
1  **To bind the DNS load balancing virtual server:**
2
3  ``bind cluster nodegroup <name> -vServer <string><!--NeedCopy-->
```

6. Bind the GSLB virtual server to the node group.

```
bind cluster nodegroup <name> -vServer <string><!--NeedCopy-->
```

7. [Optional] To set up GSLB based on VPN users, bind the VPN virtual server to the GSLB node group.

```
bind cluster nodegroup <name> -vServer <string><!--NeedCopy-->
```

8. Verify the configurations.

```
show gslb runningConfig<!--NeedCopy-->
```

To set up GSLB in a cluster by using the GUI:

Log on to the cluster IP address and perform the following operations in the Configuration tab:

1. Configure the GSLB entities.

Navigate to **Traffic Management > GSLB** to perform the required configurations.

2. Create a node group and perform other node group related configurations.

Navigate to **System > Cluster > Node Groups** to perform the required configurations.

For the detailed configurations to be performed, see the description provided in the preceding CLI procedure.

Support for GSLB parent-child topology in a cluster

Starting with NetScaler 12.1 build 49.xx, GSLB parent-child topology is supported in cluster.

For more information about the parent-child topology, see [Parent-child topology deployment using the MEP protocol](#).

To set up GSLB parent-child topology in a cluster by using the CLI**Parent site** Perform the following configuration:

1. Create a cluster node group.

```
add cluster nodegroup <name>
```

Example:

```
add cluster nodegroup parentng
```

2. Bind a single cluster node to the node group.

```
bind cluster nodegroup <name> -node <nodeId>
```

Example:

```
bind cluster nodegroup parentng -node n2
```

3. Bind the local GSLB site to the node group.

```
bind cluster nodegroup <name> -gslbSite <string>
```

Example:

```
bind cluster nodegroup parentng -gslbSite site1
```

4. Bind the ADNS (or ADNS-TCP) service or the DNS (or DNS-TCP) load balancing virtual server to the node group.

```
bind cluster nodegroup <name> -service <string>
```

Example:

```
bind cluster nodegroup parentng - service ADNS
```

5. Bind the GSLB virtual server to the node group.

```
bind cluster nodegroup <name> -vServer <string>
```

Example:

```
bind cluster nodegroup parentng -vService gslbvs1
```

Child site Perform the following configuration:

1. Create a cluster node group.

```
add cluster nodegroup <name>
```

Example:

```
add cluster nodegroup childng
```

2. Bind a single cluster node to the node group.

```
bind cluster nodegroup <name> -node <nodeId>
```

Example:

```
bind cluster nodegroup childng -node -n3
```

3. Bind the local GSLB site to the node group.

```
bind cluster nodegroup <name> -gslbSite <string>
```

Example:

```
bind cluster nodegroup childng -gslbSite site1
```

Note

For parent and child sites to exchange aggregated statistics in metric-based load balancing methods, you must add local GSLB services on the child site. The metric-based load balancing methods are least connection, least bandwidth, and least packets.

To set up GSLB parent-child topology in a cluster by using the GUI

1. Configure the GSLB entities.

Navigate to **Traffic Management > GSLB** to perform the required configurations.

2. Create a node group.

Navigate to **System > Cluster > Node Groups** to perform the required configurations.

3. In the Node Group page, select the node group to which you want to bind a node, click **Edit**, and perform the following tasks. You can also perform these tasks when adding a node group.

- Bind a node to the node group.

In **Advance Settings**, click **Cluster Nodes** and perform the following tasks:

- In **Cluster Nodes** section, click **No Cluster Node**.
- In **Select Cluster Node**, click > and select the node that you want to bind to the node group. You can also add a cluster node.

- Bind the local GSLB site to the node group.

In Advance Settings, click **GSLB Sites** and perform the following tasks:

- In the **GSLB Sites** section, click **No GSLB Site**.
- In the **Select GSLB Site**, click > and select the GSLB site that you want to bind to the node group. You can also add a GSLB site.

- Bind the GSLB virtual server to the node group.
In **Advance Settings**, click **Virtual Servers** and perform the following task:
 - In the **Virtual Servers** pane, click +.
 - In **Choose Virtual Server**, select the server that you want to bind to the node group.
- Bind the ADNS (or ADNS-TCP) service or the DNS (or DNS-TCP) load balancing virtual server to the node group.
In **Advance Settings**, click **Services** and perform the following tasks:
 - In **Services** section, click **No Service**.
 - In **Select Service**, select the service that you want to bind to the node group. You can also add a service.

Note

For child sites, you only have to bind the cluster node and local GSLB site to the node group.

Using cache redirection in a cluster

May 2, 2023

Cache redirection in a cluster works in the same way as it does on a standalone NetScaler appliance. The only difference is that the configurations are done on the cluster IP address. For more information on cache redirection, see [Cache Redirection](#).

Points to remember when using cache redirection in transparent mode on a cluster:

- Before configuring cache redirection, make sure that you have connected all nodes to the external switch and that you have linksets configured. Otherwise, client requests are dropped.
- When MAC mode is enabled on a load balancing virtual server, make sure MBF mode is enabled on the cluster by using the enable ns mode MBF command. Otherwise, the requests are sent to origin server directly instead of being sent to the cache server.

Using L2 mode in a cluster setup

September 21, 2020

Note

Supported from NetScaler 10.5 and later releases.

To use L2 mode in a cluster setup, you must make sure of the following:

- Spotted IP addresses must be available on all the nodes as required.
- Linksets must be used to communicate with the external network.
- Asymmetric topologies or asymmetric cluster LA groups are not supported.
- Cluster LA group is recommended.
- Traffic is distributed between the cluster nodes only for deployments where services exist.

Using cluster LA channel with linksets

March 26, 2024

In an asymmetric cluster topology, some cluster nodes are not connected to the upstream network. In such a case, you must use linksets. To optimize the performance, you can bind the interfaces that are connected to the switch as a cluster LA channel and then bind the channel to a linkset.

Note:

We do not recommend using an asymmetric cluster topology.

To understand how a combination of cluster LA channel and linksets can be used, consider a three-node cluster for which the upstream switch has only two ports available. You can connect two of the cluster nodes to the switch and leave the other node unconnected.

Note

Similarly, you can also use a combination of ECMP and linksets in an asymmetric topology.

Figure 1. Linksets and cluster LA channel topology

To configure cluster LA channel and linksets by using the CLI

1. Log on to the cluster IP address.
2. Bind the connected interfaces to a cluster LA channel.

```
1 add channel CLA/1 -ifnum 0/1/2 1/1/2
```

3. Bind the cluster LA channel to the linkset.

```
1 add linkset LS/1 -ifnum CLA/1
```

Backplane on LA channel

December 21, 2020

In this deployment, LA channels are used for the cluster backplane.

- NS0 - nodeId: 0, NSIP: 10.102.29.60
- NS1 - nodeId: 1, NSIP: 10.102.29.70
- NS2 - nodeId: 2, NSIP: 10.102.29.80

To deploy a cluster with the backplane interfaces as LA channels

1. Create a cluster of nodes NS0, NS1, and NS2.

a) Log on to the first node that you want to add to the cluster and do the following:

```

1 > create cluster instance 1
2 > add cluster node 0 10.102.29.60 -state ACTIVE
3 > enable cluster instance 1
4 > add ns ip 10.102.29.61 255.255.255.255 -type CLIP
5 > save ns config
6 > reboot -warm
    
```

b) Log on to the cluster IP address and do the following:

```

1 > add cluster node 1 10.102.29.70 -state ACTIVE
2 > add cluster node 2 10.102.29.80 -state ACTIVE
    
```

c) Log on to the nodes 10.102.29.70 and 10.102.29.80 to join the nodes to the cluster.

```

1 > join cluster -clip 10.102.29.61 -password nsroot
2 > save ns config
3 > reboot -warm
    
```

As seen in the preceding commands, the interfaces 0/1/1, 1/1/1, and 2/1/1 are configured as the backplane interfaces of the three cluster nodes.

2. Log on to the cluster IP address and do the following:

a) Create the LA channels for nodes NS0 and NS1.

```
1 > add channel 0/LA/1 -ifnum 0/1/1 0/1/2
2 > add channel 1/LA/2 -ifnum 1/1/1 1/1/2
```

b) Configure the backplane for the cluster nodes.

```
1 > set cluster node 0 -backplane 0/LA/1
2 > set cluster node 1 -backplane 1/LA/2
3 > set cluster node 2 -backplane 2/1/1
```

Common interfaces for client and server and dedicated interfaces for backplane

May 2, 2023

It is a one-arm deployment of the NetScaler cluster. In this deployment, the client and server networks use the same interfaces to communicate with the cluster. The cluster backplane uses dedicated interfaces for inter-node communication.

- NS0 - nodeId: 0, NSIP: 10.102.29.60
- NS1 - nodeId: 1, NSIP: 10.102.29.70
- NS2 - nodeId: 2, NSIP: 10.102.29.80

To deploy a cluster with a common interface for the client and server and a different interface for the cluster backplane

1. Create a cluster of nodes NS0, NS1, and NS2.
2. Log on to the first node that you want to add to the cluster and do the following:

```

1 > create cluster instance 1
2 > add cluster node 0 10.102.29.60 -state ACTIVE -backplane
    0/1/1
3 > enable cluster instance 1
4 > add ns ip 10.102.29.61 255.255.255.255 -type CLIP
5 > save ns config
6 > reboot -warm
    
```

3. Log on to the cluster IP address and do the following:

```

1 > add cluster node 1 10.102.29.70 -state ACTIVE -backplane
    1/1/1
2 > add cluster node 2 10.102.29.80 -state ACTIVE -backplane
    2/1/1
    
```

4. Log on to the nodes 10.102.29.70 and 10.102.29.80 to join the nodes to the cluster.

```
1 > join cluster -clip 10.102.29.61 -password nsroot
2 > save ns config
3 > reboot -warm
```

As seen in the preceding commands, the interfaces 0/1/1, 1/1/1, and 2/1/1 are configured as the backplane interfaces of the three cluster nodes.

1. On the cluster IP address, create VLANs for the backplane interfaces and for the client and server interfaces.

//For the backplane interfaces

```
1 > add vlan 10
2 > bind vlan 10 0/1/1 1/1/1 2/1/1
```

//For the interfaces that are connected to the client and server networks.

```
1 > add vlan 20
2 > bind vlan 20 0/1/2 1/1/2 2/1/2
```

2. On the switch, create VLANs for the interfaces corresponding to the backplane interfaces and the client and server interfaces. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1) switch. Similar configurations must be performed on other switches.

//For the backplane interfaces. Repeat for each interface...

```
1 > interface Ethernet2/47
2   switchport access vlan 100
3   switchport mode access
4   end
```

//For the interfaces connected to the client and server networks. Repeat for each interface...

```
1 > interface Ethernet2/47
2   switchport access vlan 200
3   switchport mode access
4   end
```

Common switch for client, server, and backplane

May 2, 2023

In this deployment, the client, server, and backplane use dedicated interfaces on the same switch to communicate with the NetScaler cluster.

- NS0 - nodeId: 0, NSIP: 10.102.29.60
- NS1 - nodeId: 1, NSIP: 10.102.29.70
- NS2 - nodeId: 2, NSIP: 10.102.29.80

To deploy a cluster with a common switch for the client, server, and backplane

1. Create a cluster of nodes NS0, NS1, and NS2.
2. Log on to the first node that you want to add to the cluster and do the following:

```

1 > create cluster instance 1
2 > add cluster node 0 10.102.29.60 -state ACTIVE -backplane
    0/1/1
3 > enable cluster instance 1
    
```

```
4 > add ns ip 10.102.29.61 255.255.255.255 -type CLIP
5 > save ns config
6 > reboot -warm
```

3. Log on to the cluster IP address and do the following:

```
1 > add cluster node 1 10.102.29.70 -state ACTIVE -backplane
    1/1/1
2 > add cluster node 2 10.102.29.80 -state ACTIVE -backplane
    2/1/1
```

4. Log on to the nodes 10.102.29.70 and 10.102.29.80 to join the nodes to the cluster.

```
1 > join cluster -clip 10.102.29.61 -password nsroot
2 > save ns config
3 > reboot -warm
```

As seen in the preceding commands, the interfaces 0/1/1, 1/1/1, and 2/1/1 are configured as the backplane interfaces of the three cluster nodes.

1. On the cluster IP address, create VLANs for the backplane, client, and server interfaces.

//For the backplane interfaces

```
1 > add vlan 10
2 > bind vlan 10 0/1/1 1/1/1 2/1/1
```

//For the client-side interfaces

```
1 > add vlan 20
2 > bind vlan 20 0/1/2 1/1/2 2/1/2
```

//For the server-side interfaces

```
1 > add vlan 30
2 > bind vlan 30 0/1/3 1/1/3 2/1/3
```

2. On the switch, create VLANs for the interfaces corresponding to the backplane interfaces and the client and server interfaces. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1) switch. Similar configurations must be performed on other switches.

//For the backplane interfaces. Repeat for each interface...

```
1 > interface Ethernet2/47
2   switchport access vlan 100
3   switchport mode access
4   end
```

//For the client interfaces. Repeat for each interface...

```
1 > interface Ethernet2/48
2   switchport access vlan 200
3   switchport mode access
4   end
```

//For the server interfaces. Repeat for each interface...

```
1 > interface Ethernet2/49
2   switchport access vlan 300
3   switchport mode access
4   end
```

Common switch for client and server and dedicated switch for backplane

May 2, 2023

In this deployment, the clients and servers use different interfaces on the same switch to communicate with the NetScaler cluster. The cluster backplane uses a dedicated switch for inter-node communication.

- NS0 - nodeId: 0, NSIP: 10.102.29.60
- NS1 - nodeId: 1, NSIP: 10.102.29.70
- NS2 - nodeId: 2, NSIP: 10.102.29.80

To deploy a cluster with the same switch for the clients and servers and a different switch for the cluster backplane

1. Create a cluster of nodes NS0, NS1, and NS2.
 - Log on to the first node that you want to add to the cluster and do the following:

```

1 > create cluster instance 1
2 > add cluster node 0 10.102.29.60 -state ACTIVE -backplane
    0/1/1
3 > enable cluster instance 1
4 > add ns ip 10.102.29.61 255.255.255.255 -type CLIP
5 > save ns config
6 > reboot -warm

```

- Log on to the cluster IP address and do the following:

```

1 > add cluster node 1 10.102.29.70 -state ACTIVE -backplane
    1/1/1
2 > add cluster node 2 10.102.29.80 -state ACTIVE -backplane
    2/1/1

```

- Log on to the nodes 10.102.29.70 and 10.102.29.80 to join the nodes to the cluster.

```

1 > join cluster -clip 10.102.29.61 -password nsroot
2 > save ns config
3 > reboot -warm

```

As seen in the preceding commands, the interfaces 0/1/1, 1/1/1, and 2/1/1 are configured as the backplane interfaces of the three cluster nodes.

2. On the cluster IP address, create VLANs for the backplane, client, and server interfaces.

//For the backplane interfaces

```

1 > add vlan 10
2 > bind vlan 10 0/1/1 1/1/1 2/1/1

```

//For the client-side interfaces

```

1 > add vlan 20
2 > bind vlan 20 0/1/2 1/1/2 2/1/2

```

//For the server-side interfaces

```

1 > add vlan 30
2 > bind vlan 30 0/1/3 1/1/3 2/1/3

```

3. On the switch, create VLANs for the interfaces corresponding to the backplane interfaces and the client and server interfaces. The following sample configurations are provided for the Cisco® Nexus 7000 C7010 Release 5.2(1) switch. Similar configurations must be performed on other switches.

//For the backplane interfaces. Repeat for each interface...

```

1 > interface Ethernet2/47
2 > switchport access vlan 100
3 > switchport mode access

```

```
4 > end
```

//For the client interfaces. Repeat for each interface...

```
1 > interface Ethernet2/48
2 > switchport access vlan 200
3 > switchport mode access
4 > end
```

//For the server interfaces. Repeat for each interface...

```
1 > interface Ethernet2/49
2 > switchport access vlan 300
3 > switchport mode access
4 > end
```

Different switch for every node

December 7, 2020

In this deployment, each cluster node is connected to a different switch and trunk links are configured between the switches.

The cluster configurations are the same as the other deployments scenarios. Most of the client-side configurations is done on the client-side switches.

Sample cluster configurations

May 2, 2023

The following example can be used to configure a four-node cluster with ECMP, cluster LA, or Linksets.

1. Create the cluster.
 - Log on to the first node.
 - Add the cluster instance.

```
1 > add cluster instance 1
```

- Add the first node to the cluster.

```
1 > add cluster node 0 10.102.33.184 -backplane 0/1/1
```

- Enable the cluster instance.

```
1 > enable cluster instance 1
```

- Add the cluster IP address.

```
1 > add ns ip 10.102.33.185 255.255.255.255 -type CLIP
```

- Save the configurations.

```
1 > save ns config
```

- Warm reboot the appliance.

```
1 > reboot -warm
```

2. Add the other three nodes to the cluster.

- Log on to cluster IP address.
- Add the second node to the cluster.

```
1 > add cluster node 1 10.102.33.187 -backplane 1/1/1
```

- Add the third node to the cluster.

```
1 > add cluster node 2 10.102.33.188 -backplane 2/1/1
```

- Add the fourth node to the cluster.

```
1 > add cluster node 3 10.102.33.189 -backplane 3/1/1
```

3. Join the added nodes to the cluster. This step is not applicable for the first node.

- Log on to each newly added node.
- Join the node to the cluster.

```
1 > join cluster -clip 10.102.33.185 -password nsroot
```

- Save the configuration.

```
1 > save ns config
```

- Warm reboot the appliance.

```
1 > reboot -warm
```

4. Configure the NetScaler cluster through the cluster IP address.

```
// Enable load balancing feature
```

```
1 > enable ns feature lb
```

```
// Add a load balancing virtual server
```

```
1 > add lb vserver first_lbserver http
2 ....
3 ....
```

5. Configure any one of the following (ECMP, cluster LA, or Linkset) traffic distribution mechanisms for the cluster.

ECMP

- Log on to the cluster IP address.
- Enable the OSPF routing protocol.

```
1 > enable ns feature ospf
```

- Add a VLAN.

```
1 > add vlan 97
```

- Bind the interfaces of the cluster nodes to the VLAN.

```
1 > bind vlan 97 -ifnum 0/1/4 1/1/4 2/1/4 3/1/4
```

- Add a spotted SNIP on each node and enable dynamic routing on it.

```
1 > add ns ip 1.1.1.10 255.255.255.0 -ownerNode 0 -
dynamicRouting ENABLED
2 > add ns ip 1.1.1.11 255.255.255.0 -ownerNode 1 -
dynamicRouting ENABLED
3 > add ns ip 1.1.1.12 255.255.255.0 -ownerNode 2 -
dynamicRouting ENABLED
4 > add ns ip 1.1.1.13 255.255.255.0 -ownerNode 3 -
dynamicRouting ENABLED
```

- Bind one of the SNIP addresses to the VLAN.

```
1 > bind vlan 97 -ipAddress 1.1.1.10 255.255.255.0
```

- Configure the routing protocol on ZebOS by using the VTYSH shell.

Static cluster LA

- Log on to the cluster IP address.
- Add a cluster LA channel.

```
1 > add channel CLA/1 -speed 1000
```

- Bind the interfaces to the cluster LA channel.

```
1 > bind channel CLA/1 0/1/5 1/1/5 2/1/5 3/1/5
```

- Perform an equivalent configuration on the switch.

Dynamic cluster LA

- * Log on to the cluster IP address.
- * Add the interfaces to the cluster LA channel.

```
1 > set interface 0/1/5 -lacpmode active -lacpkey 5 -
lagtype cluster
2 > set interface 1/1/5 -lacpmode active -lacpkey 5 -
lagtype cluster
3 > set interface 2/1/5 -lacpmode active -lacpkey 5 -
lagtype cluster
4 > set interface 3/1/5 -lacpmode active -lacpkey 5 -
lagtype cluster
```

- * Perform an equivalent configuration on the switch.

Linksets. Assume that the node with nodeId 3 is not connected to the switch. You must configure a linkset so that the unconnected node can use the other node interfaces to communicate with the switch.

- a) Log on to the cluster IP address.
- b) Add a linkset.

```
1 > add linkset LS/1
```

- c) Bind the connected interfaces to the linkset.

```
1 > bind linkset LS/1 -ifnum 0/1/6 1/1/6 2/1/6
```

6. Update the state of the cluster nodes to ACTIVE.

```
1 > set cluster node 0 -state ACTIVE
2 > set cluster node 1 -state ACTIVE
3 > set cluster node 2 -state ACTIVE
4 > set cluster node 3 -state ACTIVE
```

Using VRRP in a cluster setup

September 21, 2020

Virtual Router Redundancy Protocol (VRRP) is supported in a cluster setup for both IPv4 and IPv6. The two VRRP features supported in a cluster setup are Interface based VRRP and IP based VRRP.

IP based VRRP

In IP based VRRP, striped VIP addresses bound to the same VRID are configured on all nodes of a cluster setup. These VIP addresses are active on all the nodes

One of the cluster nodes acts as the VRID owner and sends out the VRRP advertisement to other nodes. If there is failure of the VRID owner node, another node in the cluster assumes the ownership of the VRID and starts sending VRRP advertisements. You can also assign a specific cluster node as the owner of the VRID.

Note

Citrix recommends you to use IP based method for VRRP deployment in cluster.

Configuring IP based VRRP for IPv4

Perform the following tasks on a cluster setup for configuring IP based VRRP for IPv4:

- **Add a VRID.** A VRID is an integer used by the Cluster setup to form a virtual MAC address. The generic VMAC address is in the form of 00:00:5e:00:02:<VRID>.
- **(Optional) Assign a node as the owner of the virtual MAC address.** You can set the owner node parameter (while adding or modifying VRID6) to the ID of the cluster node to assign it as the owner of the virtual MAC address. If the assigned owner node fails, one of the UP cluster nodes is dynamically elected as the owner of the virtual MAC address. You can set the owner node using the `set vrid <id> -ownerNode <positive_integer>` command.
- **Bind the VRID to the VIP address of the nodes.** Bind the created VRID to the striped VIP address.

To add a VRID by using the CLI

At the command prompt, type:

```
1 - add vrid <ID> [-ownerNode <positive_integer>]
2 - show vrid <ID>
```

To bind the VRID to VIP address by using the CLI

At the command prompt, type:

- `set ns ip <IPv4Address> -vrid <ID><!--NeedCopy-->`
- `show vrid <ID><!--NeedCopy-->`

To add a VRID by using the GUI

1. Navigate to **System > Network > VMAC** and, on the **VMAC** tab, click **Add**.
2. On the Create **VMAC** page, specify a value in the **Virtual Router ID** field and then click **Create**.

To bind the VRID to a VIP address by using the GUI

1. Navigate to **System > Network > IPs**, on the **IPV4s** tab, select a VIP address and click **Edit**.
2. Set the **Virtual Router ID** parameter while editing the VIP configuration.

```
1 > add vrid 90
2 Done
3 > set ns ip 192.0.2.90 -vrid 90
4 Done
```

Configuring IP based VRRP for IPv6

Perform the following tasks on a cluster setup for configuring IP based VRRP for IPv6:

- **Add a VRID6.** A VRID6 is an integer used by the Cluster setup to form a virtual MAC6 address. The generic VMAC6 address is in the form of 00:00:5e:00:02:<VRID6>.
- **(Optional) Assign a node as the owner of the virtual MAC6 address.** You can set the owner node parameter (while adding or modifying VRID6) to the ID of the cluster node to assign it as the owner of the virtual MAC6 address. If the assigned owner node fails, one of the UP cluster nodes is dynamically elected as the owner of the virtual MAC6 address.
- **Bind the VRID6 to the VIP6 address of the nodes.** Bind the created VRID6 to the striped VIP6 address.

To add a VRID6 by using the CLI

At the command prompt, type:

- `add vrid6 <ID> [-ownerNode <positive_integer>]<!--NeedCopy-->`
- `show vrid6 <ID><!--NeedCopy-->`

To bind the VRID6 to VIP6 address by using the CLI

At the command prompt, type:

- `set ns ip6 <IPv6Address> -vrid6 <ID><!--NeedCopy-->`
- `show vrid6 <ID><!--NeedCopy-->`

To add a VRID6 by using the GUI

1. Navigate to **System > Network > VMAC** and, on the **VMAC6** tab, click **Add**.
2. On the **Create virtual MAC6** page, specify a value in the **Virtual Router ID** field and then click **Create**.

To bind the VRID6 to a VIP6 address by using the GUI

1. Navigate to **System > Network > IPs**, on the **IPV6s** tab, select a VIP address and click **Edit**.
2. Set the **Virtual Router ID** parameter while editing the VIP6 configuration.

```
1 > add vrid6 90
2 Done
3 > set ns ip6 2001:db8::5001 - vrid6 90
4 Done
```

Interface based VRRP

In the interface based VRRP feature, the same virtual MAC address is configured on both the nodes of the cluster. This virtual MAC address is used in GARP advertisements and ARP responses for the IP addresses configured on a node. This feature is useful in an active-spare two-node cluster setup that has external devices/routers that do not accept GARP advertisements.

Note

The interface based VRRP feature is applicable only to a two-node cluster with one node in active state and the other node serving as a spare.

With the same virtual MAC address on both cluster nodes, when the active node goes down and the spare node takes over as active, the MAC address for the IP addresses on the new active node remain unchanged and the ARP tables on the external devices/routers do not need to be updated.

Configuring interface based VRRP for IPv4

Perform the following tasks on a cluster setup to configure interface based VRRP for IPv4:

- **Add a VRID.** A VRID is an integer used by the Cluster setup to form a virtual MAC address.
- **Bind the VRID to node interfaces.** Bind the interfaces to the created VRID. The bound interfaces (in the current active node) use the virtual MAC address in GARP advertisements and ARP responses for its IPv4 addresses. You must associate the VRID to the interfaces of both nodes of the active-spare cluster setup. This is because unlike in a high availability setup, interface IDs differ in a cluster setup.

To add a VRID by using the CLI

At the command prompt, type:

```
1 - add vrid <ID>
2 - show vrid <ID>
```

To bind the VRID to an interface by using the CLI

At the command prompt, type:

```
1 - bind vrid <ID> -ifnum <interface_name>
2 - show vrid <ID>
```

To add a VRID and bind it to interfaces by using the GUI

1. Navigate to **System > Network > VMAC** and, on the **VMAC** tab, click **Add**.
2. On the **Create virtual MAC** page, specify a value in the **Virtual Router ID*** field, bind interfaces in the **Associate Interfaces** section, and then click **Create**.

```
1 > add vrid 300
2 Done
3 > bind vrid 300 -ifnum 1/1/2 2/1/3
4 Done
```

Configuring interface based VRRP for IPv6

Perform the following tasks on a cluster setup to configure interface based VRRP for IPv6:

- **Add a VRID6.** A VRID6 is an integer used by the Cluster setup to form a virtual MAC6 address. The generic VMAC6 address is in the form of 00:00:5e:00:01:<VRID6>.

- **Bind the VRID6 to node interfaces.** Bind the interfaces to the created VRID6. The bound interfaces (in the current active node) use the virtual MAC6 address in GARP advertisements and ARP responses for its IPv6 addresses. You must associate the VRID6 to the interfaces of both nodes of the active-spare cluster setup. This is because unlike in a high availability setup, interface IDs differ in a cluster setup.

To add a VRID6 by using the CLI

At the command prompt, type:

```
1 - add vrid6 <ID>
2 - show vrid6 <ID>
```

To bind the VRID6 to an interface by using the CLI

At the command prompt, type:

- `bind vrid6 <ID> -ifnum <interface_name><!--NeedCopy-->`
- `show vrid6 <ID><!--NeedCopy-->`

To add a VRID6 and bind it to interfaces by using the GUI

1. Navigate **System > Network > VMAC** and, on the **VMAC6** tab, click **Add**.
2. On the **Create virtual MAC6** page, specify a value in the **Virtual Router ID** field, bind interfaces in the **Associate Interfaces** section, and then click **Create**.

```
1 > add vrid6 100
2 Done
3 > bind vrid6 100 -ifnum 0/1/1 1/1/2 2/1/3
4 Done
```

Monitoring services in a cluster using path monitoring

May 2, 2023

In a cluster setup, ownership for monitoring services is distributed among the nodes. Therefore, different nodes monitor different services. The node that monitors a service is called the service owner. Only the service owner probes the server to monitor the status of the services assigned to it. It further

communicates the status of the services to all other nodes within the cluster. The drawback with distributed monitoring is that the network connectivity and link state between all nodes and the server is not determined. To overcome this drawback, you can use path monitoring.

Note

You cannot select a node to monitor a service. The selection of nodes to monitor a service is done through an internal mechanism. You can see the owner node to monitor services by using the `show service <service name>` and `show serviceGroup <service group name>` command.

Path monitoring checks the network connectivity and link state between a node and the service provided by the server. A node sends ICMP pings to verify whether the server is reachable or not.

How path monitoring works

Consider an example of a NetScaler cluster consisting of three nodes N1, N2, and N3. N2 is the service owner that monitors the state of HTTP services (S1). It advertises the service state to other nodes in the cluster. Path monitoring is enabled on all nodes in the cluster, for all the services. Each node sends only an ICMP ping to the server. The service owner sends both the HTTP service request and an ICMP ping. Each node reports its path monitoring state to the service owner.

The following two parameters determine the service state of a node:

- S = service state advertised by the service owner
- P = path monitoring state of each node

Whether a node can reach a server or not, determines the path monitoring state for that node.

The following table shows the service state set based on the path monitoring state, when the pathMonitorIndv parameter is enabled or disabled.

| Parameter | Path monitoring state | Service state |
|---|-----------------------|---------------|
| pathMonitorIndv = NO; Is the default configuration. | P1 = DOWN | S1 = DOWN |
| | P2 = UP | S1 = DOWN |
| | P3 = UP | S1 = DOWN |
| pathMonitorIndv = YES | P1 = DOWN | S1 = DOWN |
| | P2 = UP | S1 = UP |
| | P3 = UP | S1 = UP |

In this example, the service owner decides the service state for all the nodes based on the node whose path monitoring state is set to DOWN. If the path monitoring state for any of the nodes is DOWN, then the service owner sets the service state for all the nodes as DOWN. The service state for all the nodes is set to UP only if the path monitoring state for each of the node is UP.

You can use path monitoring for individual nodes by enabling the pathMonitorIndv parameter. This parameter enables the service owner to set the service state for each node based on the path monitoring state of that respective node.

Note

If the pathMonitorIndv parameter is set, some features like persistence might break.

Configuring path monitoring

Path monitoring is applicable for all the services and service groups. Path monitoring parameter is disabled by default.

To enable path monitoring for services/service groups by using the CLI

At the command prompt, type:

```
1 add service <service name> <IP address> <service type> <port> [-  
  pathMonitor <YES | NO>] [-pathMonitorIndv <YES | NO>]  
2  
3 add servicegroup <servicegroup name> <service type> [-pathMonitor <YES  
  | NO>] [-pathMonitorIndv <YES | NO>]  
4 <!--NeedCopy-->
```

Example:

```
1 add service s1 1.1.1.1 HTTP 80 -pathMonitor YES  
2 add servicegroup sg_1 HTTP -pathMonitor YES  
3  
4 add service s1 1.1.1.1 HTTP 80 -pathMonitor YES -pathMonitorIndv YES  
5 add servicegroup sg_1 HTTP -pathMonitor YES -pathMonitorIndv YES  
6 <!--NeedCopy-->
```

You can also set the path monitoring parameter from the set command, as follows:

```
1 set service <service name> [-pathMonitor <YES | NO>] [-pathMonitorIndv  
  <YES | NO>]  
2 set servicegroup <servicegroup name> [-pathMonitor <YES | NO>] [-  
  pathMonitorIndv <YES | NO>]  
3 <!--NeedCopy-->
```

Example:

```
1 set service s1 -pathMonitor YES  
2 set servicegroup sg_1 -pathMonitor YES  
3  
4  
5 set service s1 -pathMonitorIndv YES  
6 set servicegroup sg_1 -pathMonitorIndv NO  
7 <!--NeedCopy-->
```

To enable path monitoring for services/service groups by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**.

For service groups, navigate to **Traffic Management > Load Balancing > Service Groups**.

2. In the **Services/Service Groups** pane, select a service/service group from the list, and then double-click to open it.
3. On the **Service Settings** tab, click **Edit**.
4. Select **Path Monitoring**.
5. Select **Individual Path Monitoring**, if you want to apply it, and then click **OK**.

Note

You can enable Individual Path Monitoring only if you enable Path Monitoring.

Backup and restore of cluster setup

May 2, 2023

You can back up the current state of a NetScaler cluster node. Later, you can use the backed-up files to restore the node to the same cluster state. As a precautionary measure, you must use this feature before performing an upgrade on the cluster nodes.

Back up a cluster Setup

You can take a basic or full backup depending on the following:

- Type of data to be backed up.
- Frequency at which you create a backup.
- **Basic back up.** Backs up only configuration files. You might want to perform this type of backup frequently, because the files it backs up change constantly. The files that are backed up are listed in the table.

Directory

Sub-Directory or Files

/nsconfig/

- ns.conf
- ZebOS.conf
- rc.netscaler
- snmpd.conf
- nsbefore.sh
- nsafter.sh
- inetd.conf
- ntp.conf
- syslog.conf
- newsyslog.conf
- crontab
- host.conf

- hosts
- ttys
- sshd_config
- httpd.conf
- monitrc
- rc.conf
- ssh_config
- local time
- issue
- issue.net

/var/

- download/*
- log/wicmd.log
- wi/tomcat/webapps/*
- wi/tomcat/logs/*
- wi/tomcat/conf/catalina/localhost/*
- nslw.bin/etc/krb.conf
- nslw.bin/etc/krb.keytab
- netscaler/locdb/*
- lib/likewise/db/*
- vpn/bookmark/*
- netscaler/crl
- nstemplates/*
- learnt_data/*

/netscaler/

- custom.html
- vsr.html
- **Full back up.** Apart from the files that are backed up by a basic backup, a full backup backs up some less frequently updated files. The files that are backed up when using the full backup option are listed in the table.

Directory

Sub-Directory or Files

/nsconfig/

- ssl/*
- license/*

- fips/*

/var/

- netScaler/ssl/*
- wi/java_home/jre/lib/security/cacerts/*
- wi/java_home/lib/security/cacerts/*

Important

The backup and restore do not work if CLAG is configured on an SDX cluster setup.

The backup is stored as a compressed TAR file in the /var/ns_sys_backup/ directory. To avoid issues due to non-availability of disk space, you can store a maximum of 50 backup files in this directory. You can use the rm system backup command to delete existing backup files so that you can create more backups.

When you perform the back-up operation on a CLIP of a cluster setup, back up files are created on each of the cluster nodes.

How to back up a cluster setup

To back up the cluster setup on CLIP by using the NetScaler CLI.

At the command prompt, do the following:

- Save the configuration.

```
save ns config<!--NeedCopy-->
```

- Create the backup file (basic or full).

```
“create system backup [[-level (basic | full)]][-comment ]
```

```
1  **Example**
2
3  ``create system backup cluster-backup-1 -level basic<!--
   NeedCopy-->
```

The preceding command creates a back-up TAR file on each of the cluster node with the specified file name. For example, the CLUSTER-backup-1.tgz file is created on each of the cluster node.

Note

If the file name is not specified, back up TAR files are created on each of the cluster nodes with the following naming convention:

- backup_<level>_<nsip_address of the cluster node 0>_<date-

- ```
timestamp>.tgz<!--NeedCopy-->
```
- `backup_<level>_<nsip_address of the cluster node 1>_<date-timestamp>.tgz<!--NeedCopy-->`

For example, on a three node cluster setup,

- `backup_<level>_<nsip_address of the cluster node 0>_<date-timestamp>.tgz<!--NeedCopy-->` is created on node0
  - `backup_<level>_<nsip_address of the cluster node 1>_<date-timestamp>.tgz<!--NeedCopy-->` is created on node1
  - `backup_<level>_<nsip_address of the cluster node 2>_<date-timestamp>.tgz<!--NeedCopy-->` is created on node2
- Verify the created backup files on CLIP.  
`show system backup<!--NeedCopy-->`

## Restore a cluster setup

When a cluster node becomes faulty, you can replace this node with a new node. You can set the new node for a cluster, using a backup file of the faulty node.

For example, in a three-node cluster setup, if node1 becomes faulty, you can replace this faulty node with a new node as node1. Using the restore operation, you can restore one of the faulty node's backup files on the new node.

### Note

The restore operation does not succeed if the backup file is renamed or if the contents of the file are modified.

## How to restore a cluster node

**To restore a cluster node by using the CLI At the command prompt, do the following:**

- Obtain a list of the backup files available on CLIP.  
`show system backup<!--NeedCopy-->`
- Copy the backup tar file to the `/var/ns_sys_backup` directory of the cluster node, which is to be restored.
- Add the backup tar file to the cluster node memory by running the following command on the cluster node.  
“add system backup

```
1 **Example**
2
3 ```add system backup CLUSTER-BACKUP-1.tgz<!--NeedCopy-->
```

**Note**

The command must be run on the cluster node to be restored.

- Restore the cluster node by specifying the backup file.

“restore system backup

```
1 **Example**
2
3 ```restore system backup CLUSTER-BACKUP-1.tgz<!--NeedCopy-->
```

**Note**

The command must be run on the cluster node to be restored.

- Reboot the cluster node.

reboot

**Note**

The command must be run on the cluster node to be restored.

## Upgrading or downgrading the NetScaler cluster

December 21, 2023

All the nodes of a NetScaler cluster must be running the same software version. Therefore, to upgrade or downgrade the cluster, you must upgrade or downgrade each NetScaler appliance of the cluster, one node at a time.

A node that is being upgraded or downgraded is not removed from the cluster. The node serves traffic uninterrupted, except for the downtime when the node reboots after it's upgraded or downgraded.

When you upgrade or downgrade the first cluster node, configuration propagation is disabled automatically when there is a cluster version mismatch among the cluster nodes. Configuration propagation is enabled only after you upgrade or downgrade all the cluster nodes. You cannot perform any configuration through the cluster IP address when configuration propagation is disabled.

The following table explains when the configuration propagation is disabled during the upgrade or downgrade of the first cluster node.

Upgrade/Downgrade	From version	To version	Description
Upgrade	13.1 Build 21.50 or earlier	14.1 Build 4.42 or later	Configuration propagation is disabled on the cluster after the cluster node reboots and comes up. <b>Note:</b> You must not perform any configurations through the cluster IP address while the node reboots.
Upgrade	13.1 Build 24.38 or later	14.1 Build 4.42 or later	Configuration propagation is disabled on the cluster just before the node reboots.
Downgrade	14.1 Build 4.42 or later	13.1 Build 21.50 or earlier	Configuration propagation is disabled on the cluster after the cluster node reboots and comes up. <b>Note:</b> You must not perform any configurations through the cluster IP address while the node reboots.
Downgrade	14.1 Build 4.42 or later	13.1 Build 24.38 or later	Configuration propagation is disabled on the cluster just before the node reboots.

You can also verify the status of command propagation using the following command:

```

1 show cluster instance
2 <!--NeedCopy-->

```

**Notes:**

- In a cluster setup with a maximum connection (maxConn) global parameter set to a non-zero value, CLIP connections might fail if any of the following conditions is met:
  - Upgrading the setup from NetScaler 13.0 76.x build to NetScaler 13.0 79.x build.
  - Restarting the CCO node in a cluster setup running NetScaler 13.0 76.x build.

Workarounds:

- Before upgrading a cluster setup from NetScaler 13.0 76.x build to NetScaler 13.0 79.x build, the maximum connection (maxConn) global parameter must be set to zero. After upgrading the setup, you can set the maxConn parameter to a required value and then save the configuration.
- NetScaler 13.0 76.x build is not suitable for cluster setups. Citrix recommends not to use the NetScaler 13.0 76.x build for a cluster setup.
- In a cluster setup, a NetScaler appliance might crash, when:
  - upgrading the setup from NetScaler 13.0 47.x or 13.0 52.x build to a later build, or
  - upgrading the setup to NetScaler 13.0 47.x or 13.0 52.x build

Workaround: During the upgrade process, perform the following steps:

- Disable all cluster nodes and then upgrade each cluster node.
- Enable all cluster nodes after all the nodes are upgraded.

## Points to note before upgrading or downgrading the cluster

- **IMPORTANT:**

It's important that both the upgrade changes and your customizations are applied to an upgraded NetScaler appliance. So, if you have customized configuration files in the `/etc` directory, see [Upgrade considerations for customized configuration files](#) before you proceed with the upgrade.

- You can't add cluster nodes while upgrading or downgrading the cluster software version.
- You can perform node-level configurations through the NSIP address of individual nodes. Make sure to perform the same configurations on all the nodes to maintain them in sync.
- You can't run the `start nstrace` command from the cluster IP address when the cluster is being upgraded. However, you can get the trace of individual nodes by performing this operation on individual cluster nodes using their NSIP address.
- NetScaler 13.0 76.x build isn't suitable for cluster setups. Citrix recommends not to use the NetScaler 13.0 76.x build for a cluster setup.

- NetScaler 13.0 47.x and 13.0 52.x builds aren't suitable for a cluster setup. It is because the inter-node communications aren't compatible in these builds.
- When a cluster is being upgraded, it's possible that the upgraded nodes have some additional features activated that are unavailable on the nodes that aren't yet upgraded. It results in a license mismatch warning while the cluster is being upgraded. This warning is automatically resolved when all the cluster nodes are upgraded.
- When you downgrade the cluster nodes configured with secure heartbeats to release 14.1 Build 8.50 or earlier, you must disable the secure heartbeats and then downgrade the cluster nodes.

### Important

- Citrix recommends that you wait for the previous node to become active before upgrading or downgrading the next node.
- Citrix recommends that the cluster configuration node must be upgraded/downgraded last to avoid multiple disconnects of cluster IP sessions.

## To upgrade or downgrade the software of the cluster nodes

1. Make sure that the cluster is stable and the configurations are synchronized on all the nodes.
2. Access each node through its NSIP address and perform the following:
  - Upgrade or downgrade the cluster node. For detailed information about upgrading and downgrading the software of an appliance, see [Upgrade and downgrade a NetScaler appliance](#).
  - Save the configurations.
  - Reboot the appliance.
3. Repeat step 2 for each of the other cluster nodes.

## Operations supported on individual cluster nodes

May 2, 2023

As a rule, NetScaler appliances that are a part of a cluster cannot be individually configured from their NSIP address. However, there are some operations that are an exception to this rule. These operations, when run from the NSIP address, are not propagated to other cluster nodes.

The operations are:

---

cluster instance (set      rm                      enable                      disable)

---

- 
- 

cluster node (set                                      rm)

---

- 
- 

ns trace (start                      show                      stop)

---

- 
- 

interface (set                      enable                      disable)

---

- 
- 

route (add                      rm                      set                      unset)

---

- 
- 

ARP (add                      rm                      send -all)

---

- 
- force cluster sync
- sync cluster files
- disable NTP sync
- save ns config
- reboot
- shutdown

For example, when you run the command `disable interface 1/1/1` from the NSIP address of a cluster node, the interface is disabled only on that node. Since the command is not propagated, the interface 1/1/1 remains enabled on all the other cluster nodes.

## Support for heterogeneous cluster

May 2, 2023

NetScaler appliance supports a heterogeneous cluster in a cluster deployment. A heterogeneous cluster spans nodes of different NetScaler hardware and you can have a combination of different platforms in the same cluster.

### Important

The formation or supportability of a heterogeneous cluster is possible and limited only to MPX hardware platforms.

The supportability and formation of the heterogeneous cluster depend on certain NetScaler models. The following table lists the platforms that are supported in the formation of a heterogeneous cluster, with an equal number of packet engines.

Number of Packet Engines	MPX Hardware Platforms	Supported MPX Hardware Platforms to form Heterogeneous Cluster
5	MPX 11500	MPX 14020
7	MPX 11515	MPX 14040
9	MPX 11530	MPX 14060

The following table lists the platforms that are supported in the formation of a heterogeneous cluster, with an unequal number of packet engines.

Hardware Platforms	Supported Hardware Platforms to form Heterogeneous Cluster
MPX 150XX	MPX 140XX

For more information on how to form a heterogeneous cluster deployment of NetScaler MPX appliances with the different number of packet engines across different SSL chipsets, see the **Heterogeneous cluster deployments** section in [SSL offloading configuration](#).

### Note

Before release 13.0 build 47.x, if you run the “join cluster” command from the node that has an unequal number of packet engines, the following error message appears: “Mismatch in the number of active PPEs between CCO and local node”.

### Points to note

1. The extra management CPU setting must be the same on all the cluster nodes.
2. The newly added node must have the same capacity on the data planes and backplane, as that of existing cluster nodes.
3. If there are mixed platform devices supporting different ciphers, then the cluster would agree upon a common cipher list.

### FAQs

October 10, 2023

A list of the FAQ about clustering.

#### **How many NetScaler appliances can be included in a single NetScaler cluster?**

A NetScaler cluster can include one appliance or as many as 32 NetScaler nCore hardware or virtual appliances. Each of these nodes must satisfy the criteria specified in [Prerequisites for Cluster Nodes](#).

#### **Can a NetScaler appliance be a part of multiple clusters?**

No. A NetScaler appliance can belong to one cluster only.

#### **What is a cluster IP address? What is its subnet mask?**

The cluster IP address is the management address of a NetScaler cluster. All cluster configurations must be performed by accessing the cluster through this address. The subnet mask of the cluster IP address is fixed at 255.255.255.255.

### How can I make a specific cluster node as the cluster configuration coordinator?

To manually set a specific node as the cluster configuration coordinator, you must set the priority of that node to the lowest numeric value (highest priority). To understand, let us consider a cluster with three nodes that have the following priorities:

n1 - 29, n2 - 30, n3 - 31

Here, n1 is the configuration coordinator. If you want to make n2 the configuration coordinator, you must set its priority to a value that is lower than n1, for example, 28. On saving the configuration, n2 becomes the configuration coordinator.

#### Note

n2 with its original priority value of 30 becomes the configuration coordinator when n1 goes down. The node with the next lowest priority value is selected in case the configuration coordinator goes down.

### Why are the network interfaces of a cluster represented in 3-tuple (n/u/c) notation instead of the regular 2-tuple (u/c) notation?

When a NetScaler appliance is part of a cluster, you must be able to identify the node to which the interface belongs. Therefore, the network interface naming convention for cluster nodes is modified from u/c to n/u/c, where n denotes the node Id.

### How can I set the host name for a cluster node?

The host name of a cluster node must be specified by running the **set ns hostname** command through the cluster IP address. For example, to set the host name of the cluster node with ID 2, the command is:

```
set ns hostname hostName1 -ownerNode 2
```

### Can I automatically detect NetScaler appliances so that I can add them to a cluster?

Yes. The configuration utility allows you to discover appliances that are present in the same subnet as the NSIP address of the configuration coordinator. For more information, see [Discovering NetScaler Appliances](#).

### **Is the traffic serving capability of a cluster affected if a node is removed or disabled or reboot or shutdown or made inactive?**

Yes. When any of these operations are performed on an active node of the cluster, the cluster has one less node to serve traffic. Also, existing connections on this node are terminated.

### **I have multiple standalone appliances, each of which has different configurations. Can I add them to a single cluster?**

Yes. You can add appliances that have different configurations to a single cluster. However, when the appliance is added to the cluster, the existing configurations are cleared. To use the configurations that are available on each of the individual appliances, you must:

1. Create a single \*.conf file for all the configurations.
2. Edit the configuration file to remove features that are not supported in a cluster environment.
3. Update the naming convention of interfaces from 2-tuple (u/c) format to 3-tuple (n/u/c) format.
4. Apply the configurations to the configuration coordinator node of the cluster by using the batch command.

### **Can I migrate the configurations of a standalone NetScaler appliance or an HA setup to the clustered setup?**

No. When a node is added to a clustered setup, its configurations are implicitly cleared by using the **clear ns config** command (with the **extended** option). In addition, the SNIP addresses and all VLAN configurations (except default VLAN and NSVLAN) are cleared. Therefore, it is recommended that you back up the configurations before adding the appliance to a cluster. Before using the backed-up configuration file for the cluster, you must:

1. Edit the configuration file to remove features that are not supported in a cluster environment.
2. Update the naming convention of interfaces from two-tuple (x/y) format to three-tuple (x/y/z) format.
3. Apply the configurations to the configuration coordinator node of the cluster by using the **batch** command.

### **Is backplane interfaces part of the L3 VLANs?**

Yes, by default, backplane interfaces have presence on all the L3 VLANs that are configured on the cluster.

## How can I configure a cluster that includes nodes from different networks?

### Note

Supported from NetScaler 11.0 onwards.

A cluster that includes nodes from different networks is called a L3 cluster (sometimes referred to as a cluster in INC mode). In an L3 cluster, all nodes that belong to a single network must be grouped in a single node group. Therefore, if a cluster includes two nodes each from three different networks, you have to create 3 node groups (one for each network) and associate each of these node groups with the nodes that belong to that network. For configuration information, see the steps to set up a cluster.

## How can I configure/un-configure the NSVLAN on a cluster?

Do either one of the following:

- To make the NSVLAN available in a cluster, make sure that each appliance has the same NSVLAN configured before it is added to a cluster.
- To remove the NSVLAN from a cluster node, first remove the node from the cluster and then delete the NSVLAN from the appliance.

## I have a cluster set up where some NetScaler nodes are not connected to the external network. Can the cluster still function normally?

Yes. The cluster supports a mechanism called linksets, which allows unconnected nodes to serve traffic by using the interfaces of connected nodes. The unconnected nodes communicate with the connected nodes through the cluster backplane. For more information, see [Using Linksets](#).

## How can deployments that require MAC-Based Forwarding (MBF) be supported in a clustered setup?

Deployments that use MBF must use linksets. For more information, see [Using Linksets](#).

## Can I run commands from the NSIP address of a cluster node?

No. Access to individual cluster nodes through the NSIP addresses is read-only. Therefore, when you log on to the NSIP address of a cluster node you can only view the configurations and the statistics. You cannot configure anything. However, there are some operations you can run from the NSIP address of a cluster node. For more information, see [Operations Supported on Individual Nodes](#).

### **Can I disable configuration propagation among cluster nodes?**

No, you cannot explicitly disable the propagation of cluster configurations among cluster nodes. However, during a software upgrade or downgrade, a version mismatch error can automatically disable configuration propagation.

### **Can I change the NSIP address or change the NSVLAN of a NetScaler appliance when it is a part of the cluster?**

No. To make such changes you must first remove the appliance from the cluster, perform the changes, and then add the appliance to the cluster.

### **Does the NetScaler cluster support L2 and L3 VLANs?**

Yes. A cluster supports VLANs between cluster nodes. The VLANs must be configured on the cluster IP address.

- **L2 VLAN.** You can create a layer2 VLAN by binding interfaces that belong to different nodes of the cluster.
- **L3 VLAN.** You can create a layer3 VLAN by binding IP addresses that belong to different nodes of the cluster. The IP addresses must belong to the same subnet. Make sure that one of the following criteria is satisfied. Otherwise, the L3 VLAN bindings can fail.
  - All nodes have an IP address on the same subnet as the one bound to the VLAN.
  - The cluster has a striped IP address and the subnet of that IP address is bound to the VLAN.

When you add a node to a cluster that has only spotted IPs, the sync happens before spotted IP addresses are assigned to that node. In such cases, L3 VLAN bindings can be lost. To avoid this loss, either add a striped IP or add the L3 VLAN bindings on the NSIP of the newly added node.

### **How can I configure SNMP on a NetScaler cluster?**

SNMP monitors the cluster, and all the nodes of the cluster, in the same way that it monitors a stand-alone appliance. The only difference is that SNMP on a cluster must be configured through the cluster IP address. When generating hardware specific traps, two more varbinds are included to identify the node of the cluster: node ID and NSIP address of the node.

## What details must I have available when I contact technical support for cluster-related issues?

The NetScaler appliance provides a **show techsupport -scope cluster** command that extracts configuration data, statistical information, and logs of all the cluster nodes. Run this command on the cluster IP address.

The output of this command is saved in a file named *collector\_cluster\_<nsip\_CCO>\_P\_<date-timestamp>.tar.gz* which is available in the */var/tmp/support/cluster/* directory of the configuration coordinator.

Send this archive to the technical support team to debug the issue.

## Can I use striped IP addresses as the default gateway of servers?

In cluster deployments, make sure the default gateway of the server points to a striped IP address (if you are using a NetScaler-owned IP address). For example, in the case of LB deployments with USIP enabled, the default gateway must be a striped SNIP address.

## Can I view the routing configurations of a specific cluster node from the cluster IP address?

Yes. You can view and clear the configurations specific to a node by specifying the owner node while entering the VTYSH shell.

For example, to view the output of a command on nodes 0 and 1, the command is as follows:

```
1 \> vtysh
2 ns# owner-node 0 1
3 ns(node-0 1)\# show cluster state
4 ns(node-0 1)\# exit-cluster-node
5 ns\#
```

## How can I specify the node for which I want to set the LACP system priority?

### Note

Supported from NetScaler 10.1 onwards.

In a cluster, you must set that node as the owner node by using the **set lacp** command.

**For example:** To set the LACP system priority for a node with ID 2:

```
set lacp -sysPriority 5 -ownerNode 2<!--NeedCopy-->
```

## How are IP tunnels configured in a cluster setup?

### Note

Supported from NetScaler 10.1 onwards.

Configuring IP tunnels in a cluster is the same as on a standalone appliance. The only difference is that in a cluster setup, the local IP address must be a striped SNIP address.

## How can I add a failover interface set (FIS) on the nodes of a NetScaler cluster?

### Note

Supported from NetScaler 10.5 onwards.

On the cluster IP address, specify the ID of the cluster node on which the FIS must be added, using the command as follows:

```
add fis <name> -ownerNode <nodeId>
```

### Notes

- The FIS name for each cluster node must be unique.
- A cluster LA channel can be added to a FIS. You make sure that the cluster LA channel has a local interface as a member interface.

For more information on FIS, see [Configuring failover interface set](#).

## How are net profiles configured in a cluster setup?

### Note

Supported from NetScaler 10.5 onwards.

You can bind spotted IP addresses to a net profile. This net profile can then be bound to a spotted load balancing virtual server or service (that is defined using a node group). The following recommendations must be followed, failing which, the net profile configurations are not honored and the USIP/USNIP settings are used:

### Note

- If the **strict** parameter of the node group is set to **Yes**, the net profile must contain a minimum of one IP address from each node group member.
- If the **strict** parameter of the node group is set to **No**, the net profile must include at least

one IP address from each of the cluster nodes.

## How can I configure WlonNS in a cluster setup?

### Note

Supported from NetScaler 11.0 Build 62.x onwards.

To use WlonNS on a cluster, you must do the following:

1. Make sure that the Java package and the WI package are present in the same directory on all the cluster nodes.
2. Create a load balancing virtual server that has persistency configured.
3. Create services with IP addresses as the NSIP address of each of the cluster nodes that you want to serve WI traffic. This step can only be configured using the NetScaler CLI.
4. Bind the services to the load balancing virtual server.

### Note

If you are using WlonNS over a VPN connection, make sure that the load balancing virtual server is set as WIHOME.

## Can the cluster LA channel be used for management access?

No. Management access to a cluster node, must not be configured on a cluster LA channel (for example, CLA/1) or its member interfaces. It is because when the node is INACTIVE, the corresponding cluster LA interface is marked as power down, and therefore loses management access.

## How cluster nodes communicate to each other and what are the different types of traffic that goes through the backplane?

A backplane is a set of interfaces in which one interface of each node is connected to a common switch, which is called the cluster backplane switch. The different types of traffic that goes through a backplane, which is used by internode communication are:

- Node to Node Messaging (NNM)
- Steered traffic
- Configuration propagation and synchronization

Each node of the cluster uses a special MAC cluster backplane switch address to communicate with other nodes through the backplane. The cluster special MAC is of the form: **0x02 0x00 0x6F <cluster\_id> <node\_id> <reserved>**, where <cluster\_id> is the cluster instance ID. The <node\_id> is the node number of the NetScaler appliance that is added to a cluster.

**Note**

The amount of traffic that is handled by a backplane has negligible CPU overhead.

### **What gets routed over the GRE tunnel for the Layer 3 cluster?**

Only steered data traffic goes over the GRE tunnel. The packets are steered through the GRE tunnel to the node on the other subnet.

### **How Node to Node Messaging (NNM) and heartbeat messages are exchanged, and how are they routed?**

The NNM, heartbeat messages, and cluster protocol are non-steering traffic. These messages are not sent through the tunnel, but they are routed directly.

### **What are the MTU recommendations for layer 3 cluster tunneled traffic?**

The following are the layer 3 cluster recommendations of Jumbo MTU over GRE tunnel:

- The Jumbo MTU can be configured among cluster nodes across the L3 path to accommodate GRE tunnel overhead.
- The fragmentation does not happen for full sized packets which must be steered.
- Steering of traffic continues to work even if Jumbo frames are not allowed, but with more overhead due to fragmentation.

### **How the global hash key is generated and shared across all nodes?**

The `rsskey` for a standalone appliance is generated at the boot time. In a cluster setup, the first node holds the `rsskey` of the cluster. Every new node joining to the cluster synchronizes the `rsskey`.

### **What is the need of set `rsskeytype -rsskey symmetric` command for `*:*`, `USIP on`, `useproxyport off`, `topologies`?**

It is not specific to a cluster, applies to a standalone appliance as well. With USIP ON, and use proxy port disabled, symmetric `rsskey` reduces both Core to Core (C2C) steering and node to node steering.

## What are the factors that contribute to change the CCO node?

The first node added to form a cluster setup becomes the configuration coordinator (CCO) node. The following factors contribute to change the CCO node in the cluster setup:

- When the current CCO node is removed from the cluster setup
- When the current CCO node crashes
- When the priority of the non-CCO node is changed (lower priority has higher precedence)
- In dynamic conditions like, network reachability between the nodes
- When there is change in node states –active, spare, and passive. Active nodes are preferred as CCO.
- When there is a change in configuration, and the node having the latest configuration is preferred as CCO.

## Can I form a cluster with nodes of different hardware platforms?

Yes. NetScaler appliance supports a heterogeneous cluster. A heterogeneous cluster can have a combination of different platforms in the same cluster. For more information, see [Support for heterogeneous cluster](#).

## Troubleshooting the NetScaler cluster

May 2, 2023

If a failure occurs in a NetScaler cluster, the first step in troubleshooting is to get information on the cluster instance. You can get the information by running the `show cluster instance clId` and `show cluster node nodeId` commands on the cluster nodes respectively.

If you are not able to find the issue by using the above two approaches, you can use one of the following:

- **Isolate the source of the failure.** Try bypassing the cluster to reach the server. If the attempt is successful, the problem is probably with the cluster setup.
- **Check the commands recently executed.** Run the history command to check the recent configurations performed on the cluster. You can also review the ns.conf file to verify the configurations that have been implemented.
- **Check the ns.log files.** Use the log files, available in the /var/log/ directory of each node, to identify the commands run, the status of commands, and the state changes.

- **Check the newslog files.** Use the `newslog` files, available in the `/var/nslog/` directory of each node, to identify the events that have occurred on the cluster nodes. You can view multiple `newslog` files as a single file, by copying the files to a single directory, and then running the following command:

```
1 nsconmsg -K newslog-node<id> -K newslog.node<id> -d current
```

If you still cannot resolve the issue, you can try tracing the packets on the cluster or use the `show techsupport -scope cluster` command. You can use the command to send the report to the technical support team.

## Tracing the packets of a NetScaler cluster

May 2, 2023

The NetScaler operating system provides a utility called `ns trace` to get a dump of the packets that are received and sent out by an appliance. The utility stores the packets in trace files. You can use these files to debug problems in the flow of packets to the cluster nodes. The trace files must be viewed with the Wireshark application.

Some salient aspects of the `ns trace` utility are:

- Can be configured to trace packets selectively by using classic expressions and default expressions.
- Can capture the trace in multiple formats: `ns trace format (.cap)` and TCP dump format (`.pcap`).
- Can aggregate the trace files of all cluster nodes on the configuration coordinator.
- Can merge multiple trace files into a single trace file (only for `.cap` files).

You can use the `ns trace` utility from the NetScaler command line or the NetScaler shell.

### To trace packets of a standalone appliance

Run the `start ns trace` command on the appliance. The command creates trace files in the `/var/nstrace/<date-timestamp>` directory. The trace file names are of the form `nstrace<id>.cap`.

You can view the status by running the `show ns trace` command. You can stop tracing the packets by running the `stop ns trace` command.

#### Note

You can also run the `ns trace` utility from the NetScaler shell by running the `nstrace.sh` file. However, it is recommended that you use the `ns trace` utility through the

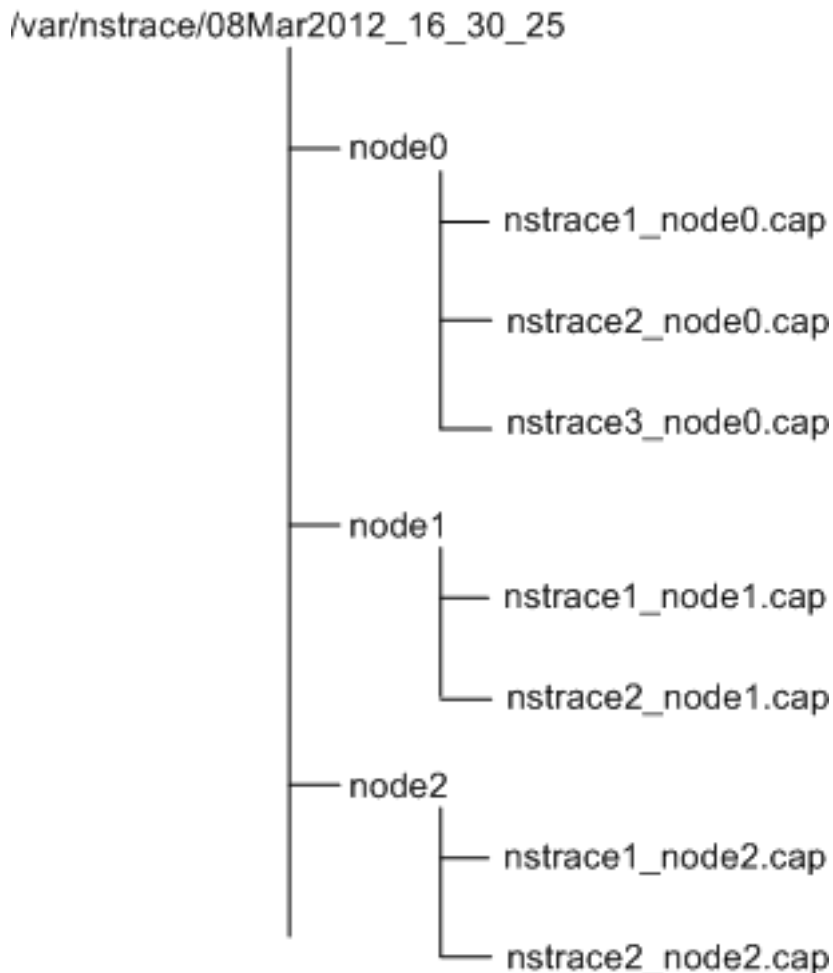

NetScaler command line interface.

### To trace packets of a cluster

You can trace the packets on all the cluster nodes and obtain all the trace files on the configuration coordinator.

Run the `start ns trace` command on the cluster IP address. The command is propagated and run on all the cluster nodes. The trace files are stored in individual cluster nodes in the `/var/nstrace/<date -timestamp>` directory. The trace file names are of the form `nstrace<id>_node<id\>.cap`.

You can use the trace files of each node to debug the nodes operations. But if you want the trace files of all cluster nodes in one location, you must run the `stop ns trace` command on the cluster IP address. The trace files of all the nodes are downloaded on the cluster configuration coordinator in the `/var/nstrace/<date-timestamp>` directory as follows:

## Merge multiple trace files

You can prepare a single file from the trace files (supported only for .Cap files) obtained from the cluster nodes. The single trace files give you a cumulative view of the trace of the cluster packets. The trace entries in the single trace file are sorted based on the time the packets were received on the cluster.

To merge the trace files, at the NetScaler shell, type:

```
1 > nstracemerge.sh -srcdir \<DIR\> -dstdir \<DIR\> -filename \<name\> -
 filesize \<num\>
```

Where,

- `srcdir` is the directory from which the trace files are merged. All trace files within this directory are merged into a single file.
- `dstdir` is the directory where the merged trace file is created.
- `Filename` is the name of the trace file that is created.
- `Filesize` is the size of the trace file.

## Examples

Following are some examples of using the ns trace utility to filter packets.

- To trace the packets on the backplane interfaces of three nodes:

### Using classic expressions:

```
1 > start nstrace -filter "INTF == 0/1/1 && INTF == 1/1/1 && INTF
 == 2/1/1"
```

### Using default expressions:

```
1 > start nstrace -filter "CONNECTION.INTF.EQ("0/1/1") &&
 CONNECTION.INTF.EQ("1/1/1") && CONNECTION.INTF.EQ("2/1/1")"
```

- To trace the packets from a source IP address 10.102.34.201 or from a system whose source port is greater than 80 and the service name is not "s1":

### Using classic expressions

```
1 > start nstrace -filter "\"SOURCEIP == 10.102.34.201 \\\| \| \\\(SVCNAME
 != s1 && SOURCEPORT > 80)\""
```

### Using default expressions

```
1 > start nstrace -filter "\"CONNECTION.SRCIP.EQ(10.102.34.201) \\\| \|
 \\\(CONNECTION.SVCNAME.NE(\\\"s1\\\") && CONNECTION.SRCPORT.GT
 \\\(80))\""
```

**Note**

For more information about filters used in `ns trace`, see [ns trace](#).

**Capturing SSL Session Keys During a Trace**

When you run the “start ns trace” command, you can set the new `capsslkeys` parameter to capture the SSL master keys for all SSL sessions. If you include this parameter, a file named `nstrace.sslkeys` is generated along with the packet trace. This file can be imported into Wireshark to decrypt the SSL traffic in the corresponding trace file.

This functionality is similar to web browsers exporting session keys that can later be imported into Wireshark for decrypting SSL traffic.

**Advantages of using SSL session keys**

Following are the advantages of using SSL session keys:

1. Generates smaller trace files that do not include the extra packets created by the SSLPLAIN mode of capturing.
2. Provides the ability to view plaintext [SP(1)] from the trace and choose whether to share the master keys file or protect sensitive data by not sharing it.

**Limitations of using SSL session keys**

Following are the limitations of using SSL session keys:

1. SSL sessions cannot be decrypted if the initial packets of the session are not captured.
2. SSL sessions cannot be captured if the Federal Information Processing Standard (FIPS) mode is enabled.

**To capture SSL session keys by using the command line interface (CLI)** At the command prompt, type the following commands to enable or disable SSL session keys in a trace file and verify trace operation.

```
1 > start nstrace -capsslkeys ENABLED
2 > show nstrace
3 Example
4 > start nstrace -capsslkeys ENABLED
5 > show nstrace
6 State: RUNNING Scope: LOCAL TraceLocation:
 "/var/nstrace/04May2016_17_51_54/..."
```

```
7 Nf: 24 Time: 3600 Size: 164
 Mode: TXB NEW_RX
8 Traceformat: NSCAP PerNIC: DISABLED FileName: 04
 May2016_17_51_54 Link: DISABLED
9 Merge: ONSTOP Doruntimecleanup: ENABLED TraceBuffers:
 5000 SkipRPC: DISABLED
10 SkipLocalSSH: DISABLED Capsslkeys: ENABLED InMemoryTrace:
 DISABLED
11 Done
```

### To configure SSL session keys by using the NetScaler GUI

1. Navigate to **Configuration > System > Diagnostics > Technical Support Tools** and click **Start new Trace** to start tracing encrypted packets on an appliance.
2. On the **Start Trace** page, select the **Capture SSL Master Keys** check box.
3. Click **OK** and **Done**.

### To import the SSL Master Keys into Wireshark

On the Wireshark GUI, navigate to **Edit > Preferences > Protocols > SSL > (Pre)-Master-Secret log filename** and specify the master key files obtained from the appliance.

## Troubleshooting common issues

December 21, 2020

### While joining a node to the cluster, I get the following message, “ERROR: Invalid interface name/number.”What must I do to resolve this error?

The said error occurs if you provided an invalid or incorrect backplane interface while using the add cluster node command to add the node. To resolve this error, verify the interface you provided while adding the node. Make sure that you have not specified the appliance’s management interface as the backplane interface, and that the <nodeId> bit of the interface is the same as the node’s Id. For example, if the nodeId is 3, the backplane interface must be 3/<c>/<u>.

**While joining a node to the cluster, I get the following message, “ERROR: Clustering cannot be enabled, because the local node is not a member of the cluster.”What must I do to resolve this error?**

This error occurs when you try to join a node without adding the node’s NSIP to the cluster. To resolve this error, you must first add the node’s NSIP address to the cluster by using the **add cluster node** command and then run the **join cluster** command.

**While joining a node to the cluster, I get the following message, “ERROR: Connection refused.”What must I do to resolve this error?**

This error can occur due to the following reasons:

- **Connectivity problems.** The node cannot connect to the cluster IP address. Try pinging the cluster IP address from the node that you are trying to join.
- **Duplicate cluster IP address.** Check to see if the cluster IP address exists on some non-cluster node. If it does, create a cluster IP address and try rejoining the cluster.

**While joining a node to the cluster, I get the following message, “ERROR: License mismatch between the configuration coordinator and the local node.”What must I do to resolve this error?**

The appliance that you are joining to the cluster must have the same licenses as the configuration coordinator. This error occurs when the licenses on the node you are joining do not match the licenses on the configuration coordinator. To resolve this error, run the following commands on both the nodes and compare the outputs.

**From the command line:**

- `show ns hardware`
- `show ns license`

**From the shell:**

- `nsconmsg -g feature -d stats`
- `ls /nsconfig/license`
- View the contents of the `/var/log/license.log` file

## **What must I do when the configurations of a cluster node are not in synchronize with the cluster configurations?**

Usually, the configurations are automatically synchronized between all the cluster nodes. However, if you feel that the configurations are not synchronized on a specific node, you must force the synchronization by running the `force cluster sync` command from the node that you want to synchronize. For more information, see [Synchronizing Cluster Configurations](#).

When configuring a cluster node, I get the following message, “ERROR: Session is read-only; connect to the cluster IP address to modify the configuration.”

All configurations on a cluster must be done through the cluster IP address and the configurations are propagated to the other cluster nodes. All sessions established through the NSIP address of individual nodes are read-only.

## **Why does the node state show “INACTIVE” when the node health shows “UP”?**

A healthy node can be in the INACTIVE state for various reasons. A scan of the `ns.log` or error counters can help you determine the exact reason.

## **How can I resolve the health of a node when its health shows “NOT UP”?**

Node health “**Not UP**” indicates that there are some issues with the node. To know the root cause, you must run the `show cluster node` command. This command displays the node properties and the reason for the node failure.

## **What must I do when the health of a node shows as “NOT UP” and the reason indicates that configuration commands have failed on a node?**

This issue arises when some commands are not run on the cluster nodes. In such cases, you must make sure that the configurations are synchronized using one of the following options:

- If some of the cluster nodes are in this state, you must perform the force cluster synchronization operation on those nodes. For more information, see [Synchronizing Cluster Configurations](#).
- If all cluster nodes are in this state, you must disable and then enable the cluster instance on all the cluster nodes.

**When I run the set virtual server command, I get the following message, “No such resource.” What must I do to resolve this issue?**

The **set vsrver** command is not supported in clustering. The **unset vsrver**, **enable vsrver**, **disable vsrver**, and **rm vsrver** commands are also not supported. However, the **show vsrver** command is supported.

**I cannot configure the cluster over a Telnet session. What must I do?**

Over a telnet session, the cluster IP address can be accessed only in read-only mode. Therefore, you cannot configure a cluster over a telnet session.

**I notice a significant time difference across the cluster nodes. What must I do to resolve this issue?**

When PTP packets are dropped due to the backplane switch or if the physical resources are over-committed in a virtual environment, the time will not get synchronized.

To synchronize the times, you must do the following on the cluster IP address:

1. Disable PTP.

**set ptp -state disable**

2. Configure Network Time Protocol (NTP) for the cluster. For more information, see [Setting up Clock Synchronization](#).

**What must I do, if there is no connectivity to the cluster IP address and the NSIP address of a cluster node?**

If you cannot access to the cluster IP address or the NSIP of a cluster node, you must access the appliance through the serial console. If the NSIP address is reachable, you can SSH to the cluster IP address from the shell by running the following command at the shell prompt:

“# ssh nsroot@

```
1 ## What must I do to recover a cluster node that has connectivity
 issues?
2
3 To recover a node that has connectivity issues:
4
5 1. Disable the cluster instance on that node (since you cannot run
 commands from the NSIP of a cluster node).
6
```

```
7 1. Run the commands required to recover the node.
8
9 1. Enable the cluster instance on that node.
10
11 ## Some nodes of the cluster have two default routes. How can I remove
 the second default route from the cluster node?
12
13 To delete the additional default route, do the following on each node
 that has the extra route:
14
15 1. Disable the cluster instance.
16
17 ``disable cluster instance <clId><!--NeedCopy-->
```

1. Remove the route.

```
rm route <network> <netmask> <gateway><!--NeedCopy-->
```

2. Enable the cluster instance.

```
enable cluster instance <clId><!--NeedCopy-->
```

### **The cluster functionality gets affected when an existing cluster node comes online. What must I do to resolve this issue?**

If the RPC password of a node is changed from the cluster IP address when that node is out of the cluster, then, when the node comes online, there is a mismatch in RPC credentials and can affect cluster functionality. To solve this issue, use the `set ns rpcNode` command to update the password on the NSIP of the node which has come online.

## **Content Switching**

May 2, 2023

In today's complex websites, you might want to present different content to different users. For example, you might want to allow users from the IP range of a customer or partner to have access to a special Web portal. You might want to present content relevant to a specific geographical area to users from that area. You might want to present content in different languages to the speakers of those languages. You might want to present content tailored to specific devices, such as smartphones, to them who use the devices. The NetScaler content switching feature enables the appliance to distribute client requests across multiple servers based on specific content that you want to present to those users.

To configure content switching, first create a basic content switching setup, and then customize it to meet your needs. This entails enabling the content switching feature, setting up load balancing for the server or servers that host each version of the content that is being switched, creating a content switching virtual server, creating policies to choose which requests are directed to which load balancing virtual server, and binding the policies to the content switching virtual server. You can then customize the setup to meet your needs by setting precedence for your policies, protecting your setup by configuring a backup virtual server, and improving the performance of your setup by redirecting requests to a cache.

## How Content Switching Works

Content Switching enables the NetScaler appliance to direct requests sent to the same Web host to different servers with different content. For example, you can configure the appliance to direct requests for dynamic content (such as URLs with a suffix of .asp, .dll, or .exe) to one server and requests for static content to another server. You can configure the appliance to perform content switching based on TCP/IP headers and payload.

You can also use content switching to configure the appliance to redirect requests to different servers with different content based on various client attributes. Some of those client attributes are:

- **Device Type.** The appliance examines the user agent or custom HTTP header in the client request for the type of device from which the request originated. Based on the device type, it directs the request to a specific Web server. For example, if the request came from a cell phone, the request is directed to a server, capable of serving content that the user can view on the cell phone. A request from a computer is directed to a different server, capable of serving content designed for a computer screen.
- **Language.** The appliance examines the Accept-Language HTTP header in the client request and determines the language used by the client's browser. The appliance then sends the request to a server that serves content in that language. For example, using content switching based on language, the appliance can send someone whose browser is configured to request content in French to a server with the French version of a newspaper. It can send someone else whose browser is configured to request content in English to a server with the English version.
- **Cookie.** The appliance examines the HTTP request headers for a cookie that the server set previously. If it finds the cookie, it directs requests to the appropriate server, which hosts custom content. For example, if a cookie is found that indicates that the client is a member of a customer loyalty program, the request is directed to a faster server or one with special content. If it does not find a cookie, or if the cookie indicates that the user is not a member, the request is directed to a server for the general public.
- **HTTP Method.** The appliance examines the HTTP header for the method used, and sends the client request to the right server. For example, GET requests for images can be directed to an

image server, while POST requests can be directed to a faster server that handles dynamic content.

- **Layer 3/4 Data.** The appliance examines requests for the source or destination IP, source or destination port, or any other information present in the TCP or UDP headers, and directs the client request to the right server. For example, requests from source IPs that belong to customers can be directed to a custom web portal on a faster server, or one with special content.

A typical content switching deployment consists of the entities described in the following diagram.

Figure 1. Content Switching Architecture

A content switching configuration consists of a content switching virtual server, a load balancing setup consisting of load balancing virtual servers and services, and content switching policies. To configure content switching, you must configure a content switching virtual server and associate it with policies and load balancing virtual servers. This process creates a *content group*—a group of all virtual servers and policies involved in a particular content switching configuration.

Content switching can be used with HTTP, HTTPS, TCP, and UDP connections. For HTTPS, you must enable SSL Offload.

When a request reaches the content switching virtual server, the virtual server applies the associated content switching policies to that request. The priority of the policy defines the order in which the policies bound to the content switching virtual server are evaluated. If you are using Advanced policy policies, when you bind a policy to the content switching virtual server, you must assign a priority to that policy. If you are using NetScaler classic policies, you can assign a priority to your policies, but are not required to do so. If you assign priorities, the policies are evaluated in the order that you set. If you do not, the NetScaler appliance evaluates your policies in the order in which they were created.

In addition to configuring policy priorities, you can manipulate the order of policy evaluation by using Goto expressions and policy bank invocations. For more details about Advanced policy configuration, see [Configuring Advanced policy Policies](#).

After it evaluates the policies, the content switching virtual server routes the request to the appropriate load balancing virtual server, which sends it to the appropriate service.

Content switching virtual servers can only send requests to other virtual servers. If you are using an

external load balancer, you must create a load balancing virtual server for it and bind its virtual server as a service to the content switching virtual server.

## Configure basic content switching

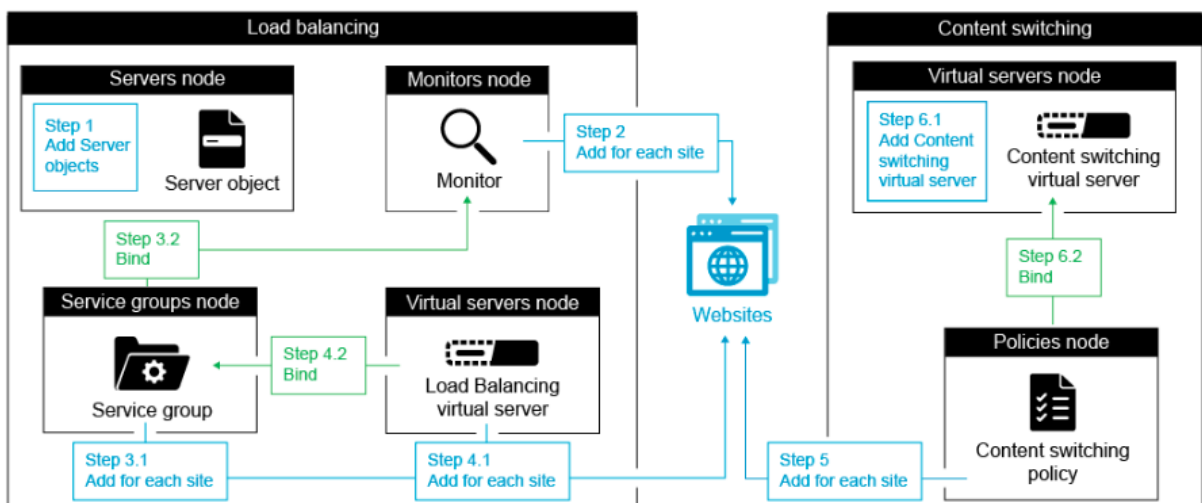

October 18, 2023

Before you configure content switching, you must understand how content switching is set up and how the services and virtual servers are connected.

To configure a basic, functional content switching setup, first enable the content switching feature. Then, create at least one content group. For each content group, create a content switching virtual server to accept requests to a group of websites that use content switching. Also create a load balancing setup, which includes a group of load balancing virtual servers to which the content switching virtual server directs requests. To specify which requests to direct to which load balancing virtual server, create at least two content switching policies, one for each type of request that is to be redirected. When you have created the virtual servers and policies, bind the policies to the content switching virtual server. You can also bind a policy to multiple content switching virtual servers. When you bind a policy, you specify the load balancing virtual server to which requests that match the policy are to be directed.

In addition to binding individual policies to a content switching virtual server, you can bind policy labels. If you create more content groups, you can bind a policy or policy label to more than one of the content switching virtual servers.

The following figure illustrates the steps involved in content switching configuration.

**Note**

After creating a content group, you can modify its content switching virtual server to customize the configuration.

**Enable content switching**

To use the content switching feature, you must enable content switching. You can configure content switching entities even though the content switching feature is disabled. However, the entities do not work.

**Enable content switching by using the CLI**

At the command prompt, type the following commands to enable content switching and verify the configuration:

```
1 enable ns feature CS
2
3 show ns feature
4 <!--NeedCopy-->
```

**Example:**

```
1 > enable feature ContentSwitch
2 Done
3 > show feature
4
5 Feature Acronym Status
6 ----- -
7 1) Web Logging WL OFF
8 2) Surge Protection SP ON
9 3) Load Balancing LB ON
10 4) Content Switching CS ON
11 .
12 .
13 .
14 22) Responder RESPONDER ON
15 23) HTML Injection HTMLInjection ON
16 24) NetScaler Push push OFF
17 Done
18 <!--NeedCopy-->
```

**Enable content switching by using the GUI**

Navigate to **System > Settings** and, in the **Modes and Features** group, select **Configure Basic Features**, and select **Content Switching**.

## Create content switching virtual servers

You can add, modify, and remove content switching virtual servers. The state of a virtual server is DOWN when you create it, because the load balancing virtual server is not yet bound to it.

### Create a virtual server by using the CLI

At the command prompt, type:

```
1 add cs vserver <name> <protocol> <IPAddress> <port>
2 <!--NeedCopy-->
```

#### Example:

```
1 add cs vserver Vserver-CS-1 HTTP 10.102.29.161 80
2 <!--NeedCopy-->
```

### Add a content switching virtual server by using the GUI

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and add a virtual server.
2. Specify a name for the content switching virtual server.

#### Note

There is a different Content Switching virtual server for each protocol. (For example, HTTP and SSL).

3. Populate the relevant fields and click **OK**.

### Content switching virtual server statistics

The content switching virtual server statistics display information such as virtual server select, request bytes, response bytes, total packets received, total packets sent, spillover threshold, spillover select, current client established connections, and virtual server down backup select.

The content switching virtual server statistics also display the summary details of the bound default load balancing virtual server.

### View statistics of content switching virtual server by using the CLI

At the command prompt, type:

```
1 stat cs vserver <name>
2 <!--NeedCopy-->
```

**Example:**

```
1 stat cs vserver CS_stats
2 <!--NeedCopy-->
```

**View statistics of content switching virtual server by using the GUI**

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**.
2. Select the virtual server and click **Statistics**.

**Configure a load balancing setup for content switching**

The content switching virtual server redirects all requests to a load balancing virtual server. You must create one load balancing virtual server for each version of the content that is being switched. It is true even when your setup has only one server for each version of the content, and you are therefore not doing any load balancing with those servers. You can also configure actual load balancing with multiple load-balanced servers that mirror each version of the content. In either scenario, the content switching virtual server needs to have a specific load balancing virtual server assigned to each version of the content that is being switched.

The load balancing virtual server then forwards the request to a service. If it has only one service bound to it, it selects that service. If it has multiple services bound to it, it uses its configured load balancing method to select a service for the request, and forwards that request to the service that it selected.

To configure a basic load balancing setup, you need to perform the following tasks:

- Create load balancing virtual servers
- Create services
- Bind services to the load balancing virtual server

For more information on load balancing, see [How load balancing works](#). For detailed instructions on setting up a basic load balancing configuration, see [Set up basic load balancing](#).

**Configure a content switching action**

You specify the target load balancing virtual server for a content switching policy when binding the policy to the content switching virtual server. Therefore, you have to configure one policy for each load balancing virtual server to which to direct traffic.

However, if your content switching policy uses a default syntax rule, you can configure an action for the policy. In the action, you can specify the name of the target load balancing virtual server, or you can configure a request-based expression that, at run time, computes the name of the load balancing virtual server to which to send the request. The action expression must be specified in the default syntax.

The expression option can drastically reduce the size of your content switching configuration, because you need only one policy per content switching virtual server. Content switching policies that use an action can also be bound to multiple content switching virtual servers, because the target load balancing virtual server is no longer specified in the content switching policy. The ability to bind a single policy to multiple content switching virtual servers helps to further reduce the size of your content switching configuration.

After you create an action, you create a content switching policy and specify the action in the policy, so that the action is performed when that policy matches a request.

**Note**

You can also, for a content switching policy that uses a default syntax rule, specify the target load balancing virtual server when binding the policy to a content switching virtual server, instead of using a separate action. For domain-based policies, URL-based policies, and rule-based policies that use classic expressions, an action is not available. So, for these types of policies, you specify the name of the target load balancing virtual server when binding the policy to a content switching virtual server.

**Configure an action that specifies the name of the target load balancing virtual server**

If you choose to specify the name of the target load balancing virtual server in a content switching action, you need as many content switching policies as you have target load balancing virtual servers. Content switching decisions, in this case, are based on the rules in the content switching policy, and the action merely specifies the target load balancing virtual server. When a request matches the policy, the request is forwarded to the specified load balancing virtual server.

**Create and verify a content switching action that specifies the name of the target load balancing virtual server, by using the CLI**

At the command prompt, type:

```
1 add cs action <name> -targetLBVserver <string> [-comment <string>]
2
3 show cs action <name>
4 <!--NeedCopy-->
```

**Example:**

```
1 > add cs action mycsaction -targetLBVserver mylbvserver -comment "
 Forwards requests to mylbvserver."
2 Done
3 > show cs action mycsaction
4 Name: mycsaction
5 Target LB Vserver: mylbvserver
6 Hits: 0
7 Undef Hits: 0
8 Action Reference Count: 0
9 Comment: "Forwards requests to mylbvserver."
10
11 Done
12 >
13 <!--NeedCopy-->
```

**Configure a content switching action that specifies the name of the target load balancing virtual server, by using the GUI**

1. Navigate to **Traffic Management > Content Switching > Actions**.
2. Configure a content switching action, and specify the name of the target load balancing virtual server.

**Configure an action that specifies an expression for selecting the target at run time**

If you choose to configure a request-based expression that can dynamically compute the name of the target load balancing virtual server, you need to configure only one content switching policy to select the appropriate virtual server. The rule for the policy can be a simple TRUE (the policy matches all requests) because, in this case, content switching decisions are based on the expression in the action. By configuring an expression in an action, you can drastically reduce the size of your content switching configuration.

If you choose to configure a request-based expression for computing the name of the target load balancing virtual server at run time, you must carefully consider how to name the load balancing virtual servers in the configuration. You must be able to derive their names by using the request-based policy expression in the action.

For example, if you are switching requests based on the URL suffix (extension of the requested resource), when naming the load balancing virtual servers, you can follow the convention of appending the URL suffix to a predetermined string, such as `mylb_`. For example, load balancing virtual servers for HTML pages and PDF files can be named `mylb_html` and `mylb_pdf`, respectively. In that case, the rule that you can use in the content switching action, to select the appropriate load balancing virtual server, is `"mylb_" + HTTP.REQ.URL.SUFFIX`. If the content switching virtual server receives

a request for an HTML page, the expression returns `mylb_html`, and the request is switched to the virtual server `mylb_html`.

### Create a content switching action that specifies an expression, by using the CLI

At the command line, type the following commands to create a content switching action that specifies an expression and verify the configuration:

```
1 add cs action <name> -targetVserverExpr <expression>) [-comment <string>]
2
3 show cs action <name>
4 <!--NeedCopy-->
```

#### Example:

```
1 > add cs action mycsaction1 -targetvserverExpr '"mylb_" + HTTP.REQ.URL.SUFFIX'
2 Done
3 > show cs action mycsaction1
4 Name: mycsaction1
5 Target Vserver Expression: "mylb_" + HTTP.REQ.URL.SUFFIX
6 Target LB Vserver: No_Target
7
8 Done
9 >
10 <!--NeedCopy-->
```

### Configure a content switching action that specifies an expression by using the GUI

1. Navigate to **Traffic Management > Content Switching > Actions**.
2. Configure a content switching action, and specify an expression that will dynamically compute the name of the target load balancing virtual server.

### Configure content switching policies

A content switching policy defines a type of request that is to be directed to a load balancing virtual server. These policies are applied in the order of the priorities assigned to them or (if you are using NetScaler classic policies and do not assign priorities when binding them) in the order in which the policies were created.

The policies can be:

- **Domain-based policies.** The NetScaler compares the domain of an incoming URL with the domains specified in the policies. The appliance then returns the most appropriate content.

Domain-based policies must be classic policies. Default syntax policies are not supported for this type of content switching policy.

- **URL-based policies.** The appliance compares an incoming URL with the URLs specified in the policies. The appliance then returns the most appropriate URL-based content, which is usually the longest matching configured URL. URL-based policies must be classic policies. Default syntax policies are not supported for this type of content switching policy.
- **Rule-based policies.** The appliance compares incoming data to expressions specified in the policies. You create rule-based policies by using either a classic expression or a default syntax expression. Both classic and default syntax policies are supported for rule-based content switching policies.

**Note**

A rule-based policy can be configured with an optional action. A policy with an action can be bound to multiple virtual servers or policy labels.

If you set a priority when binding your policies to the content switching virtual server, the policies are evaluated in order of priority. If you do not set specific priorities when binding your policies, the policies are evaluated in the order in which they were created.

For information about NetScaler classic policies and expressions, see [Configuring Classic Policies and Expressions](#). For information about Default Syntax policies, see [Configuring Default Syntax Expressions](#).

## Create a content switching policy by using the CLI

At the command prompt, type one of the following commands:

```
1 add cs policy <policyName> -domain <domain>
2
3 add cs policy <policyName> -url <URLValue>
4
5 add cs policy <policyName> -rule <RULEValue>
6
7 add cs policy <policyName> -rule <RULEValue> -action <actionName>
8 <!--NeedCopy-->
```

**Example:**

```
1 add cs policy Policy-CS-1 -url "http://example.com"
2
3 add cs policy Policy-CS-1 -domain "example.com"
4
5 add cs policy Policy-CS-1 -rule "CLIENT.IP.SRC.SUBNET(24).EQ
 (10.217.84.0)"
```

```
6
7 add cs policy Policy-CS-2 -rule "SYS.TIME.BETWEEN(GMT 2009 Nov,GMT 2009
 Dec)"
8
9 add cs policy Policy-CS-3 -rule "http.req.method.eq(GET)" -action act1
10 <!--NeedCopy-->
```

## Rename a content switching policy by using the CLI

At the command prompt, type:

```
1 rename cs policy <policyName> <newName>
2 <!--NeedCopy-->
```

### Example:

```
1 rename cs policy myCSPolicy myCSPolicy1
2 <!--NeedCopy-->
```

## Rename a content switching policy by using the GUI

Navigate to **Traffic Management > Content Switching > Policies**, select a policy and, in the Action list, select **Rename**.

## Create a content switching policy by using the GUI

1. Navigate to **Traffic Management > Content Switching > Policies**, and click **Add**.
2. Populate the relevant fields and click **Create**.

## Configure content switching policy labels

A policy label is a user-defined bind point to which policies are bound. When a policy label is invoked, all the policies bound to it are evaluated in the order of the priority that you assigned to them. A policy label can include one or more policies, each of which can be assigned its own result. A match on one policy in the policy label can result in proceeding to the next policy, invoking a different policy label or appropriate resource, or an immediate end to policy evaluation and return of control to the policy that invoked the policy label. You can create policy labels for default syntax policies only.

A content switching policy label consists of a name, a label type, and a list of policies bound to the policy label. The policy label type specifies the protocol that was assigned to the policies bound to the label. It must match the service type of the content switching virtual server to which the policy

that invokes the policy label is bound. For example, you can bind TCP Payload policies to a policy label of type TCP only. Binding TCP Payload policies to a policy label of type HTTP is not supported.

Each policy in a content switching policy label is associated with either a target (which is equivalent to the action that is associated with other types of policies, such as rewrite and responder policies) or a gotoPriorityExpression option and an invoke option. That is, for a given policy in a content switching policy label, you can specify a target, or you can set the gotoPriorityExpression option and the invoke option. Also, if multiple policies evaluate to true, only the target of the last policy that evaluates to true is considered.

You can use either the NetScaler CLI or the GUI to configure content switching policy labels. In the NetScaler CLI, you first create a policy label by using the add cs policy label command. Then, you bind policies to the policy label, one policy at a time, by using the bind cs policy label command. In the NetScaler GUI, you perform both tasks in a single dialog box.

### Create a content switching policy label by using the CLI

At the command prompt, type:

```
1 add cs policylabel <labelName> <cspolicylabelType>`
2 <!--NeedCopy-->
```

#### Example:

```
1 add cs policylabel testpollab http
2 <!--NeedCopy-->
```

### Rename a content switching policy label by using the CLI

At the command prompt, type:

```
1 rename cs policylabel <labelName> <newName>`
2 <!--NeedCopy-->
```

#### Example:

```
1 rename cs policylabel oldPolicyLabelName newPolicyLabelName
2 <!--NeedCopy-->
```

### Rename a content switching policy label by using the GUI

Navigate to **Traffic Management > Content Switching > Policy Labels**, select a policy label and, in the Action list, select **Rename**.

## Bind a policy to a content switching policy label by using the CLI

At the command prompt, type the following commands to bind a policy to a policy label and verify the configuration:

```
1 bind cs policylabel <labelName> <policyName> <priority>[-targetVserver
 <string>] | [-gotoPriorityExpression <expression>] | [-invoke <
 labeltype> <labelName>]]
2
3 show cs policylabel <labelName>
4 <!--NeedCopy-->
```

### Example:

```
1 bind cs policylabel testpollab test_Pol 100 -targetVserver LBVIP
2 show cs policylabel testpollab
3 Label Name: testpollab
4 Label Type: HTTP
5 Number of bound policies: 1
6 Number of times invoked: 0
7 Policy Name: test_Pol
8 Priority: 100
9 Target Virtual Server: LBVIP
10 <!--NeedCopy-->
```

### Note

If a policy is configured with an action, the target virtual server (targetVserver), go to priority expression (gotoPriorityExpression), and invoke (invoke) parameters are not required. If a policy is not configured with an action, you need to configure at least one of the following parameters: targetVserver, gotoPriorityExpression, and invoke.

## Unbind a policy from a policy label by using the CLI

At the command prompt, type the following commands to unbind a policy from a policy label and verify the configuration:

```
1 unbind cs policylabel <labelName> <policyName>
2
3 show cs policylabel <labelName>
4 <!--NeedCopy-->
```

### Example:

```
1 unbind cs policylabel testpollab test_Pol
2 show cs policylabel testpollab
3 Label Name: testpollab
4 Label Type: HTTP
5 Number of bound policies: 0
```

```
6 Number of times invoked: 0
7 <!--NeedCopy-->
```

## Remove a policy label by using the CLI

At the command prompt, type:

```
1 rm cs policylabel <labelName>
2 <!--NeedCopy-->
```

## Manage a content switching policy label by using the GUI

Navigate to **Traffic Management > Content Switching > Policy Labels**, configure a policy label, bind policies to the label, and optionally specify a priority, gotoPriority expression, and an invoke option.

## Bind policies to a Content Switching virtual server

After you create your content switching virtual server and policies, you bind each policy to the content switching virtual server. When binding the policy to the content switching virtual server, you specify the target load balancing virtual server.

### Note

If your content switching policy uses a default syntax rule, you can configure a content switching action for the policy. If you configure an action, you must specify the target load balancing virtual server when you are configuring the action, not when you are binding the policy to the content switching virtual server. For more information about configuring a content switching action, see [Configuring a Content Switching Action](#) section.

## Bind a policy to a content switching virtual server and select a target load balancing virtual server by using the CLI

At the command prompt, type:

```
1 bind cs vserver <name>[-lbvserver<string> -targetLBVServer<string> -
 policyname <string> -priority <positive_integer>] [-
 gotoPriorityExpression <expression>] [-type (REQUEST | RESPONSE)]
 [-invoke (<labelType> <labelName>)]
2 <!--NeedCopy-->
```

### Example:

```
1 bind cs vserver csw-vip2 -policyname csw-ape-policy2 -priority 14 -
 gotoPriorityExpression NEXT
2
3 bind cs vserver csw-vip3 -policyname rewrite-policy1 -priority 17 -
 gotoPriorityExpression
4 'q.header("a").count' -flowtype REQUEST -invoke policylabel label1
5
6 bind cs vserver Vserver-CS-1 Vserver-LB-1 -policyname Policy-CS-1 -
 priority 20
7 <!--NeedCopy-->
```

**Note**

The parameters, target load balancing virtual server (targetVserver), go to priority expression (gotoPriorityExpression), and the invoke method (invoke) cannot be used if a policy has an action.

**Bind a policy to a content switching virtual server and select a target load balancing virtual server by using the GUI**

Navigate to **Traffic Management > Content Switching > Virtual Servers**, open a virtual server and, in the

**Content Switching Policy Binding** section, bind a policy to the virtual server, and specify a target load balancing virtual server.

**Configure policy-based logging for content switching**

You can configure policy-based logging for a content switching policy. Policy-based logging enables you to specify a format for the log messages. The contents of the log message are defined by using a default syntax expression in the content switching policy. When the content switching action specified in the policy is performed, NetScaler constructs the log message from the expression and writes the message to the log file. Policy-based logging is useful if you want to test and troubleshoot a configuration in which content switching actions identify the target load balancing virtual server at run time.

**Note**

If multiple policies bound to a given virtual server evaluate to TRUE and are configured with an audit message action, NetScaler does not perform all the audit message actions. It performs only the audit message action that is configured for the policy whose content switching action is performed.

To configure policy-based logging for a content switching policy, you must first configure an audit message action. For more information about configuring an audit message action, see [Configuring](#)

[NetScaler for audit logging](#). After you configure the audit message action, you specify the action in a content switching policy.

### Configure policy-based logging for a content switching policy by using the CLI

At the command line, type the following commands to configure policy-based logging for a content switching policy and verify the configuration:

```
1 set cs policy <policyName> -logAction <string>
2
3 show cs policy <policyName>
4 <!--NeedCopy-->
```

#### Example:

```
1 > set cs policy cspol1 -logAction csLogAction
2 Done
3 > show cs policy cspol1
4
5 Policy: cspol1 Rule: TRUE Action: csact1
6 LogAction: csLogAction
7 Hits: 0
8
9 1) CS Vserver: csvs1
10 Priority: 10
11 Done
12 >
13 <!--NeedCopy-->
```

### Configure policy-based logging for a content switching policy by using the GUI

Navigate to **Traffic Management > Content Switching > Policies**, open a policy and, in the Log Action list, select a log action for the policy.

#### Verify the configuration

To verify that your content switching configuration is correct, you need to view the content switching entities. To verify proper operation after your content switching configuration has been deployed, you can view the statistics that are generated as the servers are accessed.

#### View the properties of content switching virtual servers

You can view the properties of content switching virtual servers that you have configured on NetScaler. You can use the information to verify whether the virtual server is correctly configured and, if neces-

sary, to troubleshoot. In addition to details such as name, IP address, and port, you can view the various policies bound to a virtual server, and its traffic-management settings.

The content switching policies are displayed in the order of their priority. If more than one policy has the same priority, they are shown in the order in which they are bound to the virtual server.

**Note**

If you have configured the content switching virtual server to forward traffic to a load balancing virtual server, you can also view the content switching policies by viewing the properties of the load balancing virtual server.

**View the properties of content switching virtual servers by using the CLI**

To list basic properties of all content switching virtual servers in your configuration, or detailed properties of a specific content switching virtual server, at the command prompt, type one of the following commands:

```
1 show cs vserver
2
3 show cs vserver <name>
4 <!--NeedCopy-->
```

**Example**

```
1 1.
2 show cs vserver Vserver-CS-1
3 Vserver-CS-1 (10.102.29.161:80) - HTTP Type: CONTENT
4 State: UP
5 Last state change was at Thu Jun 30 10:48:59 2011
6 Time since last state change: 6 days, 20:03:00.760
7 Client Idle Timeout: 180 sec
8 Down state flush: ENABLED
9 Disable Primary Vserver On Down : DISABLED
10 Appflow logging: DISABLED
11 Port Rewrite : DISABLED

69 <!--NeedCopy-->
```

## View content switching policies

You can view the properties of the content switching policies that you defined, such as the name, domain, and URL or expression, and use the information to find any mistakes in the configuration, or to troubleshoot if something is not working as it must.

## View the properties of content switching policies by using the CLI

To view the content switching policies configuration details, type one of the following commands:

```
1 show cs policy
2
3 show cs policy <PolicyName>
4 <!--NeedCopy-->
```

### Example:

```
1 show cs policy
2
3 show cs policy Policy-CS-1
4 <!--NeedCopy-->
```

## View the properties of content switching policies by using the GUI

Navigate to **Traffic Management > Content Switching > Policies**, select a policy and, in the Action list, select **Show Bindings**.

## View a content switching virtual server configuration by using the visualizer

The Content Switching Visualizer is a tool that you can use to view a content switching configuration in graphical format. You can use the visualizer to view the following configuration items:

- A summary of the load balancing virtual servers to which the content switching virtual server is bound.
- All services and service groups that are bound to the load balancing virtual server and all monitors that are bound to the services.
- The configuration details of any displayed element.
- Any policies bound to the content switching virtual server. These policies need not be content switching policies. Rewrite policies can also be bound to a content switching virtual server.

After you complete the content switching and load balancing configuration, you can export the entire configuration to an application template file.

### Note

The Visualizer requires a graphical interface, so it is available only through the GUI.

## View a content switching configuration by using the Visualizer in the GUI

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**.

2. In the details pane, select the virtual server that you want to view, and then click **Visualizer**.
3. In the **Content Switching Visualizer** window, you can adjust the viewable area as follows:
  - Click the **Zoom In** and **Zoom Out** icons to increase or decrease the viewable area.
  - Click the **Save Image** icon to save the graph as an image file.
  - In the Search in text field, begin typing the name of the item you are looking for. When you have typed enough characters to identify the item, its location is highlighted. To restrict the search, click the drop-down menu and select the type of element that you want to search for.
4. To view configuration details for entities that are bound to this virtual server, you can do the following:
  - To view policies that are bound to the virtual server, in the tool bar at the top of the dialog box select one or more feature-specific policy icons. If policy labels are configured, they appear in the main view area.
  - To view the configuration details for a bound service or service group, click the icon for the service, click the Related Tasks tab, and then click Show Member Services.
  - To view the configuration details for a monitor, click the icon for the monitor, click the **Related Tasks** tab, and then click **View Monitor**.
5. To view detailed statistics for any virtual server in the content switching configuration, click the virtual server for which you want to view statistics, then click the Related Tasks tab, and then click **Statistics**.
6. To view a comparative list of the parameters whose values either differ or are not defined across service containers for a load balancing virtual server, click the icon for a container, click the **Related Tasks** tab, and then click **Service Attributes Diff**.
7. To view monitor binding details for the services in a container, in the Service Attributes Diff dialog box, in the Group column for the container, click **Details**. This comparative list helps you determine which service container has the configuration you want to apply to all the service containers.
8. To view the number of requests received per second at a given point in time by the virtual servers in the configuration, and the number of select per second at a given point in time for rewrite, responder, and cache policies, click Show Stats. The statistical information is displayed on the respective nodes in the Visualizer. This information is not updated in real time. It is refreshed manually. To refresh the information, click Refresh Stats.

**Note**

This option is available only on NetScaler nCore builds.

9. To copy configuration details for an element to a document or spreadsheet, click the icon for that element, click Related Tasks, click Copy Properties, and then paste the information into a document.
10. To export the entire configuration that is displayed in the Visualizer to an application template file, click the icon for the content switching virtual server, click Related Tasks, and then click Create Template. When creating the application template, you can configure variables in some policy expressions and actions. For more information, see [AppExpert](#).

## Customizing the basic content switching configuration

October 18, 2023

After you configure a basic content switching setup, you might need to customize it to meet your requirements. You can configure HTTP and SSL content switching virtual servers to listen on multiple ports instead of creating separate virtual servers. If you want to configure content switching for a specific virtual LAN, you can configure a content switching virtual server with a listen policy.

### Support for Multiple Ports for HTTP and SSL Type Content Switching Virtual Servers

You can configure the NetScaler so that HTTP and SSL content switching virtual servers listen on multiple ports, without having to configure separate virtual servers. This feature is especially useful if you want to base a content switching decision on a part of the URL and other L7 parameters. Instead of configuring multiple virtual servers with the same IP address and different ports, you can configure one IP address and specify the port as \*. As a result, the configuration size is also reduced.

### To configure an HTTP or SSL content switching virtual server to listen on multiple ports by using the command line

At the command prompt, type:

```
add cs vserver <name> <serviceType> <IPAddress> Port *
```

#### Example

```
1 > add cs vserver cs1 HTTP 10.102.92.215 *
2 Done
3 > sh cs vserver cs1
4 cs1 (10.102.92.215:*) - HTTP Type: CONTENT
5 State: UP
6 Last state change was at Tue May 20 01:15:49 2014
7 Time since last state change: 0 days, 00:00:03.270
```

```

8 Client Idle Timeout: 180 sec
9 Down state flush: ENABLED
10 Disable Primary Vserver On Down : DISABLED
11 Appflow logging: ENABLED
12 Port Rewrite : DISABLED
13 State Update: DISABLED
14 Default: Content Precedence: RULE
15 Vserver IP and Port insertion: OFF
16 L2Conn: OFF Case Sensitivity: ON
17 Authentication: OFF
18 401 Based Authentication: OFF
19 Push: DISABLED Push VServer:
20 Push Label Rule: none
21 IcmpResponse: PASSIVE
22 RHISTate: PASSIVE
23 TD: 0
24 Done
25 <!--NeedCopy-->

```

### To configure an HTTP or SSL content switching virtual server to listen on multiple ports by using the configuration utility

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and create a virtual server of type HTTP or SSL.
2. Use an asterisk (\*) to specify the port.

### Configuring per-VLAN Wildcard Virtual Servers

If you want to configure content switching for traffic on a specific VLAN, you can create a wildcard virtual server with a listen policy that restricts it to processing traffic only on the specified VLAN.

### To configure a wildcard virtual server that listens to a specific VLAN by using the command line interface

At the command prompt, type:

```

1 add cs vserver <name> <serviceType> IPAddress `* Port *` -listenpolicy
 <expression> [-listenpriority <positive_integer>]
2 <!--NeedCopy-->

```

#### Example:

```

1 add cs vserver Vserver-CS-vlan1 ANY * *
2 -listenpolicy "CLIENT.VLAN.ID.EQ(2)" -listenpriority 10
3 <!--NeedCopy-->

```

## To configure a wildcard virtual server that listens to a specific VLAN by using the configuration utility

Navigate to **Traffic Management > Content Switching > Virtual Servers**, and configure a virtual server. Specify a listen policy that restricts it to processing traffic only on the specified VLAN.

After you have created this virtual server, you bind it to one or more services as described in [Setup basic load balancing](#).

## Configuring the Microsoft SQL Server Version Setting

You can specify the version of Microsoft® SQL Server® for a content switching virtual server that is of type MSSQL. The version setting is recommended if you expect some clients to not be running the same version as your Microsoft SQL Server product. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server's version.

### To set the Microsoft SQL Server version parameter by using the command line interface

At the command prompt, type the following commands to set the Microsoft SQL Server version parameter for a content switching virtual server and verify the configuration:

- `set cs vserver <name> -mssqlServerVersion <mssqlServerVersion>`
- `show cs vserver <name>`

#### Example

```
1 > set cs vserver myMSSQLcsvip -mssqlServerVersion 2008R2 Done > show cs
 vserver myMSSQLcsvip myMSSQLcsvip (192.0.2.13:1433) - MSSQL Type:
 CONTENT State: UP Mssql Server Version: 2008R2
 . Done >
2 <!--NeedCopy-->
```

### To set the Microsoft SQL Server version parameter by using the configuration utility

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, configure a virtual server, and specify the protocol as MSSQL.
2. In **Advanced Settings**, specify the **Server Version**.

## Enable external health check for UDP and non-HTTP TCP virtual servers

In public clouds, you can use the NetScaler appliance as a second-tier load balancer when the native load balancer is used as a first tier. The native load balancer can be an application load balancer (ALB)

or a network load balancer (NLB). Most of the public clouds do not support UDP health probes in their native load balancers. Hence, if these servers are down their actual status might not be updated. As a result, traffic is sent unconditionally to NetScaler, even if the request cannot be serviced. To monitor the health of such applications, NetScaler supports HTTP and TCP health checks.

An HTTP or TCP listener is created for a content switching virtual server when both the `probeProtocol` and `probePort` parameters are configured. The listener reflects the status of the virtual server. The `ProbeSuccessResponseCode` parameter applies only to HTTP and returns the configured string when the probe is successful.

### To enable external health check for UDP and non-HTTP TCP virtual servers by using CLI

At the command prompt, type the following command to enable an external TCP health check with the `tcpProbePort` option:

```
1 add cs vserver <name> <protocol> <IPAddress> <port> -ProbeProtocol <
 Http/TCP> -ProbePort <port-num> -ProbeSuccessResponseCode<http-code>
2 <!--NeedCopy-->
```

#### Example:

```
1 add cs vserver Vserver-CS-1 HTTP 10.102.29.161 5002 -ProbeProtocol HTTP
 -probeport 5000 -probesuccessResponseCode 200OK
2 <!--NeedCopy-->
```

### To enable external health check for UDP and non-HTTP TCP virtual servers by using GUI

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and then create a virtual server.
2. Click **Add** to create a virtual server.
3. In the **Basic Settings** pane, update the following details:
  - a) Probe Protocol –Select the protocol (HTTP or TCP) of the probe for an external health check of the virtual server.
  - b) Probe Success Response Code –Enter the response string for a successful probe. This parameter is applicable only for the HTTP protocol.
    - Default Value: 200ok
    - Maximum Length: 63
  - c) Probe Port –Enter the port number for HTTP or TCP monitoring.
4. Click **OK**.

## Content Switching for Diameter Protocol

May 2, 2023

For Diameter-protocol traffic, you can configure the NetScaler appliance (or virtual appliance) to act as a relay agent that load balances and forwards a packet to the appropriate destination on the basis of the message content (AVP value in the message). Since the appliance does not perform any application-level processing, it provides relaying services for all diameter applications as specified by the configured content switching policies. Therefore, the appliance advertises the Relay Application ID in the capability exchange answer (CEA) message when the client establishes a diameter connection. You must configure a content switching virtual server, load balancing virtual servers, and services to represent the diameter nodes. When a request reaches the content switching virtual server, the virtual server applies the content switching policies associated with that type of request. After evaluating the policies, the content switching virtual server routes the request to the appropriate load balancing virtual server, which sends it to the appropriate service.

A diameter interface provides a connection between the different diameter nodes. The following sample deployment uses Cx and Rx interfaces. A Cx interface provides a connection between a CSCF and an HSS. An Rx interface provides a connection between a CSCF and a PCRF. All the messages reach the NetScaler appliance. Depending on whether the message is for a Cx or an Rx interface, and on the content switching policies defined, the NetScaler selects an appropriate load balancing server pool.

CSCF=Call Session Control Function  
HSS=Home Subscriber Server  
PCRF=Policy and Charging Rules Function

### Sample Configuration

1. For each entity, create a service, a load balancing server, and bind the service to the virtual server.

```
1 add service svc_pcrf[1-3] 1.1.1.1[1-3] DIAMETER 3868
2 add service svc_hss[1-3] 1.1.1.2[1-3] DIAMETER 3868
3 add lb vserver vs_rx DIAMETER -persistenceType DIAMETER -
 persistavpno 263
4 add lb vserver vs_cx DIAMETER -persistenceType DIAMETER -
 persistavpno 263
```

```
5 bind lb vserver vs_rx svc_pcrf[1-3]
6 bind lb vserver vs_cx svc_hss[1-3]
7 <!--NeedCopy-->
```

2. Create a content switching virtual server and two actions (one for each load balancing virtual server). Create two content switching policies and bind these policies to the content switching virtual server, specifying a priority for each policy.

```
1 add cs vserver cs_diameter DIAMETER 10.1.1.10 3868
2 add cs action cx_action -targetLBVserver vs_cx
3 add cs action rx_action -targetLBVserver vs_rx
4 add cs policy cx_policy -rule "DIAMETER.REQ.AUTH_APPLICATION_ID.EQ
 (16777216)" -action cx_action
5 add cs policy rx_policy -rule "DIAMETER.REQ.AUTH_APPLICATION_ID.EQ
 (16777236)" -action rx_action
6 bind cs vserver cs_diameter -policyName rx_policy -priority 100
7 bind cs vserver cs_diameter -policyName cx_policy -priority 110
8 <!--NeedCopy-->
```

## Protecting the content switching setup against failure

October 18, 2023

Content switching might fail when the content switching virtual server goes DOWN or fails to handle excessive traffic, or for other reasons. To reduce the chances of failure, you can take the following measures to protect the content switching setup against failure:

### Configuring a backup virtual server

If the primary content switching virtual server is marked DOWN or DISABLED, the NetScaler appliance can direct requests to a backup content switching virtual server. It can also send a notification message to the client regarding the site outage or maintenance. The backup content switching virtual server is a proxy and is transparent to the client.

When configuring the backup virtual server, you can specify the configuration parameter `Disable Primary When Down` to ensure that, when the primary virtual server comes back up, it remains the secondary until you manually force it to take over as the primary. It is useful if you want to ensure that any updates to the database on the server for the backup are preserved, enabling you to synchronize the databases before restoring the primary virtual server.

You can configure a backup content switching virtual server when you create a content switching virtual server or when you change the optional parameters of an existing content switching virtual

server. You can also configure a backup content switching virtual server for an existing backup content switching virtual server, thus creating cascaded backup content switching virtual servers. The maximum depth of cascaded backup content switching virtual servers is 10. The appliance searches for a backup content switching virtual server that is up and accesses that content switching virtual server to deliver the content.

**Note**

If a content switching virtual server is configured with both a backup content switching virtual server and a redirect URL, the backup content switching virtual server takes precedence over the redirect URL. The redirect is used when the primary and backup virtual servers are down.

**To set up a backup content switching virtual server by using the CLI**

At the command prompt, type:

```
1 set cs vserver <name> -backupVserver <string> -disablePrimaryOnDown (ON
 |OFF)
2 <!--NeedCopy-->
```

**Example**

```
1 set cs vserver Vserver-CS-1 -backupVserver Vserver-CS-2 -
 disablePrimaryOnDown ON
2 <!--NeedCopy-->
```

**To set up a backup content switching virtual server by using the GUI**

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, configure a virtual server, and specify the protocol as MySQL.
2. In **Advanced Settings**, select **Protection**, and specify a **Backup Virtual Server**.

**Diverting excess traffic to a backup virtual server**

The spillover option diverts new connections arriving at a content switching virtual server to a backup content switching virtual server when the number of connections to the content switching virtual server exceeds the configured threshold value. The threshold value is dynamically calculated, or you can set the value. The number of established connections (in TCP) at the virtual server is compared with the threshold value. When the number of connections reaches the threshold, new connections are diverted to the backup content switching virtual server.

If the backup content switching virtual servers reach the configured threshold and are unable to take the load, the primary content switching virtual server diverts all requests to the redirect URL. If a redi-

rect URL is not configured on the primary content switching virtual server, subsequent requests are dropped.

### To configure a content switching virtual server to divert new connections to a backup virtual server by using the CLI

At the command prompt, type:

```
1 set cs vserver <name> -soMethod <methodType> -soThreshold <
 thresholdValue> -soPersistence <persistenceValue> -
 soPersistenceTimeout <timeoutValue>
2 <!--NeedCopy-->
```

#### Example

```
1 set cs vserver Vserver-CS-1 -soMethod Connection -soThreshold 1000 -
 soPersistence enabled -soPersistenceTimeout 2
2 <!--NeedCopy-->
```

### To set a content switching virtual server to divert new connections to a backup virtual server by using the GUI

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, configure a virtual server, and specify the protocol as MySQL.
2. In **Advanced Settings**, select **Protection**, and configure spillover.

### Configuring a redirection URL

You can configure a redirect URL to communicate the status of the NetScaler appliance if a content switching virtual server of type HTTP or HTTPS is DOWN or DISABLED. This URL can be local or remote.

Redirect URLs can be absolute URLs or relative URLs. If the configured redirect URL contains an absolute URL, the HTTP redirect is sent to the configured location, regardless of the URL specified in the incoming HTTP request. If the configured redirect URL contains only the domain name (relative URL), the HTTP redirect is sent to a location after appending the incoming URL to the domain configured in the redirect URL.

Citrix recommends using an absolute URL. That is, a URL ending in /, for example [www.example.com/](http://www.example.com/) instead of a relative URL. A relative URL redirection might result in the vulnerability scanner reporting a false positive.

**Note**

If a content switching virtual server is configured with both a backup virtual server and a redirect URL, the backup virtual server takes precedence over the redirect URL. A redirect URL is used when the primary and backup virtual servers are down.

When redirection is configured and the content switching virtual server is unavailable, the appliance issues an HTTP 302 redirect to the user's browser.

**To configure a redirect URL for when the content switching virtual server is unavailable by using the CLI**

At the command prompt, type:

```
1 set cs vserver <name> -redirectURL <URLValue>
2 <!--NeedCopy-->
```

**Example**

```
1 set cs vserver Vserver-CS-1 -redirectURL http://www.newdomain.com/
 mysite/maintenance
2 <!--NeedCopy-->
```

**To configure a redirect URL for when the content switching virtual server is unavailable by using the GUI**

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, configure a virtual server, and specify the protocol as MySQL.
2. In **Advanced Settings**, select **Protection**, and specify a Redirect URL.

**Configuring the state update option**

The content switching feature enables the distribution of client requests across multiple servers based on the specific content presented to the users. For efficient content switching, the content switching virtual server distributes the traffic to the load balancing virtual servers according to the content type, and the load balancing virtual servers distribute the traffic to the physical servers according to the specified load balancing method.

For smooth traffic management, it is important for the content switching virtual server to know the status of the load balancing virtual servers. The state update option helps to mark the content switching virtual server DOWN if the load balancing virtual server bound to it is marked DOWN. A load balancing virtual server is marked DOWN if all the physical servers bound to it are marked DOWN.

**When State Update is disabled:**

The status of the content switching virtual server is marked as UP. It remains UP even if there is no bound load balancing virtual server that is UP.

**When State Update is enabled:**

When you add a content switching virtual server, initially, its status is shown as DOWN. When you bind a load balancing virtual server whose status is UP, the status of the content switching virtual server becomes UP.

If more than one load balancing virtual server is bound and if one of them is specified as the default, the status of the content switching virtual server reflects the status of the default load balancing virtual server.

If more than one load balancing virtual server is bound without any of them being specified as the default, the status of the content switching virtual server is marked UP only if all the bound load balancing virtual servers are UP.

**To configure the state update option by using the CLI**

At the command prompt, type:

```
1 add cs vserver <name> <protocol> <ipAddress> <port> -stateUpdate
 ENABLED
2 <!--NeedCopy-->
```

**Example**

```
1 add cs vserver csw_vserver HTTP 10.18.250.154 80 -stateupdate ENABLED
 -cltTimeout 180
2 <!--NeedCopy-->
```

**To configure the state update option by using the GUI**

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, configure a virtual server, and specify the protocol as MySQL.
2. In **Advanced Settings**, select **Traffic Settings**, and then select **State Update**.

**Flushing the surge queue**

When a physical server receives a surge of requests, it becomes slow to respond to the clients that are currently connected to it, which leaves users dissatisfied and disgruntled. Often, the overload also causes clients to receive error pages. To avoid such overloads, the NetScaler appliance provides

features such as surge protection, which controls the rate at which new connections to a service can be established.

The appliance does connection multiplexing between clients and physical servers. When it receives a client request to access a service on a server, the appliance looks for an already established connection to the server that is free. If it finds a free connection, it uses that connection to establish a virtual link between the client and the server. If it does not find an existing free connection, the appliance establishes a new connection with the server, and establishes a virtual link between the client and the server. However, if the appliance cannot establish a new connection with the server, it sends the client request to a surge queue. If all the physical servers bound to the load balancing or content switching virtual server reach the upper limit on client connections (max client value, surge protection threshold or maximum capacity of the service), the appliance cannot establish a connection with any server. The surge protection feature uses the surge queue to regulate the speed at which connections are opened with the physical servers. The appliance maintains a different surge queue for each service bound to the virtual server.

The length of a surge queue increases whenever a request comes for which the appliance cannot establish a connection, and the length decreases whenever a request in the queue gets sent to the server or a request gets timed out and is removed from the queue.

If the surge queue for a service or service group becomes too long, you might want to flush it. You can flush the surge queue of a specific service or service group, or of all the services and service groups bound to a load balancing virtual server. Flushing a surge queue does not affect the existing connections. Only the requests present in the surge queue get deleted. For those requests, the client has to make a fresh request.

You can also flush the surge queue of a content switching virtual server. If a content switching virtual server forwards some requests to a particular load balancing virtual server, and the load balancing virtual server also receives some other requests, when you flush the surge queue of the content switching virtual server, only the requests received from this content switching virtual server are flushed. The other requests in the surge queue of the load balancing virtual server are not flushed.

**Note**

You cannot flush the surge queues of cache redirection, authentication, VPN, or GSLB virtual servers or GSLB services.

Do not use the Surge Protection feature if Use Source IP (USIP) is enabled.

**To flush a surge queue by using the CLI**

The flush ns surgeQ command works in the following manner:

- You can specify the name of a service, service group, or virtual server whose surge queue has to be flushed.

- If you specify a name while running the command, the surge queue of the specified entity is flushed. If more than one entity has the same name, the appliance flushes the surge queues of all those entities.
- If you specify the name of a service group, and a server name and port while running the command, the appliance flushes the surge queue of only the specified service group member.
- You cannot directly specify a service group member (<serverName> and <port>) without specifying the name of the service group (<name>) and you cannot specify <port> without a <serverName>. Specify the <serverName> and <port> if you want to flush the surge queue for a specific service group member.
- If you run the command without specifying any names, the appliance flushes the surge queues of all the entities present on the appliance.
- If a service group member is identified with a server name, you must specify the server name in this command; you cannot specify its IP address.

At the command prompt, type:

```
1 flush ns surgeQ [-name <name>] [-serverName <serverName> <port>].
2 <!--NeedCopy-->
```

#### Examples

```
1 1. flush ns surgeQ - name SVC1ANZGB - serverName 10.10.10.1 80
2 The above command flushes the surge queue of the service or virtual
 server that is named SVC1ANZGB and has IP address as 10.10.10
3
4 2. flush ns surgeQ
5 The above command flushes all the surge queues on the appliance.
6 <!--NeedCopy-->
```

### To flush a surge queue by using the GUI

Navigate to **Traffic Management > Content Switching > Virtual Servers**, select a virtual server and, in the Action list, select **Flush Surge Queue**.

## Managing a content switching setup

May 2, 2023

After a content switching setup is configured, it might require periodic changes. When operating systems or software is updated, or hardware wears out and is replaced, you might need to take down your setup. Load on your setup might increase, requiring more resources. You might also modify the configuration to improve performance.

These tasks might require unbinding policies from the content switching virtual server, or disabling or removing content switching virtual servers. After you have changed your setup, you might need to re-enable servers and rebind policies. You might also want to rename your virtual servers.

### **Unbinding policies from the content switching virtual server**

When you unbind a content switching policy from its virtual server, the virtual server no longer includes that policy when determining where to direct requests.

#### **To unbind a policy from a content switching virtual server by using the CLI**

At the command prompt, type:

```
unbind cs vserver <name> -policyname <string>
```

**Example:**

```
unbind cs vserver Vserver-CS-1 -policyname Policy-CS-1
```

#### **To unbind a policy from a content switching virtual server by using the GUI**

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and open the virtual server.
2. Click **Policies** section, select the policy, and click **Unbind**.

### **Removing Content Switching Virtual Servers**

You normally remove a content switching virtual server only when you no longer require the virtual server. When you remove a content switching virtual server, the NetScaler appliance first unbinds all policies from the content switching virtual server, and then removes it.

#### **To remove a content switching virtual server by using the CLI**

At the command prompt, type:

```
rm cs vserver <name>
```

**Example:**

```
rm cs vserver Vserver-CS-1
```

### To remove a content switching virtual server by using the GUI

Navigate to **Traffic Management > Content Switching > Virtual Servers**, select a virtual server, and click **Delete**.

### Disabling and Re-Enabling Content Switching Virtual Servers

Content switching virtual servers are enabled by default when you create them. You can disable a content switching virtual server for maintenance. If you disable the content switching virtual server, the state of the content switching virtual server changes to Out of Service. While out of service, the content switching virtual server does not respond to requests.

### To disable or re-enable a virtual server by using the CLI

At the command prompt, type one of the following commands:

- `disable cs vserver <name>`
- `enable cs vserver <name>`

#### Example:

```
disable cs vserver Vserver-CS-1
enable cs vserver Vserver-CS-1
```

### To disable or re-enable a virtual server by using the GUI

Navigate to **Traffic Management > Content Switching > Virtual Servers**, select a virtual server and, in the **Action** list, select **Enable** or **Disable**.

### Renaming Content Switching Virtual Servers

You can rename a content switching virtual server without unbinding it. The new name is propagated automatically to all affected parts of the NetScaler configuration.

### To rename a virtual server by using the CLI

At the command prompt, type:

```
rename cs vserver <name> <newName>
```

#### Example:

```
1 `rename cs vserver Vserver-CS-1 Vserver-CS-2`
```

### To rename a virtual server by using the GUI

Navigate to **Traffic Management > Content Switching > Virtual Servers**, select a virtual server and, in the **Action** list, select **Rename**.

### Managing content switching policies

You can modify an existing policy by configuring the rules or changing the URL of the policy, or you can remove a policy. You can also rename an existing advanced content switching policy. You can create different policies based on the URL. URL-based policies can be of different types, as described in the following table.

For more information, see [Examples of URL-Based Policies](#).

#### Note

You can configure rule-based content switching using classical policy expressions or advanced policy expressions.

### To modify, remove, or rename a policy by using the CLI

At the command prompt, type one of the following commands:

- `set cs policy <policyName> [-domain <domainValue>] [-rule <ruleValue>] [-url <URLValue>]`
- `rm cs policy <policyName>`
- `rename cs policy <policyName> <newPolicyName>`

#### Example:

```
1 set cs policy-CS-1 -domain "www.domainxyz.com"
2
3 set cs policy-CS-1 -rule "CLIENT.IP.SRC.SUBNET(22).EQ(10.100.148.0)"
4
5 set cs policy-CS-2 -rule "SYS.TIME.BETWEEN(GMT 2010 Jun,GMT 2010 Jul)"
6
7 set cs policy-CS-1 -url /sports/*
8
9 rename cs policy-CS-1 Policy-CS-11
10
11 rm cs policy-CS-1
```

### To modify, remove, or rename a policy by using the GUI

1. Navigate to **Traffic Management > Content Switching > Policies**.
2. Select the policy, and either delete it, edit it or, in the **Action** list, click **Rename**.

## Managing client connections

October 18, 2023

To ensure efficient management of client connections, you can configure the content switching virtual servers on the NetScaler appliance to use the following features:

- **Configuring the ICMP Response.** You can configure the NetScaler appliance to send ICMP responses to PING requests according to your settings. On the IP address corresponding to the virtual server, set the ICMP RESPONSE to VSVR\_CNTRL, and on the virtual server, set the ICMP virtual server RESPONSE.

The following settings can be made on a virtual server:

- When you set ICMP virtual server RESPONSE to PASSIVE on all virtual servers, the NetScaler appliance always responds.
- When you set ICMP virtual server RESPONSE to ACTIVE on all virtual servers, the ADC appliance responds even if one virtual server is UP.
- When you set ICMP virtual server RESPONSE to ACTIVE on some and PASSIVE on others, the ADC appliance responds even if one virtual server set to ACTIVE is UP.

### Redirecting Client Requests to a Cache

The NetScaler cache redirection feature redirects HTTP requests to a cache. You can significantly reduce the burden of responding to HTTP requests and improve your website performance through proper implementation of the cache redirection feature.

A cache stores frequently requested HTTP content. When you configure cache redirection on a virtual server, the NetScaler appliance sends cacheable HTTP requests to the cache and non-cacheable HTTP requests to the origin Web server. For more information on cache redirection, see [“Cache Redirection”](#).

### To configure cache redirection on a virtual server by using the CLI

At the command prompt, type:

```
set cs vserver <name> -cacheable <Value>
```

**Example** `set cs vserver Vserver-CS-1 -cacheable yes`

### To configure cache redirection on a virtual server by using the GUI

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and open a virtual server.
2. In **Advanced Settings**, select **Traffic Settings**, and select **Cacheable**.

### Enabling Delayed Cleanup of Virtual Server Connections

Under certain conditions, you can configure the down state flush setting to terminate existing connections when a service or a virtual server is marked DOWN. Terminating existing connections frees resources and in certain cases speeds recovery of overloaded load balancing setups.

### To configure the down state flush setting on a virtual server by using the CLI

At the command prompt, type:

```
set cs vserver <name> -downStateFlush <Value>
```

#### Example

```
1 set cs vserver Vserver-CS-1 -downStateFlush enabled
2 <!--NeedCopy-->
```

### To configure the down state flush setting on a virtual server by using the GUI

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and open a virtual server.
2. In **Advanced Settings**, select **Traffic Settings**, and then select **Down State Flush**.

### Rewriting Ports and Protocols for Redirection

Virtual servers and the services that are bound to them might use different ports. When a service responds to an HTTP connection with a redirect, you might need to configure the NetScaler appliance to modify the port and the protocol to ensure that the redirection goes through successfully. You do it by enabling and configuring the `redirectPortRewrite` setting.

**To configure HTTP redirection on a virtual server by using the CLI**

At the command prompt, type:

```
set cs vserver <name> -redirectPortRewrite <Value>
```

**Example**

```
1 set cs vserver Vserver-CS-1 -redirectPortRewrite enabled
2 <!--NeedCopy-->
```

**To configure HTTP redirection on a virtual server by using the GUI**

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and open a virtual server.
2. In **Advanced Settings**, select **Traffic Settings**, and select **Rewrite**.

**Inserting the IP Address and Port of a Virtual Server in the Request Header**

If you have multiple virtual servers that communicate with different applications on the same service, you must configure the NetScaler appliance to add the IP address and port number of the appropriate virtual server to the HTTP requests that are sent to that service. This setting allows applications running on the service to identify the virtual server that sent the request.

If the primary virtual server is down and the backup virtual server is up, the configuration settings of the backup virtual server are added to the client requests. If you want the same header tag to be added, regardless of whether the requests are from the primary virtual server or backup virtual server, you must configure the required header tag on both virtual servers.

**Note**

This option is not supported for wildcard virtual servers or dummy virtual servers.

**To insert the IP address and port of the virtual server in the client requests by using the CLI**

At the command prompt, type:

```
set cs vserver <name> -insertVserverIPPort <vServerIPPORT>
```

**Example**

```
1 set cs vserver Vserver-CS-1 -insertVserverIPPort 10.201.25.136:80
2 <!--NeedCopy-->
```

**To insert the IP address and port of the virtual server in the client requests by using the GUI**

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and open a virtual server.
2. In **Advanced Settings**, select **Traffic Settings** and, in the Virtual Server IP Port Insertion list, select VIPADDR or V6TOV4MAPPING, and specify a port header in the virtual server IP Port Insertion Value.

**Setting a Time-out Value for Idle Client Connections**

You can configure a virtual server to terminate any idle client connections after a configured time-out period elapses. When you configure this setting, the NetScaler appliance waits for the time you specify and, if the client is idle after that time, it closes the client connection.

**To set a time-out value for idle client connections by using the CLI**

At the command prompt, type:

```
set cs vserver <name> -cltTimeout <Value>
```

**Example**

```
1 set cs vserver Vserver-CS-1 -cltTimeout 100
2 <!--NeedCopy-->
```

**To set a time-out value for idle client connections by using the GUI**

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and open a virtual server.
2. In **Advanced Settings**, select **Traffic Settings**, and specify a **Client Idle Time-Out** value.

**Identifying Connections with the 4-tuple and Layer 2 Connection Parameters**

You can now set the L2Conn option for a content switching virtual server. With the L2Conn option set, connections to the content switching virtual server are identified by the combination of the 4-tuple (<source IP>:<source port>::<destination IP>:<destination port>) and Layer 2 connection parameters. The Layer 2 connection parameters are the MAC address, VLAN ID, and channel ID.

### To set the L2Conn option for a content switching virtual server by using the CLI

At the command line, type the following commands to configure the L2Conn parameter for a content switching virtual server and verify the configuration:

```
1 - set cs vserver <name> -l2Conn (**ON** | **OFF**)
2 - show cs vserver <name>
3 <!--NeedCopy-->
```

#### Example

```
1 > set cs vserver mycsvserver -l2Conn ON
2 Done
3 > show cs vserver mycsvserver
4 mycsvserver (192.0.2.56:80) - HTTP Type: CONTENT
5 State: UP
6 . . .
7 . . .
8 L2Conn: ON Case Sensitivity: ON
9 . . .
10 . . .
11 Done
12 >
13 <!--NeedCopy-->
```

### To set the L2Conn option for a content switching virtual server by using the GUI

1. Navigate to **Traffic Management > Content Switching > Virtual Servers**, and open a virtual server.
2. In **Advanced Settings**, select **Traffic Settings**, and then select **Layer 2 Parameters**.

## Persistence support for content switching virtual server

May 2, 2023

Applications are moving from monolithic architectures toward microservices architecture. Different versions of the same application can co-exist in the microservices architecture. NetScaler appliance must support continuous deployment of applications. It is achieved by platforms that perform Canary deployments (such as Spinnaker). In a continuous deployment setup, a newer version of an application is deployed automatically and exposed to client traffic in stages until the application is stable to take complete traffic. Also, there must be uninterrupted services to the client.

The NetScaler content switching feature enables NetScaler the appliance to distribute client requests across multiple load balancing virtual servers based on the policies bound to the content switching

virtual server.

For continuous deployments, content switching is used to select the load balancing virtual server serving various versions of an application.

In content switching, the selection of a load balancing virtual server for a specific application version changes at runtime because of the change in the content switching policies. During this transition, if some sessions are present with older versions of the application, such traffic must continue to be served by older versions only. To support the requirement, the NetScaler appliance maintains persistence across multiple load balancing groups behind a content switching virtual server. Persistence for content switching virtual server enables seamless transition of clients from one version to another.

### Supported persistence types on content switching virtual server

The following persistence types are supported on content switching virtual servers.

---

Persistence type	Description
Source IP	<b>SOURCEIP.</b> Connections from the same client IP address are parts of the same persistence session. For more details, see Source IP address persistence.
HTTP Cookie	<b>COOKIEINSERT.</b> Connections that have the same HTTP Cookie header are parts of the same persistence session. The format of the cookie that the NetScaler appliance inserts is: <b>**NSC_**</b> where NSC_XXXX is the virtual server ID that is derived from the virtual server name. For more details, see HTTP cookie persistence.
SSL Session ID	<b>SSLSESSION.</b> Connections that have the same SSL Session ID are parts of the same persistence session. For more details, see SSL session ID persistence.

---

You can configure a timeout value for persistence that is based on HTTP cookies. If you set the timeout value to 0, the ADC appliance does not specify the expiration time, regardless of the HTTP cookie version used. The expiration time then depends on the client software, and such cookies are valid only if the software is running.

Depending on the type of persistence that you have configured, the virtual server can support either 250,000 simultaneous persistent connections or any number of persistent connections up to the limits

imposed by the amount of memory on your NetScaler appliance. The following table shows which types of persistence fall into each category.

Persistence type	Number of simultaneous persistent connections supported
Source IP, SSL Session ID	250,000
HTTP Cookie	Memory limit. In CookieInsert, if the timeout is not 0, the number of connections is limited by memory.

Some types of persistence are specific to particular types of virtual server. The following table lists each type of persistence and indicates which types of persistence are supported on which types of virtual server.

Persistence type	HTTP	HTTPS	TCP	UDP/IP	SSL_BridgeSSL_TCP	RTSP	SIP_UDP
SOURCEIP	Yes	Yes	Yes	Yes	Yes	No	No
COOKIEINSERT	Yes	Yes	No	No	No	No	No
SSLSESSION	No	Yes	No	No	Yes	No	No

### Backup persistence support

You can configure the content switching virtual server to use the source IP persistence type as the backup persistence type when the cookie persistence type fails. It is useful for canary deployments in the microservices architecture.

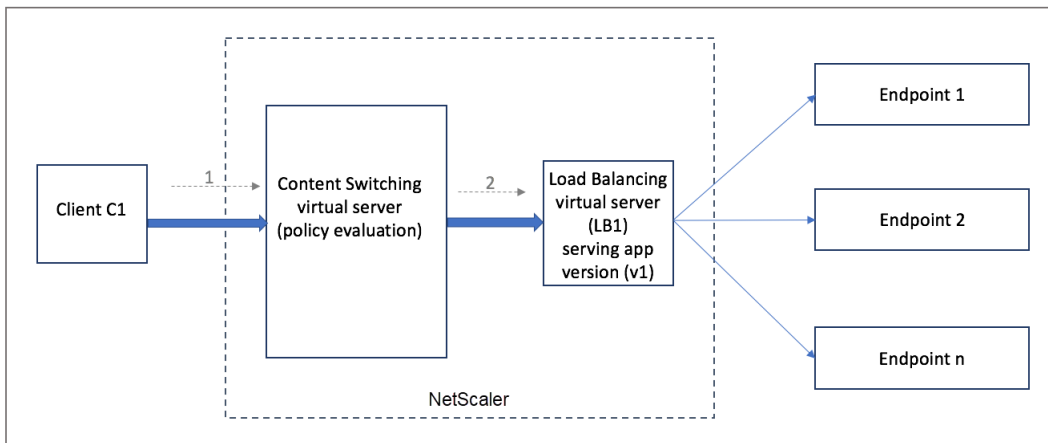

When the cookie persistence type fails, the appliance falls back to source IP based persistence only when the client browser does not return any cookie in the request. However, if the browser returns a cookie (not necessarily the persistence cookie) it is assumed that the browser supports cookies and hence backup persistence is not triggered.

You can also set a timeout value for backup persistence. Timeout is the time period for which a persistence session is in effect.

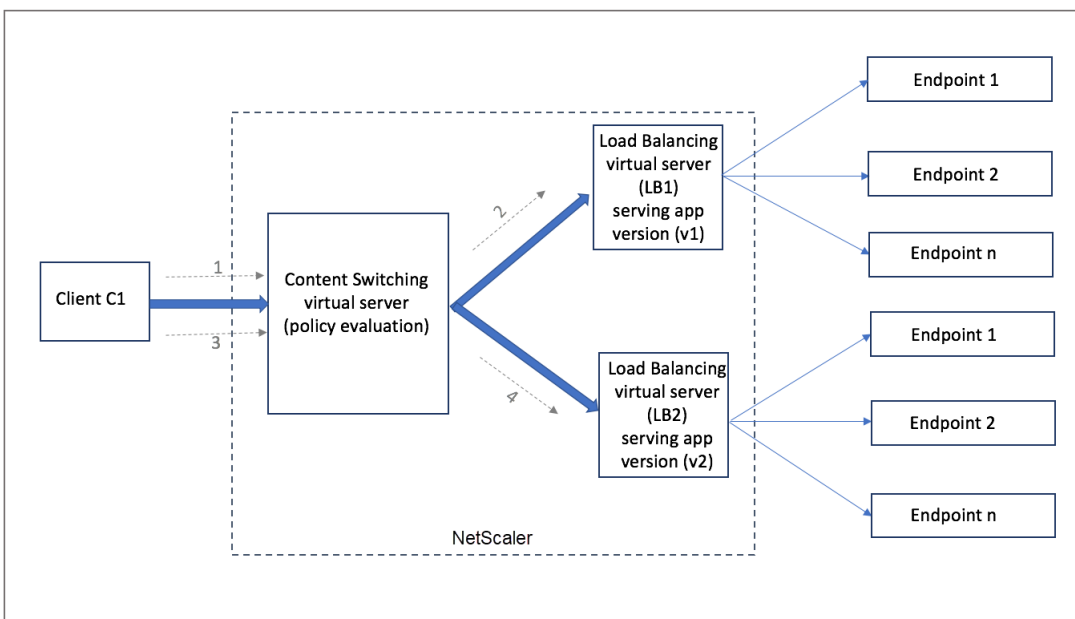

### How persistence on content switching virtual server works

#### Scenario 1: A content switching virtual server without persistence

The following example illustrates the deployment of multiple versions of an application with a content switching virtual server without persistence.

When client C1 sends a request to the application, the request is sent to the content switching virtual server in the NetScaler appliance. The content switching virtual server evaluates the policy and forwards the request to the load balancing virtual server (LB1) that is serving version v1 of the application.

Consider a new version v2 of the application is deployed and has to be exposed to a subset of users. The new load balancing virtual server (LB2) serving the v2 version is bound to the content switching virtual server by the appropriate content switching policy.

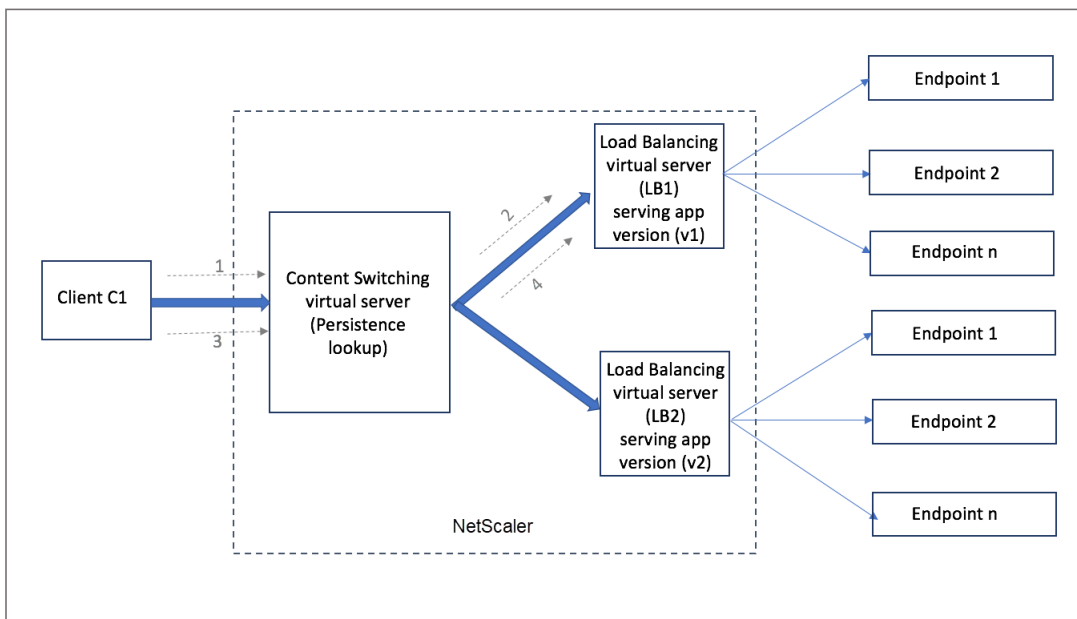

When client C1 sends a new request, the policy is evaluated again and the request is forwarded to the load balancing virtual server LB2. Thus, the transactions for stateful applications fail if multiple versions of the application are deployed.

**Scenario 2: Content switching virtual server with persistence**

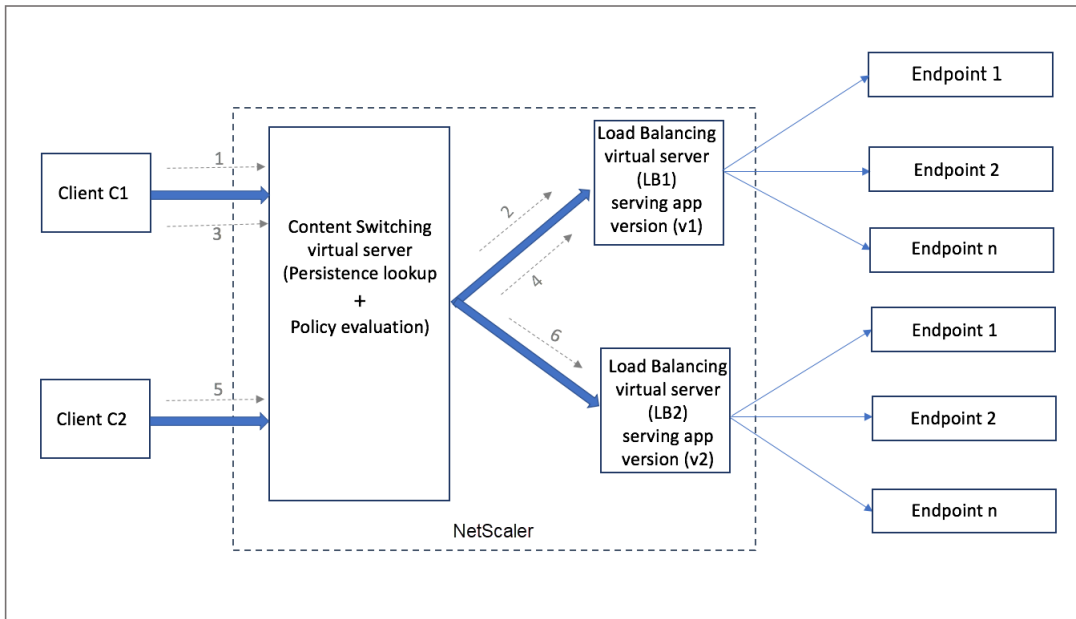

The following example illustrates the deployment of multiple versions of the application with a content switching virtual server with persistence.

When client C1 sends a request to the application, the request is sent to the content switching virtual server in the NetScaler appliance. The content switching virtual server evaluates the policy, creates a persistence session entry, and forwards the request to the load balancing virtual server LB1 that is serving version v1 of the application.

The same client C1 requests again for the application, and the request is sent to the content switching virtual server in the NetScaler appliance. A lookup for the persistence session is done, and the load balancing virtual server LB1 is taken from the existing persistence session and the request is forwarded to LB1. No breakage of the existing transaction happens with this solution; thus, maintaining the stateful nature of the application.

Let's consider a new client C2. The new request C2 is sent to the newer version of the application through policy evaluation as there is no existing persistence session for this client. It results in a successful rollout of the newer version of the application without breaking its statefulness.

Because of the persistence support, customers can deploy multiple content or different versions of the application seamlessly without impacting the existing transactions, specifically for stateful applications. It is not possible without persistence in the picture.

### Configure persistence type on content switching virtual server by using the CLI

At the command prompt, type:

```
1 set cs vserver <name> -PersistenceType <type> [-timeout <integer>]
2 <!--NeedCopy-->
```

#### Example:

```
1 set cs vserver Vserver-CS-1 -persistenceType SOURCEIP -timeout 60
2 <!--NeedCopy-->
```

### Configure persistence type on content switching virtual server by using the GUI

1. Navigate to **Traffic Management > Content Switching > Virtual Servers** and click **Add**.
2. In **Basic Settings**, configure the persistence details.

## Troubleshooting

September 6, 2023

If the content switching feature does not work as expected after you have configured it, you can use some common tools to access NetScaler resources and diagnose the problem.

### Resources for troubleshooting content switching

For best results, use the following resources to troubleshoot a content switching issue on a NetScaler appliance:

- Configuration file
- `newslog` file generated when the issue occurred
- Trace files
- Network topology diagram for the network setup of the customer
- NetScaler documentation, such as release notes, Knowledge Center articles, and Product documentation.

In addition to the preceding resources, the following tools expedite troubleshooting:

- The `iehttpheaders` or a similar utility
- The Wireshark application customized for the NetScaler trace files
- An SSH utility for command line access
- A HyperTerminal utility to access the console

### Troubleshooting content switching issues

The most common content switching issues involve the content switching feature not working at all, or working only intermittently, and Service Unavailable responses.

- **Issue**

The content switching feature is not functioning.

- **Resolution**

Check the configuration as follows:

- Verify that the appliance is licensed for content switching.
- Verify that the feature is enabled.
- From the configuration file, verify that valid content switching policies are correctly bound to the load balancing virtual servers.

- **Issue**

Client receives a 503 - Service Unavailable response.

**Resolution**

- Verify the URL and policy bindings. The client receives the 503 response when none of the policies you have configured is evaluated and no default load balancing virtual server is defined and bound to the content switching virtual server.
- From the configuration, verify the policies and the URL is accessed by the client.
- Verify that for every type of request the respective policy is evaluated. If the policy is not evaluated, check the policy expression and update it if necessary.
- Verify the URL and HTTP request and response headers. To do so, record an [HTTPHeader](#) trace and, if necessary, record the packet traces on the appliance and the client.

- **Issue**

Intermittently, the content switching feature is not working as expected.

**Resolution**

- Study the network topology diagram, if available, of the setup to understand the various devices installed between the client and the servers.
- Verify the configuration and policy bindings. Make sure that the URL in the policy expression matches to the one in the client request.
- Verify that appropriate priorities are assigned to the policies. An incorrect precedence or priority assigned to a policy can cause a problem.
- Run the following commands to verify the bindings and the values of the policy select counters in the output of the commands:  

```
show cs vserver \<CS VServer\>
show cs policy \<CS Policy\>
stat cs vserver \<CS VServer\>
```
- Using [iehttpheaders](#) or a similar utility, determine whether the HTTP headers for the requests or responses provide any pointers to the issue.
- Check the release notes and Knowledge Center articles.
- If the issue is still not resolved, contact Citrix technical support with appropriate data for further investigation.

## DataStream

May 2, 2023

The NetScaler DataStream feature provides an intelligent mechanism for request switching at the database layer by distributing requests based on the SQL query being sent.

When deployed in front of database servers, a NetScaler appliance ensures optimal distribution of traffic from the application servers and Web servers. Administrators can segment traffic according to information in the SQL query and based on database names, user names, character sets, and packet size.

You can configure load balancing to switch requests based on load balancing algorithms. Alternately, you can elaborate the switching criteria by configuring content switching to make a decision based on an SQL query parameter. You can further configure monitors to track the state of database servers.

### Note

NetScaler DataStream is supported only for MySQL and MS SQL databases. For information about the supported protocol version, character sets, special queries, and transactions, see DataStream Reference.

### How DataStream works

In DataStream, the ADC appliance is placed in-line between the application or Web servers and the database servers. On the appliance, the database servers are represented by services.

A typical DataStream deployment consists of the entities described in the following diagram.

Figure 1. DataStream Entity Model

As shown in this figure, a DataStream configuration can consist of:

- An optional content switching virtual server (CS).
- A load balancing setup consisting of load balancing virtual servers (LB1 and LB2).
- Services (Svc1, Svc2, Svc3, and Svc4).
- Content switching policies (optional).

The clients (application or Web servers) send requests to the IP address of a content switching virtual server (CS) configured on the NetScaler appliance. The appliance, then, authenticates the clients using the database user credentials configured on the appliance. The content switching virtual server (CS) applies the associated content switching policies to the requests. After evaluating the policies, the content switching virtual server (CS) routes the requests to the appropriate load balancing virtual server (LB1 or LB2). Then, the load balancing virtual server distributes the requests to the appropriate database servers (represented by services on the appliance) based on the load balancing algorithm. The NetScaler appliance uses the same database user credentials to authenticate the connection with the database server.

If a content switching virtual server is not configured on the appliance, the clients (application or Web servers) send their requests to a load balancing virtual server configured on the appliance. The NetScaler appliance authenticates the client by using the database user credentials configured on

the appliance, and then uses the same credentials to authenticate the connection with the database server. The load balancing virtual server distributes the requests to the database servers according to the load balancing algorithm. The most effective load balancing algorithm for database switching is the least connection method.

DataStream uses connection multiplexing to enable multiple client-side requests to be made over the same server-side connection. The following connection properties are considered:

- User name
- Database name
- Packet size
- Character set

## Configure database users

January 20, 2021

In databases, a connection is always stateful, which means that when a connection is established, it must be authenticated.

Configure your database user name and password on the NetScaler appliance. For example, if you have a user John configured on the database, you need to configure the user John on the ADC too. Adding database user names and passwords on the ADC adds them to the `nsconfig` file.

### Note

Names are case sensitive.

The ADC uses these user credentials to authenticate the clients, and then authenticate the server connections with the database servers.

### Add a database user by using the CLI

At the command prompt, type

```
add db user <username> - password <password>
```

#### Example:

```
1 add db user nsdbuser -password dd260427edf
2 <!--NeedCopy-->
```

## Add a database user by using the GUI

Navigate to **System > User Administration > Database Users**, and configure a database user.

If you have changed the password of the database user on the database server, you must reset the password of the corresponding user configured on the ADC appliance.

## Reset the password of a database user by using the CLI

At the command prompt, type

```
1 set db user <username> -password <password>
2 <!--NeedCopy-->
```

### Example:

```
1 set db user nsdbuser -password dd260538abs
2 <!--NeedCopy-->
```

## Reset the password of database users by using the GUI

Navigate to **System > User Administration > Database Users**, select a user, and enter new values for the password.

If a database user no longer exists on the database server, you can remove the user from the ADC appliance. However, if the user continues to exist on the database server and you remove the user from the ADC appliance, any request from the client with this user name does not get authenticated. As a result, the request is not routed to the database server.

## Remove a database user by using the CLI

At the command prompt, type

```
1 rm db user <username>
2 <!--NeedCopy-->
```

### Example:

```
1 rm db user nsdbuser
2 <!--NeedCopy-->
```

## Remove a database user by using the GUI

Navigate to **System > User Administration > Database Users**, select a user, and click **Delete**.

## Configure a database profile

January 20, 2021

A database profile is a named collection of parameters that is configured once but applied to multiple virtual servers that require those particular parameter settings. After creating a database profile, you bind it to load balancing or content switching virtual servers. You can create as many profiles as you need.

### Create a database profile by using the CLI

At the command line, type the following commands to create a database profile and verify the configuration:

```
1 add db dbProfile <name> [-interpretQuery (YES | NO)] [-stickiness (
 YES | NO)] [-kcdAccount <string>]
2
3 show db dbProfile
4 <!--NeedCopy-->
```

#### Example:

```
1 > add dbProfile myDBProfile -interpretQuery YES -stickiness YES -
 kcdAccount mykcdacct
2 Done
3 > show dbProfile myDBProfile
4 Name: myDBProfile
5 Interpret Query: YES
6 Stickyness: YES
7 KCD Account: mykcdacct
8 Reference count: 0
9
10 Done
11 >
12 <!--NeedCopy-->
```

### Create a database profile by using the GUI

Navigate to **System > Profiles** and, on the **Database Profiles** tab, configure a database profile.

### Bind a database profile to a load balancing or content switching virtual server by using the CLI

At the command line, type:

```
1 set (lb | cs) vserver <name> -dbProfileName <string>
2 <!--NeedCopy-->
```

## Bind a database profile to a load balancing or content switching virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers** or **Traffic Management > Content Switching > Virtual Servers**, and open a virtual server.
2. In **Advanced Settings**, select **Profiles** and, in the **DB Profile** list, select a profile to bind to the virtual server. To create a profile, click plus (+).

## Configure load balancing for DataStream

May 2, 2023

Before configuring a load balancing setup, you must enable the load balancing feature. Then, begin by creating at least one service for each database server in the load balancing group. With the services configured, you are ready to create a load balancing virtual server and bind the services to the virtual server.

### Note:

For databases, the load balancing can only occur on homogenous database servers (database servers that contain the exact same databases). For a configuration that contains unique databases on different servers, you must use content switching. If some of your database servers host identical content, you can use load balancing on those servers only. You can then use content switching policies to send requests to the load balancing virtual server that manages load balancing for those databases.

The NetScaler appliance currently stores the database name and login information during the database session. When a query is made to the database, it uses that information to connect to the specific database server.

## Parameter values specific to DataStream

- Protocol

Use the MYSQL protocol type for MySQL databases and MSSQL protocol type for MS SQL databases while configuring virtual servers and services. The MySQL and TDS protocols are used by

the clients to communicate with the respective database servers by using SQL queries. For information about the MySQL protocol, see <http://dev.mysql.com/doc/internals/en/client-server-protocol.html>. For information about the TDS protocol, see [http://msdn.microsoft.com/en-us/library/dd304523\(v=prot.13\).aspx](http://msdn.microsoft.com/en-us/library/dd304523(v=prot.13).aspx).

- Port

Port on which the virtual server listens for client connections. Use port 3306 for MySQL database servers.

- Method

It is recommended that you use the Least Connection method for better load balancing and lower server load. However, other methods, such as Round Robin, Least Response Time, Source IP Hash, Source IP Destination IP Hash, Least Bandwidth, Least Packets, and Source IP Source Port Hash, are also supported.

Note: URL Hash method is not supported for DataStream.

- MS SQL Server version

If you are using the Microsoft SQL Server, and you expect some clients running a different version from your Microsoft SQL Server product, set the Server Version parameter for the load balancing virtual server. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server's version. For more information about setting the Server Version parameter, see [Configuring the MySQL and Microsoft SQL server version setting](#).

- MySQL Server version

If you are using the MySQL Server, and you expect some clients running a different version from your MySQL Server product, set the Server Version parameter for the load balancing virtual server. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server's version. For more information about setting the Server Version parameter, see [Configuring the MySQL and Microsoft SQL server version setting](#).

## Configure content switching for DataStream

May 2, 2023

You can segment traffic according to information in the SQL query, based on database names, user names, character sets, and packet size.

You can configure content switching policies with Advanced policy expressions to switch content based on connection properties. For example, user name and database name, command parameters, and the SQL query to select the server.

The Advanced policy expressions evaluate traffic associated with MYSQL and MS SQL database servers. Use request-based expressions in Advanced policy policies to make request switching decisions at the content switching virtual server bind point. Use response-based expressions (expressions that begin with MYSQL.RES) to evaluate server responses to user-configured health monitors.

For information about Advanced policy expressions, see [Advanced policy Expressions: DataStream](#).

**Note:**

For databases, the load balancing can only occur on homogenous database servers (database servers that contain the exact same databases). For a configuration that contains unique databases on different servers, you must use content switching. If some of your database servers host identical content, you can use load balancing on those servers only. You can then use content switching policies to send requests to the load balancing virtual server that manages load balancing for those databases.

The NetScaler appliance currently stores the database name and login information during the database session. When a query is made to the database, it uses that information to connect to the specific database server.

### Parameter values specific to DataStream

- Protocol

Use the MYSQL protocol type for MySQL databases and MSSQL protocol type for MS SQL databases while configuring virtual servers and services. The MySQL and TDS protocols are used by the clients to communicate with the respective database servers by using SQL queries. For information about the MySQL protocol, see <http://dev.mysql.com/doc/internals/en/client-server-protocol.html>. For information about the TDS protocol, see [http://msdn.microsoft.com/en-us/library/dd304523\(v=prot.13\).aspx](http://msdn.microsoft.com/en-us/library/dd304523(v=prot.13).aspx).

- Port

Port on which the virtual server listens for client connections. Use port 3306 for MySQL database servers.

- MS SQL Server Version

If you use Microsoft SQL Server, and expect some clients running a different version from your Microsoft SQL Server product, set the Server Version parameter for the content switching virtual server. The version setting provides compatibility between the client-side and server-side

connections by ensuring that all communication conforms to the server's version. For more information about setting the Server Version parameter, see [Configuring the Microsoft SQL Server Version Setting](#).

## Configure monitors for DataStream

January 20, 2021

To track the state of each load balanced database server in real time, you need to bind a monitor to each service. The monitor is configured to test the service by sending periodic probes to the service, sometimes referred to as performing a health check. If the monitor receives a timely response to its probes, it marks the service as UP. If it does not receive a timely response to the designated number of probes, it marks the service as DOWN.

For DataStream, you need to use the built-in monitors: MYSQL-ECV and MSSQL-ECV. Using this monitor you can send an SQL request and parse the response for a string.

Before configuring monitors for DataStream, you must add database user credentials to your NetScaler appliance. For information about configuring monitors, see [Configure monitors in a load balancing setup](#).

When you create a monitor, a TCP connection is established with the database server, and the connection is authenticated by using the user name provided while creating the monitor. You can then run an SQL query to the database server and evaluate the server response to check whether it matches the configured rule.

The following examples are for MYSQL servers.

### Examples:

In the following example, the value of the error message is evaluated to determine the state of the server.

```
1 add lb monitor lb_mon1 MYSQL-ECV -sqlQuery "select * from
2 table2;" -evalrule "mysql.res.error.message.contains("Invalid
3 User")"-database "NS" -userName "user1"
4 <!--NeedCopy-->
```

In the following example, the number of rows in the response is evaluated to determine the state of the server.

```
1 add lb monitor lb_mon4 MYSQL-ECV -sqlQuery "select * from
2 table4;" -evalrule "mysql.res.atleast_rows_count(7)" -database "NS" -
 userName "user2"
3 <!--NeedCopy-->
```

In the following example, the value of a particular column is evaluated to determine the state of the server.

```
1 add lb monitor lb_mon3 MYSQL-ECV
2 -sqlQuery "select * from ABC;" -evalrule "mysql.res.row(1).double_elem
 (2) == 345.12"
3 -database "NS" -userName "user3"
4 <!--NeedCopy-->
```

The following examples are for MSSQL servers.

**Examples:**

In the following example, the value of the error message is evaluated to determine the state of the server.

```
1 add lb monitor lb_mon1 MSSQL-ECV -sqlQuery "select * from
2 table2;" -evalrule "mssql.res.error.message.contains("Invalid
3 User")"-database "NS" -userName "user1"
4 <!--NeedCopy-->
```

In the following example, the number of rows in the response is evaluated to determine the state of the server.

```
1 add lb monitor lb_mon4 MSSQL-ECV -sqlQuery "select * from
2 table4;" -evalrule "mssql.res.atleast_rows_count(7)" -database "NS" -
 userName "user2"
3 <!--NeedCopy-->
```

In the following example, the value of a particular column is evaluated to determine the state of the server.

```
1 add lb monitor lb_mon3 MSSQL-ECV
2 -sqlQuery "select * from ABC;" -evalrule "mssql.res.row(1).double_elem
 (2) == 345.12"
3 -database "NS" -userName "user3"
4 <!--NeedCopy-->
```

## Use Case 1: Configure DataStream for a primary/secondary database architecture

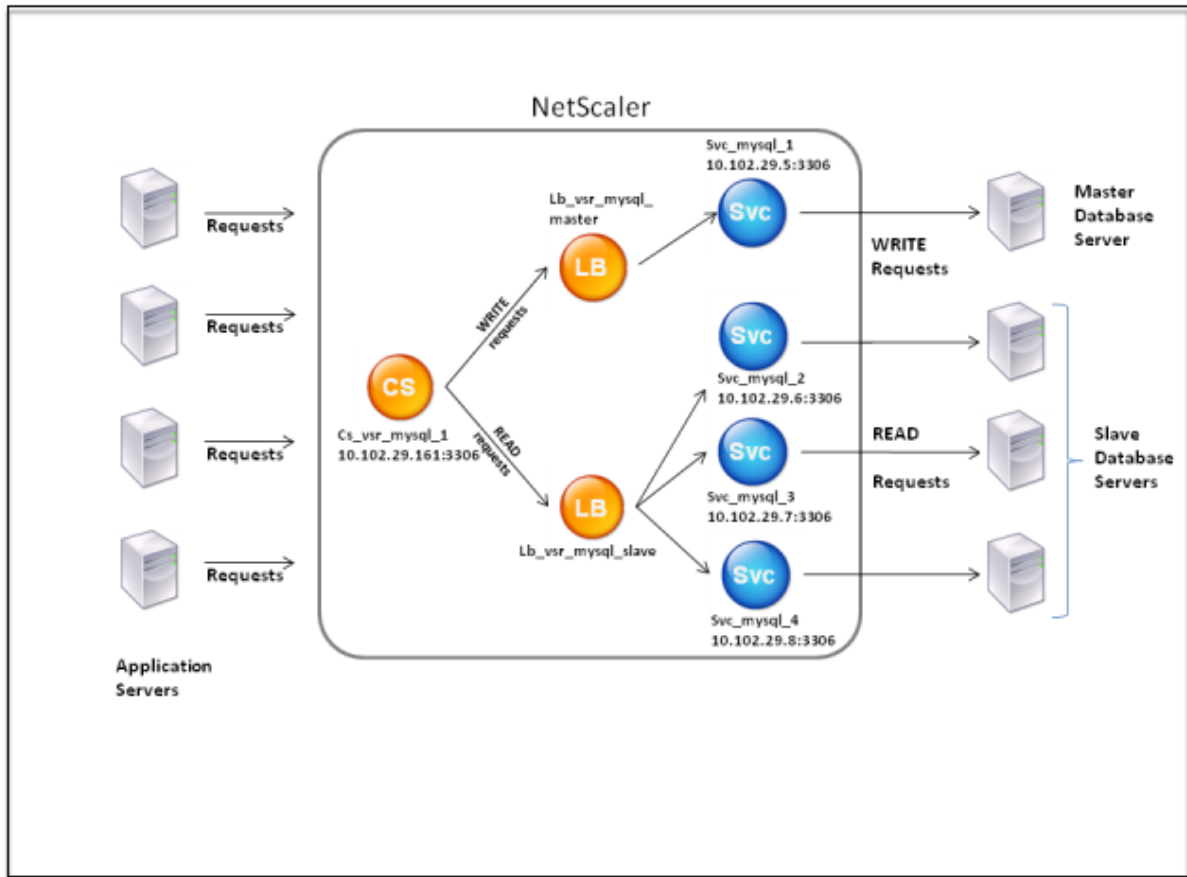

May 2, 2023

A commonly used deployment scenario is the primary/secondary database architecture where the primary database replicates all information to the secondary databases.

For primary/secondary database architecture, you might want all WRITE requests to be sent to the primary database and all READ requests to the secondary databases.

The following figure shows the entities and the values of the parameters that you need to configure on the appliance.

Figure 1. DataStream Entity Model for Primary/Secondary Database Setup

In this example scenario, a service (Svc\_mysql\_1) is created to represent the primary database and is bound to a load balancing virtual server (Lb\_vsr\_mysql\_primary). Three more services (Svc\_mysql\_2, Svc\_mysql\_3, and Svc\_mysql\_4) are created to represent the three secondary databases, and they are bound to another load balancing virtual server (Lb\_vsr\_mysql\_secondary).

A content switching virtual server (Cs\_vsr\_mysql\_1) is configured with associated policies to send all WRITE requests to the load balancing virtual server, Lb\_vsr\_mysql\_primary. All READ requests are sent to the load balancing virtual server, Lb\_vsr\_mysql\_secondary.

When a request reaches the content switching virtual server, the virtual server applies the associated content switching policies to that request. After evaluating the policies, the content switching virtual server routes the request to the appropriate load balancing virtual server, which sends it to the appropriate service.

The following table lists the names and values of the entities and the policy configured on the NetScaler appliance.

Entity Type	Name	IP Address	Protocol	Port	Expression
Services	Svc_mysql_1	198.51.100.5	MYSQL	3306	NA
	Svc_mysql_2	198.51.100.6	MYSQL	3306	NA
	Svc_mysql_3	198.51.100.7	MYSQL	3306	NA
	Svc_mysql_4	198.51.100.8	MYSQL	3306	NA
Monitor	lb_mon1	NA	MYSQL-ECV	NA	mysql.res.atleast_rows_co
Load balancing virtual servers	Lb_vsr_mysql_primary	198.51.100.201	MYSQL	3306	NA
	Lb_vsr_mysql_secondary	198.51.100.202	MYSQL	3306	NA
Content switching virtual server	Cs_vsr_mysql_1	198.51.100.161	MYSQL	3306	NA
Content switching policy	Cs_select	NA	NA	NA	<code>MYSQL.REQ. QUERY. COMMAND. contains("select")</code>

Table 1. Entity and Policy Names and Values

### To configure DataStream for a primary/secondary database setup by using the command line interface

At the command prompt, type

```

1 add db user user1 -password user1
2
3 add service Svc_mysql_1 198.51.100.5 mysql 3306
4
5 add service Svc_mysql_2 198.51.100.6 mysql 3306
6
7 add service Svc_mysql_3 198.51.100.7 mysql 3306
8
9 add service Svc_mysql_4 198.51.100.8 mysql 3306
10

```

```
11 add lb monitor lb_mon1 MYSQL-ECV -sqlQuery "select * from table1;" -
 evalrule "mysql.res.atleast_rows_count(1)" -database "NS" -userName
 "user1"
12
13 add lb vserver Lb_vsr_mysql_primary mysql 198.51.100.201 3306
14
15 add lb vserver Lb_vsr_mysql_secondary mysql 198.51.100.202 3306
16
17 bind lb vserver Lb_vsr_mysql_primary svc_mysql_1
18
19 bind lb vserver Lb_vsr_mysql_secondary svc_mysql_2
20
21 bind lb vserver Lb_vsr_mysql_secondary svc_mysql_3
22
23 bind lb vserver Lb_vsr_mysql_secondary svc_mysql_4
24
25 add cs vserver Cs_vsr_mysql_1 mysql 198.51.100.161 3306
26
27 add cs policy Cs_select -rule "MYSQL.REQ.QUERY.COMMAND.contains(\"
 select\")"
28
29 bind cs vserver Cs_vsr_mysql_1 Lb_vsr_mysql_primary
30
31 bind cs vserver Cs_vsr_mysql_1 Lb_vsr_mysql_secondary - policy
 Cs_select - priority 10
32
33 bind service Svc_mysql_1 -monitorName lb_mon1
34
35 bind service Svc_mysql_2 -monitorName lb_mon1
36
37 bind service Svc_mysql_3 -monitorName lb_mon1
38
39 bind service Svc_mysql_4 -monitorName lb_mon1
40 <!--NeedCopy-->
```

## Use Case 2: Configure the token method of load balancing for DataStream

May 2, 2023

You can configure the token method of load balancing for DataStream to base the selection of database servers on the value of the token extracted from the client (application or web server) requests. These tokens are defined by using SQL expressions. For subsequent requests with the same token, the NetScaler appliance sends the requests to the same database server that handled the initial request. Requests with the same token are sent to the same database server until the maximum connection limit is reached or the session entry has aged out.

You can use the following sample SQL expressions to define tokens:

MySQL	MS SQL
MYSQL.REQ.QUERY.TEXT	MSSQL.REQ.QUERY.TEXT
MYSQL.REQ.QUERY.TEXT(n)	MSSQL.REQ.QUERY.TEXT(n)
MYSQL.REQ.QUERY.COMMAND	MSSQL.REQ.QUERY.COMMAND
MYSQL.CLIENT.USER	MSSQL.CLIENT.USER
MYSQL.CLIENT.DATABASE	MSSQL.CLIENT.DATABASE
MYSQL.CLIENT.CAPABILITIES	

The following example shows how the NetScaler DataStream feature works when you configure the token method of load balancing.

Figure 1. DataStream and the Token Method of Load Balancing

In this example, the token is the name of the database. A request with token books is sent to Database Server1 and a request with token music is sent to Database Server2. All subsequent requests with token books are sent to Database Server1 and requests with token music are sent to Database Server2. This configuration provides pseudo persistence with the database servers.

### Configure this example by using the CLI

At the command prompt, type:

```
1 add service Service1 192.0.2.9 MYSQL 3306
```

```
2
3 add service Service2 192.0.2.11 MYSQL 3306
4
5 add lb vserver token_lb_vserver MYSQL 192.0.2.15 3306 -lbmethod token -
 rule MYSQL.CLIENT.DATABASE
6
7 bind lb vserver token_lb_vserver Service1
8
9 bind lb vserver token_lb_vserver Service2
10 <!--NeedCopy-->
```

### Configure this example by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, configure a virtual server, and specify the protocol as **MYSQL**.
2. Click in the **Service** section, and configure two services specifying the protocol as **MYSQL**. Bind these services to the virtual server.
3. In **Advanced Settings**, click **Method** and, in the **Load Balancing Method** list, select **TOKEN** and specify the expression as **MYSQL.CLIENT.DATABASE**.

### Use Case 3: Log MSSQL transactions in transparent mode

May 2, 2023

You can configure the NetScaler appliance to operate transparently between MSSQL clients and servers, and to only log or analyze details of all client-server transactions. Transparent mode is designed so that the NetScaler appliance only forwards MSSQL requests to the server, and then relays the server's responses to the clients. As the requests and responses pass through the appliance, the appliance logs information gathered from them, as specified by the audit logging or AppFlow configuration, or collects statistics, as specified by the Action Analytics configuration. You do not have to add database users to the appliance.

When operating in transparent mode, the NetScaler appliance does not perform load balancing, content switching, or connection multiplexing for the requests. However, it responds to a client's pre-login packet on behalf of the server so that it can prevent encryption from being agreed upon during the pre-login handshake. The login packet and subsequent packets are forwarded to the server.

### Summary of configuration tasks

For logging or analyzing MSSQL requests in transparent mode, you have to do the following:

- Configure the NetScaler appliance as the default gateway for both clients and servers.
- Do one of the following on the NetScaler appliance:
  - **Configure the use source IP address (USIP) option globally:** Create a load balancing virtual server with a wildcard IP address and the port number on which the MSSQL servers listen for requests (a port-specific wildcard virtual server). Then, enable the USIP option globally. If you configure a port-specific wildcard virtual server, you do not have to create MSSQL services on the appliance. The appliance discovers the services based on the destination IP address in the client requests.
  - **If you do not want to configure the USIP option globally:** Create MSSQL services with the USIP option enabled on each of them. If you configure services, you do not have to create a port-specific wildcard virtual server.
- Configure audit logging, AppFlow, or Action Analytics to log or collect statistics about the requests. If you configure a virtual server, you can bind your policies either to the virtual server or to the global bind point. If you do not configure a virtual server, you can bind your policies to only the global bind point.

### Configure transparent mode by using a wildcard virtual server

You can configure transparent mode by configuring a port-specific wildcard virtual server and enabling Use Source IP (USIP) mode globally. When a client sends its default gateway (the NetScaler appliance) a request with the IP address of an MSSQL server in the destination IP address header, the appliance checks whether the destination IP address is available. If the IP address is available, the virtual server forwards the request to the server. Otherwise, it drops the request.

### Create a wildcard virtual server by using the CLI

At the command prompt, type the following commands to create a wildcard virtual server and verify the configuration:

```
1 add lb vservice <name> <serviceType> <IPAddress> <port>
2
3 show lb vservice <name>
4 <!--NeedCopy-->
```

#### Example:

```
1 > add lb vservice wildcardLbVs MSSQL * 1433
2 Done
3 > show lb vservice wildcardLbVs
4 wildcardLbVs (*:1433) - MSSQL Type: ADDRESS
5 State: UP
6 . . .
```

```

7
8 Done
9 >
10 <!--NeedCopy-->

```

**Create a wildcard virtual server by using the GUI**

Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and create a virtual server. Specify MSSQL as the protocol and \* as the IP address.

**Enable Use Source IP (USIP) mode globally by using the CLI**

At the command prompt, type the following commands to enable USIP mode globally and verify the configuration:

```

1 enable ns mode USIP
2
3 show ns mode
4 <!--NeedCopy-->

```

**Example:**

```

1 > enable ns mode USIP
2 Done
3 > show ns mode
4
5 Mode Acronym
6 Status -----
7
8 3) Use Source IP USIP ON
9
10 Done
11 >
12 <!--NeedCopy-->

```

**Enable USIP mode globally by using the GUI**

1. Navigate to **System > Settings** and, in Modes and Features, select **Configure Modes**.
2. Select **Use Source IP**.

## Configure transparent mode by using MSSQL services

You can configure transparent mode by configuring MSSQL services and enabling USIP on each service. When a client sends its default gateway (the NetScaler appliance) a request with the IP address of an MSSQL server in the destination IP address header, the appliance forwards the request to the destination server.

### Create an MSSQL service and enable USIP mode on the service by using the CLI

At the command prompt, type the following commands to create an MSSQL service, with USIP enabled, and verify the configuration:

```
1 add_service <name> (<IP> | <serverName>) <serviceType> <port> -usip YES
2
3 show_service <name>
4 <!--NeedCopy-->
```

#### Example

```
1 > add_service myDBservice 192.0.2.0 MSSQL 1433 -usip YES
2 Done
3 > show_service myDBservice
4 myDBservice (192.0.2.0:1433) - MSSQL
5 State: UP
6 . . .
7 Use Source IP: YES Use Proxy Port: YES
8 . . .
9 Done
10 >
11 <!--NeedCopy-->
```

### Create an MSSQL service, with USIP enabled, by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and configure a service.
2. Specify the protocol as **MSSQL** and, in **Settings**, select **Use Source IP**.

## Use Case 4: Database specific load balancing

November 3, 2023

A database server farm must be load balanced not only based on the states of the servers, but also based on the availability of the database on each server. A service might be up, and a load balancing

device might show it as being in the UP state, but the requested database might be unavailable on that service. The request isn't served if a query is forwarded to a service on which the database is unavailable. Therefore, a load balancing device must be aware of the availability of a database on each service. And when making a load balancing decision, it must consider only those services on which the database is available.

As an example, consider that database servers server1, server2, and server3 host databases mydatabase1 and mydatabase2. If mydatabase1 becomes unavailable on server2, the load balancing device must be aware of that change in state. It must load balance requests for mydatabase1 across only server1 and server3. After mydatabase1 becomes available on server2, the load balancing device must include server2 in load balancing decisions. Similarly, if mydatabase2 becomes unavailable on server3, the device must load balance requests for mydatabase2 across only server1 and server2. It must include server3 in its load balancing decisions only when mydatabase2 becomes available. This load balancing behavior must be consistent across all the databases that are hosted on the server farm.

The NetScaler appliance implements this behavior by retrieving a list of all the databases that are active on a service. To retrieve the list of active databases, the appliance uses a monitor that is configured with an appropriate SQL query. If the requested database is unavailable on a service, the appliance excludes the service from load balancing decisions until it becomes available. This behavior ensures uninterrupted service to clients.

### Note

Database specific load balancing is supported for only MS SQL and MySQL service types. This support is also available for MS SQL Server configured in Always On high availability groups. For more information, see [Supported database versions, protocols, and authentication methods](#).

To set up database specific load balancing, you must configure the following:

- Enable the load balancing feature, and configure a load balancing virtual server of type MSSQL or MySQL.
- Configure the services that host the database, and bind the services to the virtual server. The monitor needs valid user credentials to log on to the database server, so you must configure a database user account on each of the servers and then add the user account to the NetScaler appliance.
- Then, you configure an MSSQL-ECV or MYSQL-ECV monitor and bind the monitor to each service.
- Finally, you must test the configuration to ensure that it's working as intended. Before you perform these configuration tasks, make sure you understand how database specific load balancing works.

## How database specific load balancing works

For database specific load balancing, you configure a monitor that periodically queries each database server for the names of all the active databases on it. The NetScaler appliance stores the results, and regularly updates the records based on the information retrieved through monitoring. When a client queries a particular database, the appliance uses the configured load balancing method to select a service, and then checks its records to determine whether the database is available on that service. If the records indicate that the database isn't available, it uses the configured load balancing method to select the next available service, and then repeats the check. The appliance forwards the query to the first available service on which the database is active.

## Enable load balancing

You can configure load balancing entities such as services and virtual servers when the load balancing feature is disabled. The entities do not function until you enable the feature.

## Enable load balancing by using the CLI

At the command prompt, type the following command to enable load balancing and verify the configuration:

```
1 enable ns feature LB
2
3 show ns feature
4 <!--NeedCopy-->
```

### Example:

```
1 > enable ns feature LoadBalancing
2 Done
3 > show ns feature
4
5 Feature Acronym Status
6 ----- -
7 1) Web Logging WL OFF
8 2) Surge Protection SP ON
9 3) Load Balancing LB ON
10 .
11 .
12 .
13 24) NetScaler Push push OFF
14 Done
15 <!--NeedCopy-->
```

## Enable load balancing by using the GUI

Navigate to **System > Settings** and, in **Configure Basic Features**, select **Load Balancing**.

## Configure a load balancing virtual server for database specific load balancing

To configure a virtual server to load balance databases based on availability, you enable the database specific load balancing parameter on the virtual server. Enabling the parameter modifies the load balancing logic so that the NetScaler appliance refers the results of the monitoring probe sent to the selected service, before forwarding the query to that service.

## Configure a load balancing virtual server for database specific load balancing using the CLI

At the command prompt, type the following command to configure a load balancing virtual server for database specific load balancing and verify the configuration:

```
1 add lb vservice <name> <serviceType> <ipAddress> <port> -dbsLb ENABLED
2
3 show lb vservice <name>
4 <!--NeedCopy-->
```

## Configure services

After you enable the load balancing feature, you must create at least one service for each application server that is to be included in your load balancing setup. The services that you configure provide the connections between the NetScaler appliance and the load balanced servers. Each service has a name and specifies an IP address, a port, and the type of data that is served.

If you create a service without first creating a server object, the IP address of the service is also the name of the server that hosts the service. If you prefer to identify servers by name rather than IP address, you can create server objects and then specify a server's name instead of its IP address when you create a service.

## Configure database users

In databases, a connection is always stateful, which means that when a connection is established, it must be authenticated.

Configure your database user name and password on the NetScaler. For example, if you have a user John configured on the database, you need to configure the user John on the ADC too. Database user names and passwords added to the ADC are added to the `nsconfig` file.

**Note**

Names are case sensitive.

The ADC uses these user credentials to authenticate the clients, and then authenticate the server connections with the database servers.

**Add a database user by using the CLI**

At the command prompt, type

```
1 add db user <username> - password <password>
2 <!--NeedCopy-->
```

**Example:**

```
1 add db user nsdbuser -password dd260427edf
2 <!--NeedCopy-->
```

**Add a database user by using the GUI**

Navigate to **System > User Administration > Database Users**, and configure a database user.

If you've changed the password of the database user on the database server, you must reset the password of the corresponding user configured on the NetScaler appliance.

**Reset the password of a database user by using the CLI**

At the command prompt, type

```
1 set db user <username> -password <password>
2 <!--NeedCopy-->
```

**Example:**

```
1 set db user nsdbuser -password dd260538abs
2 <!--NeedCopy-->
```

**Reset the password of database users by using the GUI**

Navigate to **System > User Administration > Database Users**, select a user, and enter new values for the password.

If a database user no longer exists on the database server, you can remove the user from the NetScaler appliance. However, if the user continues to exist on the database server and you remove the user from the ADC appliance, any request from the client with this user name does not get authenticated. Therefore, the user name does not get routed to the database server.

**Remove a database user by using the CLI** At the command prompt, type

```
1 rm db user <username>
2 <!--NeedCopy-->
```

**Example:**

```
1 rm db user nsdbuser
2 <!--NeedCopy-->
```

**Remove a database user by using the GUI**

Navigate to **System > User Administration > Database Users**, select a user, and click **Delete**.

**Configure a monitor to retrieve the names of active databases**

You can create a monitor to retrieve the list of all active databases on a database instance. The monitor logs on to the database server by using a valid user credentials and runs an appropriate SQL query. The SQL query you need to use depends on your SQL server deployment. For example, in an MSSQL database mirroring setup, you can use the following query to retrieve a list of active databases available on a server instance.

```
1 select name from sys.databases where state=0
2 <!--NeedCopy-->
```

In a MySQL database setup you can use the following queries to retrieve a list of active databases available on a server instance.

**Show databases:**

You also configure the monitor to evaluate the response for an error condition, and to store the results if there's no error. If the response contains an error, the monitor marks the service as DOWN. The appliance excludes the service from load balancing decisions until an error is no longer returned.

**Note**

The database specific load balancing feature is supported only for the MSSQL and MySQL service types. Therefore, the monitor type must be MSSQL-ECV or MYSQL-ECV.

### Configure a monitor to retrieve the names of all the active databases hosted on a service by using the CLI

At the command prompt, type the following commands to retrieve the names of all the active databases hosted on a service and verify the configuration:

```
1 add lb monitor <monitorName> <type> -userName <string> -sqlQuery <text>
 -evalRule <expression> -storedb ENABLED
2
3 show lb monitor <monitorName>
4 <!--NeedCopy-->
```

### Configure a monitor to retrieve the names of all the active databases hosted on a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors** and configure a monitor of type MSSQL-ECV or MYSQL-ECV.
2. In **Special Parameters**, specify a user name, query, and a rule. For example, for MSSQL-ECV, the query must be “select name from sys.databases where state=0”), and a rule must be MSSQL.RES.TYPE.NE(ERROR). For MYSQL-ECV, the query must be “show databases” and a rule must be MYSQL.RES.TYPE.NE(ERROR).

### Availability groups deployment support for MSSQL

Consider the following scenario in which database specific load balancing is configured in a high availability group deployment. S1 through S5 are the services on the ADC appliance. DB1 through DB4 are the databases on the servers represented by the services S1 through S5. AV1 and AV2 are the availability groups. Each availability group contains up to one primary database server instance and up to four secondary database server instances. A service, representing the servers in the availability group, can be primary for one availability group and secondary for another availability group. Each availability group contains different databases and one listener, which is a service. All requests arrive on the listener service that resides on the primary database. AV1 contains databases DB1 and DB2. AV2 contains databases DB3 and DB4. L1 and L2 are the listeners on AV1 and AV2 respectively. S1 is the primary service for AV1 and S2 is the primary service for AV2.

Service	List of Active Databases on the Service
S1	DB1, DB2, DB3, DB4
S2	DB3, DB4
S3	DB3, DB4
S4	DB1, DB2
S5	DB1, DB2

Availability Group	Databases	Services representing the Servers in the Availability Group
AV1	DB1, DB2	S1, S4, S5
AV2	DB3, DB4	S1, S2, S3

The queries flow as follows:

1. A READ query for AV1 is load balanced between S4 and S5. S1 is the primary for AV1.
2. A WRITE query for AV1 is directed to L1.
3. A READ query for AV2 is load balanced between S1 and S3. S2 is the primary for AV2.
4. A WRITE query for AV1 is directed to L2.

### Sample configuration

1. Configure load balancing and content switching virtual servers.
  - `add lb vserver lbwrite -dbslb enabled`
  - `add lbvserver lbread MSSQL -dbslb enabled`

- `add csvserver csv MSSQL 1.1.1.10 1433`
2. Configure two listener services, one for each availability group, and five services S1 through S5 representing databases DB1 through DB4.
    - `add service L1 1.1.1.11 MSSQL 1433`
    - `add service L2 1.1.1.12 MSSQL 1433`
    - `add service s1 1.1.1.13 MSSQL 1433`
    - `add service s2 1.1.1.14 MSSQL 1433`
    - `add service s3 1.1.1.15 MSSQL 1433`
    - `add service s4 1.1.1.16 MSSQL 1433`
    - `add service s5 1.1.1.17 MSSQL 1433`
  3. Bind the services to the load balancing virtual servers.
    - `bind lbvserver lbwrite L1`
    - `bind lbvserver lbwrite L2`
    - `bind lbvserver lbread s1`
    - `bind lbvserver lbread s2`
    - `bind lbvserver lbread s3`
    - `bind lbvserver lbread s4`
    - `bind lbvserver lbread s5`
  4. Configure database users.
    - `add db user nsdbuser1 -password dd260427edf`
    - `add db user nsdbuser2 -password ccd1234xyzw`
  5. Configure two monitors, monitor\_L1 and monitor\_L2 for each listener service, to retrieve the list of active databases in that availability group. Add a monitor, monitor1 to retrieve the list of databases for the secondary database server instance.
    - `add lb monitor monitor_L1 MSSQL-ECV -userName user1 -sqlQuery "SELECT name FROM sys.databases a INNER JOIN sys.dm_hadr_availability b ON a.replica_id=b.replica_id INNER JOIN sys.availability_group_list c on b.group_id = c.group_id INNER JOIN sys.availability_group_listen d on c.listener_id = d.listener_id WHERE b.role = 1 and d.ip_address like '1.1.1.11'" -evalRule "MSSQL.RES.TYPE.NE(ERROR)" -storedb ENABLED`
    - `add lb monitor monitor_L2 MSSQL-ECV -userName user1 -sqlQuery "SELECT name FROM sys.databases a INNER JOIN sys.dm_hadr_availability b ON a.replica_id=b.replica_id INNER JOIN sys.availability_group_list c on b.group_id = c.group_id INNER JOIN sys.availability_group_listen d on c.listener_id = d.listener_id WHERE b.role = 1 and d.`

```
ip_address like '1.1.1.12'"-evalRule "MSSQL.RES.TYPE.NE(ERROR)"-storedb ENABLED
```

- add lb monitor monitor1 MSSQL-ECV -userNameuser1 -sqlQuery "SELECT name FROM sys.databases a INNER JOIN sys.dm\_hadr\_availability\_r b ON a.replica\_id=b.replica\_id WHERE b.role = 2"-evalRule "MSSQL.RES.TYPE.NE(ERROR)"-storedb ENABLED

#### 6. Configure read and write policies.

- add cs policy pol\_write -rule "MSSQL.REQ.QUERY.TEXT.CONTAINS("insert")"
- add cs policy pol\_read -rule "MSSQL.REQ.QUERY.TEXT.CONTAINS("select")"

#### 7. Bind the policies to the content switching virtual server.

- bind csvserver csv -targetLBVserver lbwrite -policyName pol\_write -priority 11
- bind csvserver csv -targetLBVserver lbread -policyName pol\_read -priority 12

#### 8. Bind monitors to the services. Bind monitors to services L1 and L2 to get the list of active databases for the availability group for which it is the listener. Bind monitors to all the services that are bound to the read-only virtual server.

- bind service L1 -monitorName monitor\_L1
- bind service L2 -monitorName monitor\_L2
- bind service s1 -monitorName monitor1
- bind service s2 -monitorName monitor1
- bind service s3 -monitorName monitor1
- bind service s4 -monitorName monitor1
- bind service s5 -monitorName monitor1

## Configuration examples for MSSQL virtual server

### To configure a load balancing virtual server for database specific load balancing:

```
1 add lb vsrver DBSpecificLB1 MSSQL 192.0.2.10 1433 -dbsLb ENABLED
2
3 Done
4
5 show lb vsrver DBSpecificLB1
6
7 DBSpecificLB1 (192.0.2.10:1433) - MSSQL Type: ADDRESS
8 . . .
```

```
9 DBS_LB: ENABLED
10
11 Done
12 <!--NeedCopy-->
```

**To configure services:**

**add service** msservice1 5.5.5.5 MSSQL 1433

**To configure a monitor to retrieve the names of all the active databases hosted on a service by using the command line:**

```
1 add lb monitor mssql-monitor1 MSSQL-ECV -userName user1 -sqlQuery "
 select name from sys.databases where state=0" -evalRule "MSSQL.RES.
 TYPE.NE(ERROR)" -storedb EN
2
3 Done
4
5 show lb monitor mssql-monitor1
6
7 1) Name.....: mssql-monitor1 Type.....: MSSQL-ECV
8
9 ...
10
11 Special parameters: Database.....:""
12
13 User name.....:"user1"
14
15 Query...:select name from sys.databases where state=0 EvalRule...:MSSQL.
 RES.TYPE.NE(ERROR)
16
17 Version...:70 STORE_DB...:ENABLED
18
19 Done
20 <!--NeedCopy-->
```

**Configuration examples for MySQL virtual server****To configure a load balancing virtual server for database specific load balancing:**

```
1 add lb vserver DBSpecificLB1 MYSQL 192.0.2.10 3306 -dbsLb ENABLED
2
3 Done
4
5 show lb vserver DBSpecificLB1
6
7 DBSpecificLB1 (192.0.2.10:3306) - MYSQL Type: ADDRESS
8
9 . . .
10
11 DBS_LB: ENABLED
```

```
12
13 Done
14 <!--NeedCopy-->
```

**To configure services:**

```
1 add service msservice1 5.5.5.5 MYSQL 3306
2 <!--NeedCopy-->
```

**To configure a monitor to retrieve the names of all the active databases hosted on a service by using the command line:**

```
1 add lb monitor mysql-monitor1 MYSQL-ECV -userName user1 -sqlQuery "show
 databases" -evalRule "MYSQL.RES.TYPE.NE(ERROR)" -storedb ENABLED
2
3 Done
4
5 show lb monitor mysql-monitor1
6
7 1) Name.....: mysql-monitor1 Type.....: MYSQL-ECV State.....:
 ENABLED
8
9 ...
10
11 Special parameters: Database.....:""
12
13 User name.....:"user1" Query...:show databases
14
15 EvalRule...:MYSQL.RES.TYPE.NE(ERROR) STORE_DB...:ENABLED
16
17 Done
18 <!--NeedCopy-->
```

## DataStream reference

February 13, 2024

This reference describes the MySQL and TDS protocols, the database versions, the authentication methods, and the character sets supported by the DataStream feature. It also describes how the NetScaler handles transaction requests and special queries that modify the state of a connection.

You can also configure the NetScaler appliance to generate audit log messages for the DataStream feature.

### Supported database versions, protocols, and authentication methods

	MySQL Database	MS SQL Database
Database Versions	MySQL database versions 4.1, 5.0, 5.1, 5.4, 5.5, 5.6, and 5.7. MySQL database versions 8.0, 8.1, and 8.2 are supported only when native authentication is enabled for the database user.	MS SQL database versions 70, 2000, 2000SP1, 2005, 2008, 2008R2, 2012, 2014 (Kerberos Authentication support). You can configure the backend MS SQL server with TDS 7.4 on 2016, 2017, 2019, and 2022 by configuring NetScaler parameter <code>-mssqlServerVersion 2014</code> . Always On availability group is supported only in MS SQL versions 2012 and 2014.
Protocols	MySQL protocol version 10. For information about the MySQL protocol, see <a href="#">MySQL Client/Server Protocol</a>	Tabular Data Stream (TDS) protocol version 7.1 to 7.4. For information about the TDS protocol, see <a href="#">Tabular Data Stream Protocol</a>
Authentication Methods	MySQL native authentication is supported.	SQL server authentication and Windows Authentication (Kerberos/NTLM) are supported.

## Character sets

The DataStream feature supports only the UTF-8 charset.

The character set used by the client while sending a request might be different from the character set used in the database server responses. Although the charset parameter is set during the connection establishment, it can be changed at any time by sending an SQL query. The character set is associated with a connection, and therefore, requests on connections with one character set can't be multiplexed onto a connection with a different character set.

The NetScaler appliance parses the queries sent by the client and the responses sent by the database server.

The character set associated with a connection can be changed after the initial handshake by using the following two queries:

```
1 SET NAMES <charset> COLLATION <collation>
2
3 SET CHARACTER SET <charset>
4 <!--NeedCopy-->
```

## Transactions

In MySQL, transactions are identified by using the connection parameter AUTOCOMMIT or the BEGIN:COMMIT queries. The AUTOCOMMIT parameter can be set during the initial handshake, or after the connection is established by using the query SET AUTOCOMMIT.

The NetScaler appliance explicitly parses each query to determine the beginning and end of a transaction.

In the MySQL protocol, the response contains two flags to indicate whether the connection is a transaction: the TRANSACTION and AUTOCOMMIT flags.

If the connection is a transaction, the TRANSACTION flag is set. Or, if the AutoCommit mode is OFF, the AUTOCOMMIT flag isn't set. The ADC appliance parses the response, and if either the TRANSACTION flag is set or the AUTOCOMMIT flag isn't set, it does not do connection multiplexing. When these conditions are no longer true, the ADC appliance begins connection multiplexing.

### Note

Transactions are also supported for MS SQL.

## Special queries

There are special queries, such as SET and PREPARE, that modify the state of the connection and might break request switching, and therefore, these queries need to be handled differently.

On receiving a request with special queries, the NetScaler appliance sends an OK response to the client and also, stores the request in the connection.

When a non-special query, such as INSERT and SELECT, is received along with a stored query, the ADC appliance looks for the server-side connection on which the stored query has already been sent to the database server. If no such connections exist, the ADC appliance creates a connection, and sends the stored query first, and then, sends the request with the non-special query.

In SET, USE db, and INIT\_DB special queries, the appliance modifies a field in the server side connection corresponding to the special query. This modification results in better reuse of the server side connection.

Only 16 queries are stored in each connection.

The following is a list of the special queries for which the ADC appliance has a modified behavior.

- SET query

The SET SQL queries define variables that are associated with the connection. These queries are also used to define global variables, but as of now, the ADC appliance is unable to differentiate between local and global variables. For this query, the ADC appliance uses the ‘store and forward’ mechanism.

- USE <db> query

Using this query, the user can change the database associated with a connection. In this case, the ADC appliance parses the <db> value sent and modifies a field in the server side connection to reflect the new database to be used.

- INIT\_DB command

Using this query, the user can change the database associated with a connection. In this case, the ADC appliance parses the <init\_db> value sent and modifies a field in the server side connection to reflect the new database to be used.

- COM\_PREPARE

The ADC appliance stops request switching on receiving this command.

- PREPARE query

This query is used to create prepared statements that are associated with a connection. For this query, the ADC appliance uses the ‘store and forward’ mechanism.

## Audit log message support

You can now configure the NetScaler appliance to generate audit log messages for the DataStream feature. Audit log messages are generated when client-side and server-side connections are established, closed, or dropped. The categories of messages that you can log and view are ERROR and INFO. Error messages for client-side connections begin with “CS” and error messages for server-side connections begin with “SS.” Additional information is provided where necessary. For example, log messages for closed connections (CS\_CONN\_CLOSED) include only the connection ID. However, log messages for established connections (CS\_CONN\_ESTD) include information such as the user name, database name, and the client IP address in addition to the connection ID.

## Domain Name System

May 2, 2023

**Note:** From release 13.0 build 41.x, the NetScaler appliance in ADNS and proxy mode is fully compliant with DNS flag day 2019.

You can configure the NetScaler appliance to function as an authoritative domain name server (ADNS server) for a domain. Add the DNS resource records that belong to the domain for which the appliance is authoritative and configure resource record parameters. You can also configure the appliance as a proxy DNS server that load balances a farm of DNS name servers that are either within or outside your network. Configure the appliance as an end resolver and forwarder. You can configure DNS suffixes that enable name resolution when fully qualified domain names are not configured. The appliance also supports the DNS ANY query that retrieves all the records that belong to a domain.

You can configure the appliance to concurrently function as an authoritative DNS server for one domain and a DNS proxy server for another domain. When you configure the appliance as the authoritative DNS server or DNS proxy server for a zone, you can enable the appliance to use the TCP for response sizes that exceed the size limit specified for the User Datagram Protocol (UDP).

## How DNS Works on the NetScaler

You can configure the NetScaler appliance to function as an ADNS server, DNS proxy server, end resolver, and forwarder. You can add DNS resource records on the NetScaler appliance, including the following records:

- Service (SRV) records
- IPv6 (AAAA) records
- Address (A) records
- Mail exchange (MX) records
- Canonical name (CNAME) records
- Pointer (PTR) records
- Start of authority (SOA) records
- Text (TXT) records
- Name Authority Pointer (NAPTR) records
- DNSKEY records
- Certificate Authority Authorization (CAA) records

Also, you can configure the NetScaler to load balance external DNS name servers.

The NetScaler appliance can be configured as the authority for a domain. Add valid SOA and NS records for the domain.

An ADNS server is a DNS server that contains complete information about a zone.

To configure the NetScaler appliance as an ADNS server for a zone, you must add an ADNS service, and then configure the zone. To do so, you add valid SOA and NS records for the domain. When a

client sends a DNS request, the NetScaler appliance searches the configured resource records for the domain name. You can configure the ADNS service to be used with the NetScaler Global Server Load Balancing (GSLB) feature.

You can delegate a subdomain, by adding NS records for the subdomain to the zone of the parent domain. You can then make the NetScaler authoritative for the subdomain, by adding a “glue record” for each of the subdomain name servers. If GSLB is configured, the NetScaler makes a GSLB load balancing decision based on its configuration and replies with the IP address of the selected virtual server. The following figure shows the entities in an ADNS GSLB setup and a DNS proxy setup.

Figure 1. DNS Proxy Entity Model

The NetScaler appliance can function as a DNS proxy. Caching of DNS records, which is an important function of a DNS proxy, is enabled by default on the NetScaler appliance. Caching enables the NetScaler appliance to provide quick responses for repeated translations. Create a load balancing DNS virtual server, and DNS services, and then bind these services to the virtual server.

The NetScaler provides two options, minimum time to live (TTL) and maximum TTL for configuring the lifetime of the cached data. The cached data times out as specified by your settings for these two options. The NetScaler checks the TTL of the DNS record coming from the server. If the TTL is less than the configured minimum TTL, it is replaced with the configured minimum TTL. If the TTL is

greater than the configured maximum TTL, it is replaced with the configured maximum TTL.

The NetScaler also allows caching of negative responses for a domain. A negative response indicates that information about a requested domain does not exist, or that the server cannot provide an answer for the query. The storage of this information is called *negative caching*. Negative caching helps speed up responses to queries on a domain, and can optionally provide the record type.

A negative response can be one of the following:

- NXDOMAIN error message - If a negative response is present in the local cache, the NetScaler returns an error message (NXDOMAIN). If the response is not in the local cache, the query is forwarded to the server, and the server returns an NXDOMAIN error to the NetScaler. The NetScaler caches the response locally, then returns the error message to the client.
- NODATA error message - The NetScaler sends a NODATA error message, if the domain name in query is valid but records of the given type are not available.

The NetScaler supports recursive resolution of DNS requests. In recursive resolution, the resolver (DNS client) sends a recursive query to a name server for a domain name. If the queried name server is authoritative for the domain, it responds with the requested domain name. Otherwise, the NetScaler queries the name servers recursively until the requested domain name is found.

Before you can apply the recursive query option, you must first enable it. You can also set the number of times the DNS resolver must send a resolution request (DNS retries) if a DNS lookup fails.

You can configure the NetScaler as a DNS forwarder. A forwarder passes DNS requests to external name servers. The NetScaler allows you to add external name servers and provides name resolution for domains outside the network. The NetScaler also allows you to set the name lookup priority to DNS or Windows Internet Name Service (WINS).

## **Enable the ADC appliance to use DNS to resolve the host name to its respective IP address**

**Note:** You require an SSH utility to access the command line interface (CLI) of the appliance.

By default, the ADC appliance cannot resolve the host name to its respective IP address. Complete the following tasks to enable the name resolution on the appliance:

1. Define name servers.
2. Define a DNS suffix.

### **Points to note**

Perform the DNS lookup from the CLI. DNS lookups from the shell prompt of the FreeBSD operating system fail because the entry in the `/etc/resolv.conf` file points to the 127.0.0.2 IP address.

The following commands are replaced with the `drill` command in the FreeBSD CLI of the appliance reachable with the `shell` command:

```
1 - host
2 - dig
3 - getent/MIP
4 - nslookup
5 <!--NeedCopy-->
```

For example, instead of running `dig www.google.com @8.8.8.8` to query the “A” record “www.google.com” at the name server “8.8.8.8”, you can run `drill www.google.com @8.8.8.8` command. The `drill` command performs exactly the same as the `dig` command does.

```
1 root@lab# drill www.google.com @8.8.8.8
2 ;; ->HEADER<- opcode: QUERY, rcode: NOERROR, id: 57980

```

If the appliance cannot ping the DNS server on its SNIP address, the server status shows as down. Successful ping is important when the appliance is behind a firewall.

### CLI configuration

At the command prompt, type:

```
1 add dns nameServer <Name_Server_IP_Address>
2 add dns suffix <DNS_Suffix>
3 <!--NeedCopy-->
```

To verify the configuration, type:

```
1 show dns nameServer
2 show dns suffix
3 <!--NeedCopy-->
```

To test DNS resolution, type:

```
1 show dns addrec <Host_Name>
2 <!--NeedCopy-->
```

### GUI configuration

1. Navigate to **Traffic Management > DNS > Names Servers > Add**.
2. In the **Create Name Server** dialog box enter the name server IP Address and click **Create**.
3. Navigate to **Traffic Management > DNS > DNS Suffix > Add**.
4. In the **Create DNS Suffix** dialog box, enter the DNS Suffix, such as example.com, to be used for all host queries and click **Create**.

### Round Robin DNS

When a client sends a DNS request to find the DNS resource record, it receives a list of IP addresses resolving to the name in the DNS request. The client then uses one of the IP addresses in the list, generally, the first record or IP address. Hence, a single server is used for the total TTL of the cache and is overloaded when many requests arrive.

When the NetScaler receives a DNS request, it responds by changing the order of the list of DNS resource records in a round robin method. This feature is called *round robin DNS*. Round robin distributes the traffic equally between data centers. The NetScaler performs this function automatically. You do not have to configure this behavior.

### Functional Overview

If the NetScaler is configured as an ADNS server, it returns the DNS records in the order in which the records are configured. When the NetScaler is configured as a DNS proxy, it returns the DNS records in the order in which it receives the records from the server. The order of the records present in the cache matches the order in which records are received from the server.

The NetScaler then changes the order in which records are sent in the DNS response in a round robin method. The first response contains the first record in sequence, the second response contains the second record in sequence, and the order continues in the same sequence. Thus, clients requesting the same name can connect to different IP addresses.

**Round Robin DNS Example** As an example of round robin DNS, consider DNS records that have been added as follows:

```

1 add dns addRec ns1 1.1.1.1 add dns addRec ns1 1.1.1.2 add dns
 addRec ns1 1.1.1.3 add dns addRec ns1 1.1.1.4
2 <!--NeedCopy-->

```

The domain, abc.com is linked to an NS record as follows:

```

1 add dns nsrec abc.com. ns1
2 <!--NeedCopy-->

```

When the NetScaler receives a query for the A record of ns1, the Address records are served in a round robin method as follows. In the first DNS response, 1.1.1.1 is served as the first record:

```

1 ns1. 1H IN A 1.1.1.1 ns1.
 1H IN A 1.1.1.2 ns1.
 1H IN A 1.1.1.3 ns1.
 1H IN A 1.1.1.4
2 <!--NeedCopy-->

```

In the second DNS response, the second IP address, 1.1.1.2 is served as the first record:

```

1 ns1. 1H IN A 1.1.1.2 ns1.
 1H IN A 1.1.1.3 ns1.
 1H IN A 1.1.1.4 ns1.
 1H IN A 1.1.1.1
2 <!--NeedCopy-->

```

In the third DNS response, the third IP address, 1.1.1.3 is served as the first record:

```

1 ns1. 1H IN A 1.1.1.3 ns1.
 1H IN A 1.1.1.4 ns1.
 1H IN A 1.1.1.1 ns1.
 1H IN A 1.1.1.2
2 <!--NeedCopy-->

```

## Configure DNS resource records

May 2, 2023

You configure resource records on the Citrix® ADC appliance when you configure the appliance as an ADNS server for a zone. You can also configure resource records on the appliance if the resource records belong to a zone for which the appliance is a DNS proxy server. On the appliance, you can configure the following record types:

- Service records
- AAAA records
- Address records

- Mail Exchange records
- Name Server records
- Canonical records
- Pointer records
- NAPTR records
- Start of Authority records
- Text records
- Certificate Authority Authorization (CAA) records

The following table lists the record types that you can configure for a domain name record on the NetScaler appliance. For example, you can configure a maximum of 25 IP addresses for one record.

Table 1. Record Type and Number Configurable

Record Type	Number of Records
Address (A)	25
IPv6 (AAAA)	5
Mail exchange (MX)	12
Name server (NS)	16
Service (SRV)	8
Pointer (PTR)	20
Canonical name (CNAME)	1
Start of Authority (SOA)	1
Text (TXT)	20
Naming Authority Pointer (NAPTR)	20
Certificate Authority Authorization (CAA)	20

**Note:**

The maximum number of IP addresses for a specific host name is 25. However, the number of different address records can be more than 25.

## Create SRV records for a service

May 2, 2023

The SRV record provides information about the services available on the NetScaler appliance. An SRV record contains the following information:

- Name of the service and the protocol
- Domain name
- TTL
- DNS class
- Priority of the target
- Weight of records with the same priority
- Port of the service
- Host name of the service.

The NetScaler chooses the SRV record that has the lowest priority setting first. If a service has multiple SRV records with the same priority, clients use the weight field to determine which host to use.

### Add an SRV record by using the CLI

At the command prompt, type the following commands to add an SRV record and verify the configuration:

```
1 - add dns srvRec <domain> <target> -priority <positive_integer> -
 weight <positive_integer> -port <positive_integer> [-TTL <secs>]
2 - sh dns srvRec <domain>
3 <!--NeedCopy-->
```

#### Example:

```
1 > add dns srvRec _http._tcp.example.com nameserver1.com -priority 1 -
 weight 1 -port 80
2 Done
3 > show dns srvRec _http._tcp.example.com
4 1) Domain Name : _http._tcp.example.com
5 Target Host : nameserver1.com
6 Priority : 1 Weight : 1
7 Port : 80 TTL : 3600 secs
8 Done
9 <!--NeedCopy-->
```

### Modify or remove an SRV record by using the CLI

- To modify an SRV record, type:
  - The `set dns srvRec` command
  - The name of the domain for which the SRV record is configured
  - The name of the target host that hosts the associated service

- The parameters to be changed, with their new values
- To remove an SRV record, type:
  - The `rm dns srvRec` command
  - The name of the domain for which the SRV record is configured
  - The name of the target host that hosts the associated service

## Configure an SRV record by using the GUI

Navigate to **Traffic Management > DNS > Records > SRV Records** and create an SRV record.

## Create AAAA records for a domain name

January 6, 2021

An AAAA resource record stores a single IPv6 address.

## Add an AAAA record by using the CLI

At the command prompt, type the following commands to add an AAAA record and verify the configuration:

```
1 - add dns aaaaRec <hostName> <IPv6Address> ... [-TTL <secs>]
2 - show dns aaaaRec <hostName>
3 <!--NeedCopy-->
```

### Example:

```
1 > add dns aaaaRec www.example.com 2001:0db8:0000:0000:0000:0000:1428:57
 ab
2 Done
3 > show dns aaaaRec www.example.com
4 1) Host Name : www.example.com
5 Record Type : ADNS TTL : 5 secs
6 IPV6 Address : 2001:db8::1428:57ab
7 Done
8 <!--NeedCopy-->
```

To remove an AAAA record and all the IPv6 addresses associated with the domain name, type the `rm dns aaaaRec` command and the domain name for which the AAAA record is configured. To remove only a subset of the IPv6 addresses associated with the domain name in an AAAA record, type the following:

- `rm dns aaaaRec` command
- The domain name for which the AAAA record is configured
- The IPv6 addresses that you want to remove

## Add an AAAA record by using the GUI

Navigate to **Traffic Management > DNS > Records > AAAA Records** and create an AAAA record.

## Create address records for a domain name

May 2, 2023

Address (A) records are DNS records that map a domain name to an IPv4 address.

You cannot delete Address records for a host participating in global server load balancing (GSLB). However, the NetScaler deletes Address records added for GSLB domains when you unbind the domain from a GSLB virtual server. Only user-configured records can be deleted manually. You cannot delete a record for a host referenced by records such as NS, MX, or CNAME.

## Add an Address record by using the CLI

At the command prompt, type the following commands to add an Address record and verify the configuration:

```
1 - add dns addRec <hostName> <IPAddress> [-TTL <secs>]
2 - show dns addRec <hostName>
3 <!--NeedCopy-->
```

### Example:

```
1 > add dns addRec ns.example.com 192.0.2.0
2 Done
3 > show dns addRec ns.example.com
4 1) Host Name : ns.example.com
5 Record Type : ADNS TTL : 5 secs
6 IP Address : 192.0.2.0
7 Done
8 <!--NeedCopy-->
```

To remove an Address record and all the IP addresses associated with the domain name, type the `rm dns addRec` command and the domain name for which the Address record is configured. To remove only a subset of the IP addresses associated with the domain name in an Address record, type the following:

- `rm dns addRec` command
- The domain name for which the Address record is configured
- The IP addresses that you want to remove

## Add an Address record by using the GUI

Navigate to **Traffic Management > DNS > Records > Address Records** and create an Address record.

## Create MX records for a mail exchange server

January 6, 2021

Mail Exchange (MX) records are used to direct email messages across the Internet. An MX record contains an MX preference that specifies the MX server to be used. The MX preference values range from 0 through 65536. An MX record contains a unique MX preference number. You can set the MX preference and the TTL values for an MX record.

When an email message is sent through the Internet, a mail transfer agent sends a DNS query requesting the MX record for the domain name. This query returns a list of host names of mail exchange servers for the domain, along with a preference number. If there are no MX records, the request is made for the Address record of that domain. A single domain can have multiple mail exchange servers.

## Add an MX record by using the CLI

At the command prompt, type the following commands to add an MX record and verify the configuration:

```
1 - add dns mxRec <domain> -mx <string> -pref <positive_integer> [-TTL <
 secs>]
2 - show dns mxRec <domain>
3 <!--NeedCopy-->
```

### Example:

```
1 > add dns mxRec example.com -mx mail.example.com -pref 1
2 Done
3 > show dns mxRec example.com
4 1) Domain : example.com MX Name : mail.example.com
5 Preference : 1 TTL : 5 secs
6 Done
```

```
7 <!--NeedCopy-->
```

## Modify or remove an MX record by using the CLI

- To modify an MX record, type the `set dns mxRec` command, the name of the domain for which the MX record is configured, the name of the MX record, and the parameters to be changed, with their new values.
- To set the TTL parameter to its default value, type the `unset dns mxRec` command, the name of the domain for which the MX record is configured, the name of the MX record, and -TTL without any TTL value. You can use the `unset dns mxRec` command to unset only the TTL parameter.
- To remove an MX record, type the `rm dns mxRec` command, the name of the domain for which the MX record is configured, and the name of the MX record.

## Add an MX record by using the GUI

Navigate to **Traffic Management > DNS > Records > Mail Exchange Records** and create an MX record.

## Create NS Records for an authoritative server

January 6, 2021

Name Server (NS) records specify the authoritative server for a domain. You can configure a maximum of 16 NS records. You can use an NS record to delegate the control of a subdomain to a DNS server.

## Create an NS record by using the CLI

At the command prompt, type the following commands to create an NS record and verify the configuration:

```
1 - add dns nsRec <domain> <nameServer> [-TTL <secs>]
2 - show dns nsRec <domain>
3 <!--NeedCopy-->
```

### Example:

```
1 > add dns nsRec example.com nameserver1.example.com
2 Done
3 > show dns nsRec example.com
```

```
4 1) Domain : example.com NameServer : nameserver1.example.com
5 TTL : 5 sec
6 Done
7 <!--NeedCopy-->
```

To remove an NS record, type the `rm dns nsRec` command, the name of the domain to which the NS record belongs, and the name of the name server.

## Create an NS record by using the GUI

Navigate to **Traffic Management > DNS > Records > Name Server Records** and create an NS record.

## Create CNAME records for a subdomain

May 2, 2023

A canonical name record (CNAME record) is an alias for a DNS name. These records are useful when multiple services query the DNS server. The host that has an address (A) record cannot have a CNAME record.

Sometimes, a NetScaler appliance in proxy mode requests an address record from the cache instead of the server.

## Add a CNAME record by using the CLI

At the command prompt, type the following commands to create a CNAME record and verify the configuration:

```
1 - add dns cnameRec <aliasName> <canonicalName> [-TTL <secs>]
2 - show dns cnameRec <aliasName>
3 <!--NeedCopy-->
```

### Example:

```
1 > add dns cnameRec www.example.com www.examp1enw.com
2 Done
3 > show dns cnameRec www.example.com
4 Alias Name Canonical Name TTL
5 1) www.example.com www.examp1enw.com 5 secs
6 Done
7 <!--NeedCopy-->
```

To remove a CNAME record for a given domain, type the `rm dns cnameRec` command and the alias of the domain name.

### Add a CNAME record by using the GUI

Navigate to **Traffic Management > DNS > Records > Canonical Records** and create a CNAME record.

### Cache CNAME records

When deployed in a proxy mode, the ADC appliance does not always send the query for an address record to the back-end server. This behavior occurs when for an answer to a query for an address record, a partial CNAME chain is present in the cache. There are few conditions in which the ADC caches the partial CNAME record and serves the query from the cache. Following are the conditions:

- NetScaler must be deployed in a proxy mode.
- The response from the back-end server must have a CNAME chain, for which the record type of the last entry in the answer section must be a CNAME and the question type not a CNAME.
- The response from the back-end server cannot be a No-data or NX-Domain.
- The response from the back-end server has to be an authoritative response.

### Create NAPTR records for telecommunications domain

May 2, 2023

NAPTR (Naming Address Pointer) is one of the most commonly used DNS records in the telecommunications domain. NAPTR records map the Internet telephony address space to the Internet address space. They therefore enable a mobile device to send a request to the correct server. The combination of NAPTR records with Service Records (SRV) allows the chaining of multiple records to form complex rewrite rules that produce new domain labels or uniform resource identifiers (URIs). The DNS code for NAPTR is 35.

NetScalers support NAPTR in two modes: ADNS mode and proxy mode. In proxy mode, the ADC caches the response from the servers and uses the cached records to server future queries. A maximum of 20 NAPTR records can be added for a particular domain in NetScaler. NetScaler caches the reply to a DNS NAPTR record query. Any subsequent requests for the NAPTR record are served from the cache.

## Create a NAPTR record by using CLI

At the command prompt, type the following commands to add a NAPTR record and verify the configuration:

```
add dns naptrRec <order> <preference>[flags<string>][services<string>]
>](regex<expressions>|-replacement<string>)[-TTL<secs>]
```

## Remove a NAPTR record by using CLU

```
rm dns naptrRec<domain> (<order> <preference> [-flags <string>] [-
services <string>] (-regex <expression> | -replacement <string>)) | -
recordId <positive_integer>@)
```

## Configure a NAPTR record using GUI

Navigate to **Traffic Management > DNS > Records > NAPTR Records** and create an NAPTR record.

## Create PTR records for IPv4 and IPv6 addresses

January 6, 2021

A pointer (PTR) record translates an IP address to its domain name. IPv4 PTR records are represented by the octets of an IP address in reverse order with the string “in-addr.arpa.” appended at the end. For example, the PTR record for the IP address 1.2.3.4 is 4.3.2.1.in-addr.arpa.

IPv6 addresses are reverse mapped under the domain IP6.ARPA. IPv6 reverse-maps use a sequence of nibbles separated by dots with the suffix “.IP6.ARPA” as defined in RFC 3596. For example, the reverse lookup domain name corresponding to the address, 4321:0:1:2:3:4:567:89ab would be b.a.9.8.7.6.5.0.4.0.0.0.3.0.0.0.2.0.0.0.1.0.0.0.0.0.0.1.2.3.4.IP6.ARPA.

## Add a PTR record by using the CLI

At the command prompt, type the following commands to add a PTR record and verify the configuration:

```
1 - add dns ptrRec <reverseDomain> <domain> [-TTL <secs>]
2 - show dns ptrRec <reverseDomain>
3 <!--NeedCopy-->
```

**Example:**

```
1 > add dns ptrRec 0.2.0.192.in-addr.arpa example.com
2 Done
3 > show dns ptrRec 0.2.0.192.in-addr.arpa
4 1) Reverse Domain Name : 0.2.0.192.in-addr.arpa
5 Domain Name : example.com TTL : 3600 secs
6 Done
7 <!--NeedCopy-->
```

To remove a PTR record, type the `rm dns ptrRec` command and the reverse domain name associated with the PTR record

**Add a PTR record by using the GUI**

Navigate to **Traffic Management > DNS > Records > PTR Records** and create a PTR record.

**Create SOA records for authoritative information**

January 6, 2021

A Start of Authority (SOA) record is created only at the zone apex and contains information about the zone. The record includes, among other parameters, the primary name server, contact information (email), and default (minimum) time-to-live (TTL) values for records.

**Create an SOA record by using the CLI**

At the command prompt, type the following commands to add an SOA record and verify the configuration:

```
1 - add dns soaRec <domain> -originServer <originServerName> -contact <
 contactName>
2 - sh dns soaRec <do main>
3 <!--NeedCopy-->
```

**Example:**

```
1 > add dns soaRec example.com -originServer nameserver1.example.com -
 contact admin.example.com
2 Done
3 > show dns soaRec example.com
4 1) Domain Name : example.com
5 Origin Server : nameserver1.example.com
6 Contact : admin.example.com
```

```

7 Serial No. : 100 Refresh : 3600 secs Retry : 3 secs
8 Expire : 3600 secs Minimum : 5 secs TTL : 3600 secs
9 Done
10 <!--NeedCopy-->

```

## Modify or remove an SOA record by using the CLI

- To modify an SOA record, type the `set dns soaRec` command, the name of the domain for which the record is configured, and the parameters to be changed, with their new values.
- To remove an SOA record, type the `rm dns soaRec` command and the name of the domain for which the record is configured.

## Configure an SOA record by using the GUI

Navigate to **Traffic Management > DNS > Records > SOA Records** and create an SOA record.

## Create TXT records for holding descriptive text

May 2, 2023

Domain hosts store TXT records for informative purposes. A TXT record's RDATA component, which consists of one or more character strings of variable length, can store practically any information that a recipient might need to know about the domain. It can also include information about the service provider, contact person, email addresses, and associated details. SPF (Sender Policy Framework) protection has been the most prominent use case for the TXT record.

All configuration types (authoritative DNS, DNS proxy, end resolver, and forwarder configurations) on the NetScaler appliance support TXT records. You can add a maximum of 20 TXT resource records to a domain. Each resource record is stored with a unique, internally generated record ID. A TXT resource record can contain up to six strings, each of which can contain up to 255 characters. You can view the ID of a record and use it to delete the record. However, you cannot modify a TXT resource record.

## Create a TXT resource record by using the CLI

At the command prompt, type the following commands to create a TXT resource record and verify the configuration:

```

1 - add dns txtRec <domain> <string> ... [-TTL <secs>]
2 - show dns txtRec [<domain> | -type <type>]
3 <!--NeedCopy-->

```

**Example:**

```

1 > add dns txtRec www.example.com "Contact: Mark" "Email: mark@example.
 com" -TTL 36000
2 Done
3 > show dns txtRec www.example.com
4 1) Domain : www.example.com Record id: 13783 TTL : 36000 secs
 Record Type : ADNS
5 "Contact: Mark"
6 "Email: mark@example.com"
7 Done
8 <!--NeedCopy-->

```

**Split the string in a TXT resource record using CLI**

If you have a string that is more than 255 characters, you can split the strings, considering the six string limit. Each string can be of length 254 bytes.

```

1 add dns txtrec domain.com "string1" "string2" string3 "string4"
2 <!--NeedCopy-->

```

**Example:**

```

1 add dns txtrec exampledomain.com "Contact: Evan" "Email: evan@example.
 com" "Contact: Mark" "Email: mark1@example.com"
2 <!--NeedCopy-->

```

**Remove a TXT resource record by using the CLI**

At the command prompt, type the following commands to remove a TXT resource record and verify the configuration:

```

1 - rm dns txtRec <domain> (<string> ... | -recordId <positive_integer>)
2 - show dns txtRec [<domain> | -type <type>]
3 <!--NeedCopy-->

```

**Example:**

You can use the `show dns txtRec` command first to view the record ID of the TXT resource record that you want to remove, as shown:

```

1 > show dns txtRec www.example.com
2 1) Domain : www.example.com Record id: 36865 TTL : 36000 secs
 Record Type : ADNS
3 "Contact: Evan"
4 "Email: evan@example.com"
5 2) Domain : www.example.com Record id: 14373 TTL : 36000 secs
 Record Type : ADNS
6 "Contact: Mark"

```

```
7 "Email: mark1@example.com"
8 Done
9 <!--NeedCopy-->
```

The simpler method of deleting a TXT record is to use the record ID. If you want to provide the strings, enter them in the order in which they are stored in the record. In the following example, the TXT record is deleted by using its record ID.

```
1 >rm dns txtRec www.example.com -recordID 36865
2 Done
3 > show dns txtRec www.example.com
4 1) Domain : www.example.com Record id: 14373 TTL : 36000 secs
 Record Type : ADNS
5 "Contact: Mark"
6 "Email: mark1@example.com"
7 Done
8 <!--NeedCopy-->
```

## Configure a TXT record by using the GUI

Navigate to **Traffic Management > DNS > Records > TXT Records** and create a TXT record.

## Create CAA records for a domain name

May 2, 2023

Certificate Authority Authorization (CAA) is a type of DNS record that allows the domain owners to specify which Certificate Authority (CA) can issue SSL certificates for the domain.

A secure connection to a service requires SSL/TLS certificates to ensure the identity of the host and establish a secure channel. Not having CAA records can cause a security risk as anybody can generate a Certificate Signing Request (CSR) for the domain and get the certificate signed by any CA.

CAA records provide an extra layer of protection to your web presence by allowing the domain owner to declare which certificate authorities are allowed to issue a certificate for the domain. If there is a request for a certificate from a non-authorized CA, then the CAA record notifies the domain owner about the same. If a CAA record is not present for a domain, any CA is allowed to issue the certificate for that domain.

The NetScaler appliance supports DNS CAA records in the following modes:

- **Proxy:** The appliance caches CAA record response from back-end servers and responds to further queries of the same type from the cache.

- **ADNS:** The appliance responds to the CAA record type DNS queries from the configured DNS records.

**Note:**

- You can add a maximum of 20 CAA records per domain name.
- Recursive resolver and forwarder modes are not supported.

**Add a CAA record using the CLI**

At the command prompt, type the following command:

```
1 add dns caaRec <domain> <issuer-string> -tag <tag-string> -flag [None |
 Critical] [-TTL <secs>]
2 <!--NeedCopy-->
```

Example:

```
1 > add dns caaRec newdomain string1 -tag Issue -flag None [-TTL 3600]
2 <!--NeedCopy-->
```

Show command details

```
1 > show dns caaRec
2
3 1) Domain : newdomain ECS Subnet : None Record id: 39423 TTL :
 3600 secs Record Type : ADNS
4
5 Value: string1
6
7 Tag: issue
8
9 Flag: NONE
10
11 2) Domain : test.com ECS Subnet : None Record id: 2572 TTL : 5
 secs Record Type : ADNS
12
13 Value: ca1.test.com
14
15 Tag: issue
16
17 Flag: NONE
18 <!--NeedCopy-->
```

To remove a CAA record, type the following command at the command prompt:

```
1 rm dns caaRec <domain> <issuer-string> -tag <tag-string> | -recordId <
 positive_integer>@)
2 <!--NeedCopy-->
```

Example:

```
1 rm dns caaRec newdomain -recordId 39423
2 <!--NeedCopy-->
```

**Note:**

-recordId @ is not supported in a cluster.

## Add a CAA record using the GUI

Navigate to **Traffic Management > DNS > Records > CAA Records** and create an Address record.

## View DNS statistics

May 2, 2023

You can view the DNS statistics generated by the NetScaler appliance. The DNS statistics include run-time, configuration, and error statistics.

## View DNS records statistics by using the CLI

At the command prompt, type:

```
stat dns
```

**Example:**

```
1 > stat dns
2 DNS Statistics
3
4 Runtime Statistics
5 Dns queries 21
6 NS queries 8
7 SOA queries 18
8 .
9 .
10 .
11 Configuration Statistics
12 AAAA records 17
13 A records 36
14 MX records 9
15 .
16 .
17 .
18 Error Statistics
19 Nonexistent domain 17
```

```
20 No AAAA records 0
21 No A records 13
22 .
23 .
24 .
25 Done
26 <!--NeedCopy-->
```

## View DNS records statistics by using the GUI

1. Navigate to **Traffic Management > DNS**.
2. In the details pane, click **Statistics**.

## Configure a DNS zone

May 2, 2023

A DNS zone entity on the NetScaler appliance facilitates the ownership of a domain on the appliance. A zone on the appliance also enables you to implement DNS Security Extensions (DNSSEC) for the zone, or to offload the zone's DNSSEC operations from the DNS servers to the appliance. DNSSEC sign operations are performed on all the resource records in a DNS zone. Therefore, if you want to sign a zone, or if you want to offload DNSSEC operations for a zone, you must first create the zone on the NetScaler appliance.

Create a DNS zone on the appliance in the following scenarios:

- The NetScaler appliance owns all the records in a zone, that is, the appliance is operating as the authoritative DNS server for the zone. The zone must be created with the proxyMode parameter set to NO.
- The NetScaler appliance owns only a subset of the records in a zone. All the other resource records in the zone are hosted on a set of back-end name servers. The appliance is configured as a DNS proxy server for these back-end servers. A typical configuration where the NetScaler appliance owns only a subset of the resource records in the zone is a global server load balancing (GSLB) configuration. The NetScaler appliance owns only the GSLB domain names, while the back-end name servers own all the other records. The zone must be created with the proxyMode parameter set to YES.
- You want to offload DNSSEC operations for a zone from your authoritative DNS servers to the appliance. The zone must be created with the proxyMode parameter set to YES. You might have to configure more settings for the zone.

The current topic describes how to create a zone for the first two scenarios. For more information about how to configure a zone for offloading DNSSEC operations to the appliance, see [Offload DNSSEC operations to the NetScaler appliance](#).

**Note**

If the ADC appliance is operating as the authoritative DNS server for a zone, you must create the Start of Authority (SOA) and name server (NS) records for the zone before you create the zone. If the NetScaler is operating as the DNS proxy server for a zone, SOA and NS records must not be created on the NetScaler appliance. For more information about creating SOA and NS records, see [Configure DNS resource records](#).

When you create a zone, all existing domain names and resource records that end with the name of the zone are automatically treated as a part of the zone. Also, any new resource records created with a suffix that matches the name of the zone are implicitly included in the zone.

### Create a DNS zone on the NetScaler appliance by using the CLI

At the command prompt, type the following command to add a DNS zone to the NetScaler appliance and verify the configuration:

```
1 - add dns zone <zoneName> -proxyMode (YES | NO)
2 - show dns zone [<zoneName> | -type <type>]
3 <!--NeedCopy-->
```

**Example:**

```
1 > add dns zone example.com -proxyMode Yes
2 Done
3 > show dns zone example.com
4 Zone Name : example.com
5 Proxy Mode : YES
6 Done
7 <!--NeedCopy-->
```

### Modify or remove a DNS zone by using the CLI

- To modify a DNS zone, type the `set dns zone` command, the name of the DNS zone, and the parameters to be changed, with their new values.
- To remove a DNS zone, type the `rm dns zone` command and the name of the DNS zone.

### Configure a DNS zone by using the GUI

Navigate to **Traffic Management > DNS > Zones** and create a DNS zone.

## Configure the NetScaler as an ADNS server

November 28, 2023

You can configure the ADC appliance to function as an authoritative domain name server (ADNS) for a domain. As an ADNS server for a domain, the NetScaler resolves DNS requests for all types of DNS records that belong to the domain. To configure the NetScaler to function as an ADNS server for a domain, you must create an ADNS service and configure NS and Address records for the domain on the NetScaler. The ADNS service can be configured using the subnet IP address (SNIP) or a separate IP address. The following topology diagram shows a sample configuration and the flow of requests and responses.

Figure 1. NetScaler as an ADNS

The following table shows the parameters that are configured for the ADNS service illustrated in the preceding topology diagram.

Entity type	Name	IP address	Type	Port
ADNS Service	Service-ADNS-1	10.102.29.51	ADNS	53

Table 1. Example of ADNS Service Configuration

To configure an ADNS setup, you must configure the ADNS service. For instructions on configuring the ADNS service, see [Load balancing](#).

During DNS resolution, the ADNS server directs the DNS proxy or local DNS server to query the NetScaler for the IP address of the domain. Because the NetScaler is authoritative for the domain, it sends the IP address to the DNS proxy or local DNS server. The following diagram describes the placement and role of the ADNS server in a GSLB configuration.

Figure 2. GSLB Entity Model

Note: In ADNS mode, if you remove SOA and ADNS records, the following do not function for the domain hosted by the NetScaler: ANY query (for more information about the ANY query, see [DNS ANY query](#)), and negative responses, such as NODATA and NXDOMAIN.

### Create an ADNS service

An ADNS service is used for global service load balancing. For more information about creating a GSLB setup, see [Global server load balancing](#). You can add, modify, enable, disable, and remove an ADNS service. For instructions on creating an ADNS service, see [Configure services](#).

**Notes:**

- You can configure the ADNS service to use SNIP or any new IP address.
- You can configure the ADNS DOT service to encrypt the DNS traffic for the ADNS server.

When you create an ADNS service, the NetScaler responds to DNS queries on the configured ADNS service IP and port.

When you create an ADNS DOT service, NetScaler sends an encrypted DNS response.

You can verify the configuration by viewing the properties of the ADNS service. You can view properties such as name, state, IP address, port, protocol, and maximum client connections.

### **Configure the ADNS setup to use TCP**

By default, some clients use the User Datagram Protocol (UDP) for DNS, which specifies a limit of 512 bytes for the payload length of UDP packets. To handle payloads that exceed 512 bytes in size, the client must use TCP. To enable DNS communications over TCP, you must configure the NetScaler appliance to use the TCP protocol for DNS. The NetScaler then sets the truncation bit in the DNS response packets. The truncation bit specifies that the response is too large for UDP and that the client must send the request over a TCP connection. The client then uses the TCP protocol on port 53 and opens a new connection to the NetScaler. The NetScaler listens on port 53 with the IP address of the ADNS service to accept the new TCP connections from the client.

To configure the NetScaler to use the TCP protocol, you must configure an ADNS\_TCP service. For instructions on creating an ADNS\_TCP service, see [Load balancing](#).

**Important**

To configure the NetScaler to use UDP for DNS and use TCP only when the payload length of UDP exceeds 512 bytes, you need to configure the ADNS and ADNS\_TCP services. The IP address of the ADNS\_TCP service must be the same as the IP address of the ADNS service.

### **Add DNS resource records**

After you create an ADNS service, you can add DNS records. For instructions on adding DNS records, see [Configure DNS resource records](#).

### **Remove ADNS services**

For instructions on removing services, see [Load balancing](#)

## Configure domain delegation

Domain delegation is the process of assigning responsibility for a part of the domain space to another name server. Therefore, during domain delegation, the responsibility for responding to the query is delegated to another DNS server. Delegation uses NS records.

In the following example, sub1.abc.com is the subdomain for abc.com. The procedure describes the steps to delegate the subdomain to the name server ns2.sub1.abc.com and add an Address record for ns2.sub1.abc.com.

To configure domain delegation, you need to perform the following tasks, which are described in the sections that follow:

1. Create an SOA record for a domain.
2. Create an NS record to add a name server for the domain.
3. Create an Address record for the name server.
4. Create an NS record to delegate the subdomain.
5. Create a glue record for the name server.

### Create an SOA record

For instructions on configuring SOA records, see [Create SOA records for authoritative information](#).

### Create an NS record for a name server

For instructions on configuring an NS record, see [Create NS records for an authoritative server](#). In the **Name Server** list, select the primary authoritative name server, for example, ns1.abc.com.

### Create an address record

For instructions on configuring Address records, see [Create address records for a domain name](#). In the Host Name and IP address text boxes, type the domain name for the DNS Address record and the IP address, for example, ns1.abc.com and 10.102.11.135, respectively.

### Create an NS record for domain delegation

For instructions on configuring NS records, see [Create NS records for an authoritative server](#). In the **Name Server** list, select the primary authoritative name server, for example, ns2.sub1.abc.com.

## Create a glue record

NS records are typically defined immediately after the SOA record (not a restriction.) A domain must have at least two NS records. If an NS record is defined within a domain, it must have a matching Address record. This Address record is referred to as a glue record. Glue records speed up DNS queries.

For instructions on adding glue records for a subdomain, see the procedure for adding an Address (A) record, [Configure DNS resource records](#).

For instructions on configuring Address records, see [Create address records for a domain name](#). In the Host Name and IP address text boxes, type the domain name for the DNS Address record and the IP address, for example, ns2.sub1.abc.com and 10.102.12.135, respectively.

## Configure the NetScaler appliance as a DNS proxy server

November 28, 2023

As a DNS proxy server, the ADC appliance can function as a proxy for either a single DNS server or a group of DNS servers. The flow of requests and responses is illustrated in the following sample topology diagram.

Figure 1. NetScaler as DNS proxy

By default, the NetScaler appliance caches responses from DNS name servers. When the appliance receives a DNS query, it checks for the queried domain in its cache. If the address for the queried do-

main is present in its cache, the NetScaler returns the corresponding address to the client. Otherwise, it forwards the query to a DNS name server that checks for the availability of the address and returns it to the NetScaler. The NetScaler then returns the address to the client.

For requests for a domain that has been cached earlier, the NetScaler serves the Address record of the domain from the cache without querying the configured DNS server.

For the DOT request for a domain, if the cached information is not encrypted, NetScaler forwards the query to a DNS name server that checks for the availability of the address and returns it to NetScaler. NetScaler encrypts the address and response to the client. It also caches the records with a secure option. For the UDP or TCP request for a domain that has a secure option enabled, NetScaler serves the address record of the domain from the cache without querying the configured DNS server.

The appliance discards a record stored in its cache when the time-to-live (TTL) value of the record reaches the configured value. A client that requests an expired record has to wait until the NetScaler retrieves the record from the server and updates its cache. To avoid this delay, the NetScaler proactively updates the cache by retrieving the record from the server before the record expires.

The following table lists sample names and the values of the entities that need to be configured on the NetScaler.

Table 1. Example of DNS Proxy Entity Configuration

Entity type	Name	IP address	Type	Port
LB virtual server	Vserver-DNS-1	10.102.29.40	DNS	53
Services	Service-DNS-1	10.102.29.50	DNS	53
Services	Service-DNS-2	10.102.29.51	DNS	53

The following diagram shows the entities of a DNS Proxy and the values of the parameters to be configured on the NetScaler.

Figure 2. DNS Proxy Entity Model

**Note**

To configure the DNS proxy feature, you need to know how to configure load balancing services and virtual servers.

**Create a load balancing virtual server**

To configure a DNS Proxy on the NetScaler, configure a load balancing virtual server of type DNS. To configure a DNS virtual server to load balance a set of DNS servers that support recursive queries, you must set the Recursion Available option. With this option, the RA bit is set to ON in the DNS replies from the DNS virtual server.

For instructions on creating a load balancing virtual server, see [Load Balancing](#).

**Create DNS services**

After creating a load balancing virtual server of type DNS, you must create DNS services. You can add, modify, enable, disable, and remove a DNS service. For instructions on creating a DNS service, see [Load Balancing](#).

**Bind a load balancing virtual server to DNS services**

To complete the DNS Proxy configuration, you must bind the DNS services to the load balancing virtual server. For instructions on binding a service to a load balancing virtual server, see [Load Balancing](#).

## Configure the DNS proxy setup to use TCP

Some clients use the User Datagram Protocol (UDP) for DNS communications. However, UDP specifies a maximum packet size of 512 bytes. When payload lengths exceed 512 bytes, the client must use TCP. When a client sends the NetScaler appliance a DNS query, the appliance forwards the query to one of the name servers. If the response is too large for a UDP packet, the name server sets the truncation bit in its response to the NetScaler. The truncation bit indicates that the response is too large for UDP and that the client must send the query over a TCP connection. The ADC appliance relays the response to the client with the truncation bit intact. It waits for the client to initiate a TCP connection with the IP address of the DNS load balancing virtual server, on port 53. The client sends the request over a TCP connection. The NetScaler appliance then forwards the request to the name server and relays the response to the client.

To configure the NetScaler to use the TCP protocol for DNS, you must configure a load balancing virtual server and services, both of type `DNS_TCP`. You can configure monitors of type `DNS_TCP` to check the state of the services. For instructions on creating `DNS_TCP` virtual servers, services, and monitors, see [Load Balancing](#).

For updating the records proactively, the NetScaler uses a TCP connection to the server to retrieve the records.

### Important

To configure the NetScaler to use UDP for DNS and use TCP only when the payload length of UDP exceeds 512 bytes, you need to configure both `DNS` and `DNS_TCP` services. The IP address of the `DNS_TCP` service must be the same as the IP address of the `DNS` service.

## Configure time-to-live values for DNS entries

The TTL is the same for all DNS records with the same domain name and record type. If the TTL value is changed for one of the records, the new value is reflected in all records of the same domain name and type. The default TTL value is 3600 seconds. The minimum is 0, and the maximum is 604800. If a DNS entry has a TTL value less than the minimum or greater than the maximum, it is saved as the minimum or maximum TTL value, respectively.

## Specify the minimum and maximum TTL by using the CLI

At the NetScaler command prompt, type the following commands to specify the minimum and maximum TTL and verify the configuration:

```
1 - set dns parameter [-minTTL <secs>] [-maxTTL <secs>]
2 - show dns parameter
3 <!--NeedCopy-->
```

**Example:**

```
1 > set dns parameter -minTTL 1200 -maxTTL 1800
2 Done
3 > show dns parameter
4 DNS parameters:
5 DNS retries: 5
6 Minimum TTL: 1200 Maximum TTL: 1800
7 .
8 .
9 .
10 Done
11 >
12 <!--NeedCopy-->
```

**Specify the minimum and maximum TTL by using the GUI**

1. Navigate to **Traffic Management > DNS**.
2. In the details pane, under Settings, click Change DNS settings.
3. In the Configure DNS Parameters dialog box, in TTL, in the Minimum and Maximum text boxes, type the minimum and maximum time to live (in seconds), respectively, and then click OK.

**Note:** When the TTL expires, the record is deleted from the cache. The NetScaler proactively contacts the servers and obtains the DNS record just before the DNS record expires.

**Flush DNS records**

You can delete all DNS records present in the cache. For example, you might want to flush DNS records when a server is restarted after modifications are made.

**Delete all proxy records by using the CLI**

At the NetScaler command prompt, type:

```
flush dns proxyRecords
```

**Delete all proxy records by using the GUI**

1. Navigate to **Traffic Management > DNS > Records**.
2. In the details pane, click Flush Proxy Records.

## Add DNS resource records

You can add DNS records to a domain for which the NetScaler appliance is configured as a DNS proxy server. For information about adding DNS records, see [Configuring DNS Resource Records](#).

## Remove a load balancing DNS virtual server

For information about removing a load balancing virtual server, see [Load Balancing](#).

## Limit the number of concurrent DNS requests on a client connection

You can limit the number of concurrent DNS requests on a single client connection, which is identified by the `<clientip:port>-<vserver ip:port>` tuple. Concurrent DNS requests are those requests that the NetScaler appliance has forwarded to the name servers and for which the appliance is awaiting responses. Limiting the number of concurrent requests on a client connection enables you to protect the name servers when a hostile client attempts a Distributed Denial of Service (DDoS) attack by sending a flood of DNS requests. When the limit for a client connection is reached, subsequent DNS requests on the connection are dropped until the outstanding request count goes below the limit. This limit does not apply to the requests that the NetScaler appliance serves out of its cache.

The default value for this parameter is 255. This default value is sufficient in most scenarios. If the name servers serve many concurrent DNS requests under normal operating conditions, you can specify either a large value or a value of zero (0). A value of 0 disables this feature and specifies that there is no limit to the number of DNS requests that are allowed on a single client connection. This parameter is a global parameter and applies to all the DNS virtual servers that are configured on the NetScaler appliance.

The default value for this parameter is 255. This default value is sufficient in most scenarios. If the name servers serve many concurrent DNS requests under normal operating conditions, you can specify either a large value or a value of zero (0). A value of 0 disables this feature and specifies that there is no limit to the number of DNS requests that are allowed on a single client connection. This parameter is a global parameter and applies to all the DNS virtual servers that are configured on the NetScaler appliance.

The default value for this parameter is 255. This default value is sufficient in most scenarios. If the name servers serve many concurrent DNS requests under normal operating conditions, you can specify either a large value or a value of zero (0). A value of 0 disables this feature and specifies that there is no limit to the number of DNS requests that are allowed on a single client connection. This parameter is a global parameter and applies to all the DNS virtual servers that are configured on the NetScaler appliance.

### Specify the maximum number of concurrent DNS requests allowed on a single client connection by using the CLI

At the command prompt, type the following commands to specify the maximum number of concurrent DNS requests allowed on a single client connection and verify the configuration:

```
1 - set dns parameter -maxPipeline <positive_integer>
2 - show dns parameter
3 <!--NeedCopy-->
```

#### Example:

```
1 > set dns parameter -maxPipeline 1000
2 Done
3 > show dns parameter
4 DNS parameters:
5 DNS retries: 5
6 .
7 .
8 .
9 Max DNS Pipeline Requests: 1000
10 Done
11 <!--NeedCopy-->
```

### Specify the maximum number of concurrent DNS requests allowed on a single client connection by using the GUI

1. Navigate to **Traffic Management > DNS**.
2. In the details pane, click Change DNS settings.
3. In the Configure DNS Parameters dialog box, specify a value for Max DNS Pipeline Requests.
4. Click OK.

## Configure the NetScaler as an end resolver

May 2, 2023

A resolver is a procedure that is invoked by an application program that translates a domain/host name to its resource record. The resolver interacts with the LDNS, which looks up the domain name to obtain its IP address. The NetScaler can provide end-to-end resolution for DNS queries.

In recursive resolution, the NetScaler appliance queries different name servers recursively to access the IP address of a domain. When the NetScaler receives a DNS request, it checks its cache for the DNS record. If the record is not present in the cache, it queries the root servers configured in the ns.conf

file. The root name server reports back with the address of a DNS server that has detailed information about the second-level domain. The process is repeated until the required record is found.

When you start the NetScaler appliance for the first time, 13 root name servers are added to the ns.conf file. The NS and Address records for the 13 root servers are also added. You can modify the ns.conf file, but the NetScaler does not allow you to delete all 13 records. At least one name server entry is required for the appliance to perform name resolution. The following diagram illustrates the process of name resolution.

Figure 1. Recursive resolution

In the process shown in the diagram, when the name server receives a query for the address of s1.s2.s3.com, it first checks the root name servers for s1.s2.s3.com. A root name server reports back with the address of the .com name server. If the address of s1.s2.s3.com is found in the name server, it responds with a suitable IP address. Otherwise, it queries other name servers for s3.com, then for s2.s3.com to retrieve the address of s1.s2.s3.com. In this way, resolution always starts from root name servers and ends with the domain's authoritative name server.

**Note**

For recursive resolution functionality, caching must be enabled.

**Enable recursive resolution**

To configure the NetScaler appliance to function as an end resolver, you must enable recursive resolution on the appliance. You must also add a DNS name server with the local option for the feature to work.

**Enable recursive resolution by using the CLI**

At the command prompt, type the following commands to enable recursive resolution and verify the configuration:

```
1 - set dns parameter -recursion ENABLED
2 - show dns parameter
3 <!--NeedCopy-->
```

**Example:**

```
1 > set dns parameter -recursion ENABLED
2 Done
3 > show dns parameter
4 DNS parameters:
5 .
6 .
7 .
8 Recursive Resolution : ENABLED
9 .
10 .
11 .
12 Done
13 <!--NeedCopy-->
```

**Enable recursive resolution by using the GUI**

1. Navigate to **Traffic Management > DNS**.
2. In the details pane, under Settings, click Change DNS settings.
3. In the Configure DNS Parameters dialog box, select the Enable recursion check box, and then click OK.

## Add a name server (when the NetScaler appliance acts as a resolver) by using the CLI

At the command prompt, type:

```
1 add dns nameServer ((<IP> [-local]) | <dnsVserverName>)
2 <!--NeedCopy-->
```

### Example:

```
1 add dns nameServer 10.102.9.19 -local
2 show dns nameServer
3 1) 10.102.9.19 LOCAL - State: UP Protocol: UDP
4 Done
5 <!--NeedCopy-->
```

**Local** - Mark the IP address as one that belongs to a local recursive DNS server on the NetScaler appliance. The appliance recursively resolves queries received on an IP address that is marked as being local.

For recursive resolution to work, the global DNS parameter, `recursion`, must also be set.

If no name server is marked as being local, the appliance functions as a stub resolver and load balances the name servers.

## Add a name server by using the GUI

Navigate to **Traffic Management > DNS > Name Servers** and create a name server.

## Enable DNS root referral

DNS root referral is disabled by default. When enabled, the ADC appliance responds with the root referral records.

Send a root referral if a client queries a domain name that is unrelated to the domains configured/ cached on the NetScaler appliance. If the setting is disabled, the appliance sends a blank response instead of a root referral. Applicable to domains for which the appliance is authoritative. Disable the parameter when the appliance is under attack from a client that is sending a flood of queries for unrelated domains.

## Enable root referral by using the CLI

At the command prompt, type the following commands to enable recursive resolution and verify the configuration:

```
1 - set dns parameter -dnsrootReferral ENABLED
2 - show dns parameter
```

```
3 <!--NeedCopy-->
```

**Example:**

```
1 > set dns parameter -recursion ENABLED
2 Done
3 > show dns parameter
4 DNS parameters:
5 .
6 .
7 .
8 DNS Root Referral : ENABLED
9 .
10 .
11 .
12 Done
13 <!--NeedCopy-->
```

**Enable root referral by using the GUI**

1. Navigate to **Traffic Management > DNS**.
2. In the details pane, under **Settings**, click **Change DNS settings**.
3. In the **Configure DNS Parameters** dialog box, select the **Enable Root Referral** check box, and then click **OK**.

**Set the Number of Retries**

Configure the ADC appliance to make a preconfigured number of attempts (called DNS retries) when it does not receive a response from the server to which it sends a query. By default, the number of DNS retries is set to 5.

**Set the number of DNS retries by using the CLI**

At the command prompt, type the following commands to set the number of retries and verify the configuration:

```
1 - set dns parameter -retries <positive_integer>
2 - show dns parameter
3 <!--NeedCopy-->
```

**Example:**

```
1 > set DNS parameter -retries 3
2 Done
3 > show dns parameter
```

```
4 DNS parameters:
5 DNS retries: 3
6 .
7 .
8 .
9 Done
10 <!--NeedCopy-->
```

### Set the number of retries by using the GUI

1. Navigate to **Traffic Management > DNS**.
2. In the details pane, under Settings, click Change DNS settings.
3. In the Configure DNS Parameters dialog box, in the DNS Retries text box, type the DNS resolver request retry count, and then click OK.

## Configure the NetScaler appliance as a forwarder

May 2, 2023

A forwarder is a server that forwards DNS queries to DNS servers that are outside the forwarder server's network. Queries that cannot be resolved locally are forwarded to other DNS servers. A forwarder accumulates external DNS information in its cache as it resolves DNS queries. To configure the NetScaler appliance as a forwarder, you must add an external name server.

The NetScaler appliance allows you to add external name servers to which it can forward the name resolution queries that cannot be resolved locally. To configure the NetScaler appliance as a forwarder, you must add the name servers to which it must forward name resolution queries. You can specify the lookup priority to specify the name service that the NetScaler appliance must use for name resolution.

For information on how to configure the NetScaler appliance as a forwarder, see [Add a name server \(when the NetScaler appliance acts as a forwarder\) by using the CLI](#).

#### Note:

The NetScaler appliance in forwarder mode supports TCP, UDP, and UDP-TCP name servers.

- If you have configured a TCP name server, then the NetScaler appliance sends the DNS request over TCP.
- If you have configured a UDP name server, then the NetScaler appliance sends the DNS request over UDP.
- If you have configured a UDP-TCP name server, then the NetScaler appliance sends the DNS

request over UDP. However if the truncated bit is set in the DNS response, the appliance sends such DNS requests over TCP.

## Add a name server

You can create a name server by specifying its IP address or by configuring an existing virtual server as the name server.

- **IP address-based name server** - An external name server to contact for domain name resolution. If multiple IP address-based name servers are configured on the appliance, and the local parameter is not set on any of them, incoming DNS queries are load balanced across all the name servers, in round robin fashion.
- **Virtual server-based name server** - A DNS virtual server configured in the NetScaler. For more fine-grained control on how external DNS name servers are load balanced (for example, you want a load balancing method other than round robin), do the following:
  - Configure a DNS virtual server on the appliance
  - Bind the external name servers as its services
  - Specify the name of the virtual server in this command.

To verify the configuration, you can use the `show dns nameServer` command.

To remove a name server, at the NetScaler CLI, type the `rm dns nameServer` command followed by the IP address of the name server.

To view the details of the DNS nameserver, at the NetScaler CLI, type the `show dns nameServer` command followed by the IP address of the name server.

## Add a name server (when the NetScaler appliance acts as a forwarder) by using the CLI

At the command prompt, type;

```
1 add dns nameServer ((<IP> | <dnsVserverName>)
2 <!--NeedCopy-->
```

Or

```
1 add dns nameServer ((<IP> | <dnsVserverName>) [-type <type>]
2 <!--NeedCopy-->
```

### Examples:

```
1 add dns nameServer dnsVirtualNS
2
3 add dns nameServer 192.0.2.11 -type TCP
4
```

```
5 add dns nameServer 192.0.2.12 -type UDP_TCP
6
7
8 add dns nameServer 192.0.2.10
9 show dns nameServer 192.0.2.10
10
11 1) 192.0.2.10 - State: UP Protocol: UDP
12 Done
13 <!--NeedCopy-->
```

**Note:**

If the name server type is not specified, a UDP name server is created by default. To create a name server of type TCP or UDP\_TCP, you must specify the type.

When you specify the type as UDP\_TCP, two name servers (one UDP name server and one TCP name server) are created for the given IP address.

**Add a name server (when the NetScaler appliance acts as a resolver) by using the CLI**

Specify the `local` parameter for a recursive resolver. Enable recursion using the `set dns parameter` command.

At the command prompt, type:

```
1 add dns nameServer ((<IP> [-local]) | <dnsVserverName>)
2 show dns nameServer
3 set dns parameter -recursion ENABLED
4 show dns parameter
5 <!--NeedCopy-->
```

**Example:**

```
1 add dns nameServer 10.102.9.19 -local
2 show dns nameServer
3 1) 10.102.9.19 LOCAL - State: UP Protocol: UDP
4 Done
5 set dns parameter -recursion ENABLED
6 Done
7 show dns parameter
8 DNS parameters:
9 .
10 .
11 .
12 Recursive Resolution : ENABLED
13 .
14 .
15 .
16 Done
17 <!--NeedCopy-->
```

**Local** - Mark the IP address as one that belongs to a local recursive DNS server on the NetScaler appliance. The appliance recursively resolves queries received on an IP address that is marked as being local.

For recursive resolution to work, the global DNS parameter, `recursion`, must also be set.

If no name server is marked as being local, the appliance functions as a stub resolver and load balances the name servers.

### Add a name server by using the GUI

Navigate to **Traffic Management > DNS > Name Servers** and create a name server.

### Set DNS lookup priority

You can set the lookup priority to either DNS or WINS. This option is used in the SSL VPN mode of operation.

### Set the lookup priority to DNS by using the CLI

At the command prompt, type the following commands to set the lookup priority to DNS and verify the configuration:

```
1 - set dns parameter -nameLookupPriority (DNS | WINS)
2 - show dns parameter
3 <!--NeedCopy-->
```

#### Example:

```
1 > set dns parameter -nameLookupPriority DNS
2 Done
3 > show dns parameter
4 .
5 .
6 .
7 Name lookup priority : DNS
8 .
9 .
10 .
11 Done
12 <!--NeedCopy-->
```

### Set lookup priority to DNS by using the GUI

1. Navigate to **Traffic Management > DNS**.

2. In the details pane, under **Settings**, click **Change DNS settings**.
3. In the **Configure DNS Parameters** dialog box, under **Name Lookup Priority**, select DNS or WINS, and then click **OK**.

**Note**

If the DNS virtual server that you have configured is DOWN and if you set the `-nameLookupPriority` to DNS, the NetScaler does not attempt WINS lookup. Therefore, if a DNS virtual server is not configured or is disabled, set the `-nameLookupPriority` to WINS.

## Disable and enable name servers

The following procedure describes the steps to enable or disable an existing name server.

### Enable or disable a name server by using the CLI

At the command prompt, type the following commands to enable or disable a name server and verify the configuration:

```
1 - (enable | disable) dns nameServer <IPAddress>
2 - show dns nameServer <IPAddress>
3 <!--NeedCopy-->
```

**Example:**

```
1 > disable dns nameServer 10.102.9.19
2 Done
3 > show dns nameServer 10.102.9.19
4 1) 10.102.9.19: LOCAL - State: OUT OF SERVICE
5 Done
6 <!--NeedCopy-->
```

### Enable or disable a name server by using the GUI

1. Navigate to **Traffic Management > DNS > Name Servers**.
2. In the details pane, select the name server that you want to enable or disable.
3. Click **Enable** or **Disable**. If a name server is enabled, the **Disable** option is available. If a name server is disabled, the **Enable** option is available.

## Configure NetScaler as a non-validating security aware stub-resolver

May 2, 2023

Starting with NetScaler 12.1 build 49.xx, NetScaler acts as a non-validating security aware stub-resolver. To enable this support, the AD bit is set in the DNS header and the DO bit is unset in the OPT header. When the AD bit is set and the DO bit is unset, the upstream recursive resolver validates the DNSSEC response. If the validation is successful, the recursive resolver responds without DNSSEC RRs. If the DNSSEC validation fails, then the recursive resolver returns with a SERVFAIL response.

**Important:**

The AD bit is set by default in the ADC forwarder. The AD bit is not set for DBS initiated queries.

## Jumbo frames support for DNS to handle responses of large sizes

May 2, 2023

Starting with NetScaler 12.1 build 49.xx, DNS supports jumbo frames for handling UDP responses greater than 1,280 bytes. Previously, the NetScaler appliance only supported UDP packet size only up to 1,280 bytes.

You can set the maximum UDP packet size that the appliance can handle in proxy, ADNS, and forwarder modes by configuring the Maximum UDP Packet Size parameter value. For example, if the Maximum UDP Packet Size parameter value is set to 4096, the appliance can handle DNS response of size 4,096 bytes.

**Important**

- In proxy mode, the least size between the client request OPT payload size and the Maximum UDP Packet Size value is considered for sending DNS queries to the back end. For example, if the client request OPT payload size is 3000, and the Maximum UDP Packet Size value is 4096, 3,000 bytes DNS queries are sent to the back end.

Also, from the back end, the appliance can receive responses of large sizes and process responses of large sizes.

- In forwarder mode, the appliance sets the OPT payload size equal to the UDP packet size parameter value.
- If the DNS records are local to the appliance, then the appliance can compose response sizes as large as the Maximum UDP Packet Size parameter value. This setting is applicable for ADNS, proxy, and recursive resolvers.

### To configure the maximum UDP packet size using the CLI

At the command prompt, type:

```
1 set dns parameter [-maxUDPPacketSize <positive_integer>]
2 <!--NeedCopy-->
```

**Example:**

```
1 set dns parameter -maxUDPPacketSize 10000
2 <!--NeedCopy-->
```

**Note:**

The minimum and maximum value that you can set for the Maximum UDP Packet Size parameter is 512 and 16384 respectively. Default value is 1280.

**To configure the maximum UDP packet size using the GUI**

1. Navigate to **Traffic Management > DNS**.
2. In the details pane, click **Change DNS settings**.
3. In Maximum UDP Packet Size, specify the maximum UDP packet size.
4. Click **OK**.

**Configure DNS logging**

May 2, 2023

You can configure the NetScaler appliance to log the DNS requests and responses that it handles. The appliance logs the DNS requests and responses in SYSLOG format. You can choose to log either DNS requests or DNS responses, or both, and send the syslog messages to a remote log server. The log messages can be used to:

- Audit the DNS responses to the client
- Audit DNS clients
- Detect and prevent DNS attacks
- Troubleshoot

A NetScaler appliance can log the following sections in the DNS request or response, based on your configuration:

- Header Section
- Questions Section
- Answer Section
- Authority Section
- **Additional** Section

## DNS profiles

You can use a DNS profile to configure the various DNS parameters that you want the DNS endpoint to apply to the DNS traffic. In the profile, you can enable logging, caching, and negative caching.

**Important:** From the NetScaler 11.0 release, enabling DNS caching using global DNS parameters have been deprecated. You can enable or disable DNS caching using DNS profiles. You can now enable DNS caching for an individual virtual server by enabling DNS caching in a DNS profile and setting the DNS profile to the individual virtual server.

DNS profiles support the following types of DNS logging:

- DNS Query Logging
- DNS Answer Section Logging
- DNS Extended Logging
- DNS Error Logging

### DNS query logging

You can configure a NetScaler appliance to log only the DNS queries that are received by the DNS endpoints on the appliance.

**Note:** If errors occur during processing of a query, they are logged if this option is set in the DNS profile.

Following is an example of a query log message:

```
1 DNS DNS_QUERY 143 0 : U:10.102.27.70#61297:10.102.27.73#53/22142/Q/
2 (RD)/NO/1/0/0/0#test.com./1#
3 <!--NeedCopy-->
```

### DNS answer section logging

You can configure a NetScaler appliance to log all the **Answer** sections in the DNS responses that the appliance sends to the client. DNS Answer Section logging is useful when the NetScaler is configured as a DNS resolver, or in GLSB use cases.

Following is an example of a DNS answer section log:

```
1 DNS DNS_RESPONSE 6678 0 : U:100.100.100.210#32776:100.100.100.10#
2 53/61373/Q/(RD,AA,RA,R)/NO/1/1/2/4#n1.citrix.com1./
3 28#ANS#AAAA/120/1111:2345:6789:ffab:abcd:effa:1234:3212##
4 <!--NeedCopy-->
```

## DNS extended logging

To configure a NetScaler appliance to log Authority and **Additional** sections in the DNS responses, enable Extended logging with Answer Section logging.

**Note:** If errors occur during processing of either queries or responses, the errors are logged if this option is set in the DNS profile.

Following is an example of a message logged when the cache lookup is completed and the response is embedded in the packet:

```
1 DNS DNS_RESPONSE 2252 0 : T:100.100.100.118#21411:100.100.100.10
2 #53/48537/Q/(RD,AA,CD,RA,R)/NO/1/1/2/6#a1.citrix.com1./1#ANS#A/
3 120/1.1.1.1##AUTH#citrix.com1/NS/120/n2.citrix.com1#n1.citrix.com1##ADD
4 #n1.citrix.com1
5 /A/120/1.1.1.1#1.1.1.2##n1.citrix.com1/AAAA/120/
6 1111:2345:6789:ffab:abcd:effa:1234:3212##n2.citrix.com1/A/120/2.1.1.2
7 ##n2.citrix.com1/AAAA/120/2222:faff:3212:8976:123:1241:64:ff9b##OPT
8 /0/1280/DO##
9 <!--NeedCopy-->
```

## DNS error logging

You can configure a NetScaler appliance to log the errors or failures that occur when it processes a DNS query or response. For these errors, the appliance logs the DNS header, **Question** sections and OPT records.

Following is an example of a message logged when an error occurs during processing of a DNS request or response:

```
1 DNS DNS_ERROR 149 0 : U:10.102.27.70#27832:10.102.27.73#53/61153/Q/
2 (RD)/NO/1/0/0/0#test.com./1140#Packet Dropped
3 <!--NeedCopy-->
```

## Policy based logging

You can configure custom logging based on DNS expressions by configuring the logAction on DNS policies, Rewrite, or Responder policies. You can specify that logging occurs only when a particular DNS policy evaluates to true. For more information, see [Configure policy based logging for DNS](#).

## Understand the NetScaler syslog log message format

NetScaler appliance log DNS requests and responses in the following Syslog format:

```
1 <transport> :<client IP>#<client ephemeral port>:<DNS endpoint IP>#<
 port>
2 : <query id> /opcode/header flags/rcode/question section count/answer
 section count
3 / auth section count / additional section count #<queried domain name>
4 /<queried type>#...
5 <!--NeedCopy-->
```

- **<transport>**:
  - T = TCP
  - U = UDP
- **<client IP>#< client ephemeral port >**: DNS client IP address and port number
- **<DNS endpoint IP>#<port>**: NetScaler DNS endpoint IP address and port number
- **<query id>**:  
Query ID
- **<opcode>**: Operation code. Supported Values:
  - Q: query
  - I: inverse query
  - S: status
  - X0: unassigned
  - N: notify
  - U: update
  - X1-10: unassigned values
- **<header flags>**: Flags. Supported Values:
  - RD: recursion desired
  - TC: truncated
  - AA: authoritative response
  - CD: check disabled
  - AD: authenticated data
  - Z: unassigned
  - RA: recursion available
  - R: response
- **<rcode>**: Response Code. Supported Values:
  - NO: no error
  - F format error
  - S: server failure

- NX: non-existent domain
  - NI: not implemented
  - R: query refused
  - YX: Name Exists when it must not
  - YXR: RR Set Exists when it must not
  - NXR: RR Set that must exist does not
  - NAS: Server Not Authoritative for zone
  - NA: Not Authorized
  - NZ: Name not contained in zone
  - X1-5: unassigned
- **/question section count/answer section count/auth section count/additional section count:** Question section, Authority section count, and **Additional** section count in the DNS request
  - **<queried domain name>/<queried type>:** Queried domain and queried type in the DNS request
  - **#ANS#<record type>/<ttd>/.. #AUTH#<domain name>/<record type>/<ttd>.. #ADD#<domain name>/<record type>/<ttd>...:**

In DNS responses:

Answer Section is logged if answer section logging is enabled in the DNS profile. Authority and **Additional** sections are logged if extended logging is enabled in the DNS profile. The log format would differ depending on the type of record. For more information see Understanding the Record Logging Format.

- ANS: answer section
  - AUTH: authority
  - ADD: **Additional** section
- **OPT/<edns version>/UDP max payload size/DO:** OPT record format in the DNS log
  - **OPT/<EDNS version>/<UDP payload size>/<“DO”or empty based on whether DNSSEC OK bit is set or not>/<value of RDLEN>/ECS/<Q/R>/<option length>/<Family>/<Source Prefix-Length>/<Scope Prefix-Length>/<ECS Address>:**

If the DNS query or response includes the EDNS Client Subnet (ECS) option, then that is also logged in the OPT record format in the DNS log file.

When a DNS query with an ECS option that includes either an IPv4 or IPv6 address is sent, the ECS option is logged with either of the following options;

- “ECS/Q”indicating that the values in the log are from the query
- “ECS/R”indicating that the values in the log are from the response.

The value of Scope Prefix-Length is also set appropriately. In the DNS Query, it is set to zero, and for response, it is set to the calculated value.

The following table describes the logged details in various scenarios:

Scenario	ECS option set in the DNS Query	ECS option set in the DNS Response	Logged Details
Both query logging and extended logging enabled	Yes	Yes	ECS option is logged with the string “ECS/R/” and the Scope Prefix-Length is set to the calculated value.
Both query logging and extended logging enabled	Yes	No	ECS option is logged with the string “ECS/Q/” and the Scope Prefix-Length is set to zero.
Query logging is enabled, but extended logging is not enabled	Yes	Yes	ECS option is logged with the string “ECS/Q/” and the Scope Prefix-Length is set to zero.
Query logging & extended logging are not enabled	Yes	Yes	ECS option is not logged.
Query logging is enabled, but extended logging is not enabled	Yes	No	ECS option is logged with the string “ECS/Q/” and the Scope Prefix-Length is set to zero.
Query logging is not enabled, but extended logging is enabled	Yes	Yes	ECS option is logged with the string “ECS/R/” and the Scope Prefix-Length is set to the calculated value.
Query logging is not enabled, but extended logging is enabled	Yes	No	ECS option is not logged.

## Understand the record logging format

Following is an example of the record logging format in a Syslog message:

```

1 <domainname>/<record type>/ <record ttl> / <resource record data>#<
 resource record data>#.....##
2 <!--NeedCopy-->

```

Where:

Record Type	Sample Format	Resource Record Data / Format
Address (A) record	A/5/1.1.1.1#1.1.1.2#1.1.1.3##	IPv4 address
AAAA record	AAAA/5/1::1#1::2#1::3##	IPv6 address
SOA record	SOA/3600/ns1.dnslogging.test./root.dnslogging.test/10/3600/3/3600/5##	Origin logging test details. Resource record format is: //////////////##
NS record	NS/5/ns1.dnslogging.test	Host name of the nameserver.
MX record	#MX/5/10/host1.dnslogging.test.#10/host2.dnslogging.test##	Priority of the mail exchange server host name
CNAME record logging	CNAME/5/host1.dnslogging.test.##	Canonical name
SRV record	SRV/5/1/2/3/host1.dnslogging.test#5/6/host2.dnslogging.test.##	Priority, weight, port, and target
TXT record	TXT/5/dns+logging##	Data comprises all the texts.
NAPTR record	NAPTR/5/10/11////dnslogging#20/10/SIP/sip.dnslogging.test##	Priority, weight, regexp, target, and proto
DNSKEY record	DNSKEY/5/1/3/5/AwEAAanP0K+i5bnR5U4781760EjDjMq2C/6JZgiDBZhSONF	Resource record for DNSKEY
PTR record	PTR/3600/test.com.#test4.com.##	Domain name

## Limitations of DNS logging

DNS logging has the following limitations:

- If response logging is enabled, only the following record types are logged:
  - Address (A) record
  - AAAA record
  - SOA record
  - NS record
  - MX record
  - CNAME record

- SRV record
- TXT record
- NAPTR record
- DNSKEY record
- PTR record

For all other record types, only L3/L4 parameters, DNS Header, and Question section are logged.

- RRSIG records are not logged even if response logging is enabled.
- DNS64 is not supported.
- DNS proactive update requests or responses are logged according to the settings in the default profile.
- On the virtual server, if sessionless option and response logging is enabled, L3/L4 parameters, DNS Header, and DNS Question section are logged instead of the response.
- The maximum size of the syslog message is 1024 bytes.
- If you have set a DNS profile for a DNS policy with action type Rewrite Response, the NetScaler appliance does not log the query or the manipulated responses. To log the required information you must use an audit message action in the DNS policy.
- DNS transactions that are due to DNS monitoring traffic are not logged.

## Configuring DNS logging

Following is an overview of configuring DNS logging:

1. Create a Syslog action and enable DNS in the action.
2. Create a Syslog policy and specify the Syslog action in the policy.
3. Globally bind the Syslog policy to enable logging of all NetScaler system events. Or, bind the Syslog policy to a specific load balancing virtual server.
4. Create a DNS profile and define any of the following types of logging that you want to enable:
  - DNS Query Logging
  - DNS Answer Section Logging
  - DNS Extended Logging
  - DNS Error Logging
5. Configure any of the following, based on your requirement:
  - DNS service and virtual server for DNS
  - ADNS service
  - NetScaler as a forwarder

- NetScaler as a resolver
6. Set the created DNS profile to one of the DNS entities.

### Configure DNS logging for NetScaler configured as DNS Proxy by using the CLI

1. Add a syslog action and enable DNS in the action. At the command prompt, type:

```

1 add audit syslogAction <name> (<serverIP> | -lbVserverName <string
 >) [-serverPort <port>] -logLevel <logLevel> ... [-dateFormat <
 dateFormat>] [-logFacility <logFacility>] [-tcp (NONE | ALL)]
 [-acl (ENABLED | DISABLED)] [-timeZone (GMT_TIME |
 LOCAL_TIME)] [-userDefinedAuditlog (YES | NO)] [-
 appflowExport (ENABLED |DISABLED)] [-lsn (ENABLED | DISABLED
)] [-alg (ENABLED | DISABLED)] [-transport (TCP | UDP)] [-
 tcpProfileName <string>] [-maxLogDataSizeToHold <
 positive_integer>] [-dns (ENABLED | DISABLED)]
2 <!--NeedCopy-->

```

#### Example:

```

add audit syslogAction nssyslogact1 10.102.151.136 -logLevel
CRITICAL ERROR WARNING NOTICE INFORMATIONAL DEBUG -logFacility
LOCAL4 -timeZone LOCAL_TIME -dns ENABLED

```

2. Create a syslog policy and specify the created syslog action in the policy. At the command prompt, type:

```

add audit syslogPolicy <name> <rule> <action>

```

#### Example:

```

add audit syslogPolicy syslogpol1 ns_true nssyslogact1

```

3. Bind the syslog policy globally. At the command prompt, type:

```

bind system global [<policyName> [-priority <positive_integer>]]

```

#### Example:

```

bind system global syslogpol1

```

4. Create a DNS profile and enable any of the following type of logs that you want to configure:

- DNS Query Logging
- DNS Answer Section Logging
- DNS Extended Logging
- DNS Error Logging

At the command prompt, type:

```
add dns profile <dnsProfileName> [-dnsQueryLogging (ENABLED |
 DISABLED)] [-dnsAnswerSecLogging (ENABLED | DISABLED)] [-
 dnsExtendedLogging (ENABLED | DISABLED)] [-dnsErrorLogging (
 ENABLED | DISABLED)] [-cacheRecords (ENABLED | DISABLED)] [-
 cacheNegativeResponses (ENABLED | DISABLED)]
```

**Example:**

```
add dns profile dnsprofile1 -dnsQueryLogging ENABLED
```

5. Configure service of type DNS. At the command prompt, type:

```
add service <name> <serverName> <serviceType> <port>
```

**Example:**

```
add service svc1 10.102.84.140 dns 53
```

6. Configure a load balancing virtual server of service type DNS.

```
add lb vserver <name> <serviceType> <ip> <port>
```

**Example:**

```
add lb vserver lb1 dns 100.100.100.10 53
```

7. Bind the service to the virtual server. At the command prompt, type:

```
bind lb vserver <name> <serviceName>
```

**Example:**

```
bind lb vserver lb1 svc1
```

8. Set the created DNS profile to the virtual server. At the command prompt, type:

```
set lb vserver <name> [- dnsProfileName <string>]
```

**Example:**

```
set lb vserver lb1 -dnsProfileName dnsprofile1
```

**Sample DNS logging configuration for NetScaler appliance configured as DNS proxy**

```
1 > add audit syslogAction nssyslogact1 10.102.151.136 -logLevel
2 CRITICAL ERROR WARNING NOTICE INFORMATIONAL DEBUG -logFacility LOCAL4 -
 timeZone
3 LOCAL_TIME -dns ENABLED
4 Done
5 > add audit syslogPolicy syslogpol1 ns_true nssyslogact1
6 Done
7 > bind system global syslogpol1
8 Done
```

```
9 > add dns profile dnsprofile1 -dnsqueryLogging ENABLED
10 Done
11 > add lb vserver lb1 dns 100.100.100.10 53 -dnsProfileName dnsprofile1
12 Done
13 > add service svc1 10.102.84.140 dns 53
14 Done
15 > bind lb vserver lb1 svc1
16 Done
17 <!--NeedCopy-->
```

### Sample DNS logging configuration for NetScaler appliance configured as ADNS

```
1 > add audit syslogAction nssyslogact1 10.102.151.136 -logLevel CRITICAL
2 ERROR WARNING NOTICE INFORMATIONAL DEBUG -logFacility LOCAL4 -timeZone
 LOCAL_TIME
3 -dns ENABLED
4 Done
5 > add audit syslogPolicy syslogpol1 ns_true nssyslogact1
6 Done
7 > bind system global syslogpol1
8 Done
9 > add dns profile dnsprofile1 -dnsqueryLogging ENABLED
10 Done
11 > add lb vserver lb1 dns 100.100.100.10 53 -dnsProfileName dnsprofile1
12 Done
13 > add service svc1 10.102.84.140 dns 53
14 Done
15 > bind lb vserver lb1 svc1
16 Done
17 <!--NeedCopy-->
```

### Sample DNS logging configuration for NetScaler appliance configured as a forwarder

```
1 > add audit syslogAction nssyslogact1 10.102.151.136 -logLevel CRITICAL
2 ERROR WARNING NOTICE INFORMATIONAL DEBUG -logFacility LOCAL4 -timeZone
 LOCAL_TIME
3 -dns ENABLED
4 Done
5 > add audit syslogPolicy syslogpol1 ns_true nssyslogact1
6 Done
7 > bind system global syslogpol1
8 Done
9 > add dns profile dnsprofile1 -dnsqueryLogging ENABLED
10 Done
11 > add dns nameserver 8.8.8.8 -dnsProfileName dnsprofile1
12 Done
13 <!--NeedCopy-->
```

## Sample DNS logging configuration for a NetScaler appliance configured as a resolver

```
1 > add audit syslogAction nssyslogact1 10.102.151.136
2 -logLevel CRITICAL ERROR WARNING NOTICE INFORMATIONAL DEBUG -
 logFacility LOCAL4
3 -timeZone LOCAL_TIME -dns ENABLED
4 Done
5 > add audit syslogPolicy syslogpol1 ns_true nssyslogact1
6 Done
7 > bind system global syslogpol1
8 Done
9 > add dns profile dnsprofile1 -dnsqueryLogging ENABLED
10 Done
11 > set dns parameter -recursion enabled
12 Done
13 > add nameserver 1.1.1.100 -local dnsProfileName dnsprofile1
14 Done
15 <!--NeedCopy-->
```

### Configure policy based logging for DNS

Policy based logging enables you to specify a format for log messages. The contents of a log message are defined by using an Advanced policy expression. When the message action specified in the policy is performed, the NetScaler appliance constructs the log message from the expression and writes the message to the log file. You can configure the appliance to log only when a particular DNS policy evaluates to True.

#### Note

If you have set a DNS policy with a DNS profile for the request side, the NetScaler appliance logs only the query.

To configure policy based logging for a DNS policy, you must first configure an audit message action. For more information about configuring an audit message action, see [Configure the NetScaler appliance for audit logging](#). After configuring the audit message action, specify the message action in a DNS policy.

### Configure policy based logging for a DNS policy by using the CLI

At the command prompt, type the following commands to configure policy based logging for a DNS policy and verify the configuration:

```
1 - add dns action <actionName> <actionType> [-IPAddress <ip_addr|
 ipv6_addr> ... | -viewName <string> | -preferredLocList <string>
 ...] [-TTL <secs>] [-dnsProfileName <string>]
```

```

2 - set dns policy <name> [<rule>] [-actionName <string>] [-logAction <
 string>]
3 - show dns policy [<name>]
4 <!--NeedCopy-->

```

**Example 1:**

In a GSLB deployment, if you want to respond with different IP addresses to the client requests coming from a particular subnet, instead of responding with IP addresses used for general purposes (such as the IP addresses of internal users), you can configure a DNS policy with the action type as DNS view. In this case, you can configure DNS logging on the specified DNS action such that you can log the specific responses.

```

1 > add dns profile dns_prof1 -dnsqueryLogging enABLED -
 dnsanswerSecLogging enABLED
2 Done
3 > add dns view dns_view1
4 Done
5 > add dns action dns_act1 viewName -view dns_view1 - dnsprofileName
 dns_prof1
6 Done
7 > add dns policy dns_pol1 "CLIENT.IP.SRC.APPLY_MASK(255.255.255.0).EQ
 (100.100.100.0) "
8 dns_act1
9 Done
10 > bind dns global dns_pol1 100 -gotoPriorityExpression END -type
 REQ_DEFAULT
11 Done
12 > bind gslb service site_1_svc -viewName dns_view1 123.1.1.1
13 Done
14 > bind gslb service site_5_svc -view dns_view1 132.1.1.1
15 Done
16 <!--NeedCopy-->

```

**Note:** In the preceding configuration, if you query for the domain configured on a GSLB virtual server, for example, *sampletest.com*, all the internal users of subnet 100.100.100.0/24 are served with the DNS view IP addresses, and the responses are logged. Client requests for other subnets are not logged.

**Example 2:**

If you want to log only the queries for the domain *example.com*, you can create a DNS profile with query logging enabled and set the DNS profile to a DNS action with the action type

**NOOP**, and then create a DNS policy and set the DNS action. For example:

```

1 >add dns profile query_logging -dnsqueryLogging ENABLED
2 Done
3 >add dns action dns_act1 NOOP -dnsprofileName query_logging
4 Done
5 >add dns policy dns_pol1 DNS.REQ.QUESTION.DOMAIN.EQ("example.com")
 dns_act1
6 Done

```

```
7 <!--NeedCopy-->
```

## Configure log action for the DNS policy to log client IP address

Logging action can be used to log the source IPs for the DNS queries using the following expression and use it as part of the log action in the DNS policy.

```
1 > add audit messageaction log_act_custom INFORMATIONAL "\"ClientIP:\"
 CLIENT.IP.SRC\" ECS IP:\"+((DNS.REQ.OPT.ECS.IP).typecast_text_t ALT
 \"NONE\")"
2 Done
3 <!--NeedCopy-->
```

The earlier expression captures both the source IP as in the IP header and the ECS IP from the DNS ECS option, and either of it can be excluded as required.

## Sample DNS logging configuration for a NetScaler appliance to log client IP address

If you want to sample the logging of the DNS queries, it can be done using the following expression. This will log one out of 10 queries.

```
1 > add audit messageaction log_action_srcip_1of10 INFORMATIONAL "\"
 OneOf10: Source IP : \"+client.ip.src"
2 Done
3 > add responder policy logsrcip_1of10 "sys.random.mul(10).lt(1)" NOOP -

## Configuring DNS suffixes

May 2, 2023

You can configure DNS suffixes that enable the NetScaler appliance to complete non-fully qualified domain names during name resolution. For example, while resolving a not fully qualified domain name abc, if a DNS suffix example.com is configured, the appliance appends the suffix to the domain name. Then it resolves the domain name. In this case, it would resolve abc.example.com. If DNS suffixes are not configured, the appliance appends a period to the non-fully qualified domain names and resolves the domain name.

## Create DNS suffixes

DNS suffixes have significance and are valid only when the NetScaler is configured as an end resolver or forwarder. You can specify a suffix of up to 127 characters.

### Notes:

- The order of DNS suffixes is important. The ADC appliance tries the configured suffixes in a serial order and stops when it gets a successful response for a suffix.
- At a time only one domain name is processed. All the available suffixes are appended with the domain name until a successful response is received.

**For Example:** If the domain name is `www` and the suffixes are `abc.com` and `abc`. The NetScaler appliance tries `www.abc.com` first and if that does not return a successful response, then the appliance tries `www.abc`. If `www.abc.com` returns a successful response, then the appliance will not try with the next suffix.

- The appliance uses all the suffixes in the order in which they are added until it receives a successful response.

## Create DNS suffixes by using the CLI

At the command prompt, type the following commands to create a DNS suffix and verify the configuration:

```
1 - add dns suffix <dnsSuffix>
2 - show dns suffix <dnsSuffix>
3 <!--NeedCopy-->
```

### Example:

```
1 > add dns suffix example.com
2 Done
3 > show dns suffix example.com
4 1) Suffix: example.com
5 Done
6
7 <!--NeedCopy-->
```

To remove a DNS suffix by using the NetScaler command line, at the command prompt, type the `rm dns suffix` command and the name of the DNS suffix.

## Create DNS suffixes by using the GUI

Navigate to **Traffic Management > DNS > DNS Suffix** and create DNS suffixes.

## DNS ANY query

May 2, 2023

An ANY query is a type of DNS query that retrieves all records available for a domain name. The ANY query must be sent to a name server that is authoritative for a domain.

### Behavior in ADNS mode

In the ADNS mode, the NetScaler appliance returns the records held in its local cache. If there are no records in the cache, the appliance returns the NXDOMAIN (negative) response.

If the NetScaler can match the domain delegation records, it returns the NS records. Otherwise, it returns the NS records of the root domain.

### Behavior in DNS proxy mode

In proxy mode, the NetScaler appliance checks its local cache. If there are no records in the cache, the appliance passes the query to the server.

### Behavior for Global Server Load Balancing (GSLB) domains

If a GSLB domain is configured on the ADC appliance and an ANY query is sent for the GSLB (site) domain, the appliance returns the IP address of the GSLB service. It selects this service through a load balancing decision. If the multiple IP response (MIR) option is enabled, the IP addresses of all GSLB services are sent.

For the NetScaler to return these records when it responds to the ANY query, all records corresponding to a GSLB domain must be configured on the NetScaler.

#### Note

If records for a domain are distributed between the NetScaler and a server, only records configured on the NetScaler are returned.

The NetScaler provides the option to configure DNS views and DNS policies. These views and policies are used for performing global server load balancing. For more information, see [Global Server Load Balancing](#).

## Configure negative caching of DNS records

May 2, 2023

The NetScaler appliance supports caching of negative responses for a domain. A negative response indicates that information about a requested domain does not exist, or that the server cannot provide an answer for the query. The storage of this information is called negative caching. Negative caching helps speed up responses to queries about a domain.

### Note:

Negative caching is supported only when the back-end server is configured as an authoritative DNS (ADNS) server for the queried domain.

A negative response can be one of the following:

- NXDOMAIN error message —The authoritative DNS servers respond with the NXDOMAIN error message when the queried domain name does not have any records configured on the server. This message implies that the queried domain is an invalid or a non-existent domain name.
- NODATA error message —If the domain name in the query is valid but records of the given type are not available, the appliance sends a NODATA error message.

When negative caching is enabled, the appliance caches the negative response from the DNS server and serves the future requests from the cache only. This action helps speed up responses to queries and also to reduce the back-end DNS traffic. Negative caching can be used in all deployments, that is, when a NetScaler appliance is serving as a proxy, as an end resolver, or as a forwarder.

You can enable or disable negative caching using a DNS profile, for more information see, [DNS profiles](#). By default, negative caching is enabled in the default DNS profile (`default-dns-profile`) that are bound by default to a DNS virtual server or in the newly created DNS profile.

### Enable or disable negative caching by using the CLI

At the command prompt, type the following commands to enable or disable negative caching and verify the configuration:

```
1 - add dns profile <dnsProfileName> [-cacheRecords (ENABLED | DISABLED
)] [-cacheNegativeResponses (ENABLED | DISABLED)]
2 - show dns profile [<dnsProfileName>]
3 <!--NeedCopy-->
```

### Example of a default DNS profile:

```
1 > sh dns profile default-dns-profile
```

```

2 1) default-dns-profile
3 Query logging : DISABLED Answer section logging :
 DISABLED
4 Extended logging : DISABLED Error logging : DISABLED
5 Cache Records : ENABLED Cache Negative Responses: ENABLED
6 Done
7 <!--NeedCopy-->

```

### Example of a newly created DNS profile:

```

1 > add dnsprofile dns_profile1 -cacheRecords ENABLED -
 cacheNegativeResponses ENABLED
2 Done
3 > show dns profile dns_profile1
4 1) dns_profile1
5 Query logging : DISABLED Answer section logging :
 DISABLED
6 Extended logging : DISABLED Error logging : DISABLED
7 Cache Records : ENABLED Cache Negative Responses: ENABLED
8 Done
9 <!--NeedCopy-->

```

### Specify service or virtual server level DNS parameters by using the CLI

At the command prompt, perform the following:

1. Configure the DNS profile.

```
add dns profile <dnsProfileName> [-cacheRecords (ENABLED |
 DISABLED)] [-cacheNegativeResponses (ENABLED | DISABLED)]
```

2. Bind the DNS profile to the service or virtual server.

To bind the DNS profile to the service:

```
set service <name> [-dnsProfileName <string>]
```

#### Example:

```

1 >set service service1 -dnsProfileName dns_profile1
2 Done
3 <!--NeedCopy-->

```

To bind the DNS profile to the virtual server:

```
set lb vserver <name> [-dnsProfileName <string>]
```

#### Example:

```

1 >set lb vserver lbvserver1 -dnsProfileName dns_profile1
2 Done
3 <!--NeedCopy-->

```

## Specify service or virtual server level DNS parameters by using the GUI

1. Configure the HTTP profile.

Navigate to **System > Profiles > DNS Profile**, and create the DNS profile.

2. Bind the HTTP profile to the service or virtual server.

Navigate to **Traffic Management > Load Balancing > Services/Virtual Servers**, and create the DNS profile, that must be bound to the service or the virtual server.

## Rate limiting negative response served by the appliance

You can set a threshold for negative responses being served by the NetScaler appliance from the cache. When the threshold is set, the appliance serves the response from the cache until the threshold is reached. Once the threshold is reached, the appliance drops the requests instead of responding with an NXDOMAIN response.

Setting a rate limit for negative responses has the following advantages.

- Save the resources on the NetScaler appliance.
- Prevent any malicious queries for non-existent domain names.

**Note:** You can set a threshold for negative responses only for the domains for which the ADC appliance is configured as an authoritative domain name server. You cannot set a threshold for cached records received from the authoritative back-end name servers.

## Rate limiting negative response served by the cache by using the CLI

At the command prompt, type

```
1 set dns parameter -NXDOMainRateLimitThreshold <positive-integer>
2 <!--NeedCopy-->
```

### Example:

```
1 set dns parameter -NXDOMainRateLimitThreshold 1000
2 <!--NeedCopy-->
```

**NXDOMainRateLimitThreshold:** When this parameter is set to a positive integer value, responses are served from the cache until this threshold (in seconds) is reached. Once the threshold exceeds, the requests are dropped. The threshold configured is per packet engine.

### Rate limiting negative response served by the cache by using the GUI

1. Navigate to **Traffic Management > DNS** and click **Change DNS Settings**.
2. In the **Configure DNS parameters** page, in the **NXDOMAIN Rate Limit Threshold** field, enter the threshold value until which the responses must be served from the cache.

**Note:** The value in the **NXDOMAIN Threshold Crossed** displays the number of times the requests are dropped after the threshold is reached.

### Cache EDNS0 client subnet data when the NetScaler appliance is in proxy mode

December 4, 2023

In NetScaler Proxy mode, if a back-end server that supports an EDNS0 Client Subnet (ECS) sends a response containing the ECS option, the NetScaler appliance does the following:

- It forwards the response as-is to the client and
- Stores the response in the cache, along with the client subnet information.

DNS requests that are from the same subnet of the same domain, and for which the server would send the same response, are then served from the cache.

**Note:**

- ECS caching is disabled by default. Enable caching of EDNS0 client-subnet data in the associated DNS profile.
- The number of subnets that you can cache for a domain is limited to the available subnet IDs, that is, 1270 in the NetScaler appliance. Optionally, you can set the limit to a lower number (minimum value: 1 ipv4/ipv6).

### Enable caching of ECS responses by using the CLI

At the command prompt, type:

```
set dns profile <dnsProfileName> -cacheECSResponses (ENABLED |
DISABLED)
```

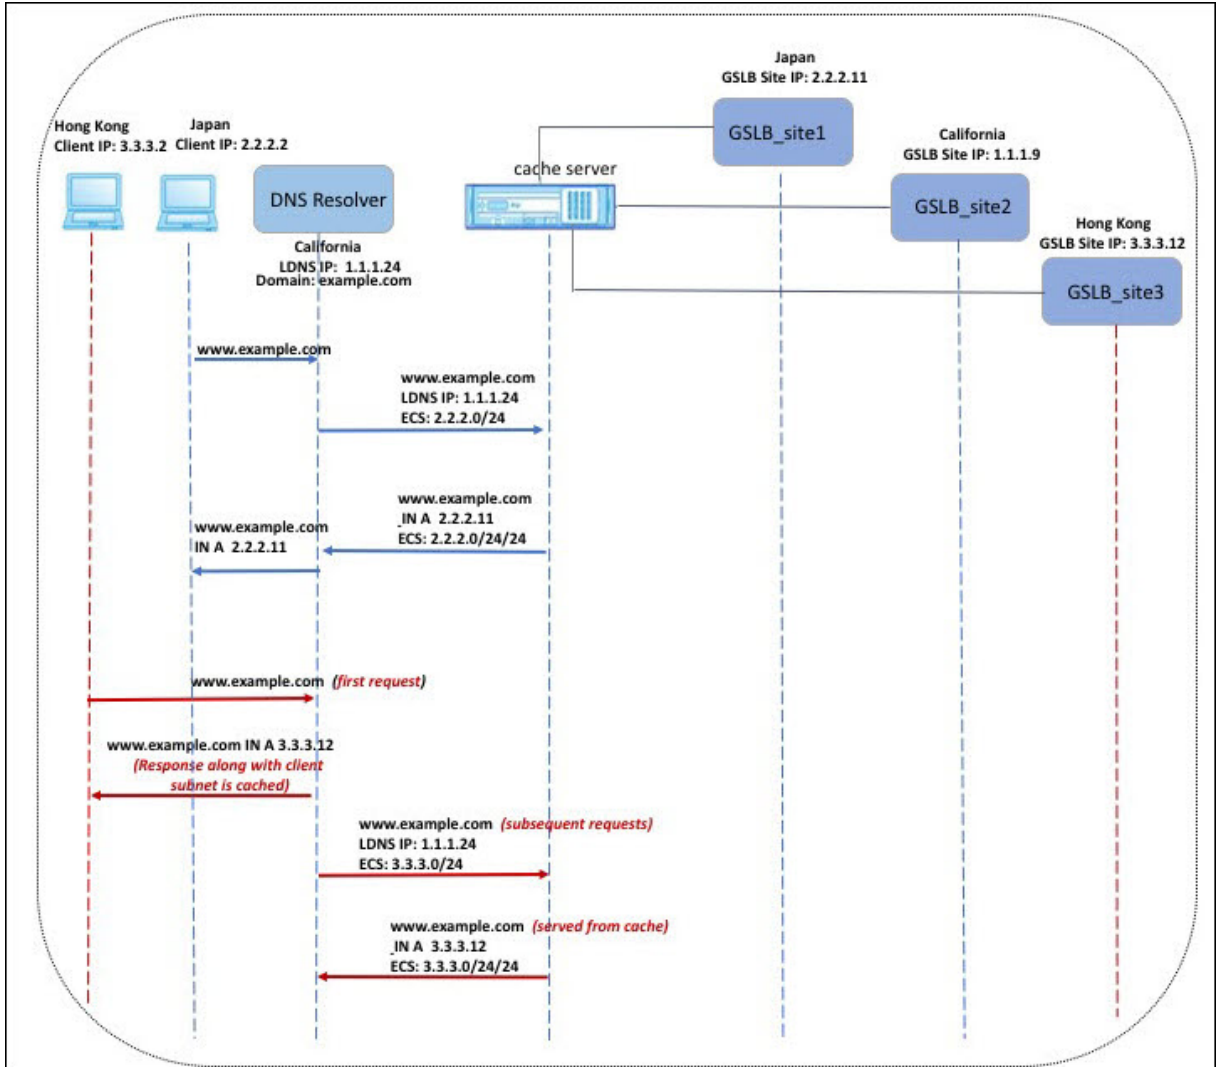

### Limit the number of subnets that can be cached per domain by using the CLI

At the command prompt, type:

```
set dns profile <dnsProfileName> -maxSubnetsPerDomain <positive_integer>
>
```

**Example:**

In the example shown in the preceding figure, the client at IP address 2.2.2.2 sends a query for www.example.com to the DNS resolver. The DNS resolver sends the following response:

www.example.com IN A, IP is 2.2.2.11, and ECS 2.2.2.0/24/24

At this point, the response and the client-subnet identifier (2.2.2.0/24) are cached. Further requests from the same subnet and domain are served from the cache.

For example, if the client’s IP address is 2.2.2.100 and the query is for www.example.com, the query is served from the cache instead of being sent to the back-end server.

## Domain name system security extensions

May 2, 2023

DNS Security Extensions (DNSSEC) is an Internet Engineering Task Force (IETF) standard. It aims to provide data integrity and data origin authentication in communications between name servers and clients while still transmitting UDP responses in clear text. DNSSEC specifies a mechanism that uses asymmetric key cryptography and a set of new resource records that are specific to its implementation.

The DNSSEC specification is described in:

- RFC 4033, “DNS Security Introduction and Requirements”
- RFC 4034, “Resource Records for the DNS Security Extensions”
- RFC 4035, “Protocol Modifications for the DNS Security Extensions”

The operational aspects of implementing DNSSEC within DNS are discussed in RFC 4641, “DNSSEC Operational Practices.”

You can configure DNSSEC on the NetScaler. You can generate and import keys for signing DNS zones. You can configure DNSSEC for zones for which the NetScaler is authoritative. You can configure the ADC as a DNS proxy server for signed zones hosted on a farm of back-end name servers. If the ADC is authoritative for a subset of the records belonging to a zone for which the ADC is configured as a DNS proxy server, you can include the subset of records in the DNSSEC implementation.

## Configure DNSSEC

November 28, 2023

Perform the following steps to configure DNSSEC:

1. Enable DNSSEC on the NetScaler appliance.
2. Create a zone signing key and a key signing key for the zone.
3. Add the two keys to the zone.
4. Sign the zone with the keys.

The NetScaler appliance does not act as a DNSSEC resolver. DNSSEC on the ADC is supported only in the following deployment scenarios:

1. ADNS—NetScaler is the ADNS and generates the signatures itself.

2. Proxy—NetScaler acts as a DNSSEC proxy. It is assumed that the NetScaler is placed in front of the ADNS/LDNS servers in a trusted mode. The ADC acts only as a proxy caching entity and does not validate any signatures.

## Enable and disable DNSSEC

Enable DNSSEC on the NetScaler for the ADC to respond to DNSSEC-aware clients. By default, DNSSEC is enabled.

You can disable the DNSSEC feature if you do not want the NetScaler to respond to clients with DNSSEC-specific information.

### Enable or disable DNSSEC by using the CLI

At the command prompt, type the following commands to enable or disable DNSSEC and verify the configuration:

```
1 - set dns parameter -dnssec (ENABLED | DISABLED)
2 - show dns parameter
3 <!--NeedCopy-->
```

### Example:

```
1 > set dns parameter -dnssec ENABLED
2 Done
3 > show dns parameter
4 DNS parameters:
5 DNS retries: 5
6 .
7 .
8 .
9 DNSEC Extension: ENABLED
10 Max DNS Pipeline Requests: 255
11 Done
12
13 <!--NeedCopy-->
```

### Enable or disable DNSSEC by using the GUI

1. Navigate to **Traffic Management > DNS**.
2. In the details pane, click Change DNS settings.
3. In the **Configure DNS Parameters** dialog box, select or clear the **Enable DNSSEC Extension** check box.

## Create DNS keys for a zone

For each DNS zone that you want to sign, you must create two pairs of asymmetric keys. One pair, called the zone signing key (ZSK), is used to sign all the resource record sets in the zone. The second pair is called the key signing key (KSK) and is used to sign only the DNSKEY resource records in the zone.

When the ZSK and the KSK are created, the `suffix.key` is appended to the names of the public components of the keys. The `suffix.private` is appended to the names of their private components. The appending happens automatically.

The NetScaler also creates a Delegation Signer (DS) record and appends the suffix `.ds` to the name of the record. If the parent zone is a signed zone, you must publish the DS record in the parent zone to establish the chain of trust.

When you create a key, the key is stored in the `/nsconfig/dns/` directory, but it is not automatically published in the zone. After you create a key by using the `create dns key` command, you must explicitly publish the key in the zone by using the `add dns key` command. The process of generating a key is separate from the process of publishing the key in a zone to enable you to use alternative means to generate keys. For example, you can import keys generated by other key-generation programs (such as `bind-keygen`) by using the Secure FTP (SFTP) and then publish the keys in the zone. For more information about publishing a key in a zone, see [Publish a DNS key in a zone](#).

Perform the steps described in this topic to create a zone signing key and then repeat the steps to create a key signing key. The example that follows the command syntax first creates a zone signing key pair for the zone `example.com`. The example then uses the command to create a key signing key pair for the zone.

From release 13.0 build 61.x, the NetScaler appliance now supports stronger crypto algorithms, such as RSASHA256 and RSASHA512, to authenticate a DNS zone. Previously, only the RSASHA1 algorithm was supported.

### Create a DNS key by using the CLI

At the command prompt, type:

```
create dns key -zoneName <string> -keyType <keyType> -algorithm <algorithm> -keySize <positive_integer> -fileNamePrefix <string>
```

#### Example:

```
1 > create dns key -zoneName example.com -keyType zsk -algorithm
 RSASHA256 -keySize 1024 -fileNamePrefix example.com.zsk.rsasha1.1024
2 File Name: /nsconfig/dns/example.com.zsk.rsasha1.1024.key (public); /
 nsconfig/dns/example.com.zsk.rsasha1.1024.private (private); /
 nsconfig/dns/example.com.zsk.rsasha1.1024.ds (ds)
```

```
3 This operation may take some time, Please wait...
4 Done
5 > create dns key -zoneName example.com -keyType ksk -algorithm
 RSASHA512 -keySize 4096 -fileNamePrefix example.com.ksk.rsasha1.4096
6 File Name: /nsconfig/dns/example.com.ksk.rsasha1.4096.key (public); /
 nsconfig/dns/example.com.ksk.rsasha1.4096.private (private); /
 nsconfig/dns/example.com.ksk.rsasha1.4096.ds (ds)
7 This operation may take some time, Please wait...
8 Done
9 <!--NeedCopy-->
```

### Create a DNS key by using the GUI

1. Navigate to **Traffic Management > DNS**.
2. In the details area, click **Create DNS Key**.
3. Enter values for the different parameters and click **Create**.

## ← Create DNS Key

Zone Name\*

Type\*

Algorithm\*

 ⓘ

Size\*

File Name Prefix\*

 ⓘ

Passphrase For Encrypted Keys

 ⓘ

Note: To modify the file name prefix of an existing key:

- Click the arrow next to the **Browse** button.
- Click either **Local** or **Appliance** (depending on whether the existing key is stored on your local computer or in the `/nsconfig/dns/` directory on the appliance)
- Browse to the location of the key, and then double-click the key.  
The **File Name Prefix** box is populated with only the prefix of the existing key. Modify the prefix accordingly.

## Publish a DNS key in a zone

A key (zone signing key or key signing key) is published in a zone by adding the key to NetScaler. A key must be published in a zone before you sign the zone.

Before you publish a key in a zone, the key must be available in the `/nsconfig/dns/` directory. If you created the DNS key on another computer (for example, by using the `bind-keygen` program), ensure that the key is added to the `/nsconfig/dns/` directory. Then publish the key in the zone. Use the ADC GUI to add the key to the `/nsconfig/dns/` directory. Or, use some other program to import the key to the directory, such as the Secure FTP (SFTP).

Use the `add dns key` command for each public-private key pair that you want to publish in a given zone. If you created a ZSK pair and a KSK pair for a zone, use the `add dns key` command to first publish one of the key pairs in the zone. Repeat the command to publish the other key pair. For each key that you publish in a zone, a DNSKEY resource record is created in the zone.

The example that follows the command syntax first publishes the zone signing key pair (that was created for the `example.com` zone) in the zone. The example then uses the command to publish the key signing key pair in the zone.

## Publish a key in a zone by using the CLI

At the command prompt, type the following command to publish a key in a zone and verify the configuration:

```
1 - add dns key <keyName> <publickey> <privatekey> [-expires <
 positive_integer> [<units>]] [-notificationPeriod <positive_integer>
 [<units>]] [-TTL <secs>]
2 - show dns zone [<zoneName> | -type <type>]
3 <!--NeedCopy-->
```

## Example:

```
1 > add dns key example.com.zsk example.com.zsk.rsasha1.1024.key example.
 com.zsk.rsasha1.1024.private -expires 121 -TTL 5
2 Done
3 > add dns key example.com.ksk example.com.ksk.rsasha1.4096.key example.
 com.ksk.rsasha1.4096.private -expires 121 -TTL 5
4 Done
5 > show dns zone example.com
6 Zone Name : example.com
7 Proxy Mode : NO
8 Domain Name : example.com
9 Record Types : NS SOA DNSKEY
10 Domain Name : ns1.example.com
11 Record Types : A
12 Domain Name : ns2.example.com
13 Record Types : A
```

```

14 Done
15 <!--NeedCopy-->

```

### Publish a key in a DNS zone by using the GUI

Navigate to **Traffic Management > DNS > Keys**.

**Note:** For Public Key and Private Key, to add a key that is stored on your local computer, click the arrow next to the **Browse** button, click **Local**, browse to the location of the key, and then double-click the key.

### Configure a DNS key

You can configure the parameters of a key that has been published in a zone. You can modify the key's expiry time period, notification period, and time-to-live (TTL) parameters. If you change the expiry time period of a key, the appliance automatically re-signs all the resource records in the zone with the key. The re-signing happens if the zone is signed with the particular key.

### Configure a key by using the CLI

At the command prompt, type the following command to configure a key and verify the configuration:

```

1 - set dns key <keyName> [-expires <positive_integer> [<units>]] [-
 notificationPeriod <positive_integer> [<units>]] [-TTL <secs>]
2 - show dns key [<keyName>]
3 <!--NeedCopy-->

```

### Example:

```

1 > set dns key example.com.ksk -expires 30 DAYS -notificationPeriod 3
 DAYS -TTL 3600
2 Done
3 > show dns key example.com.ksk
4 1) Key Name: example.com.ksk
5 Expires: 30 DAYS Notification: 3 DAYS TTL: 3600
6 Public Key File: example.com.ksk.rsasha1.4096.key
7 Private Key File: example.com.ksk.rsasha1.4096.private
8 Done
9 <!--NeedCopy-->

```

### Configure a key by using the GUI

1. Navigate to **Traffic Management > DNS > Keys**.

2. In the details pane, click the key that you want to configure, and then click Open.
3. In the Configure DNS Key dialog box, modify the values of the following parameters as shown:
  - Expires—expires
  - Notification Period—notificationPeriod
  - TTL—TTL
4. Click OK.

### Sign and unsign a DNS zone

To secure a DNS zone, you must sign the zone with the keys that have been published in the zone. When you sign a zone, the NetScaler creates a Next Secure (NSEC) resource record for each owner name. Then, it uses the key signing key to sign the DNSKEY resource record set. Finally, it uses the ZSK to sign all the resource record sets in the zone, including the DNSKEY resource record sets and NSEC resource record sets. Each sign operation results in a signature for the resource record sets in the zone. The signature is captured in a new resource record called the RRSIG resource record.

After you sign a zone, save the configuration.

### Sign a zone by using the CLI

At the command prompt, type the following command to sign a zone and verify the configuration:

```
1 - sign dns zone <zoneName> [-keyName <string> ...]
2 - show dns zone [<zoneName> | -type (ADNS | PROXY | ALL)]
3 - save config
4 <!--NeedCopy-->
```

### Example:

```
1 > sign dns zone example.com -keyName example.com.zsk example.com.ksk
2 Done
3 > show dns zone example.com
4 Zone Name : example.com
5 Proxy Mode : NO
6 Domain Name : example.com
7 Record Types : NS SOA DNSKEY RRSIG NSEC
8 Domain Name : ns1.example.com
9 Record Types : A RRSIG NSEC
10 Domain Name : ns2.example.com
11 Record Types : A RRSIG
12 Domain Name : ns2.example.com
13 Record Types : RRSIG NSEC
14 Done
15 > save config
16 Done
```

```
17 <!--NeedCopy-->
```

## Unsign a zone by using the CLI

At the command prompt, type the following command to unsign a zone and verify the configuration:

```
1 - unsign dns zone <zoneName> [-keyName <string> ...]
2 - show dns zone [<zoneName> | -type (ADNS | PROXY | ALL)]
3 <!--NeedCopy-->
```

### Example:

```
1 > unsign dns zone example.com -keyName example.com.zsk example.com.ksk
2 Done
3 > show dns zone example.com
4 Zone Name : example.com
5 Proxy Mode : NO
6 Domain Name : example.com
7 Record Types : NS SOA DNSKEY
8 Domain Name : ns1.example.com
9 Record Types : A
10 Domain Name : ns2.example.com
11 Record Types : A
12 Done
13 <!--NeedCopy-->
```

## Sign or unsign a zone by using the GUI

1. Navigate to **Traffic Management > DNS > Zones**.
2. In the details pane, click the zone that you want to sign, and then click Sign/Unsign.
3. In the Sign/Unsign DNS Zone dialog box, do one of the following:
  - To sign the zone, select the check boxes for the keys (zone signing key and key signing key) with which you want to sign the zone.  
You can sign the zone with more than one zone signing key or key signing key pair.
  - To unsign the zone, clear the check boxes for the keys (zone signing key and key signing key) with which you want to unsign the zone.  
You can unsign the zone with more than one zone signing key or key signing key pair.
4. Click OK.

## View the NSEC records for a given record in a zone

You can view the NSEC records that the NetScaler automatically creates for each owner name in the zone.

### View the NSEC record for a given record in a zone by using the CLI

At the command prompt, type the following command to view the NSEC record for a given record in a zone:

```
show dns nsecRec [<hostName> | -type (ADNS | PROXY | ALL)]
```

#### Example:

```
1 > show dns nsecRec example.com
2 1) Domain Name : example.com
3 Next Nsec Name: ns1.example.com
4 Record Types : NS SOA DNSKEY RRSIG NSEC
5 Done
6 <!--NeedCopy-->
```

### View the NSEC record for a given record in a zone by using the GUI

1. Navigate to **Traffic Management > DNS > Records > Next Secure Records**.
2. In the details pane, click the name of the record for which you want to view the NSEC record. The NSEC record for the record you select is displayed in the Details area.

### Remove a DNS key

Remove a key from the zone in which it is published when the key has expired or if the key has been compromised. When you remove a key from the zone, the zone is automatically unsigned with the key. Removing the key with this command does not remove the key files present in the /nsconfig/dns/ directory. If the key files are no longer needed, they have to be explicitly removed from the directory.

### Remove a key from the NetScaler by using the CLI

At the command prompt, type the following command to remove a key and verify the configuration:

```
1 - rm dns key <keyName>
2 - show dns key <keyName>
3 <!--NeedCopy-->
```

#### Example:

```
1 > rm dns key example.com.zsk
2 Done
3 > show dns key example.com.zsk
4 ERROR: No such resource [keyName, example.com.zsk]
5
6 <!--NeedCopy-->
```

## Remove a key from the NetScaler by using the GUI

1. Navigate to **Traffic Management > DNS > Keys**.
2. In the details pane, click the name of the key that you want to remove from the ADC, and then click Remove.

## Revoke a DNS key

Although the key rollover is usually scheduled in advance, sometimes it becomes necessary to roll over the key immediately if the key is suspected to be compromised. In such cases, the compromised key must be phased out quickly before the new key can be activated. To ensure a smooth transition, it is recommended to keep a secondary key in a ready state, which can be activated immediately in case the key is compromised. By using the revoke key method, you can save time in activating the secondary key and removing the compromised key.

### Note:

If you revoke the key it will remain in the system unless you explicitly delete it. Since the auto-rollover option is set, the system will auto-rollover the key after the configured expiration date if you do not delete it manually. During the auto-rollover process, a new key will be created for you to use based on your needs.

## Enable revoke using CLI

At the command prompt type:

```
set dns key <keyName> [-revoke]
```

Example:

```
Set dns key secure.example.zsk -revoke
```

## Enable revoke using GUI

1. Navigate to **Traffic Management > DNS > Keys**.
2. In the details pane, click the key that you want to configure, and then click **Open**.
3. In the **Configure DNS Key** page, select or clear **Revoke**.
4. Click **Ok**.

## Automatic key rollover

In NetScaler, you can automate the key rollover process based on the configured frequency period. By automating the rollover process, you can rule out the chances of missing the rollover of keys. NetScaler takes care of creating keys, publishing, activating, signing, and un-signing the key, and removing the old key automatically if the automatic rollover option is enabled. Also, SNMP notification about the addition, activation, and removal of the old key is sent.

**Note:**

If the zone transfer parameter is enabled in GSLB sites, the rollover keys are transferred to all the GSLB sites.

If you are upgrading from a build that doesn't support the zone transfer to one that supports it, enable the rollover feature for an existing key. Before enabling the key rollover option, ensure that the key has not expired.

## Configure automatic key rollover using CLI

At the command prompt, type:

```
1 set dns key <keyName> [-autoRollover (ENABLED | DISABLED)] [-
 RolloverMethod <PrePublication | DoubleSignature | DoubleRRset>]
2 <!--NeedCopy-->
```

Example:

```
Set dns key secure.example.zsk - autoRollover Enabled -RolloverMethod
Prepublication
```

## Configure automatic key rollover using GUI

1. Navigate to **Traffic Management > DNS > Keys**.
2. In the details pane, click the key that you want to configure, and then click Open.
3. In the **Configure DNS Key** page, update the following parameters:
  - Auto Rollover - Enable the option to automate the key rollover.
  - Rollover Method - Select a rollover method.
4. Click Ok.

## SNMP Alarm

you can enable the SNMP alarm for the DNSSEC keys events when auto-rollover is enabled. When you enable an SNMP alarm, NetScaler generates a corresponding alarm (DNSSEC-KEY-AUTOMGMT-STATUS-SUCCESS or DNSSEC-KEY-AUTOMGMT-STATUS-FAILURE) based on whether the event is successful or a failure. For example, when you create a DNSSEC Key and the create event is successful, a DNSSEC-KEY-AUTOMGMT-STATUS-SUCCESS alarm is generated.

For more information on SNMP alarm, see [Configuring the NetScaler to generate SNMP traps] (/en-us/citrix-adc/current-release/system/snmp/generating-snmp-traps-on-citrix-adc.html)

## DNS Zone Transfer

To synchronize the DNSSEC keys with other DNS servers, you must enable the Zone Transfer parameter. Synchronizing the keys from one DNS server to other DNS servers in the GSLB site is possible only if the AutomaticConfigSync option is enabled. For more information on real-time synchronization, see Real-time synchronization between sites participating in GSLB.

The DNS zone transfer is possible in Netscaler where GSLB is configured for each DNS server in a different location.

For more information on synchronization, see [Synchronize the configuration in a GSLB setup](#).

The DNS zone transfer is possible in NetScaler where GSLB is configured. Ensure you configure GSLB for each DNS server in a different location.

### Enable or disable zone transfer using CLI

At the command prompt, type:

```
set dns parameter - ZoneTransfer (ENABLED | DISABLED)
```

Example:

```
1 set dns parameter - ZoneTransfer ENABLED
2
3 Done
4 <!--NeedCopy-->
```

### Enable or disable zone transfer using GUI

1. Navigate to **Traffic Management > DNS**.
2. In the details pane, under **Settings**, click **Change DNS settings**.
3. In the **Configure DNS Parameters** page, select or clear **Zone Transfer**.

## Configure DNSSEC when the NetScaler is authoritative for a zone

May 2, 2023

When the NetScaler is authoritative for a given zone, all the resource records in the zone are configured on the ADC. To sign the authoritative zone, you must create the zone signing and the key signing keys for the zone, add the keys to the ADC, and then sign the zone. For more information, see:

- [Create DNS keys for a zone](#)
- [Publish a DNS key in a zone](#)
- [Sign and unsign a DNS zone.](#)

If any GSLB domains configured on the ADC belong to the zone being signed, the GSLB domain names are signed along with the other records that belong to the zone.

After you sign a zone, responses to requests from DNSSEC-aware clients include the RRSIG resource records along with the requested resource records. DNSSEC must be enabled on the ADC. For more information about enabling DNSSEC, see [Enable and disable DNSSEC](#).

Finally, after you configure DNSSEC for the authoritative zone, you must save the NetScaler configuration.

## Configure DNSSEC for a zone for which the NetScaler is a DNS proxy server

May 2, 2023

The procedure for signing a zone for which the NetScaler is configured as a DNS proxy server depends on whether the ADC owns a subset of the zone information owned by the back-end name servers. If it does, the configuration is considered a partial zone ownership configuration. If the ADC does not own a subset of the zone information, the NetScaler configuration for managing the back-end servers is considered a zone-less DNS proxy server configuration. The basic DNSSEC configuration tasks for both NetScaler configurations are the same. However, signing the partial zone on the NetScaler requires some additional configuration steps.

**Note:** The terms zone-less proxy server configuration and partial zone are used only in the context of the NetScaler appliance.

**Important:** When configured in proxy mode, the ADC does not perform signature verification on DNSSEC responses before updating the cache.

If you configure the ADC as a DNS proxy to load balance DNSSEC aware resolvers (servers), you must set the Recursion Available option while configuring the DNS virtual server. If a DNSSEC query arrives with Checking Disabled (CD) bit set, the query is passed on to the server with the CD bit retained. The response from the server is not cached.

### **Configure DNSSEC for a zone-less DNS proxy server configuration**

For a zone-less DNS proxy server configuration, zone signing must be performed on the back-end name servers. On the NetScaler, you configure the ADC as a DNS proxy server for the zone. Create a load balancing virtual server of protocol type DNS. Configure services on the ADC to represent the name servers. Then bind the services to the load balancing virtual server. For more information about these configuration tasks, see [Configure the NetScaler as a DNS proxy server](#).

When a client sends the ADC a DNS request with the DNSSEC OK (DO) bit set, the ADC checks its cache for the requested information. If the resource records are not available in its cache, the ADC forwards the request to one of the DNS name servers. Then, it relays the response from the name server to the client. Also, the ADC caches the RRSIG resource records along with the response from the name server. Subsequent requests from DNSSEC-aware clients are served from the cache (including the RRSIG resource records), subject to the time-to-live (TTL) parameter. If a client sends a DNS request without setting the DO bit, the ADC responds with only the requested resource records. It does not include the RRSIG resource records that are specific to DNSSEC.

### **Configure DNSSEC for a partial zone ownership configuration**

In some ADC configurations, even though the authority for a zone lies with the back-end name servers, a subset of the resource records belonging to the zone might be configured on the ADC. The ADC owns (or is authoritative for) only this subset of records. Such a subset of records can be considered to constitute a *partial zone* on the ADC. The ADC owns the partial zone. All other records are owned by the back-end name servers.

A typical partial zone configuration on the NetScaler is seen when:

- Global Server Load Balancing (GSLB) domains are configured on the ADC
- The GSLB domains are a part of a zone for which the back-end name servers are authoritative.

Signing a zone that includes only a partial zone on the ADC involves:

- Including the partial zone information in the back-end name server zone files
- Signing the zone on the back-end name servers
- Signing the partial zone on the ADC.

The same key set must be used to sign the zone on the name servers and the partial zone on the ADC.

### Sign the zone on the back-end name servers

1. Include the resource records that are contained in the partial zone, in the zone files of the name servers.
2. Create keys and use the keys to sign the zone on the back-end name servers.

### Sign the partial zone on the NetScaler

1. Create a zone with the name of the zone owned by the back-end name servers. When configuring the partial zone, set the proxyMode parameter to YES. This zone is the partial zone that contains the resource records owned by the ADC.

For example, if the name of the zone that is configured on the back-end name servers is example.com, you must create a zone named example.com on the ADC. Set the proxyMode parameter to YES. For more information about adding a zone, see [Configure a DNS zone](#).

#### Note

Do not add SOA and NS records for the zone. These records must exist on the ADC for a zone for which the ADC is authoritative.

2. Import the keys (from one of the back-end name servers) to the ADC and then add them to the /nsconfig/dns/ directory. For more information about how you can import a key and add it to the ADC, see [Publish a DNS key in a zone](#).
3. Sign the partial zone with the imported keys. When you sign the partial zone with the keys, the ADC generates RRSIG and NSEC records for the resource record sets and individual resource records in the partial zone, respectively. For more information about signing a zone, see [sign and unsign a DNS zone](#).

## Configure DNSSEC for global server load balancing (GSLB) domain names

May 2, 2023

If GSLB is configured on the NetScaler and the ADC is authoritative for the zone to which the GSLB domain names belong, all GLSB domain names are signed when the zone is signed. For more information about signing a zone for which the ADC is authoritative, see [Configure DNSSEC when the NetScaler appliance is authoritative for a zone](#).

If the GSLB domains belong to a zone for which the back-end name servers are authoritative, you must:

- First sign the zone on the name servers.
- Then sign the partial zone on the ADC to complete the DNSSEC configuration for the zone.

For more information, see [Configure DNSSEC for a partial zone ownership configuration](#).

## Zone maintenance

November 28, 2023

From a DNSSEC perspective, zone maintenance involves rolling over Zone Signing Keys and Key Signing Keys when key expiry is imminent. These zone maintenance tasks can be performed manually or you can automate the process by enabling the auto rollover feature. When automated, the zone is re-signed automatically. However, manual intervention is required to update the DS record in the parent zone.

### Re-sign an updated zone

When a zone is updated (add a record or modify an existing record), the appliance automatically re-signs the new (or modified) record. If a zone contains multiple zone signing keys, the appliance re-signs the new (or modified) record with the key used to sign the zone.

### Zone Transfer in GSLB

Updating a DNS key in all the GSLB sites can be a time-consuming process, and there is a possibility of missing an update in one or more GSLB sites. To prevent this occurrence, you can use the zone transfer option to synchronize the DNS keys in other GSLB sites after updating it in one DNS server. When the zone transfer is enabled, all the DNS configuration records related to all the zones are synced to other GSLB sites.

**Note:**

Zone or DNSSEC setting is optional for GSLB domains.

To configure the zone transfer, see [Configure DNSSEC](#).

### Roll over DNSSEC keys

**Note:** Manually or automatically roll over the DNSSEC keys (KSK, ZSK) before they expire.

On the NetScaler, you can use the prepublish and double signature methods to perform a rollover of the Zone Signing Key and Key Signing Key. More information about these two rollover methods is available in RFC 4641, “DNSSEC Operational Practices.”

The following topics map commands on the ADC to the steps in the rollover procedures discussed in RFC 4641.

The key expiry notification is sent through an SNMP trap called `dnskeyExpiry`. Three MIB variables, `dnskeyName`, `dnskeyTimeToExpire`, and `dnskeyUnitsOfExpiry` are sent along with the `dnskeyExpiry` SNMP trap. For more information, see *NetScaler SNMP OID Reference* at [NetScaler 12.0 SNMP OID Reference](#). This SNMP alarm is sent only when automatic key rollover option is not enabled.

### Automatic key rollover

Automating the key rollover eliminates the need to keep track of the key expiry date and the chances of missing the rollover of keys. When creating a new key, you can automate the key rollover process on a scheduled date.

To configure an automatic key rollover, see [Configure DNSSEC](#).

### Prepublish key rollover

RFC 4641, “DNSSEC Operational Practices” defines four stages for the prepublish-key rollover method: initial, new DNSKEY, new RRSIGs, and DNSKEY removal. Each stage is associated with a set of tasks that you must perform on the ADC. Following are the descriptions of each stage and the tasks that you must perform. The rollover procedure described here can be used for both Key Signing Keys and Zone Signing Keys.

- **Stage 1: Initial.** The zone contains only those key sets with which the zone has currently been signed. The state of the zone in the initial stage is the state of the zone just before you begin the key rollover process.

**Example:**

Consider the key, `example.com.zsk1`, with which the zone `example.com` is signed. The zone contains only those RRSIGs generated by the `example.com.zsk1` key, which is due for expiry. The Key Signing Key is `example.com.ksk1`.

- **Stage 2: New DNSKEY.** A new key is created and published in the zone. That is, the key is added to the ADC, but the zone is not signed with the new key until the pre-roll phase is complete. In this stage, the zone contains the old key, the new key, and the RRSIGs generated by the old key. Publishing the new key for the complete duration of the pre-roll phase gives the DNSKEY resource record corresponding to the new key time to propagate to the secondary name servers.

**Example:**

A new key `example.com.zsk2` is added to the `example.com` zone. The zone is not signed with `example.com.zsk2` until the pre-roll phase is complete. The `example.com` zone contains DNSKEY resource records for both `example.com.zsk1` and `example.com.zsk2`.

**NetScaler commands:**

Perform the following tasks on NetScaler:

- Create a DNS key by using the `create dns key` command.  
For more information about creating a DNS key, including an example, see [Create DNS keys for a zone](#).
- Publish the new DNS key in the zone by using the `add dns key` command.  
For more information about publishing the key in the zone, including an example, see [Publish a DNS key in a zone](#).

- **Stage 3: New RRSIGs.** The zone is signed with the new DNS key and then unsigned with the old DNS key. The old DNS key is not removed from the zone and remains published until the RRSIGs generated by the old key expire.

**Example:**

The zone is signed with `example.com.zsk2` and then unsigned with `example.com.zsk1`. The zone continues to publish `example.com.zsk1` until the RRSIGs generated by `example.com.zsk1` expire.

**NetScaler commands:**

Perform the following tasks on NetScaler:

- Sign the zone with the new DNS key by using the `sign dns zone` command.
- Unsign the zone with the old DNS key by using the `unsign dns zone` command.

For more information about signing and unsigned a zone, including examples, see [Sign and unsign a DNS zone](#).

- **Stage 4: DNSKEY Removal.** When the RRSIGs generated by the old DNS key expire, the old DNS key is removed from the zone.

**Example:**

The old DNS key `example.com.zsk1` is removed from the `example.com` zone.

**NetScaler commands**

On the ADC, you remove the old DNS key by using the `rm dns key` command. For more information about removing a key from a zone, including an example, see [Remove a DNS key](#).

## Double signature key rollover

RFC 4641, “DNSSEC Operational Practices” defines three stages for double signature key rollover: initial, new DNSKEY, and DNSKEY removal. Each stage is associated with a set of tasks that you must perform on the ADC. Following are the descriptions of each stage and the tasks that you must perform. The rollover procedure described here can be used for both Key Signing Keys and Zone Signing Keys.

- **Stage 1: Initial.** The zone contains only those key sets with which the zone has currently been signed. The state of the zone in the initial stage is the state of the zone just before you begin the key rollover process.

### Example:

Consider the key, `example.com.zsk1`, with which the zone `example.com` is signed. The zone contains only those RRSIGs generated by the `example.com.zsk1` key, which is due for expiry. The Key Signing Key is `example.com.ksk1`.

- **Stage 2: New DNSKEY.** The new key is published in the zone and the zone is signed with the new key. The zone contains the RRSIGs that are generated by the old and the new keys. The minimum duration for which the zone must contain both sets of RRSIGs is the time required for all the RRSIGs to expire.

### Example:

A new key `example.com.zsk2` is added to the `example.com` zone. The zone is signed with `example.com.zsk2`. The `example.com` zone now contains the RRSIGs generated from both keys.

## NetScaler commands

Perform the following tasks on NetScaler:

- Create a DNS key by using the `create dns key` command.

For more information about creating a DNS key, including an example, see [Create DNS keys for a zone](#).

- Publish the new key in the zone by using the `add dns key` command.

For more information about publishing the key in the zone, including an example, see [Publish a DNS key in a zone](#).

- Sign the zone with the new key by using the `sign dns zone` command.

For more information about signing a zone, including examples, see [Sign and unsign a DNS zone](#).

- **Stage 3: DNSKEY Removal.** When the RRSIGs generated by the old DNS key expire, the old DNS key is removed from the zone.

**Example:**

The old DNS key `example.com.zsk1` is removed from the `example.com` zone.

**NetScaler commands:**

On NetScaler, you remove the old DNS key by using the `rm dns key` command.

For more information about removing a key from a zone, including an example, see [Remove a DNS key](#).

**Double-RRset**

RFC 7583, “DNSSEC Key Rollover Timing Considerations” defines three stages for double rrsset rollover: initial, new DNSKEY, and DNSKEY removal. Each stage is associated with a set of tasks that you must perform on NetScaler. Following are the descriptions of each stage and the tasks that you must perform. The rollover procedure described here is used for Key Signing Keys.

- **Stage 1: Initial.** The zone contains only those key sets and records with which the zone has currently been signed. The state of the zone in the initial stage is the state of the zone just before you begin the key rollover process.

**Example:**

Consider the key, `example.com.zsk1`, and `key.example.com.ksk1`, with which the zone `example.com` and DNSSEC Key are signed respectively. The zone contains only those DNSKEY RRSIGs generated by the `example.com.ksk1` key, that are due for expiry.

- **Stage 2: New DNSKEY.** New DNSKEY. The new KSK key is created, and published in the zone. Two DNSSEC Keys and RRSig are available in the zone, one created by old key and one by new key. Update the new DS record in the parent zone. Now, the parent zone has two DS records one for the newly created key and one for the old key.

**Note:**

It might take some time for the DS record to become available in the parent zone.

The zone contains the RRSIGs that are generated by the old and the new keys. In order for the zone to contain both sets of RRSIGs, it is necessary to wait for the expiry of all RRSIGs, which is the TTL value for the DNSKEY record. Additionally, you must consider the propagation delay in the case of DNS hierarchy.

**Example:**

```
1 A new key example.com.ksk2 is added to the example.com zone. The zone
 is signed with example.com.ksk2. The example.com zone now contains
 the RRSIGs generated from both keys.
2
```

```

3 **NetScaler commands**
4
5 Perform the following tasks on NetScaler:
6
7 - Create a DNS key by using the `create dns key` command.
8
9 For more information about creating a DNS key, including an example
 , see [Create DNS keys for a zone](/en-us/citrix-adc/current-
 release/dns/dnssec/configure-dnssec.html).
10
11 - Publish the new key in the zone by using the `add dns key` command.
12
13 For more information about publishing the key in the zone,
 including an example, see [Publish a DNS key in a zone](/en-us/
 citrix-adc/current-release/dns/dnssec/configure-dnssec.html).
14
15 - Sign the zone with the new key by using the `sign dns zone` command.
16
17 For more information about signing a zone, including examples, see
 [Sign and unsign a DNS zone](/en-us/citrix-adc/current-release/
 dns/dnssec/configure-dnssec.html).

```

- **Stage 3: Unsign zone with old key.**

Once sufficient time has elapsed for the new DNSSEC key to be cached in resolvers, zone can be unsigned with old key.

Unsign the zone with the old key by using the `unsign dns zone` command.

For more information about unsigned a zone, including examples, see [Sign and unsign a DNS zone](#).

- **Stage 4: DNSKEY Removal.** When the RRSIGs generated by the old DNS key expire, the old DNS key is removed from the zone.

**Note:**

Ensure that you have unsigned the zone before deleting the key.

```

1 **Example:**
2
3 The old DNS key example.com.ksk1 is removed from the example.com zone.
4
5 **NetScaler commands:**
6
7 On the ADC, you remove the old DNS key by using the `rm dns key`
 command. For more information about removing a key from a zone,
 including an example, see [Remove a DNS key](/en-us/citrix-adc/
 current-release/dns/dnssec/configure-dnssec.html).

```

## Offload DNSSEC operations to the NetScaler

May 2, 2023

For DNS zones for which your DNS servers are authoritative, DNSSEC operations can be offloaded to the ADC appliance. In a DNSSEC offloading deployment, a DNS server sends unsigned responses. The ADC signs the response dynamically before relaying it to the client. The ADC also caches the signed response. Apart from reducing the load on the DNS servers, offloading DNSSEC operations to the ADC gives you the following benefits:

- You can sign records that the DNS servers generate programmatically. Such records cannot be signed by routine zone signing operations performed on the DNS servers.
- You can serve signed responses to clients even if you have not implemented DNSSEC on your servers.

For setting up DNSSEC offloading, you must configure a DNS load balancing virtual server, configure services that represent the DNS servers, and then bind the services to the virtual server. For information about configuring a DNS load balancing virtual server, configuring services, and binding the services to the virtual server, see [Configure a DNS zone](#).

Create a zone entity on the ADC for each DNS zone whose DNSSEC operations you want to offload. For each DNS zone, you must enable the Proxy Mode and DNSSEC Offload parameters. You can optionally configure NSEC record generation for an offloaded zone. To create a DNS zone entity for DNSSEC offloading, follow the instructions in this topic.

To complete the configuration, you must generate DNS keys for the zone, add the keys to the zone, and then sign the zone with the keys. This process is the same as for normal DNSSEC. For information about creating keys, adding keys to a zone, and signing the zone, see [Domain name system security extensions](#).

After you configure DNS offloading, you must flush the DNS cache on the NetScaler. Flushing the DNS cache ensures that any unsigned records in the cache are removed and then replaced by signed records. For information about flushing the DNS cache, see [Flush DNS records](#).

### Enable DNSSEC offloading for a zone by using the CLI

At the command line, type the following commands to enable DNSSEC offloading for a zone and verify the configuration:

```
1 - add dns zone <zoneName> -proxyMode YES -dnssecOffload ENABLED [-nsec
 (ENABLED | DISABLED)
2 - show dns zone
3 <!--NeedCopy-->
```

**Example:**

```
1 > add dns zone example.com -proxyMode YES -dnssecOffload ENABLED nsec
 ENABLED
2 Done
3 > show dns zone example.com
4 Zone Name : example.com
5 Proxy Mode : YES
6 DNSSEC Offload: ENABLED NSEC: ENABLED
7 Done
8 <!--NeedCopy-->
```

**Enable DNSSEC offloading for a zone by using the GUI**

1. Navigate to **Traffic Management > DNS > Zones**.
2. In the details pane, do one of the following:
  - To create a zone on the NetScaler, click Add.
  - To configure DNSSEC offloading for an existing zone, double-click the zone.
3. In the Create DNS Zone or Configure DNS Zone dialog box, select the Proxy Mode and DNSSEC Offload check boxes.
4. Optionally, if you want the NetScaler to generate NSEC records for the zone, select the NSEC check box.

**Admin partition support for DNSSEC**

May 2, 2023

In a partitioned NetScaler appliance, the DNS keys that are generated are stored in the following locations:

- Default partition: /nsconfig/dns/
- Non-default partition: /nsconfig/partitions/<partitionname>/dns/

You can now add a password to the DNS key. To add a password to the DNS key, you must first add the password in the `create dns key` command. Then provide the same password in the `add dns key` command when adding the DNS key to the ADC appliance. For example:

```
create dns key -zoneName com -keytype kSK -algorithm rsASHA1 -keysize
4096 - fileNamePrefix com.ksk.rsasha1.4096 -password 1jsfd3Wa
add dns key com.zsk.4096 /nsconfig/dns/com.zsk.rsasha1.4096.private -
password 1jsfd3Wa
```

**Note:**

- For a default partitioned environment, the keys are read from the default location `/nsconfig/dns/`. However, if the keys are stored in a different location, the path name has to be provided in the `add dns key -private` command. Example, `add dns key -private <path name>`.
- For a non-default partitioned environment, the keys are read from the default location `/nsconfig/partitions/<partitionname>/dns/`.

## Supporting wildcard DNS domains

May 2, 2023

Wildcard DNS domains are used to handle requests for nonexistent domains and subdomains. In a zone, use wildcard domains to redirect queries for all nonexistent domains or subdomains to a particular server, instead of creating a separate Resource Record (RR) for each domain. The most common use of a wildcard DNS domain is to create a zone that can be used to forward mail from the internet to some other mail system.

In DNS resolution, wildcard RRs support the wildcard domain. The wildcard RRs are used to synthesize the responses to queries for a nonexistent domain name. For example, if you queried `http://image.example.com`, and the subdomain “image” did not exist, you might be redirected to `example.com`.

A wildcard record has an asterisk (\*) character as the leftmost label of a domain name. For example, `*.example.com`. An asterisk at any other place in the domain name does signify a wildcard DNS record. For example, `new.*.example.com` is not a valid wildcard DNS record.

**Note**

- Wildcard domain is supported only when the NetScaler appliance is authoritative for the zone and is configured as an ADNS or a DNS proxy server.
- Wildcard domain is not supported for NS and SOA records.
- Wildcard domain cannot be applied when the query is in another zone.
- Wildcard domain cannot be applied when the QNAME or a name between the wildcard domain and the QNAME is known to exist.

### Example configuration

```
1 add dns soaRec example.com -originServer n1.example.com -contact admin.example.com
```

```
2
3 add dns nsRec example.com n1.example.com
4
5 add dns nsRec example.com n2.example.com
6
7 add dns zone example.com -proxyMode no
8
9 add dns addrec www.example.com 2.2.2.2
10
11 add dns addrec *.example.com 10.10.10.10
12
13 add dns addrec *.example.com 10.10.10.11
14
15 add dns aaaarec *.example.com 2001::1
16 <!--NeedCopy-->
```

In the example, a wildcard domain name is added for an A and AAAA record.

When a query is received for a domain name that exists in the zone, the NetScaler appliance responds with the corresponding response. For example, for `www.example.com`, the appliance responds with 2.2.2.2 in the example.

For a nonexistent domain name that matches with a wildcard type, a synthesized response is delivered.

In the example, the NetScaler appliance responds with 10.10.10.10 and 10.10.10.11 for a domain name `nonexist.example.com` or `xyz.example.com`.

Wildcard synthesis is not applicable for a domain name that exists in the zone.

For example, for the query `www.example.com` and type AAAA, the NetScaler appliance does not synthesize with wildcard, because `www.example.com` exists with type A. In the example, the NetScaler appliance responds with a NODATA response.

For a query say `abc.example.com` and type AAAA, the NetScaler appliance responds with a synthesized response. For example, for `www.example.com`, the appliance responds with 2001::1 in the example.

## Mitigate DNS DDoS attacks

May 2, 2023

DNS servers are one of the most critical components of a network, and they must be defended against attacks. One of the most basic types of DNS attacks is the DDoS attack. Attacks of this type are on the rise and can be destructive. You can do the following to mitigate DDoS attacks:

- Flush negative records.

- Restrict the time to live (TTL) of negative records.
- Preserve NetScaler memory by limiting the memory consumed by the DNS cache.
- Retain DNS records in the cache.
- Enable DNS cache bypass.

## Flush negative records

A DNS attack fills the cache with negative records (NXDOMAIN and NODATA). As a result, responses to legitimate requests are not cached, so new requests are sent to a back-end server for DNS resolution. Responses are therefore delayed.

You can now flush the negative DNS records from the NetScaler appliance's DNS cache.

### Flush negative cache records by using the CLI

At the command prompt, type:

```
flush dns proxyrecords -type (dnsRecordType | negRecType)NXDOMAIN |
NODATA
```

#### Example:

```
flush dns proxyrecords -negRecType NODATA
```

### Flush of negative cache records by using the GUI

1. Navigate to **Configuration > Traffic Management > DNS > Records**.
2. In the details pane, click **Flush Proxy Records**.
3. In the **Flush Type** box, select **Negative Records**.
4. In the **Negative Records Type** box, select either **NXDOMAIN** or **NODATA**.

## Protection against random subdomain and NXDOMAIN attacks

To prevent random subdomain and NXDOMAIN attacks, you can restrict the DNS cache memory, and you can adjust the TTL values for negative records.

To limit the amount of memory consumed by the DNS cache, specify the maximum cache size (in MB), and also the cache size (in MB) for storing negative responses. When either limit is reached, no more entries are added to the cache. Also, syslog messages are logged and, if you have configured SNMP traps, SNMP traps are generated. If these limits are not set, caching continues until the system memory is exhausted.

A higher TTL value for negative records can result in storing records that are not valuable for a long time. A lower TTL value results in sending more requests to the back-end server.

The TTL of the negative record is set to a value that can be the lesser of the TTL value or the "Expires" value of the SOA record.

**Note:**

- This limitation is added per packet engine. For example, if the maxCacheSize is set to 5 MB and the appliance has 3 packet engines, the total cache size is 15 MB.
- The cache size for the negative records must be less than or equal to the maximum cache size.
- If you reduce the DNS cache memory limit to a value lower than the amount of data already cached, the cache size remains above the limit until the data ages out. That is, exceeds its TTL0 or is flushed (`flush dns proxyrecords` command, or Flush Proxy Records in the NetScaler GUI).
- To configure SNMP traps, see [Configuring the NetScaler to Generate SNMP Traps](#).

**Limit the memory consumed by the DNS Cache by using the CLI**

At the command prompt, type:

```
set dns parameter -maxCacheSize <MBytes> -maxNegativeCacheSize <MBytes>
```

**Example:**

```
set dns parameter - maxCacheSize 100 -maxNegativeCacheSize 25
```

**Limit the memory consumed by the DNS Cache by using the GUI**

Navigate to **Configuration > Traffic Management > DNS**, click **Change DNS Settings**, and set the following parameters:

- Max Cache Size in MB
- Max Negative Cache Size in MB

**Restrict the TTL of negative records by using the CLI**

At the command prompt, type:

```
set dns parameter -maxnegcacheTTL <secs>
```

**Example:**

```
set dns parameter -maxnegcacheTTL 360
```

### Restrict the TTL of negative records by using the GUI

1. Navigate to **Configuration > Traffic Management > DNS**.
2. Click **Change DNS Settings** and set the **Max Negative Cache TTL in sec** parameter.

### Retain DNS records in the cache

An attack can flood the DNS cache with non-important entries but can cause flushing of the already cached legitimate records to make room for the new entries. To prevent attacks from filling the cache with invalid data, you can retain the legitimate records even after they exceed their TTL values.

If you enable the `cacheNoExpire` parameter, the records currently in the cache are retained until you disable the parameter.

#### Note:

- This option can be used only when the maximum cache size is specified (`maxCacheSize` parameter).
- If `maxnegcacheTTL` is configured and `cacheNoExpire` is enabled, `cacheNoExpire` takes priority.

### Retain DNS records in the cache by using the CLI

At the command prompt, type:

```
set dns parameter -cacheNoExpire (ENABLED | DISABLED)
```

#### Example:

```
set dns parameter -cacheNoExpire ENABLED
```

### Retain DNS records in the cache by using the GUI

1. Navigate to **Configuration > Traffic Management > DNS** and click **Change DNS Settings**.
2. Select **Cache No Expire**.

### Enable DNS cache bypass

For greater visibility and control of DNS requests, set the `cacheHitBypass` parameter to forward all requests to the back-end servers and allow the cache to be built but not used. After the cache is built, you can disable the parameter so that requests are served from the cache.

### Enable DNS cache bypass by using the CLI

At the command prompt, type:

```
set dns parameter -cacheHitBypass (ENABLED | DISABLED)
```

#### Example:

```
set dns parameter -cacheHitBypass ENABLED
```

### Enable DNS cache bypass by using the GUI

1. Navigate to **Configuration > Traffic Management > DNS** and click **Change DNS Settings**.
2. Select **Cache Hit Bypass**.

### Prevent the Slowloris attack

A DNS query spanning multiple packets, presents the potential threat of a [Slowloris](#) attack. The NetScaler appliance can silently drop DNS queries that are split into multiple packets.

You can set the `splitPktQueryProcessing` parameter to ALLOW or DROP a DNS query if the query is split into multiple packets.

**Note:** This setting is applicable only for DNS TCP.

### Limit the DNS queries to a single packet by using the CLI

At the command prompt, type:

```
set dns parameter -splitPktQueryProcessing (ALLOW | DROP)
```

#### Example:

```
set dns parameter -splitPktQueryProcessing DROP
```

### Limit DNS queries to a single packet by using the GUI

1. Navigate to **Configuration > Traffic Management > DNS** and click **Change DNS Settings**.
2. In the **Split Packet Query Processing** box, choose **ALLOW** or **DROP**.

## Collect statistics of the DNS responses served from the cache

You can collect statistics of the DNS responses served from the cache. Then use these statistics to create a threshold beyond which more DNS traffic is dropped, and enforce this threshold with a bandwidth based policy. Previously, bandwidth calculation for a DNS load balancing virtual server was not accurate, because the number of requests served from the cache was not reported.

In proxy mode, the statistics for Request bytes, Response bytes, Total Packets received, and Total Packets sent statistics are continuously updated. Previously, these statistics were not always updated, particularly for a DNS load balancing virtual server.

Proxy mode also now enables you to determine the number of DNS responses served from the cache. To collect these statistics, the following options have been added to the `stat lb vserver <DNSvirtualServerName>` command:

- **Requests** –Total number of requests received by the DNS or DNS\_TCP virtual server. Includes the requests forwarded to the back end and the requests answered from the cache.
- **Vserver hits** –Total number of requests forwarded to the back end. The number of requests served from the cache is the difference between the total number of requests and the number of requests served from the virtual server.
- **Responses** –Total number of responses sent by this virtual server. For example, if a DNS LB virtual server received 5 DNS requests, forwarded 3 of them to the back end, and served 2 of them from the cache, the corresponding value of each of these statistics would be as follows:
  - **Vserver hits:** 3
  - **Requests:** 5
  - **Responses:** 5

## Use case: Configure the automatic DNSSEC key management feature

February 27, 2024

Use the following steps to enable the auto rollover feature on a non-GSLB site.

### Note

Use this procedure if you have a DNS deployment on a NetScaler and not required to replicate it on other devices.

In this example, we have used the following details:

- Domain name: example.com

- Origin Server: nameserver1.example.com
- NameServer: nameserver2.example.com
- Contact: admin.example.com
- Keys: Key 1 for ZSK and Key 2 for KSK

1. Create SOA and NS record (name is to be the same as zone name)

At the command prompt, type:

```
1 add dns soaRec example.com -originServer nameserver1.example.com -
 contact admin.example.com
2 <!--NeedCopy-->
```

2. Create a DNS zone record. Set the proxy mode to No for authoritative zones.

```
1 add dns zone example.com -proxyMode no
2 <!--NeedCopy-->
```

3. Create DNS keys

**Note:**

The command creates three files in the system with the filename prefix: private, key, and ds.

```
1 create dns key -zoneName example.com -fileNamePrefix Key1.zsk -
 keytype zsk -keysize 1024 -algorithm rsASHA256
2 create dns key -zoneName example.com -fileNamePrefix Key2.ksk -
 keytype ksk -keysize 1024 -algorithm rsASHA256
3 <!--NeedCopy-->
```

4. Publish the keys in the zone.

**Note:**

Enable the automatic rollover option and specify the expiration date, along with the notification period. A warning message is displayed regarding the activation of the key.

```
1 add dns key Key1.zsk Key1.zsk.key Key1.zsk.private -autoRollover
 enABLED -expires 30 days -notificationPeriod 7 days -
 rolloverMethod doublesignature
2
3 Warning: The key should be in an activated state for rollover.
 Please use sign DNS zone operation to activate the key
4 Done
5
6 add dns key Key2.ksk Key2.ksk.key Key2.ksk.private -autoRollover
 enABLED -expires 120 days -notificationPeriod 15 days -
 rolloverMethod doublerrSet
7
```

```
8 Warning: The key should be in an activated state for rollover.
 Please use sign DNS zone operation to activate the key
9 Done
10 <!--NeedCopy-->
```

5. Activate the key using the sign zone command.

```
sign dns zone example.com -keyName Key1.zsk Key2.ksk
```

6. Update the DS record for the new key in the parent zone.

7. Enable the auto-save key option in DNS parameters.

```
set dns parameter -autosaveKeyOps enABLED
```

**Note:**

To ensure timely monitoring of all key activity, an SNMP alarm is sent. The SNMP alarms are sent for newly generated keys once the active keys are deleted.

## Use case: Configure the automatic DNSSEC key management on GSLB deployment

February 27, 2024

Perform the following steps to enable the auto rollover feature on a GSLB site. If you want a secondary DNS resolver and want to duplicate the DNS configuration and DNS keys, ensure to have the following configurations:

- Basic GSLB sites
- License for GSLB
- Firewall policies

**Note**

Once the setup is completed, the main primary GSLB does the key rollover operations and synchronization to the subordinates' sites.

In this example, we have used the following details:

- Domain name: example.com
- Origin Server: nameserver1.example.com
- NameServer: nameserver2.example.com
- Contact: admin.example.com

- Keys: Key 1 for ZSK and Key 2 for KSK
1. Enable the `gslbautomaticConfigSync` and `gslbsyncsaveConfig` parameters.

At the command prompt, type:

```
1 set gslb parameter -automaticConfigSync enabled -gslbsyncsaveConfig
 enabled
2
3 Warning: The Saveconfig command might not get applied to GSLB sites
 that are down during the sync operation, so it is recommended to
 apply saveconfig on the master node again when down GSLB site comes
 up.
4 Done
5 <!--NeedCopy-->
```

1. Enable DNS zone transfer in DNS parameters.

At the command prompt, type:

```
1 set dns parameter -zoneTransfer enABLED
2 Done
3 <!--NeedCopy-->
```

2. Create SOA and NS record (name should be the same as zone name).

At the command prompt, type:

```
1 add dns soaRec example.com -originServer nameserver1.example.com -
 contact admin.example.com
2 Done
3 add dns nsrec example.com nameserver2.example.com
4 Done
5 <!--NeedCopy-->
```

3. Create a DNS zone record. Set Proxy mode as No for authoritative zones.

```
1 add dns zone example.com -proxyMode no
2 <!--NeedCopy-->
```

4. Create DNS keys

**Note:**

The command creates three files in the system with the filename prefix: private, key, and ds.

```
1 create dns key -zoneName example.com -fileNamePrefix Key1.zsk -
 keytype zsk -keysize 1024 -algorithm rsASHA256
2 create dns key -zoneName example.com -fileNamePrefix Key2.ksk -
 keytype ksk -keysize 1024 -algorithm rsASHA256
3 <!--NeedCopy-->
```

## 5. Publish the keys in the zone.

**Note:**

Enable the automatic rollover option and specify the expiration date, along with the notification period. A warning message is displayed regarding the activation of the key.

```

1 add dns key Key1.zsk Key1.zsk.key Key1.zsk.private -autoRollover
 enABLED -expires 30 days -notificationPeriod 7 days -
 rolloverMethod doublesignature
2
3 Warning: The key should be in an activated state for rollover.
 Please use sign DNS zone operation to activate the key
4 Done
5
6 add dns key Key2.ksk Key2.ksk.key Key2.ksk.private -autoRollover
 enABLED -expires 120 days -notificationPeriod 15 days -
 rolloverMethod doublerrSet
7
8 Warning: The key should be in an activated state for rollover.
 Please use sign DNS zone operation to activate the key
9 Done
10 <!--NeedCopy-->

```

## 6. Activate the key using the sign zone command.

```

1 sign dns zone example.com -keyName Key1.zsk Key2.ksk
2 <!--NeedCopy-->

```

## 7. Enable the auto-save key option in DNS parameters.

```

1 set dns parameter -autosaveKeyOps enabled
2 <!--NeedCopy-->

```

## 8. Run the show DNS key command.

The show command lists the following details:

- Key state - The state of an existing key.
- Expiry date - The date when the current key expires.
- Notification period - This parameter defines the number of days before the key expires that a notification should be sent.  
In case auto rollover is enabled, a successor key is created at this period before expiry.
- Key Tag - Unique identifier for a key.
- Automatic rollover status - The current state of the automatic rollover.
- Rollover method - Rollover method for the specified key.

```

1 show dns key
2
3 1) Key Name: test1.zsk Key Tag: 33216 Key Type: ZSK

```

```
4 Zone Name: test1.com Key State: Activated
5 Expires: 30 DAYS Notification: 7 DAYS TTL: 5
6 Automatic Rollover: ENABLED Rollover Method: DoubleSignature
7 Public Key File: test1.zsk.key
8 Private Key File: test1.zsk.private
9 Create Time: Wed Oct 11 04:30:40 2023
10 Activation Time: Wed Oct 11 04:32:05 2023
11 Deactivation Time: Fri Nov 10 04:31:05 2023
12 Deletion Time: Fri Nov 10 04:33:05 2023
13 2) Key Name: test1.ksk Key Tag: 5554 Key Type: KSK
14 Zone Name: test1.com Key State: Activated
15 Expires: 120 DAYS Notification: 15 DAYS TTL: 5
16 Automatic Rollover: ENABLED Rollover Method: DoubleRRSet
17 Public Key File: test1.ksk.key
18 Private Key File: test1.ksk.private
19 Create Time: Wed Oct 11 04:31:44 2023
20 Activation Time: Wed Oct 11 04:32:05 2023
21 Deactivation Time: Thu Feb 8 04:31:05 2024
22 Deletion Time: Thu Feb 8 04:33:05 2024
23 Done
24 <!--NeedCopy-->
```

## Use case: How to revoke a compromised active key

February 27, 2024

Perform the following procedure to revoke the compromised active key.

Point to note:

- **Overlap period:** To facilitate a smooth transition, we recommend you to have an overlapping time during which both old and new keys are active.
- **DNSKEY TTL values:** TTL determines the duration DNS records are cached. Set appropriate TTL values to allow for new key activation.
- **Propagation time:** When planning to revoke a compromised key, make sure to consider the time needed for the new key to be updated on all GSLB sites before it can be used.
- **Delay in updating parent zone:** When updating DS records in the parent zone, be aware of potential delays. These delays can impact your domain's security and reliability. Registrars have specific timelines and requirements for updating DS records in the parent zone.

In this use case, the existing keys are key 1 and key 2. Key 1 is active and is used to sign the DNSKEY RRSET. Key 2 is the stand-by key, it is in the DNSKEY RRSet but was not used to sign the RRSet. When the active key (key 1) is compromised, perform the following:

1. Create a key 3

At the command prompt, type:

```
1 create dns key -zoneName example.com -fileNamePrefix Key3.ksk -
 keytype ksk -keysize 1024 -algorithm rsASHA256
2 <!--NeedCopy-->
```

1. Activate the key 2 using the sign zone command.

At the command prompt, type:

```
1 sign dns zone example.com -keyName Key2.ksk
2 Done
3
4 <!--NeedCopy-->
```

1. Update the DS record for the new key in the parent zone.
2. Verify whether the new key is updated in all GSLB sites.
3. Revoke the compromised active key (key 1)

At the command prompt, type:

```
set dns key Key1.ksk -revoke
```

4. Monitor the DNSSEC key status
5. Delete the compromised key (key 1)

**Note:**

If you revoke the key (key 1), it remains in the system unless you explicitly delete it. When the auto-rollover option is set, the system auto-rollovers the key after the configured expiration date if you do not delete it manually. During the auto-rollover process, a new key is created for you to use based on your needs.

At the command prompt, type:

```
rm dns key Key 1
```

Key 2 is now the active key and key 3 is the stand-by key

**Note:**

The revoke procedure is the same for ZSK keys, except for updating the parent zone after deleting the key.

## Firewall Load Balancing

May 2, 2023

Firewall load balancing distributes traffic across multiple firewalls, providing fault tolerance and increased throughput. Firewall load balancing protects your network by:

- Dividing the load between the firewalls, which eliminates a single point of failure and allows the network to scale.
- Increasing high availability.

Configuring a NetScaler appliance for firewall load balancing is similar to configuring load balancing, with the exception that the recommended service type is ANY, recommended monitor type is PING, and the load balancing virtual server mode is set to MAC.

You can set up firewall load balancing in a sandwich, an enterprise, or multiple-firewall environment configuration. The sandwich environment is used for load balancing traffic entering the network from outside and traffic leaving the network to the internet and involves configuring two NetScaler appliances, one on each side of a set of firewalls. You configure an enterprise environment for load balancing traffic leaving the network to the internet. The enterprise environment involves configuring a single NetScaler appliance between the internal network and the firewalls that provide access to the Internet. The multiple-firewall environment is used for load balance traffic coming from another firewall. Having firewall load balancing enabled on both the sides of NetScaler appliance improves the traffic flow in both the egress and ingress direction and ensures faster processing of the traffic. The multiple-firewall environment involves configuring a NetScaler appliance sandwiched between two firewalls.

**Important:** If you configure static routes on the NetScaler appliance for the destination IP address and enable L3 mode, the NetScaler appliance uses its routing table to route the traffic instead of sending the traffic to the load balancing vserver.

**Note:** For FTP to work, an additional virtual server or service should be configured on the NetScaler appliance with IP address and port as \* and 21 respectively, and the service type specified as FTP. In this case, the NetScaler appliance manages the FTP protocol by accepting the FTP control connection, modifying the payload, and managing the data connection, all through the same firewall.

Firewall Load Balancing supports only some of the load balancing methods supported on the NetScaler appliance. Also, you can configure only a few types of persistence and monitors.

### **Firewall Load Balancing Methods**

The following load balancing methods are supported for firewall load balancing.

- Least Connections
- Round Robin
- Least Packets
- Least Bandwidth

- Source IP Hash
- Destination IP Hash
- Source IP Destination IP Hash
- Source IP Source Port hash
- Least Response Time Method (LRTM)
- Custom Load

## Firewall Persistence

Only SOURCEIP, DESTIP, and SOURCEIPDESTIP based persistence are supported for firewall load balancing.

## Firewall Server Monitoring

Only PING and transparent monitors are supported in firewall load balancing. You can bind a PING monitor (default) to the backend service that represents the firewall. If a firewall is configured not to respond to ping packets, you can configure transparent monitors to monitor hosts on the trusted side through individual firewalls.

## Sandwich Environment

May 2, 2023

A NetScaler deployment in a sandwich mode can load balance network traffic through firewalls in both directions: ingress (traffic entering the network from the outside, such as the internet) and egress (traffic leaving the network to the internet).

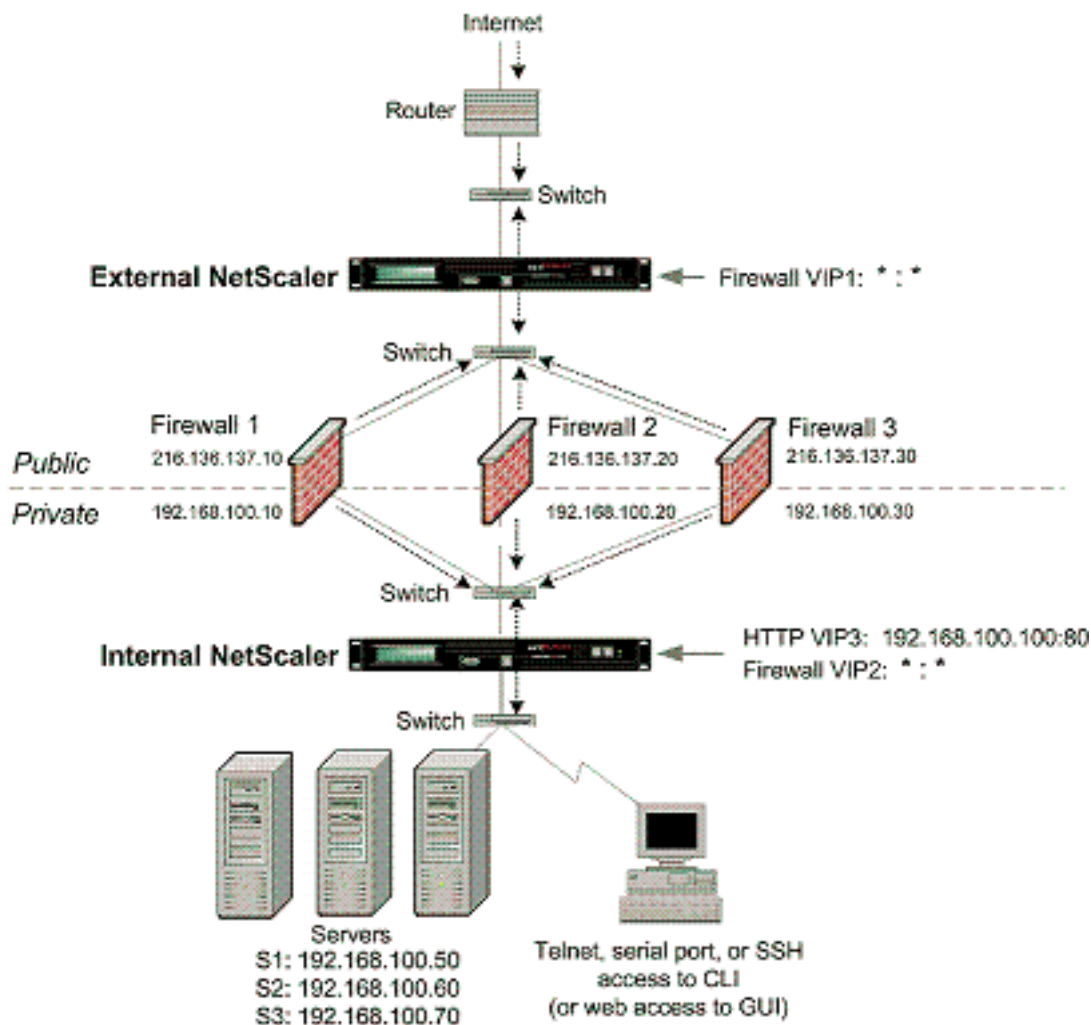

In this setup, a NetScaler is located on each side of a set of firewalls. The NetScaler placed between the firewalls and the Internet, called the external NetScaler that handles ingress traffic selects the best firewall, based on the configured method. The NetScaler between the firewalls and the private network, called the internal NetScaler tracks the firewall from which the initial packet for a session is received. It then makes sure that all subsequent packets for that session are sent to the same firewall.

The internal NetScaler can be configured as a regular traffic manager to load balance traffic across the private network servers. This configuration also allows traffic originating from the private network (egress) to be load balanced across the firewalls.

The following diagram shows the sandwich firewall load balancing environment.

Figure 1. Firewall Load Balancing (Sandwich)

The service type ANY configures the NetScaler to accept all traffic.

To avail benefits related to HTTP and TCP, configure the service and virtual server with type HTTP or TCP. For FTP to work, configure the service with type FTP.

### Configuring the External NetScaler in a Sandwich Environment

Perform the following tasks to configure the external NetScaler in a sandwich environment

- Enable the load balancing feature.
- Configure a wildcard service for each firewall.
- Configure a monitor for each wildcard service.
- Configure a wildcard virtual server for traffic coming from the Internet.
- Configure the virtual server in MAC rewrite mode.
- Bind services to the wildcard virtual server.
- Save and Verify the Configuration.

## Enable the load balancing feature

**To enable load balancing by using the command line interface** At the command prompt, type the following command to enable load balancing and verify the configuration:

```
1 enable ns feature LB
2 show ns feature
3 <!--NeedCopy-->
```

### Example:

```
1 > enable ns feature LoadBalancing
2 Done
3 > show ns feature
4
5 Feature Acronym Status
6 ----- -
7 1) Web Logging WL OFF
8 2) Surge Protection SP ON
9 3) Load Balancing LB ON
10 .
11 .
12 .
13 24) NetScaler Push push OFF
14 Done
15 <!--NeedCopy-->
```

**To enable load balancing by using the configuration utility** Navigate to **System > Settings** and, in **Configure Basic Features**, select **Load Balancing**.

## Configure a wildcard service for each firewall

**To configure a wildcard service for each firewall by using the command line interface** At the command prompt, type:

```
1 add service <name> <serverName> ANY *
2 <!--NeedCopy-->
```

### Example:

```
1 add service Service-HTTP-1 10.102.29.5 ANY *
2 <!--NeedCopy-->
```

**To configure a wildcard service for each firewall by using the configuration utility** Navigate to **Traffic Management > Load Balancing > Services** and add a service. Specify **ANY** in the **Protocol** field and \* in the Port field.

## Configure a monitor for each wildcard service

A PING monitor is bound by default to the service. You need to configure a transparent monitor to monitor hosts on the trusted side through individual firewalls. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the NetScaler appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the firewall is UP but one of the next hop devices from that firewall is down, the appliance includes the firewall while performing load balancing and forwards the packet to the firewall. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor, if any of the devices (including the firewall) are down, the service is marked as DOWN and the firewall is not included when the appliance performs firewall load balancing.

Binding a transparent monitor overrides the PING monitor. To configure a PING monitor in addition to a transparent monitor, after you create and bind a transparent monitor, you need to bind a PING monitor to the service.

**To configure a transparent monitor by using the command line interface** At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

```
1 add lb monitor <monitorName> <type> [-destIP <ip_addr|ipv6_addr|*>] [-transparent (YES | NO)]
2 bind lb monitor <monitorName> <serviceName>
3 <!--NeedCopy-->
```

### Example:

```
1 add monitor monitor-HTTP-1 HTTP -destip 10.10.10.11 -transparent YES
2 bind monitor monitor-HTTP-1 fw-svc1
3 To bind a PING monitor, type the following command:
4 bind monitor PING fw-svc1
5 <!--NeedCopy-->
```

**To create and bind a transparent monitor by using the configuration utility** Navigate to **Traffic Management > Load Balancing > Monitors**, and then create and bind a transparent monitor.

## Configure a wildcard virtual server for traffic coming from the Internet

**To configure a wildcard virtual server for traffic coming from the Internet by using the command line interface** At the command prompt, type:

```
1 add lb vserver <name> ANY * *
2 <!--NeedCopy-->
```

**Example:**

```
1 add lb vserver Vserver-LB-1 ANY * *
2 <!--NeedCopy-->
```

**To configure a wildcard virtual server for traffic coming from the Internet by using the configuration utility** Navigate to **Traffic Management > Load Balancing > Virtual Servers** and create a wildcard virtual server. Specify **ANY** in the **Protocol** field and \* in the Port field.

**Configure the virtual server in MAC rewrite mode**

**To configure the virtual server in MAC rewrite mode by using the command line interface** At the command prompt, type:

```
1 set lb vserver <name>@ -m <RedirectionMode>
2 <!--NeedCopy-->
```

**Example:**

```
1 set lb vserver Vserver-LB-1 -m MAC
2 <!--NeedCopy-->
```

**To configure the virtual server in MAC rewrite mode by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB-1).
2. Edit the **Basic Settings** section, and click **more**.
3. From the **Redirection Mode** drop-down list, select **MAC Based**.

**Bind services to the wildcard virtual server**

**To bind a service to the wildcard virtual server by using the command line interface** At the command prompt, type:

```
1 bind lb vserver <name> <serviceName>
2 <!--NeedCopy-->
```

**Example:**

```
1 bind lb vserver Vserver-LB-1 Service-HTTP-1
2 <!--NeedCopy-->
```

**To bind a service to the wildcard virtual server by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers** and select the virtual server for which you want to bind the service.
2. Click in the **Services** section and select a service to bind.

**Save and Verify the Configuration**

When you've finished the configuration tasks, be sure to save the configuration. Ensure that the settings are correct.

**To save and verify the configuration by using the command line interface** At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

```
1 save ns config
2 show vserver
3 <!--NeedCopy-->
```

**Example:**

```
1 save config
2 sh lb vserver FWLBVIP1
3 FWLBVIP1 (*:*) - ANY Type: ADDRESS
4 State: UP
5 Last state change was at Mon Jun 14 06:40:14 2010
6 Time since last state change: 0 days, 00:00:11.240
7 Effective State: UP ARP:DISABLED
8 Client Idle Timeout: 120 sec
9 Down state flush: ENABLED
10 Disable Primary Vserver On Down : DISABLED
11 No. of Bound Services : 2 (Total) 2 (Active)
12 Configured Method: SRCIPDESTIPHASH
13 Mode: MAC
14 Persistence: NONE
15 Connection Failover: DISABLED
16
17 1) fw_svc_1 (10.102.29.251: *) - ANY State: UP Weight: 1
18 2) fw_svc_2 (10.102.29.18: *) - ANY State: UP Weight: 1
19 Done
20 show service fw-svc1
21 fw-svc1 (10.102.29.251:*) - ANY
22 State: DOWN
23 Last state change was at Thu Jul 8 10:04:50 2010
24 Time since last state change: 0 days, 00:00:38.120
25 Server Name: 10.102.29.251
26 Server ID : 0 Monitor Threshold : 0
27 Max Conn: 0 Max Req: 0 Max Bandwidth: 0 kbits
28 Use Source IP: NO
```

```

49 Last response: Success - ICMP echo reply received.
50 Response Time: 1.415 millisec
51 Done
52 <!--NeedCopy-->
```

## Configuring the Internal NetScaler in a Sandwich Environment

Perform the following tasks to configure the internal NetScaler in a sandwich environment

For traffic from the server (egress)

- Enable the load balancing feature.
- Configure a wildcard service for each firewall.
- Configure a monitor for each wildcard service.
- Configure a wildcard virtual server to load balance the traffic sent to the firewalls.
- Configure the virtual server in MAC rewrite mode.
- Bind firewall services to the wildcard virtual server.

For traffic across private network servers

- Configure a service for each virtual server.
- Configure a monitor for each service.
- Configure an HTTP virtual server to balance traffic sent to the servers.
- Bind HTTP services to the HTTP virtual server.
- Save and Verify the Configuration.

## Enable the load balancing feature

You can configure load balancing entities such as services and virtual servers when the load balancing feature is disabled. But they will not function until you enable the feature.

**To enable load balancing by using the command line interface** At the command prompt, type the following command to enable load balancing and verify the configuration:

```
1 enable ns feature LB
2 show ns feature
3 <!--NeedCopy-->
```

### Example:

```
1 > enable ns feature LoadBalancing
2 Done
3 > show ns feature
4
5 Feature Acronym Status
6 ----- -
7 1) Web Logging WL OFF
8 2) Surge Protection SP ON
9 3) Load Balancing LB ON
10 .
11 .
12 .
13 24) NetScaler Push push OFF
14 Done
15 <!--NeedCopy-->
```

**To enable load balancing by using the configuration utility** Navigate to **System > Settings** and, in Configure Basic Features, select **Load Balancing**.

## Configure a wildcard service for each firewall

**To configure a wildcard service for each firewall by using the command line interface** At the command prompt, type:

```
1 add service <name> <serverName> ANY *
2 <!--NeedCopy-->
```

### Example:

```
1 add service Service-HTTP-1 10.102.29.5 ANY *
2 <!--NeedCopy-->
```

**To configure a wildcard service for each firewall by using the configuration utility** Navigate to **Traffic Management > Load Balancing > Services** and add a service. Specify **ANY** in the **Protocol** field and **\*** in the **Port** field.

### Configure a monitor for each wildcard service

A PING monitor is bound by default to the service. You need to configure a transparent monitor to monitor hosts on the trusted side through individual firewalls. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the NetScaler appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the firewall is UP but one of the next hop devices from that firewall is down, the appliance includes the firewall while performing load balancing and forwards the packet to the firewall. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor, if any of the devices (including the firewall) are down, the service is marked as DOWN and the firewall is not included when the appliance performs firewall load balancing.

Binding a transparent monitor overrides the PING monitor. To configure a PING monitor in addition to a transparent monitor, after you create and bind a transparent monitor, you need to bind a PING monitor to the service.

**To configure a transparent monitor by using the command line interface** At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

```
1 add lb monitor <monitorName> <type> [-destIP <ip_addr|ipv6_addr|*>] [-transparent (YES | NO)]
2 bind lb monitor <monitorName> <serviceName>
3 <!--NeedCopy-->
```

### Example:

```
1 add monitor monitor-HTTP-1 HTTP -destip 10.10.10.11 -transparent YES
2 bind monitor monitor-HTTP-1 fw-svc1
3 <!--NeedCopy-->
```

### To create and bind a transparent monitor by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Monitors** and create a monitor.
2. In the **Create Monitor** dialog box, enter the required parameters, and select **Transparent**.

## Configure a wildcard virtual server to load balance the traffic sent to the firewalls

**To configure a wildcard virtual server to load balance the traffic sent to the firewalls by using the command line interface** At the command prompt, type:

```
1 add lb vserver <name> ANY * *
2 <!--NeedCopy-->
```

### Example:

```
1 add lb vserver Vserver-LB-1 ANY * *
2 <!--NeedCopy-->
```

**To configure a wildcard virtual server for traffic coming from the Internet by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers** and create a wildcard virtual server.
2. Specify **ANY** in the Protocol field and **\*** in the Port field.

**To configure a wildcard virtual server to load balance the traffic sent to the firewalls by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters as shown:
  - Name—name
4. In Protocol, select ANY, and in IP Address and Port, select \*.
5. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

## Configure the virtual server in MAC rewrite mode

**To configure the virtual server in MAC rewrite mode by using the command line interface** At the command prompt, type:

```
1 set lb vserver <name>@ -m <RedirectionMode>
2 <!--NeedCopy-->
```

### Example:

```
1 set lb vserver Vserver-LB-1 -m MAC
2 <!--NeedCopy-->
```

### To configure the virtual server in MAC rewrite mode by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB-1).
2. Edit the **Basic Settings** section, and click **more**.
3. From the **Redirection Mode** drop-down list, select **MAC Based**.

### Bind firewall services to the wildcard virtual server

**To bind firewall services to the wildcard virtual server by using the command line interface** At the command prompt, type:

```
1 bind lb vserver <name> <serviceName>
2 <!--NeedCopy-->
```

#### Example:

```
1 bind lb vserver Vserver-LB-1 Service-HTTP-1
2 <!--NeedCopy-->
```

### To bind firewall services to the wildcard virtual server by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and select a virtual server.
2. Click in the Service section, and select a service to bind.

Note: You can bind a service to multiple virtual servers.

### Configure a service for each virtual server

**To configure a service for each virtual server by using the command line interface** At the command prompt, type:

```
1 add service <name> <serverName> HTTP <port>
2 <!--NeedCopy-->
```

#### Example:

```
1 add service Service-HTTP-1 10.102.29.5 HTTP 80
2 <!--NeedCopy-->
```

**To configure a service for each virtual server by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Services**, and configure a service for each virtual server.
2. Specify **HTTP** in the **Protocol** field, and select **HTTP** under **Available Monitors**.

**To configure a service for each virtual server by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters as shown:
  - Service Name—name
  - Server—serverName
  - Port—port
4. In Protocol, specify HTTP. Under Available Monitors, select HTTP.
5. Click Create, and then click Close. The service you created appears in the Services pane.

**Configure a monitor for each service**

**To bind a monitor to a service by using the command line interface** At the command prompt, type:

```
1 bind lb monitor <monitorName> <ServiceName>
2 <!--NeedCopy-->
```

**Example:**

```
1 bind mon monitor-HTTP-1 Service-HTTP-1
2 <!--NeedCopy-->
```

**To bind a monitor to a service by using the configuration utility** Navigate to **Traffic Management > Load Balancing > Services**, double-click a service, and add a monitor.

**Configure an HTTP virtual server to balance traffic sent to the servers**

**To configure an HTTP virtual server to balance traffic sent to the servers by using the command line interface** At the command prompt, type:

```
1 add lb vserver <name> HTTP <ip> <port>
2 <!--NeedCopy-->
```

**Example:**

```
1 add lb vserver Vserver-LB-1 HTTP 10.102.29.60 80
2 <!--NeedCopy-->
```

### To configure an HTTP virtual server to balance traffic sent to the servers by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Services**, and configure an HTTP virtual server.
2. Specify **HTTP** in the **Protocol** field.

### To configure an HTTP virtual server to balance traffic sent to the servers by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters as shown:
  - Name—name
  - IP Address—IP Address  
Note: If the virtual server uses IPv6, select the IPv6 check box and enter the address in IPv6 format (for example, **1000:0000:0000:0000:0005:0600:700a:888b**).
  - Port—port
4. Under Protocol, select HTTP.
5. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

### Save and Verify the Configuration

When you've finished the configuration tasks, be sure to save the configuration. You should also check to make sure that the settings are correct.

**To save and verify the configuration by using the command line interface** At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

- `save ns config`
- `show vserver`

**Example:**

```
1 save config
2 show lb vserver FWLBVIP2
3 FWLBVIP2 (*:*) - ANY Type: ADDRESS
4 State: UP
5 Last state change was at Mon Jun 14 07:22:54 2010
6 Time since last state change: 0 days, 00:00:32.760
7 Effective State: UP
8 Client Idle Timeout: 120 sec
9 Down state flush: ENABLED
10 Disable Primary Vserver On Down : DISABLED
11 No. of Bound Services : 2 (Total) 2 (Active)
12 Configured Method: LEASTCONNECTION
13 Current Method: Round Robin, Reason: A new service is bound
14 Mode: MAC
15 Persistence: NONE
16 Connection Failover: DISABLED
17
18 1) fw-int-svc1 (10.102.29.5: *) - ANY State: UP Weight: 1
19 2) fw-int-svc2 (10.102.29.9: *) - ANY State: UP Weight: 1
20 Done
21 show service fw-int-svc1
22 fw-int-svc1 (10.102.29.5:*) - ANY
23 State: DOWN
24 Last state change was at Thu Jul 8 14:44:51 2010
25 Time since last state change: 0 days, 00:01:50.240
26 Server Name: 10.102.29.5
27 Server ID : 0 Monitor Threshold : 0
28 Max Conn: 0 Max Req: 0 Max Bandwidth: 0 kbits
29 Use Source IP: NO
30 Client Keepalive(CKA): NO
31 Access Down Service: NO
32 TCP Buffering(TCPB): NO
33 HTTP Compression(CMP): NO
34 Idle timeout: Client: 120 sec Server: 120 sec
35 Client IP: DISABLED
36 Cacheable: NO
37 SC: OFF
38 SP: OFF
39 Down state flush: ENABLED
40
41 1) Monitor Name: monitor-HTTP-1
42 State: DOWN Weight: 1
43 Probes: 9 Failed [Total: 9 Current: 9]
44 Last response: Failure - Time out during TCP connection
45 establishment stage
46 Response Time: 2000.0 millisec
46 2) Monitor Name: ping
47 State: UP Weight: 1
48 Probes: 3 Failed [Total: 0 Current: 0]
49 Last response: Success - ICMP echo reply received.
50 Response Time: 1.275 millisec
51 Done
```

**To save and verify the configuration by using the configuration utility**

1. In the **Details** pane, click **Save**.
2. In the **Save Config** dialog box, click **Yes**.
3. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
4. In the **Details** pane, select the virtual server that you created in step 5.
5. Verify that the settings displayed in the **Details** pane are correct.
6. Navigate to **Traffic Management > Load Balancing > Services**.
7. In the **Details** pane, select the services that you created in step 5.
8. Verify that the settings displayed in the **Details** pane are correct.

**Monitoring a Firewall Load Balancing Set up in a Sandwich Environment**

After the configuration is up and running, you should view the statistics for each service and virtual server to check for possible problems.

**Viewing the Statistics of a Virtual Server**

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the NetScaler appliance. You can display a summary of statistics for all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name
- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of hits

**To display virtual server statistics by using the command line interface** To display a summary of the statistics for all the virtual servers currently configured on the NetScaler, or for a single virtual server, at the command prompt, type:

```
1 stat lb vservice [-detail] [<name>]
2 <!--NeedCopy-->
```

**Example:**

```

1 >stat lb vserver -detail
2 Virtual Server(s) Summary
3
4 vsvrIP port Protocol State Req/s
5 Hits/s
6 One * 80 HTTP UP 5/s
7 Two * 0 TCP DOWN 0/s
8 Three * 2598 TCP DOWN 0/s
9 dnsVirtualNS 10.102.29.90 53 DNS DOWN 0/s
10 BRVSERV 10.10.1.1 80 HTTP DOWN 0/s
11 LBVIP 10.102.29.66 80 HTTP UP 0/s
12 Done
13 <!--NeedCopy-->

```

**To display virtual server statistics by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers > Statistics**.
2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server, and click **Statistics**.

**Viewing the Statistics of a Service**

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in surge queue, current server connections, and so forth using the service statistics.

**To view the statistics of a service by using the command line interface** At the command prompt, type:

```

1 stat service <name>
2 <!--NeedCopy-->

```

**Example:**

```

1 stat service Service-HTTP-1
2 <!--NeedCopy-->

```

**To view the statistics of a service by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Services > Statistics**.
2. If you want to display the statistics for only one service, select the service, and click **Statistics**.

## Enterprise Environment

May 2, 2023

In the enterprise setup, the NetScaler is placed between the firewalls connecting to the public Internet and the internal private network and handles egress traffic. The NetScaler selects the best firewall based on the configured load balancing policy.

The following diagram shows the enterprise firewall load balancing environment

Figure 1. Firewall Load Balancing (Enterprise)

The service type ANY configures the NetScaler to accept all traffic.

To avail benefits related to HTTP and TCP, configure the service and vserver with type HTTP or TCP. For FTP to work, configure the service with type FTP.

### Configuring the NetScaler in an Enterprise Environment

Perform the following tasks to configure a NetScaler in an enterprise environment.

For traffic from the server (egress)

- Enable the load balancing feature.
- Configure a wildcard service for each firewall.
- Configure a monitor for each wildcard service.

- Configure a wildcard virtual server to load balance the traffic sent to the firewalls.
- Configure the virtual server in MAC rewrite mode.
- Bind firewall services to the wildcard virtual server.

For traffic across private network servers

- Configure a service for each virtual server.
- Configure a monitor for each service.
- Configure an HTTP virtual server to balance traffic sent to the servers.
- Bind HTTP services to the HTTP virtual server.
- Save and Verify the Configuration.

In the below configuration example, one of the firewall servers is shown in the network topology diagram (Figure 1) is considered.

### Enable the load balancing feature

You can configure load balancing entities such as services and virtual servers when the load balancing feature is disabled, but they will not function until you enable the feature.

**To enable load balancing by using the command line interface** At the command prompt, type the following command to enable load balancing and verify the configuration:

- enable ns feature LB
- show ns feature

#### Example:

```

1 > enable ns feature LoadBalancing
2 Done
3 > show ns feature
4
5 Feature Acronym Status
6 ----- -
7 1) Web Logging WL OFF
8 2) Surge Protection SP ON
9 3) Load Balancing LB ON
10 .
11 .
12 .
13 24) NetScaler Push push OFF
14 Done
15 <!--NeedCopy-->

```

**To enable load balancing by using the configuration utility** Navigate to System > Settings and, in Configure Basic Features, select Load Balancing.

## Configure a wildcard service for each firewall

**To configure a wildcard service for each firewall by using the command line interface** At the command prompt, type:

```
1 add service <name> <serverName> ANY *
2 <!--NeedCopy-->
```

### Example:

```
1 add service Service-HTTP-1 192.168.100.10 ANY *
2 <!--NeedCopy-->
```

## To configure a wildcard service for each firewall by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters as shown:
  - Service Name—name
  - Server—serverName
4. In Protocol, select ANY, and in Port, select \*.
5. Click Create, and then click Close. The service you created appears in the Services pane.

## Configure a monitor for each wildcard service

A PING monitor is bound by default to the service. You will need to configure a transparent monitor to monitor hosts on the trusted side through individual firewalls. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the NetScaler appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the firewall is UP but one of the next hop devices from that firewall is down, the appliance includes the firewall while performing load balancing and forwards the packet to the firewall. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor, if any of the devices (including the firewall) are down, the service is marked as DOWN and the firewall is not included when the appliance performs firewall load balancing.

Binding a transparent monitor will override the PING monitor. To configure a PING monitor in addition to a transparent monitor, after you create and bind a transparent monitor, you need to bind a PING monitor to the service.

**To configure a transparent monitor by using the command line interface** At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

```
1 add lb monitor <monitorName> <type> [-destIP <ip_addr|ipv6_addr|*>] [-transparent (YES | NO)]
2 bind lb monitor <monitorName> <serviceName>
3 <!--NeedCopy-->
```

**Example:**

```
1 add monitor monitor-HTTP-1 HTTP -destip 10.10.10.11 -destport 80 -transparent YES
2 bind monitor monitor-HTTP-1 fw-svc1
3 <!--NeedCopy-->
```

**To create and bind a transparent monitor by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Monitors.
  2. In the details pane, click Add.
  3. In the Create Monitor dialog box, specify values as shown:
    - Name\*
    - Type\*—type
    - Destination IP
    - Transparent
- \* A required parameter
4. Click Create, and then click Close. In the Monitors pane, select the monitor that you just configured and verify that the settings displayed at the bottom of the screen are correct.

**Configure a wildcard virtual server to load balance the traffic sent to the firewalls**

The traffic passing through firewalls is meant for different proxies or servers that are placed behind the firewalls. These proxies or servers can have different IP addresses and ports. For the traffic to pass transparently through the firewalls, the IP address and port of the virtual server load balancing the firewalls must be set as \* to accept traffic for any IP address and port.

**To configure a wildcard virtual server to load balance the traffic sent to the firewalls by using the command line interface** At the command prompt, type:

```
1 add lb vsrver <name> ANY * *
2 <!--NeedCopy-->
```

**Example:**

```
1 add lb vserver Vserver-LB-1 ANY * *
2 <!--NeedCopy-->
```

**To configure a wildcard virtual server to load balance the traffic sent to the firewalls by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters as shown:
  - Name—name
4. In Protocol, select ANY, and in IP Address and Port, select \*.
5. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

**Configure the virtual server in MAC rewrite mode**

**To configure the virtual server in MAC rewrite mode by using the command line interface** At the command prompt, type:

```
1 set lb vserver <name>@ -m <RedirectionMode>
2 <!--NeedCopy-->
```

**Example:**

```
1 set lb vserver Vserver-LB-1 -m MAC
2 <!--NeedCopy-->
```

**To configure the virtual server in MAC rewrite mode by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB-1), and then click Open.
3. On the Advanced tab, under Redirection Mode, click MAC-Based.
4. Click OK.

**Bind firewall services to the wildcard virtual server**

**To bind firewall services to the wildcard virtual server by using the command line interface** At the command prompt, type:

```
1 bind lb vserver <name> <serviceName>
2 <!--NeedCopy-->
```

**Example:**

```
1 bind lb vserver Vserver-LB-1 Service-HTTP-1
2 <!--NeedCopy-->
```

**To bind firewall services to the wildcard virtual server by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and select a virtual server.
2. Click in the Service section, and select a service to bind.

Note: You can bind a service to multiple virtual servers.

**Configure a service for each virtual server**

**To configure a service for each virtual server by using the command line interface** At the command prompt, type:

```
1 add service <name> <serverName> HTTP <port>
2 <!--NeedCopy-->
```

**Example:**

```
1 add service Service-HTTP-1 192.168.100.10 HTTP 80
2 <!--NeedCopy-->
```

**To configure a service for each virtual server by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters as shown:
  - Service Name—name
  - Server—serverName
  - Port—port
4. In Protocol, specify HTTP. Under Available Monitors, select HTTP.
5. Click Create, and then click Close. The service you created appears in the Services pane.

**Configure a monitor for each service**

**To bind a monitor to a service by using the command line interface** At the command prompt, type:

```
1 bind lb monitor <monitorName> <ServiceName>
2 <!--NeedCopy-->
```

**Example:**

```
1 bind mon monitor-HTTP-1 Service-HTTP-1
2 <!--NeedCopy-->
```

**To bind a monitor to a service by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open the service, and add a monitor.

**Configure an HTTP virtual server to balance traffic sent to the servers**

**To configure an HTTP virtual server to balance traffic sent to the servers by using the command line interface** At the command prompt, type:

```
1 add lb vsver <name> HTTP <ip> <port>
2 <!--NeedCopy-->
```

**Example:**

```
1 add lb vsver Vserver-LB-1 HTTP 10.102.29.60 80
2 <!--NeedCopy-->
```

**To configure an HTTP virtual server to balance traffic sent to the servers by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click Add.
3. In the Create Virtual Server (Load Balancing) dialog box, specify values for the following parameters as shown:
  - Name—name
  - IP Address—IPAddress  
Note: If the virtual server uses IPv6, select the IPv6 check box and enter the address in IPv6 format (for example, **1000:0000:0000:0000:0005:0600:700a:888b**).
  - Port—port
4. Under Protocol, select HTTP.
5. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

## Bind HTTP services to the HTTP virtual server

**To bind HTTP services to the wildcard virtual server by using the command line interface** At the command prompt, type:

```
1 bind lb vserver <name> <serviceName>
2 <!--NeedCopy-->
```

### Example:

```
1 bind lb vserver Vserver-LB-1 Service-HTTP-1
2 <!--NeedCopy-->
```

## To bind HTTP services to the wildcard virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and select a virtual server.
2. Click in the Service section, and select a service to bind.

Note: You can bind a service to multiple virtual servers.

## Save and Verify the Configuration

When you've finished the configuration tasks, be sure to save the configuration. You should also check to make sure that the settings are correct.

**To save and verify the configuration by using the command line interface** At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

- save ns config
- show vserver

### Example:

```
1 save config
2 show lb vserver FWLBVIP2
3 FWLBVIP2 (*:*) - ANY Type: ADDRESS
4 State: UP
5 Last state change was at Mon Jun 14 07:22:54 2010
6 Time since last state change: 0 days, 00:00:32.760
7 Effective State: UP
8 Client Idle Timeout: 120 sec
9 Down state flush: ENABLED
10 Disable Primary Vserver On Down : DISABLED
11 No. of Bound Services : 2 (Total) 2 (Active)
12 Configured Method: LEASTCONNECTION
```

```
13 Current Method: Round Robin, Reason: A new service is bound
14 Mode: MAC
15 Persistence: NONE
16 Connection Failover: DISABLED
17
18 1) fw-int-svc1 (192.168.100.10: *) - ANY State: UP Weight: 1
19 Done
20 show service fw-int-svc1
21 fw-int-svc1 (192.168.100.10:*) - ANY
22 State: UP
23 Last state change was at Thu Jul 8 14:44:51 2010
24 Time since last state change: 0 days, 00:01:50.240
25 Server Name: 192.168.100.10
26 Server ID : 0 Monitor Threshold : 0
27 Max Conn: 0 Max Req: 0 Max Bandwidth: 0 kbits
28 Use Source IP: NO
29 Client Keepalive(CKA): NO
30 Access Down Service: NO
31 TCP Buffering(TCPB): NO
32 HTTP Compression(CMP): NO
33 Idle timeout: Client: 120 sec Server: 120 sec
34 Client IP: DISABLED
35 Cacheable: NO
36 SC: OFF
37 SP: OFF
38 Down state flush: ENABLED
39
40 1) Monitor Name: monitor-HTTP-1
41 State: UP Weight: 1
42 Probes: 9 Failed [Total: 0 Current: 0]
43 Last response: Success - HTTP response code 200
44 received
45 Response Time: 100.0 millisec
46 2) Monitor Name: ping
47 State: UP Weight: 1
48 Probes: 3 Failed [Total: 0 Current: 0]
49 Last response: Success - ICMP echo reply received.
50 Response Time: 1.275 millisec
51 Done
52 <!--NeedCopy-->
```

### To save and verify the configuration by using the configuration utility

1. In the details pane, click Save.
2. In the Save Config dialog box, click Yes.
3. Navigate to Traffic Management > Load Balancing > Virtual Servers.
4. In the details pane, select the virtual server that you created in step 5 and verify that the settings displayed in the Details pane are correct.
5. Navigate to Traffic Management > Load Balancing > Services.
6. In the details pane, select the service that you created in step 5 and verify that the settings dis-

played in the Details pane are correct.

## Monitoring a Firewall Load Balancing Setup in an Enterprise Environment

After the configuration is up and running, you should view the statistics for each service and virtual server to check for possible problems.

### Viewing the Statistics of a Virtual Server

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the NetScaler appliance. You can display a summary of statistics for all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name
- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of hits

**To display virtual server statistics by using the command line interface** To display a summary of the statistics for all the virtual servers currently configured on the NetScaler appliance, or for a single virtual server, at the command prompt, type:

```
1 stat lb vserver [-detail] [<name>]
2 <!--NeedCopy-->
```

### Example:

```
1 >stat lb vserver -detail
2 Virtual Server(s) Summary
3
4 vsvrIP port Protocol State Req/s
5 Hits/s
6 One * 80 HTTP UP 5/s
7 Two * 0 TCP DOWN 0/s
8 Three * 2598 TCP DOWN 0/s
9 dnsVirtualNS 10.102.29.90 53 DNS DOWN 0/s
10 BRVSERV 10.10.1.1 80 HTTP DOWN 0/s
```

9	LBVIP	10.102.29.66	80	HTTP	UP	0/s
		0/s				
10	Done					
11						
12						
13	<!--NeedCopy-->					

### To display virtual server statistics by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers > Statistics.
2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server, and click Statistics.

### Viewing the Statistics of a Service

Updated: 2013-08-28

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in surge queue, current server connections, and so forth using the service statistics.

**To view the statistics of a service by using the command line interface** At the command prompt, type:

```
1 stat service <name>
2 <!--NeedCopy-->
```

#### Example:

```
1 stat service Service-HTTP-1
2 <!--NeedCopy-->
```

### To view the statistics of a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services > Statistics.
2. If you want to display the statistics for only one service, select the service, and click Statistics.

## Multiple-Firewall Environment

May 2, 2023

In a multiple-firewall environment, the NetScaler appliance is placed between two sets of firewalls, the external set connecting to the public Internet, and the internal set connecting to the internal private network. The external set typically handles the egress traffic. These firewalls mainly implement access control lists to allow or deny access to external resources. The internal set typically handles the ingress traffic. These firewalls implement security to safeguard the intranet from malicious attacks apart from load-balancing the ingress traffic. The multiple-firewall environment allows you to load-balance traffic coming from another firewall. By default, the traffic coming from a firewall is not load balanced on the other firewall across a NetScaler appliance. Having firewall load balancing enabled on both the sides of NetScaler improves the traffic flow in both the egress and ingress direction and ensures faster processing of the traffic.

The following figure shows a multiple-firewall load balancing environment

Figure 1. Firewall Load Balancing (multiple-firewall)

With a configuration like the one shown in Figure 1, you can configure the NetScaler to load balance the traffic through the an internal firewall even if it is load balanced by an external firewall. For example,

with this feature configured, the traffic coming from the external firewalls (firewalls 1, 2, and 3) is load balanced on the internal firewalls (firewalls 4, 5, and 6) and vice versa.

Firewall load balancing is supported only for MAC mode LB virtual server.

The service type ANY configures the NetScaler to accept all traffic.

To avail benefits related to HTTP and TCP, configure the service and virtual server with type HTTP or TCP. For FTP to work, configure the service with type FTP.

## Configuring the NetScaler in a Multiple-Firewall Environment

To configure a NetScaler appliance in a multiple-firewall environment, you have to enable the load balancing feature, configure a virtual server to load balance the egress traffic across the external firewalls, configure a virtual server to load balance the ingress traffic across the internal firewalls, and enable firewall load balancing on the NetScaler appliance. To configure a virtual server to load balance traffic across a firewall in the multiple-firewall environment, you need to:

1. Configure a wildcard service for each firewall
2. Configure a monitor for each wildcard service
3. Configure a wildcard virtual server to load balance the traffic sent to the firewalls
4. Configure the virtual server in MAC rewrite mode
5. Bind firewall services to the wildcard virtual server

### Enabling the load balancing feature

To configure and implement load balancing entities such as services and virtual servers, you need to enable the load balancing feature on the NetScaler device.

#### To enable load balancing by using the CLI:

At the command prompt, type the following command to enable load balancing and verify the configuration:

```
1 enable ns feature <featureName>
2 show ns feature
3 <!--NeedCopy-->
```

#### Example:

```
1 enable ns feature LoadBalancing
2 Done
3 show ns feature
4 Feature Acronym Status
5 -----
6 1) Web Logging WL OFF
```

```
7 2) Surge Protection SP ON
8 3) Load Balancing LB ON
9 .
10 .
11 .
12 24) NetScaler Push push OFF
13 Done
14 <!--NeedCopy-->
```

**To enable load balancing by using the GUI:**

1. In the navigation pane, expand System, and then click Settings.
2. In the Settings pane, under Modes and Features, click Change basic features.
3. In the Configure Basic Features dialog box, select the Load Balancing check box, and then click Ok.

**Configuring a wildcard service for each firewall**

To accept traffic from all the protocols, you need to configure wildcard service for each firewall by specifying support for all the protocols and ports.

**To configure a wildcard service for each firewall by using the CLI:**

At the command prompt, type the following command to configure support for all the protocols and ports:

```
1 add service <name>@ <serverName> <serviceType> <port_number>
2 <!--NeedCopy-->
```

**Example:**

```
1 add service fw-svc1 10.102.29.5 ANY *
2 <!--NeedCopy-->
```

**To configure a wildcard service for each firewall by using the GUI:**

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Services dialog box, specify values for the following parameters as shown:
  - Service Name—name
  - Server—serverName

-\* A required parameter
4. In Protocol, select Any and in Port, select \*.
5. Click Create, and then click Close. The service you created appears in the Services pane.

## Configuring a monitor for each service

A PING monitor is bound by default to the service. You will need to configure a transparent monitor to monitor hosts on the trusted side through individual firewalls. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the NetScaler appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the firewall is UP but one of the next hop devices from that firewall is down, the appliance includes the firewall while performing load balancing and forwards the packet to the firewall. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor, if any of the devices (including the firewall) are down, the service is marked as DOWN and the firewall is not included when the appliance performs firewall load balancing.

Binding a transparent monitor will override the PING monitor. To configure a PING monitor in addition to a transparent monitor, after you create and bind a transparent monitor, you need to bind a PING monitor to the service.

### To configure a transparent monitor by using the CLI:

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

```
1 add lb monitor <monitorName> <type> [-destIP <ip_addr|ipv6_addr|*>] [-transparent (YES | NO)]
2 bind lb monitor <monitorName> <serviceName>
3 <!--NeedCopy-->
```

### Example:

```
1 add monitor monitor-HTTP-1 HTTP -destip 10.10.10.11 -transparent YES
2 bind monitor monitor-HTTP-1 fw-svc1
3 <!--NeedCopy-->
```

The NetScaler appliance learns the server L2 parameters from the monitor that is bound to the service. For UDP-ECV monitors, configure a receive string to enable the appliance to learn the L2 parameters of the server. If the receive string is not configured and the server does not respond, then the appliance does not learn the L2 parameters but the service is set to UP. The traffic for this service is blackholed.

### To configure a receive string by using the CLI:

At the command prompt, type the following command:

```
1 add lb monitor <monitorName> <type> [-destIP <ip_addr|ipv6_addr|*>] [-transparent (YES | NO)] [-send <string>] [-recv <string>]
2 <!--NeedCopy-->
```

### Example:

```
1 add lb monitor monitor-udp-1 udp-ecv -destip 10.10.10.11 -transparent
 YES - send "test message" - recv "site_is_up"
2 <!--NeedCopy-->
```

**To create and bind a transparent monitor by using the GUI:**

1. Navigate to Traffic Management > Load Balancing > Monitors.
  2. In the details pane, click Add.
  3. In the Create Monitor dialog box, specify values for the following parameters as shown:
    - Name\*
    - Type\*—type
    - Destination IP
    - Transparent
- \* A required parameter
4. Click Create, and then click Close. In the Monitors pane, select the monitor that you just configured and verify that the settings displayed at the bottom of the screen are correct.

**Configuring a virtual server to load balance the traffic sent to the firewalls**

To load balance any kind of traffic, you need to configure a wildcard virtual server specifying the protocol and port as any value.

**To configure a virtual server to load balance the traffic sent to the firewalls by using the CLI:**

At the command prompt, type the following command:

```
1 add lb vserver <name>@ <serviceType> <IPAddress> <port_number>
2 <!--NeedCopy-->
```

**Example:**

```
1 add lb vserver Vserver-LB-1 ANY * *
2 <!--NeedCopy-->
```

**To configure a virtual server to load balance the traffic sent to the firewalls by using the GUI:**

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, click Add.
3. In Protocol, select Any, and in IP Address and Port, select \*.
4. Click Create, and then click Close. The virtual server you created appears in the Load Balancing Virtual Servers pane.

## Configuring the virtual server to MAC rewrite mode

To configure the virtual server to use MAC address for forwarding the incoming traffic, you need to enable the MAC rewrite mode.

### To configure the virtual server in MAC rewrite mode by using the CLI:

At the command prompt, type the following command:

```
1 set lb vserver <name>@ -m <RedirectionMode>
2 <!--NeedCopy-->
```

### Example:

```
1 set lb vserver Vserver-LB-1 -m MAC
2 <!--NeedCopy-->
```

### To configure the virtual server in MAC rewrite mode by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB1), and then click Open.
3. On the Advanced tab, under the Redirection Mode mode, click Open.
4. Click Ok.

## Binding firewall services to the virtual server

To access a service on NetScaler appliance, you need to bind it to a wildcard virtual server.

### To bind firewall services to the virtual server by using the CLI:

At the command prompt, type the following command:

```
1 bind lb vserver <name>@ <serviceName>
2 <!--NeedCopy-->
```

### Example:

```
1 bind lb vserver Vserver-LB-1 Service-HTTP-1
2 <!--NeedCopy-->
```

### To bind firewall services to the virtual server by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Vserver-LB1), and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Services tab, select the Active check box next to the service that you want to bind to the virtual server (for example, Service-HTTP-1).

4. Click Ok.

### Configuring the multiple-firewall load balancing on the NetScaler appliance

To load balance traffic on both the sides of a NetScaler using firewall load balancing, you need to enable multiple-firewall load balancing by using the `vServerSpecificMac` parameter.

#### To configure multiple-firewall load balancing by using the CLI:

At the command prompt, type the following command:

```
1 set lb parameter -vServerSpecificMac <status>
2 <!--NeedCopy-->
```

#### Example:

```
1 set lb parameter -vServerSpecificMac ENABLED
2 <!--NeedCopy-->
```

#### To configure multiple-firewall load balancing by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure the redirection mode (for example, Configure Load Balancing parameters).
3. In the Set Load Balancing Parameters dialog box, select the Virtual Server Specific MAC check box.
4. Click Ok.

### Saving and Verifying the Configuration

When you've finished the configuration tasks, be sure to save the configuration. You should also check to make sure that the settings are correct.

#### To save and verify the configuration by using the CLI:

At the command prompt, type the following commands to configure a transparent monitor and verify the configuration:

- `save ns config`
- `show vserver`

#### Example:

```
1 save config
2 show lb vserver FWLBVIP2
3 FWLBVIP2 (*:*) - ANY Type: ADDRESS
4 State: UP
```

```
5 Last state change was at Mon Jun 14 07:22:54 2010
6 Time since last state change: 0 days, 00:00:32.760
7 Effective State: UP
8 Client Idle Timeout: 120 sec
9 Down state flush: ENABLED
10 Disable Primary Vserver On Down : DISABLED
11 No. of Bound Services : 2 (Total) 2 (Active)
12 Configured Method: LEASTCONNECTION
13 Current Method: Round Robin, Reason: A new service is bound
14 Mode: MAC
15 Persistence: NONE
16 Connection Failover: DISABLED
17
18 1) fw-int-svc1 (10.102.29.5: *) - ANY State: UP Weight: 1
19 2) fw-int-svc2 (10.102.29.9: *) - ANY State: UP Weight: 1
20 Done
21 show service fw-int-svc1
22 fw-int-svc1 (10.102.29.5:*) - ANY
23 State: DOWN
24 Last state change was at Thu Jul 8 14:44:51 2010
25 Time since last state change: 0 days, 00:01:50.240
26 Server Name: 10.102.29.5
27 Server ID : 0 Monitor Threshold : 0
28 Max Conn: 0 Max Req: 0 Max Bandwidth: 0 kbits
29 Use Source IP: NO
30 Client Keepalive(CKA): NO

46 Response Time: 2000.0 millisec
46 2) Monitor Name: ping
47 State: UP Weight: 1
48 Probes: 3 Failed [Total: 0 Current: 0]
49 Last response: Success - ICMP echo reply received.
50 Response Time: 1.275 millisec
51 Done
52 <!--NeedCopy-->
```

**To save and verify the configuration by using the GUI:**

1. In the details pane, click Save.

2. In the Save Config dialog box, click Yes.
3. Navigate to Traffic Management > Load Balancing > Virtual Servers.
4. In the details pane, select the virtual server that you created in step 5 and verify that the settings displayed in the Details pane are correct.
5. Navigate to Traffic Management > Load Balancing > Services.
6. In the details pane, select the service that you created in step 5 and verify that the settings displayed in the Details pane are correct.

## Monitoring a Firewall Load Balancing Setup in a Multiple-Firewall Environment

After the configuration is up and running, you should view the statistics for each service and virtual server to check for possible problems.

### Viewing the Statistics of a Virtual Server

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the NetScaler appliance. You can display a summary of statistics for all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name
- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of hits

**To display virtual server statistics by using the command line interface** To display a summary of the statistics for all the virtual servers currently configured on the NetScaler appliance, or for a single virtual server, at the command prompt, type:

```
1 stat lb vsrvr [-detail] [<name>]
2 <!--NeedCopy-->
```

#### Example:

```
1 >stat lb vsrvr -detail
2 Virtual Server(s) Summary
3 vsrvrIP port Protocol State Req/s
 Hits/s
```

4	One		*	80	HTTP	UP	5/s
		0/s					
5	Two		*	0	TCP	DOWN	0/s
		0/s					
6	Three		*	2598	TCP	DOWN	0/s
		0/s					
7	dnsVirtualNS	10.102.29.90		53	DNS	DOWN	0/s
		0/s					
8	BRVSERV	10.10.1.1		80	HTTP	DOWN	0/s
		0/s					
9	LBVIP	10.102.29.66		80	HTTP	UP	0/s
		0/s					
10	Done						
11							
12							
13	<!--NeedCopy-->						

### To display virtual server statistics by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Virtual Servers > Statistics.
2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server, and click Statistics.

### Viewing the Statistics of a Service

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in surge queue, current server connections, and so forth using the service statistics.

### To view the statistics of a service by using the CLI:

At the command prompt, type:

```
1 stat service <name>
2 <!--NeedCopy-->
```

### Example:

```
1 stat service Service-HTTP-1
2 <!--NeedCopy-->
```

### To view the statistics of a service by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Services > Statistics.
2. If you want to display the statistics for only one service, select the service, and click Statistics.

## Global Server Load Balancing

May 2, 2023

### Notes:

- From release 13.0 build 41.x, global server load balancing (GSLB) deployments using the NetScaler appliance are fully compliant with DNS flag day 2019.
- The GSLB feature is included with the NetScaler Advance and Premium edition licenses. The NetScaler option license is supported with the Standard edition.

NetScaler appliances configured for GSLB provide disaster recovery and ensure continuous availability of applications by protecting against points of failure in a WAN. GSLB balances the load across data centers by directing client requests to the closest or best performing data center, or to surviving data centers if there is an outage.

In a typical configuration, a local DNS server sends client requests to a GSLB virtual server, to which are bound GSLB services. A GSLB service identifies a load balancing or content switching virtual server, which can be at the local site or a remote site. If the GSLB virtual server selects a load balancing or content switching virtual server at a remote site, it sends the virtual server's IP address to the DNS server. The DNS server sends it to the client. The client then resends the request to the new virtual server at the new IP.

The GSLB entities that you must configure are the GSLB sites, the GSLB services, the GSLB virtual servers, load balancing or content switching virtual servers, and authoritative DNS (ADNS) services. You must also configure MEP. You can also configure DNS views to expose different parts of your network to clients accessing the network from different locations.

### Note:

To take full advantage of GSLB features, use ADC appliances for load balancing or content switching at each data center, so that your GSLB configuration can use the proprietary MEP to exchange site metrics.

### How GSLB works

With ordinary DNS, when a client sends a domain name system (DNS) request, it receives a list of IP addresses of the domain or service. Generally, the client chooses the first IP address in the list and initiates a connection with that server. The DNS server uses a technique called DNS round robin to rotate through the IPs on the list. It sends the first IP address to the end of the list and promotes the others after it responds to each DNS request. This technique ensures equal distribution of the load,

but it does not support disaster recovery, load balancing based on load or proximity of servers, or persistency.

When you configure GSLB on ADC appliances and enable MEP, the DNS infrastructure is used to connect the client to the data center that best meets the set criteria. The criteria can designate the following:

- Least loaded data center
- Closest data center
- Data center that responds most quickly to requests from the client's location
- A combination of those metrics and SNMP metrics.

An appliance tracks the location, performance, load, and availability of each data center. It uses these factors to select the data center to send the client request.

The following figure illustrates a basic GSLB topology.

A GSLB configuration consists of a group of GSLB entities on each appliance in the configuration. These entities include GSLB sites, GSLB services, GSLB service groups, GSLB virtual servers, load balancing servers, content switching servers, and ADNS services.

## GSLB deployment types

May 2, 2023

NetScaler appliances configured for global server load balancing (GSLB) provide for disaster recovery and ensure continuous availability of applications by protecting against points of failure in a wide area network (WAN). GSLB can balance the load across data centers by directing client requests to the closest or best performing data center, or to surviving data centers in the event of an outage.

The following are some of the typical GSLB deployment types:

- [Active-active site deployment](#)
- [Active-passive site deployment](#)

- [Parent-child topology deployment](#)

## Active-active site deployment

May 2, 2023

An active-active site consists of multiple active data centers. Client requests are load balanced across active data centers. This deployment type can be used when you have a need for global distribution of traffic in a distributed environment.

All the sites in an active-active deployment are active, and all the services for a particular application/domain are bound to the same GSLB virtual server. Sites exchange metrics through the Metrics Exchange Protocol (MEP). Site metrics exchanged between the sites include the status of each load balancing and content switching virtual server, current number of connections, current packet rate, and current bandwidth usage. The NetScaler appliance needs this information to perform load balancing across the sites.

An active-active deployment can include a maximum of 32 GSLB sites, because MEP cannot synchronize more than 32 sites. No backup sites are configured in this deployment type.

The NetScaler appliance sends client requests to the appropriate GSLB site as determined by the GSLB method specified in the GSLB configuration.

For an active-active deployment, you can configure the following GSLB methods.

- Round Robin
- Least Connections
- Least Response Time
- Least Bandwidth
- Least Packets
- Source IP Hash
- Custom Load
- Round Trip Time (RTT)
- Static Proximity

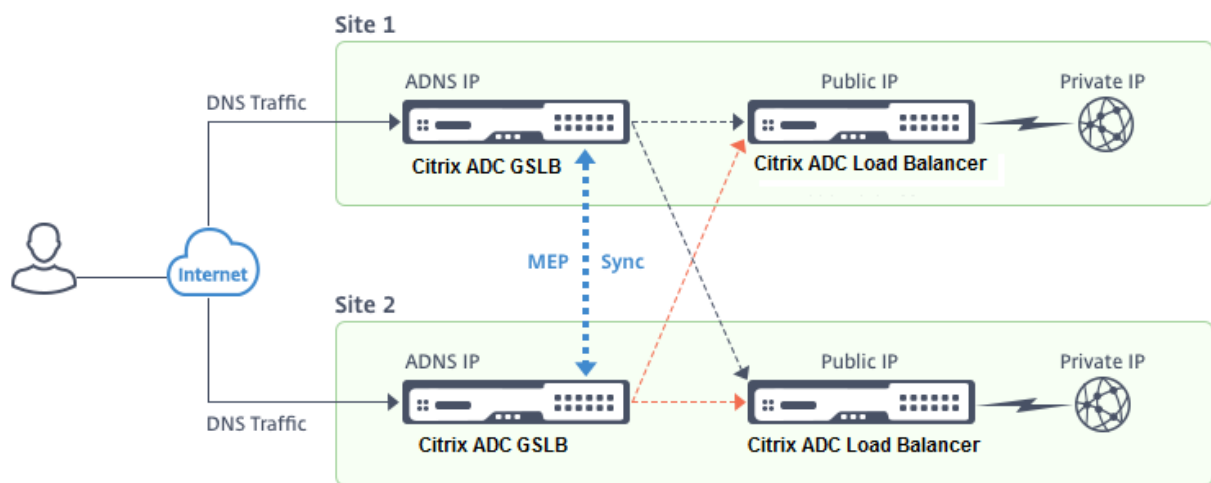

Note:

- If MEP is disabled, the following GSLB methods default to the Round Robin method.
  - RTT
  - Least Connections
  - Least Bandwidth
  - Least Packets

- Least Response Time
- In the static proximity GLSB method, the appliance sends the request to the IP address of the site that best matches the proximity criteria.
- In the Round Trip Time method, the dynamic round trip time (RTT) values are used to select the IP address of the best performing site. RTT is a measure of the delay in the network between the client's local DNS server and a data resource.

### GSLB active-active data center topology

In the diagram, Site 1 and Site 2 are active GSLB sites.

When the client sends a DNS request, it lands in one of the active sites.

If Site 1 receives the client request, the GSLB virtual server in Site 1 selects a load balancing or content switching virtual server and sends the virtual server's IP address to the DNS server, which sends it to the client. The client then resends the request to the new virtual server at the new IP address.

As both sites are active, the GSLB algorithm evaluates the services at both sites when making a selection as determined by the configured GSLB method.

### Active-passive site deployment

September 21, 2020

An active-passive site consists of an active and a passive data center. This deployment type is ideal for disaster recovery.

In this type of deployment, some of the sites (remote sites) are reserved only for disaster recovery. These sites do not participate in any decision making until all the active sites are DOWN. A passive site does not become operational unless a disaster event triggers a failover.

Once you have configured the primary data center, replicate the configuration for the backup data center and designate it as the passive GSLB site by designating a GSLB virtual server at that site as the backup virtual server.

An active-passive deployment can include a maximum of 32 GSLB sites, because MEP cannot synchronize more than 32 sites.

For an active-passive deployment, you can configure the following GSLB methods.

- Round Robin
- Least Connections
- Least Response Time
- Least Bandwidth
- Least Packets
- Source IP Hash
- Custom Load
- Round Trip Time (RTT)
- Static Proximity

**Note:**

- If MEP is disabled, the following algorithm methods default to Round Robin.
  - RTT
  - Least Connections
  - Least Bandwidth
  - Least Packets
  - Least Response Time
- In the static proximity GLSB method, the appliance sends the request to the IP address of the site that best matches the proximity criteria.
- In the Round Trip Time method, the dynamic round trip time (RTT) values are to select the IP address of the best performing site. RTT is a measure of the delay in the network between the client's local DNS server and a data resource.

**GSLB active-passive datacenter topology**

In the diagram, Site 1 is an active site and Site 2 is a passive site, which has the same configuration as that of Site 1.

If Site 1 goes DOWN, Site 2 becomes operational.

When the client sends a DNS request, the request can land in any of the sites. However, the services are selected only from the active site (Site1) as long as it is UP.

Services from the passive site (Site 2) are selected only if the active site (Site 1) is DOWN.

## Parent-child topology deployment using the MEP protocol

May 2, 2023

NetScaler GSLB provides global server load balancing and disaster recovery by creating mesh connections between all the involved sites and making intelligent load balancing decisions. Each site communicates with the others to exchange server and network metrics through the Metric Exchange Protocol (MEP), at regular intervals. However, with the increase in the number of peer sites, the volume of MEP traffic increases exponentially because of the mesh topology. To overcome this, you can use a parent-child topology. The parent-child topology also supports larger deployments. In addition to the 32 parent sites, you can configure 1024 child sites.

The GSLB parent-child topology is a two-level hierarchical design with the following characteristics:

- At the top level are parent sites, which have peer relationships with other parents.
- Each parent can have multiple child sites.
- Each parent site exchanges health information with its child sites and with other parent sites.
- A child site communicates only with its parent site.
- In a parent-child relationship for GSLB, only the parent site responds to ADNS queries. The child sites act as normal load balancing sites.
- Configure an ADNS service or DNS load balancing virtual server only in the parent site.

- A parent site can have a normal GSLB configuration, that is, services from local and all remote sites, but a child site can have local services only. Also, only the parent sites have GSLB virtual servers configured.

**Note**

- In a parent-child topology, the exchange of site metrics is initiated from the lower of two IP addresses. However, from NetScaler release 11.1 build 51.x, the parent sites initiate connections to the child sites, and not the opposite way. Because the parent sites have information about all the child sites in the GSLB setup.
- In a parent-parent connection, the exchange of site metrics is still initiated from the lower IP of two IP addresses.
- In a parent-child topology, GSLB services are not always required to be configured on a child site. However, if you have more configuration such as client authentication, client IP address insertion, or other SSL-specific requirement, you must add an explicit GSLB service on the child site and configure it accordingly.
- In a parent-child topology, the parent site and the child site can be on different NetScaler software versions. However, to use the GSLB automaticConfigSync option to synchronize the configuration across the parent sites, all parent sites must be on the same NetScaler software versions. If you are not using the automaticConfigSync option, then the parent site and the child site can be on different NetScaler software versions but make sure that you are not using any of the new features in the latest release. This is also applicable, in general, to two NetScaler nodes participating in GSLB.

**Basic parent-child topology**

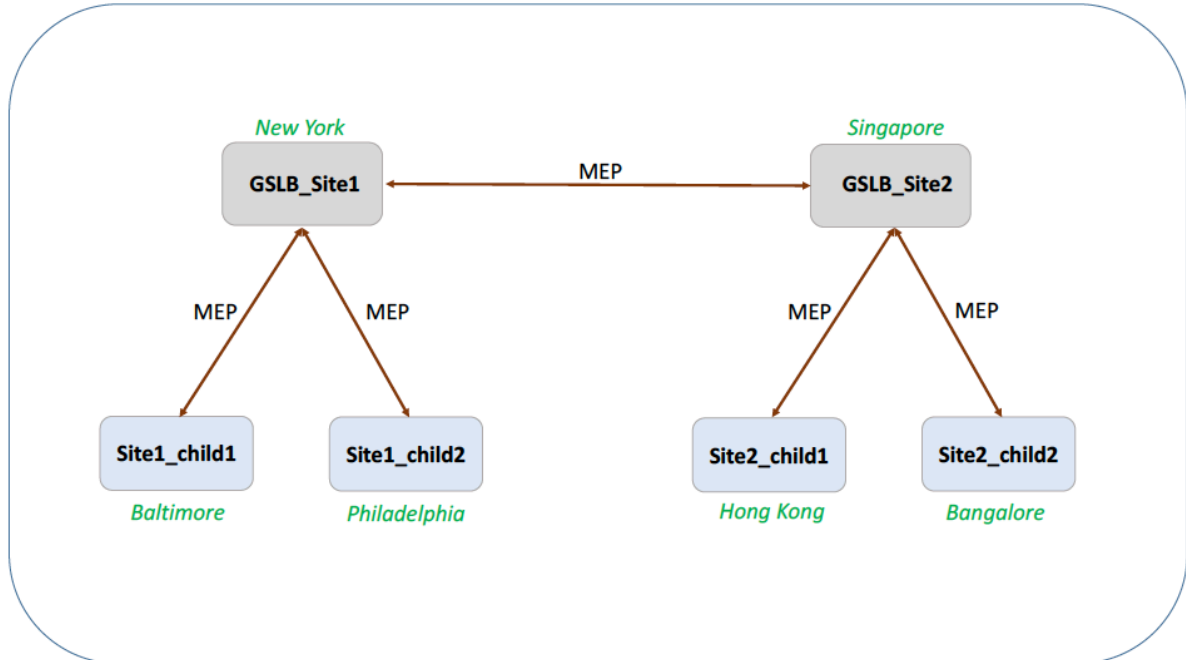

In the diagram, SiteP1 and SiteP2 are parent sites in a peer relationship. Site P1C1 and P2C1 are the child sites of P1 and P2 respectively.

## Setting up a parent-child configuration for GSLB

If you have a firewall configured at a GSLB site, make sure that port 3011 is open.

The following diagram displays a sample parent-child configuration.

- The configuration of a child site includes the child site and its parent site, but no other parent or child sites.
- Network metrics, such as RTT and persistence session information, are synchronized only across the parent sites. Therefore, parameters such as `nwMetricExchange` and `sessionExchange` are disabled by default on all the child sites.
- To verify the correct parent-child configuration, check the states of all the GSLB services bound to the parent sites.

### To set up a parent-child configuration for GSLB by using the CLI:

1. On each parent site, configure all its child sites, its peer parent sites, and the child sites associated with the peer sites:

Use the following command while adding a parent site:

```

1 add gslb site <siteName> <siteIPAddress> [-publicIP <ip_addr |
 ipv6_addr|*>]
2 <!--NeedCopy-->

```

Use the following command while adding a child site:

```

1 add gslb site <siteName> <siteIPAddress> [-publicIP <ip_addr |
 ipv6_addr|*>] [-parentSite <string>]

```

```
2 <!--NeedCopy-->
```

2. On the child sites, configure the child site and also associate the child site with its parent:

**Note:**

Configure the parent site and child site association correctly. For example, you must configure Site1\_child1 with GSLB\_Site1. You cannot configure Site1\_child1 with GSLB\_Site2.

Use the following command to configure the parent site with which the child site is associated:

```
1 add gslb site <siteName> <siteIPAddress> [-publicIP <ip_addr |
 ipv6_addr|*>]
2 <!--NeedCopy-->
```

Use the following command to add a child site and associate it with its parent site:

```
1 add gslb site <siteName> <siteIPAddress> [-publicIP <ip_addr |
 ipv6_addr|*>] [-parentSite <string>]
2 <!--NeedCopy-->
```

For a complete example of a parent-child configuration, using the command line interface, see [Example of a Complete Parent-Child Configuration, Using the CLI](#).

**Note**

If the load balancing virtual server IP address is a private IP address and the public IP address is different from this IP address, you need to configure a GSLB service for the local load balancing virtual server on the child site. This is required for statistics collection between the parent and the child site.

On the child site, at the command prompt, type:

```
add gslb service <name> <private IP/lb vserver IP> http 80 -
sitename <childsitename name> -publicip <public IP of LB vserver>
```

**Example:**

```
add gslb service Service-GSLB 192.168.1.3 http 80 -GSLB_Site11
site 11_lb1 172.16.1.1
```

Where 192.168.1.3 is a private IP address of the load balancing virtual server and 172.16.1.1 is a public IP address of the load balancing virtual server.

## Backing up a parent site

**Note:** This feature was introduced in NetScaler release 11.1 build 51.x. To use the backup parent site topology, make sure that the parent site and the child sites are on NetScaler 11.1 build 51.x and later.

The backup parent site topology is useful in scenarios wherein many child sites are associated with a parent site. If this parent site goes DOWN, all of its child sites become unavailable. To prevent this, you can now configure a backup parent site to which the child sites can connect if the original parent site is DOWN. The parent site sends the backup parent list to the child sites through the MEP messages.

When a parent site is DOWN, the other parent sites in the GSLB get to know that a particular parent site is DOWN through MEP because MEP to that parent site is DOWN. The other parent sites in the GSLB setup look up the backup chain of the peer parent. The parent site with the highest preference adopts the child sites of the parent that went DOWN. The new parent then initiates a connection with the child site. A child site can accept or reject the connection after evaluating its existing connections and the information in the backup list. It takes a few seconds for the backup parent to adopt the child sites.

When the original parent site is back UP, it tries to establish connections with its child sites that have migrated to a different parent. When a connection attempt is successful, the child site is reassigned to its original parent site.

**Note:**

- Only parent sites can be configured as backups, and this configuration can only be done at the parent site.
- All child sites use the backup parent set.
- Synchronization is done only on the parent sites. GSLB child sites' configuration is not affected by synchronization. This is because the parent site and the child site configurations are not identical. The child sites configuration consists only of its own and its parent site's details. Also, GSLB services are not always required to be configured in the child sites.

Consider the configuration shown in the following figure, in which:

- SiteP1, SiteP2, and SiteP3 are the parent sites.
- Child\_site1, Child\_site2, and Child\_site3 are the child sites of SiteP1, SiteP2, and SiteP3 respectively.
- Backup parent sites;
  - SiteP1 backup parents - SiteP2 (higher preference) and SiteP3
  - SiteP2 backup parents –SiteP3 (higher preference) and SiteP1
  - SiteP3 backup parents –SiteP1 (higher preference) and SiteP2

**Note:** For illustration purposes, the figure shows only one backup parent for each parent site.

The following list summarizes the behavior of the parent and child sites under various scenarios:

- Scenario 1: SiteP1 goes DOWN.
  - SiteP2 and SiteP3 detect that SiteP1's MEP connection is DOWN. SiteP2 is higher in the preference list of backup parents for SiteP1, so it tries to initiate a connection to Child\_site1. SiteP3 assumes that Child\_site1 is now the child site of parent SiteP2.
  - SiteP2 sends Child\_Site1 the list of SiteP1's backup parents (SiteP2 and SiteP3) to Child\_site1. Child\_site1 uses the list to decide whether to accept or reject the connection from SiteP2. It accepts the connection and becomes a child of SiteP2.
  - When SiteP1 is back UP, it sends Child\_site1 a connection request. The new request takes precedence and Child\_site 1 migrates to SiteP1.
- Scenario 2: Only the MEP connection between SiteP1 and SiteP2 has gone DOWN. Child\_site1 rejects SiteP2's connection request, because its parent, SiteP1, is still UP.
- Scenario 3: SiteP3 and Child\_Site1 detect that SiteP1 is DOWN, and the MEP connection between SiteP3 and SiteP2 is also DOWN. However, SiteP2 detects that SiteP1 is UP, and the MEP connection between SiteP1 and SiteP2 is UP.
  - SiteP2 does not take any action.
  - SiteP3 checks SiteP1's backup list and finds that SiteP2 has a higher preference than SiteP3. But SiteP2 is DOWN, so SiteP3 tries to establish a connection with Child\_site1. Child\_site1 has detected that SiteP1 is DOWN, so it accepts SiteP3's connection request.
  - Now the connection between SiteP1 and SiteP2 goes DOWN. SiteP2 checks SiteP1's backup list and finds itself as the most preferred backup, so it tries to connect to

Child\_site1. Child\_site1 evaluates the new connection request based on SiteP1's list and finds SiteP2 as the most preferred backup, so it migrates to SiteP2 from SiteP3.

## To configure a backup parent site by using the command line interface

At the command prompt type:

```
1 set gslb site <sitename> -backupParentlist <bkp_site1> <bkp_site2> ... <
 bkp_site5>
2 <!--NeedCopy-->
```

<sitename> is the current parent site.

### Example:

For the parent site (SiteP1), the sites (SiteP2 and SiteP3) are configured as the backup parent sites.

```
1 set gslb site SiteP1 -backupParentlist SiteP2 SiteP3
2 <!--NeedCopy-->
```

### Note:

- You cannot add a new site as a backup parent. You must first add all the sites, and then configure the site as a backup parent.
- To remove a backup parent, you must use the unset command, which unsets all the sites that were previously configured as backup parent sites.

## To configure a backup parent site by using the GUI

1. Navigate to **Configuration > Traffic Management > GSLB > Sites**.
2. Add a new site or select an existing site.
3. Choose the **Backup Parent Sites** option box while creating or configuring the GSLB site.

## GSLB configuration entities

May 2, 2023

A GSLB configuration consists of a group of GSLB entities on each appliance in the configuration. These entities include the following:

- GSLB Sites
- GSLB Services

- GSLB Virtual Servers
- Load Balancing or Content Switching Virtual Servers
- ADNS Services
- DNS VIPs

## **GSLB Sites**

A typical GSLB setup consists of data centers, each of which has various network appliances that may or may not be NetScaler appliances. The data centers are called GSLB sites. Each GSLB site is managed by a NetScaler appliance that is local to that site. Each of these appliances treats its own site as the local site and all other sites, managed by other appliances, as remote sites.

If the appliance that manages a site is the only NetScaler appliance in that data center, the GSLB site hosted on that appliance acts as a bookkeeping placeholder for auditing purposes, because no metrics can be collected. Typically, this happens when the appliance is used only for GSLB, and other products in the data center are used for load balancing or content switching.

## **Relationships among GSLB Sites**

The concept of sites is central to NetScaler GSLB implementations. Unless otherwise specified, sites form a peer relationship among themselves. This relationship is used first to exchange health information and then to distribute load as determined by the selected algorithm. In many situations, however, a peer relationship among all GSLB sites is not desirable. Reasons for not having an all-peer implementation could be;

- To clearly separate GSLB sites. For example, to separate sites that participate in resolving DNS queries from the traffic management sites.
- To reduce the volume of Metric Exchange Protocol (MEP) traffic, which increases exponentially with an increasing number of peer sites.

These goals can be achieved by using parent and child GSLB sites.

## **GSLB Services**

A GSLB service is usually a representation of a load balancing or content switching virtual server, although it can represent any type of virtual server. The GSLB service identifies the virtual server's IP address, port number, and service type. GSLB services are bound to GSLB virtual servers on the NetScaler appliances managing the GSLB sites. A GSLB service bound to a GSLB virtual server in the same data center is local to the GSLB virtual server. A GSLB service bound to a GSLB virtual server in a different data center is remote from that GSLB virtual server.

#### Note

Sites and services are inherently linked to indicate proximity between the two. That is, all services must belong to a site, and are assumed to be in the same location as the GSLB site for proximity purposes. Likewise, services and virtual servers are linked, so that the logic is linked to the resources that are available.

### GSLB Virtual Servers

A GSLB virtual server has one or more GSLB services bound to it, and load balances traffic among those services. It evaluates the configured GSLB methods (algorithms) to select the appropriate service to which to send a client request. Because the GSLB services can represent either local or remote servers, selecting the optimal GSLB service for a request has the effect of selecting the data center that should serve the client request.

The domain for which global server load balancing is configured must be bound to the GSLB virtual server, because one or more services bound to the virtual server will serve requests made for that domain.

Unlike other virtual servers configured on a NetScaler appliance, a GSLB virtual server does not have its own virtual IP address (VIP).

### Load Balancing or Content Switching Virtual Servers

A load balancing or content switching virtual server represents one or many physical servers on the local network. Clients send their requests to the load balancing or content switching virtual server's virtual IP (VIP) address, and the virtual server balances the load across the physical servers. After a GSLB virtual server selects a GSLB service representing either a local or a remote load balancing or content switching virtual server, the client sends the request to that virtual server's VIP address.

For more information about load balancing or content switching virtual servers and services, see [Load Balancing](#) or [Content Switching](#).

### ADNS Services

An ADNS service is a special kind of service that responds only to DNS requests for domains for which the NetScaler appliance is authoritative. When an ADNS service is configured, the appliance owns the ADNS service IP address and advertises it. Upon reception of a DNS request by an ADNS service, the appliance checks for a GSLB virtual server bound to that domain. If a GSLB virtual server is bound to the domain, it is queried for the best IP address to which to send the DNS response.

## DNS VIPs

A DNS virtual IP is a virtual IP (VIP) address that represents a load balancing DNS virtual server on the NetScaler appliance. DNS requests for domains for which the NetScaler appliance is authoritative can be sent to a DNS VIP.

## GSLB methods

May 2, 2023

Unlike traditional DNS servers that simply respond with the IP addresses of the configured servers, a NetScaler appliance configured for GSLB responds with the IP addresses of the services, as determined by the configured GSLB method. By default, the GSLB virtual server is set to the least connection method. If all GSLB services are down, the appliance responds with the IP addresses of all the configured GSLB services.

GSLB methods are algorithms that the GSLB virtual server uses to select the best-performing GSLB service. After the host name in the Web address is resolved, the client sends traffic directly to the resolved service IP address.

The NetScaler appliance provides the following GSLB methods:

- Round Robin
- Least Connections
- Least Response Time
- Least Bandwidth
- Least Packets
- Source IP Hash
- Custom Load
- Round Trip Time (RTT)
- Static Proximity

For GSLB methods to work with a remote site, either MEP must be enabled or explicit monitors must be bound to the remote services. If MEP is disabled, RTT, Least Connections, Least Bandwidth, Least Packets and Least Response Time methods default to Round Robin.

The Static Proximity and RTT load balancing methods are specific to GSLB.

### Specifying a GSLB method other than static proximity or dynamic RTT

For information about the Round Robin, Least Connections, Least Response Time, Least Bandwidth, Least Packets, Source IP Hash, or Custom Load method, see [Load Balancing](#).

## To change the GSLB method by using the CLI

At the command prompt, type:

```
1 set gslb vserver <name> -lbMethod GSLBMethod
2 <!--NeedCopy-->
```

### Example:

```
1 set gslb vserver Vserver-GSLB-1 -lbMethod ROUNDROBIN
2 <!--NeedCopy-->
```

## To change the GSLB method by using the GUI

1. Navigate to **Traffic Management > GSLB > Virtual Servers**.
2. In the details pane, select a GSLB virtual server and click **Open**.
3. In the Configure GSLB Virtual Server dialog box, on the Method and Persistence tab, under Method, select a method from the Choose Method list.
4. Click **OK**, and verify that the method you selected appears under Details at the bottom of the screen.

## GSLB algorithms

May 2, 2023

The following algorithms are supported for GSLB.

- **Round Robin:** When a GSLB virtual server is configured to use the round robin method, it continuously rotates a list of the services that are bound to it. When the virtual server receives a request, it assigns the connection to the first service in the list, and then moves that service to the bottom of the list.
- **Least Response Time:** When the GSLB virtual server is configured to use the least response time method, it selects the service with the lowest value. Where, lowest value = current active connections X average response time.

You can configure this method for HTTP and Secure Sockets Layer (SSL) services only. The response time (also called Time to First Byte, or TTFB) is the time interval between sending a request packet to a service and receiving the first response packet from the service. The NetScaler appliance uses response code 200 to calculate TTFB.

- **Least Connections:** When a GSLB virtual server is configured to use the least connection GSLB algorithm (or method), it selects the service with the fewest active connections. This is the default method, because, in most circumstances, it provides the best performance.
- **Least Bandwidth:** A GSLB virtual server configured to use the least bandwidth method selects the service that is currently serving the least amount of traffic, measured in megabits per second (Mbps).
- **Least Packets:** A GSLB virtual server configured to use the least packets method selects the service that has received the fewest packets in the last 14 seconds.
- **Source IP Hash:** A GSLB virtual server configured to use the source IP hash method uses the hashed value of the client IPv4 or IPv6 address to select a service. To direct all requests from source IP addresses that belong to a particular network to a specific destination server, you must mask the source IP address. For IPv4 addresses, use the `netMask` parameter. For IPv6 addresses, use the `v6NetMaskLength` parameter.
- **Custom Load:** Custom load balancing is performed on server parameters such as CPU usage, memory, and response time. When using the custom load method, the NetScaler appliance usually selects a service that is not handling any active transactions. If all of the services in the GSLB setup are handling active transactions, the appliance selects the service with the smallest load. A special type of monitor, known as a load monitor, calculates the load on each service in the network. The load monitors do not mark the state of a service, but they do take services out of the GSLB decision when those services are not UP.
- **Static Proximity:** GSLB uses an IP-address based static proximity database to determine the proximity between the client's local DNS server and the GSLB sites. The NetScaler appliance responds with the IP address of a site that best matches the proximity criteria.
- **Round Trip Time:** RTT is a measure of time or delay in the network between the client's local DNS server and a data resource. The NetScaler appliance probes the client's local DNS server and gathers RTT metric information. The appliance then uses this metric to make its load balancing decision. Global server load balancing monitors the real-time status of the network and dynamically directs the client request to the data center with the lowest RTT value.
- **API Method:** GSLB uses a REST API to determine the best performing GSLB service. In the API method, when GSLB receives a DNS request from a client, it evaluates the request against the specified rule.

For more details, see [Load Balancing](#).

## Static proximity

May 2, 2023

The static proximity method for GSLB uses an IP-address based static proximity database to determine the proximity between the client's local DNS server and the GSLB sites. The NetScaler appliance responds with the IP address of a site that best matches the proximity criteria.

If two or more GSLB sites at different geographic locations serve the same content, the NetScaler appliance maintains a database of IP address ranges and uses the database for decisions about the GSLB sites to which to direct incoming client requests.

For the static proximity method to work, you must either configure the NetScaler appliance to use an existing static proximity database populated through a location file or add custom entries to the static proximity database. After adding custom entries, you can set their location qualifiers. After configuring the database, you are ready to specify static proximity as the GSLB method.

For details about configuring static proximity, see [Configuring Static Proximity](#).

## Dynamic round trip time method

May 2, 2023

Dynamic round trip time (RTT) is a measure of time or delay in the network between the client's local DNS server and a data resource. To measure dynamic RTT, the NetScaler appliance probes the client's local DNS server and gathers RTT metric information. The appliance then uses this metric to make its load balancing decision. Global server load balancing monitors the real-time status of the network and dynamically directs the client request to the data center with the lowest RTT value.

When a client's DNS request for a domain comes to the NetScaler appliance configured as the authoritative DNS for that domain, the appliance uses the RTT value to select the IP address of the best performing site to send it as a response to the DNS request.

The NetScaler appliance uses different mechanisms, such as ICMP echo request or reply (PING), UDP, and TCP to gather the RTT metrics for connections between the local DNS server and participating sites. The appliance first sends a ping probe to determine the RTT. If the ping probe fails, a DNS UDP probe is used. If that probe also fails, the appliance uses a DNS TCP probe.

These mechanisms are represented on the NetScaler appliance as Load Balancing Monitors and are easily identified due to their use of the "ldns" prefix. The three monitors, in their default order, are:

- [ldns-ping](#)

- `ldns-dns`
- `ldns-tcp`

These monitors are built into the appliance and are set to safe defaults. But they are customizable like any other monitor on the appliance.

You can change the default order by setting it explicitly as a GSLB parameter. For example, to set the order to be the DNS UDP query followed by the PING and then TCP, type the following command:

```
1 set gslb parameter -ldnsprobeOrder DNS PING TCP
2 <!--NeedCopy-->
```

Unless they have been customized, the NetScaler appliance performs UDP and TCP probing on port 53, however unlike regular load balancing monitors the probes need not be successful to provide valid RTT information. ICMP port unavailable messages, TCP Resets and DNS error responses, which would usually constitute a failure are all acceptable for calculating the RTT value.

Once the RTT data has been compiled, the appliance uses the proprietary metrics exchange protocol (MEP) to exchange RTT values between participating sites. After calculating RTT metrics, the appliance sorts the RTT values to identify the data center with the best (smallest) RTT metric.”

If RTT information is not available (for example, when a client’s local DNS server accesses the site for the first time), the NetScaler appliance selects a site by using the round robin method and directs the client to the site.

To configure the dynamic method, you configure the site’s GSLB virtual server for dynamic RTT. You can also set the interval at which local DNS servers are probed to a value other than the default.

## **Configure a GSLB virtual server for dynamic RTT**

To configure a GSLB virtual server for dynamic RTT, you specify the RTT load balancing method.

The NetScaler appliance regularly validates the timing information for a given local server. If a change in latency exceeds the configured tolerance factor, the appliance updates its database with the new timing information and sends the new value to other GSLB sites by performing a MEP exchange. The default tolerance factor is 5 milliseconds (ms).

The RTT tolerance factor must be the same throughout the GSLB domain. If you change it for a site, you must configure identical RTT tolerance factors on all NetScaler appliances deployed in the GSLB domain.

### **To configure a GSLB virtual server for dynamic RTT by using the command line interface**

At the command prompt, type:

```
1 set gslb vserver <name> -lbMethod RTT -tolerance <value>
2 <!--NeedCopy-->
```

**Example:**

```
1 set gslb vserver Vserver-GSLB-1 -lbMethod RTT -tolerance 10
2 <!--NeedCopy-->
```

**To configure a GSLB virtual server for dynamic RTT by using the configuration utility**

Navigate to **Traffic Management > GSLB > Virtual Servers** and double-click the virtual server.

**Set the probing interval of local DNS servers**

The NetScaler appliance uses different mechanisms, such as ICMP echo request or reply (PING), TCP, and UDP to obtain RTT metrics for connections between the local DNS server and participating GSLB sites. By default, the appliance uses a ping monitor and probes the local DNS server every 5 seconds. The appliance then waits 2 seconds for the response. If a response is not received in that time, it uses the TCP DNS monitor for probing.

However, you can modify the time interval for probing the local DNS server to accommodate your configuration.

**To modify the probing interval by using the command line interface**

At the command prompt, type:

```
1 set lb monitor <monitorName> <type> -interval <integer> <units> -
 resptimeout <integer> <units>
2 <!--NeedCopy-->
```

**Example:**

```
1 set lb monitor ldns-tcp LDNS-TCP -interval 10 sec -resptimeout 5 sec
2 <!--NeedCopy-->
```

**To modify the probing interval by using the configuration utility**

Navigate to **Traffic Management > Load Balancing > Monitors**, and double-click the monitor that you want to modify (for example, ping).

## API method

May 15, 2023

You can use the API method to determine the best performing GSLB service. The API method for GSLB uses a REST API to determine the best performing GSLB service.

In the API method, when GSLB receives a DNS request from a client, it evaluates the request against the specified rule. If GSLB encounters the HTTP callout expression, `SYS.HTTP_CALLOUT(<name>)`, it invokes a REST API request to an HTTP callout agent. GSLB uses the response from the HTTP callout agent to decide the best performing service. In the DNS response, GSLB returns the IP address of the best performing service, back to the client.

### To configure a GSLB API method by using the CLI

Perform the following to configure the GSLB API method:

1. Configure an HTTP callout.

For more information, see [Configuring an HTTP callout](#).

At the command prompt, type:

```
1 add policy httpCallout <name> [-IPAddress <ip_addr|ipv6_addr>] [-
 port <port>] [-vServer <string>] [-returnType <returnType>] [-
 httpMethod (GET | POST)] [-hostExpr <string>] [-urlStemExpr <
 string>] [-headers <name(value)> ...] [-parameters <name(value)
 > ...] [-bodyExpr <string>] [-fullReqExpr <string>] [-scheme (
 http | https)] [-resultExpr <string>] [-cacheForSecs <secs>] [-
 comment <string>]
2 <!--NeedCopy-->
```

Example:

```
1 add policy httpCallout GSLB_Method_API -IPAddress 208.111.39.237 -
 port 443 -returnType TEXT -hostExpr “ \ ” hopx.gslb.com\ “ ” -
 urlStemExpr “ \ ” /zones/1/customers/92395/apps/6/decision\ “ ”
 -headers Authorization(“ Basic 19fbe6db-4332-4e3f-a8bc-
 ee47bdc726f8”) -parameters ip(DNS.REQ.OPT.ECS.IP.
 TYPECAST_TEXT_T ALT CLIENT.IP.SRC.TYPECAST_TEXT_T) -scheme
 https -resultExpr “ HTTP.RES.BODY(HTTP.RES.CONTENT_LENGTH).
 XPATH_JSON(xp%/providers/Val[1]/provider%) ” -cacheForSecs 30
2 <!--NeedCopy-->
```

2. Specify the API method for load balancing. GSLB evaluates the DNS request against the specified rule.

At the command prompt, type:

```

1 add gslb vserver <name> <serviceType> [-lbMethod <lbMethod>] [-
 backupLBMethod <backupLBMethod>] -rule <expression>
2 <!--NeedCopy-->

```

Example:

```

1 add gslb vserver vs1 HTTP -lbMethod API -backupLBMethod ROUNDROBIN
 -rule "sys.http_callout(GSLB_Method_API)"
2 <!--NeedCopy-->

```

### Sample configuration for integrating GSLB and ITM using API as the LB method

This configuration allows GSLB to use the internet visibility aspects of the Citrix intelligent traffic management (ITM) to determine the best performing GSLB service.

```

1 /* Enable ns features */
2
3 enable ns feature lb gslb cs
4
5 /* This is a named expression that is used in the HTTP callout, used
 for result expression. */
6
7 add policy expression exp1 "HTTP.RES.BODY(HTTP.RES.CONTENT_LENGTH).
 XPATH_JSON(xp%/providers/Val[1]/provider%)"
8
9 /* This is a named expression that is used in HTTP callout, used for
 host expression. */
10
11 add policy expression exp2 "\"hopx.cedexis.com\""
12
13 /* This is the HTTP callout configured to request the ITM for the GSLB
 decision. */
14
15 add policy httpCallout ITM_OpenMix_API -IPAddress 208.111.39.237 -port
 80 -returnType TEXT -hostExpr exp2 -urlStemExpr "\"/zones/1/
 customers/61770/apps/3/decision\"" -headers Authorization("Basic
 a310697a-1d69-48bf-8f36-55742a8e894e") -parameters ip(DNS.REQ.OPT.
 ECS.IP.TYPECAST_TEXT_T ALT CLIENT.IP.SRC.TYPECAST_TEXT_T) -scheme
 http -resultExpr exp1 -cacheForSecs 30
16
17 /* Add service 1 */
18 add service sg1 98.136.103.24 HTTP 80 -gslb NONE -maxClient 0 -maxReq 0
 -cip DISABLED -usip NO -useproxyport YES -sp OFF -cltTimeout 180 -
 svrTimeout 360 -CKA NO -TCPB NO -CMP NO
19
20 /* Add service 2 */
21 add service sg2 172.217.194.113 HTTP 80 -gslb NONE -maxClient 0 -maxReq
 0 -cip DISABLED -usip NO -useproxyport YES -sp OFF -cltTimeout 180
 -svrTimeout 360 -CKA NO -TCPB NO -CMP NO
22

```

```
23 /* Add ADNS service */
24
25 add service adns1 10.102.217.106 ADNS 53 -gslb NONE -maxClient 0 -
 maxReq 0 -cip DISABLED -usip NO -useproxyport NO -sp OFF -cltTimeout
 120 -svrTimeout 120 -CKA NO -TCPB NO -CMP NO
26
27 /* Add lb vserver 1 for service 1 */
28 add lb vserver lbvs1 HTTP 10.102.217.116 80 -persistenceType NONE -
 cltTimeout 180
29
30 /* Add lb vserver 2 for service 2 */
31 add lb vserver lbvs2 HTTP 10.102.217.117 80 -persistenceType NONE -
 cltTimeout 180
32
33 /* Bind service 1 to lb vserver 1 */
34
35 bind lb vserver lbvs1 sg1
36
37 /* Bind service 2 to lb vserver 2 */
38
39 bind lb vserver lbvs2 sg2
40
41 /* Configure API GSLB method on GSLB virtual server to call the HTTP
 callout. This HTTP callout requests the ITM for the GSLB decision
 and returns GSLB service name, which should serve the request. */
42
43 add gslb vserver vs1 HTTP -lbMethod API -backupLBMethod ROUNDROBIN -
 rule "sys.http_callout(ITM_OpenMix_API)" -tolerance 0 -ECS ENABLED
44
45 /* Add GSLB site */
46
47 add gslb site site1 10.102.217.106 -publicIP 10.102.217.106
48
49 /* Add GSLB service 1 */
50
51 add gslb service aws_ec2_ap_south_1_asia_pacific_mumbai_1
 10.102.217.116 HTTP 80 -publicIP 10.102.217.116 -publicPort 80 -

66 <!--NeedCopy-->
```

## Configure static proximity

May 2, 2023

For the static proximity method to work, you must either configure the NetScaler appliance to use an existing static proximity database populated through a location file or add custom entries to the static proximity database. After adding custom entries, you can set their location qualifiers. After configuring the database, you are ready to specify static proximity as the GSLB method.

This document includes the following information:

- [Adding a Location File to Create a Static Proximity Database](#)
- [Adding Custom Entries to a Static Proximity Database](#)
- [Setting the Location Qualifiers](#)
- [Specifying the Proximity Method](#)
- [Synchronizing GSLB Static Proximity Database](#)

## Add a location file to create a static proximity database

September 22, 2023

A static proximity database is a UNIX-based ASCII file. Entries added to this database from a location file are called static entries. Only one location file can be loaded on a NetScaler appliance. Adding a new location file overrides the existing file. The number of entries in the static proximity database is limited by the configured memory in the NetScaler appliance.

The static proximity database can be created in the default format or in a format derived from commercially configured third party databases (such as [www.maxmind.com](http://www.maxmind.com) and [www.ip2location.com](http://www.ip2location.com)).

The NetScaler appliance includes the following two IP geolocation database files. These are GeoLite2 files, published by MaxMind.

- Citrix\_Netscaler\_InBuilt\_GeoIP\_DB\_IPv4
- Citrix\_Netscaler\_InBuilt\_GeoIP\_DB\_IPv6

These database files are available in a format supported by the NetScaler appliance in the directory `/var/netscaler/inbuilt_db`.

You can use these IP geolocation databases as the location file for the static proximity based GSLB method, or in location based policies.

These databases vary in the details that they provide. There is no strict enforcement of the database file format, except that the default file has format tags. The database files are ASCII files that use a comma as the field delimiter. There are differences in the structure of fields and the representation of IP addresses in the locations.

The format parameter describes the structure of the file to the NetScaler appliance. Specifying an incorrect value for the format option can corrupt the internal data.

**Notes:**

- After an upgrade, if the `/var/netscaler/inbuilt_db/` directory contains the database file (Citrix\_Netscaler\_InBuilt\_GeoIP\_DB.csv) from the earlier NetScaler software versions, the file is retained.
- The default location of the database file is `/var/netscaler/locdb`, and on a high availability (HA) setup, an identical copy of the file must be present in the same location on both NetScaler appliances.
- If the location file is stored in a location other than the default location, then specify the path of the location file.
- For admin partitions, the default path is: `/var/partitions/<partitionName>/netscaler/locdb`.
- Some databases provide short country names according to ISO-3166 and long country names as well. The NetScaler uses short names when storing and matching qualifiers.
- To create a static proximity database, log on to the UNIX shell of the NetScaler appliance and use an editor to create a file with the location details in one of the NetScaler supported formats.
- NetScaler appliance is shipped with the GeoLite2 database (IPv4 and IPv6) but NetScaler does not maintain or update the MaxMind GeoLite2 database regularly. If necessary, you can get the GeoLite2 database from <https://www.maxmind.com> and convert it to NetScaler database format. For more information, see [Script to convert MaxMind GeoLite2 database format to NetScaler database format](#).

### **To add a static location file by using the CLI**

At the command prompt, type:

---

```

1 add locationFile <locationFile> [-format <format>]
2 - show locationFile
3 <!--NeedCopy-->

```

**Example:**

```

1 add locationFile /var/netscaler/locdb/nsgeo1.0 -format netscaler
2 Done
3
4 show locationFile
5 Location File: /var/netscaler/locdb/nsgeo1.0
6 Format: netscaler
7 Done
8 >
9 <!--NeedCopy-->

```

**Example:**

```

1 add locationFile /var/netscaler/inbuilt_db/
 Citrix_Netscaler_InBuilt_GeoIP_DB_IPv4 -format netscaler
2
3 add locationFile6 /var/netscaler/inbuilt_db/
 Citrix_Netscaler_InBuilt_GeoIP_DB_IPv6 -format netscaler
4 <!--NeedCopy-->

```

**To add a static location file by using the GUI:**

1. Navigate to **AppExpert > Location**, click the **Static Database** tab.
2. Click **Add** to add a static location file.

You can view an imported location file database by using the **View Database** dialog box in the configuration utility. There is no CLI equivalent.

**To view a static location file by using the GUI:**

1. Navigate to **AppExpert > Location**, click the **Static Database** tab.
2. Select a static location file, and from the **Action** list, click **View Database**.

**To convert a location file into the NetScaler format:**

By default, when you add a location file, it is saved in the NetScaler format. You can convert a location file of other formats into the NetScaler format.

**Note:**

The `nsmmap` option can be accessed only from the command line interface. The conversion is possible only into the NetScaler format.

**To convert the static database format, at the CLI prompt, type the following command:**

```

1 nsmmap -f <inputFileFormat> -o <outputFileName> <inputFileName>
2 <!--NeedCopy-->

```

**Example:**

```
1 nsmap -f ip-country-region-city -o nsfile.ns ip-country-region-city.
 CSV
2 <!--NeedCopy-->
```

**Script to convert MaxMind GeoLite2 database format to NetScaler database format**

MaxMind GeoIP database cannot be used directly in NetScaler. The MaxMind GeoIP database must be converted into NetScaler format and then loaded for IP location detection in the GSLB static proximity method and other features like policies.

You can use a script to convert the GeoLite2 database format to NetScaler database format. This script can be used to convert both IPv4 and IPv6 files.

The script is available in the location: <https://github.com/citrix/MaxMind-GeoIP-Database-Conversion-Citrix-ADC-Format>

**Steps to convert GeoIP2 database to NetScaler format**

1. Download the GeoLite2 City or GeoLite2 Country database in .csv format from <https://dev.maxmind.com/geoip/geoip2/geolite2/>.
2. Copy the file in a NetScaler directory (say /var). Unzip the file using the following shell command, which would create a directory with the same name.

```
tar -xf <filename>
```

3. Download the script Convert\_GeoIPDB\_To\_Netscaler\_Format.pl from <https://github.com/citrix/MaxMind-GeoIP-Database-Conversion-Citrix-ADC-Format> and copy it to the directory created in step #2.
4. To check the acceptable options for the script execution, run the following command:

```
perl Convert_GeoIPDB_To_Netscaler_Format.pl -help
```

Various options available are:

- <filename> IPv4 output file. Default output file name: Netscaler\_Maxmind\_GeoIP\_DB\_IPv4.csv
  - -p <filename> IPv6 output file. Default output file name: Netscaler\_Maxmind\_GeoIP\_DB\_IPv6.csv
  - -logfile <filename> File containing list of events/messages
  - -debug Prints all the messages to STDOUT
5. Run the following command to convert the GeoLite2 database format to NetScaler database format.

```
perl Convert_GeoIPDB_To_Netscaler_Format.pl
```

**Note:**

The operation can take up to 5 minutes.

The default file names used in the script are that of the MaxMind GeoLite2 City based database. If you have downloaded the GeoLite2 Country database, you must provide the input file names accordingly as listed.

- `-b <filename>` name of IPv4 block file to be converted. Default file name: GeoLite2-City-Blocks-IPv4.csv
- `-i <filename>` name of IPv6 block file to be converted. Default file name: GeoLite2-City-Blocks-IPv6.csv
- `-l <filename>` name of location file to be converted. Default file name: GeoLite2-City-Locations-en.csv

**Example:**

```
1 perl Convert_GeoIPDB_To_Netscaler_Format.pl -b GeoLite2-City-
 Blocks-IPv4.csv -i GeoLite2-City-Blocks-IPv6.csv -l GeoLite2-
 City-Locations-en.csv
2 <!--NeedCopy-->
```

The following are the output files generated after running the script.

- Netscaler\_Maxmind\_GeoIP\_DB\_IPv4.csv
  - Netscaler\_Maxmind\_GeoIP\_DB\_IPv6.csv
6. Once the conversion of the database into NetScaler format is complete, use the following command to start using it.

```
add locationFile <locationFile>
```

## Add a third-party static database file on a NetScaler appliance

Perform the following steps to add a third-party static database file on a NetScaler appliance.

1. Obtain the location database file from a third-party vendor, such as [www.maxmind.com](http://www.maxmind.com).

**Note:**

If you download the location database file from [www.maxmind.com](http://www.maxmind.com), you can use the readily available script to convert it into NetScaler database format. For information on using the script, see [Script to convert MaxMind GeoLite2 database format to NetScaler database format](#).

For location databases downloaded from other third-party vendors, you must convert

them to NetScaler database format before adding them to a NetScaler appliance.

2. Run the following command to add a static location file:

```
1 add location file <locationfile Name>
2 <!--NeedCopy-->
```

**Note:**

- If the location database file is not placed in the default `/var/netscaler/locdb` location, then the `<locationfile Name>` must contain the location of the file along with the file name.
- Before you run the `add location file <locationfile Name>` command:
  - Make sure that the location database file is present in one of the directories of the NetScaler appliance.
  - Run the `sync HA files` command on the high availability setup and the `sync cluster files` command in a cluster setup. These commands ensure that the location database file is copied to the secondary appliance of the high availability pair and peer nodes of the cluster.

3. Run the following command to ensure that the location database is loaded:

```
1 show locationParameter
2 <!--NeedCopy-->
```

This command displays location parameters related to static proximity-based load balancing. A maximum of 3M-1 (3 million minus one) entries can be loaded. When the database loading is in progress, the command displays `Loading: In progress`. After the loading is completed, the command displays `Loading: Idle`.

4. Run the following command to view the location of the GSLB site:

```
1 show gslb service
2 <!--NeedCopy-->
```

**Note**

- If the database is loaded correctly, the location of the GSLB sites is automatically populated in the database.
- You can specify only one location file in the configuration on the appliance.
- If no match is found for an incoming IP address, the request is processed using the Round Robin method.

5. Run the following command to configure the GSLB method on the appliance:

```
1 set gslb vserver GSLBVserverName -lbMethod MethodType
2 <!--NeedCopy-->
```

## Add custom entries to a static proximity database

February 17, 2023

Custom entries take precedence over static entries in the proximity database. You can add a maximum of 3000 custom entries. For a custom entry, denote all omitted qualifiers with an asterisk (\*) and, if qualifiers have a period or space in the name, enclose the parameter in double quotation marks. The first 31 characters are evaluated for each qualifier. You can also provide the longitude and latitude of the geographical location of the IP address-range for selecting a service with the static proximity GSLB method.

### To add custom entries by using the command line interface

At the command prompt, type the following commands to add a custom entry to the static proximity database and verify the configuration.

```
1 add location < IPfrom> < IPto> <preferredLocation> [-longitude <integer>
 >[-latitude <integer>]]
2 show location
3 <!--NeedCopy-->
```

#### Example:

```
1 > add location 192.168.100.1 192.168.100.100 *.us.ca.mycity
2 Done
3 <!--NeedCopy-->
```

```
1 > show location
2 1) IP from 192.168.100.1 IP to 192.168.100.100
3 Continent.Country.REgion.City.ISP.Organization =
4 North America.us.ca.mycity.*.
5 Coordinated: Not specified
6 Done
7 <!--NeedCopy-->
```

### Parameters for adding custom entries

- **From IP Address:** First IP address in the range that is in dotted decimal notation.  
This is a mandatory argument.
- **To IP Address:** Last IP address in the range that is in dotted decimal notation.  
This is a mandatory argument.

- **Location Name:** String of qualifiers that is in dotted notation describes the geographical location of the IP address range. Each qualifier is more specific than the one that precedes it, as in continent.country.region.city.isp.organization. For example, "NA.US.CA.San Jose.ATT.citrix".

This is a mandatory argument. Maximum Length: 197

**Note:**

A qualifier that includes a dot (.) or space ( ) must be enclosed in double quotation marks.

- **longitude:** Numerical value that is in degrees specifies the longitude of the geographical location of the IP address-range.

Maximum value: 180

- **latitude:** Numerical value that is in degrees specifies the latitude of the geographical location of the IP address-range.

Maximum value: 180

**Note:**

Longitude and latitude parameters are used for selecting a service with the static proximity GSLB method. If they are not specified, selection is based on the qualifiers specified for the location.

## To add custom entries by using the configuration utility

Navigate to **AppExpert > Location**, click the **Custom Entries** tab, and add the custom entries.

## Set location qualifiers

May 2, 2023

The database used to implement static proximity has the location of the GSLB sites. Each location has an IP address range and up to six qualifiers for that range. The qualifiers are literal strings and are compared in a prescribed order at run time. Every location must have at least one qualifier. The qualifier labels define the meaning of the qualifiers (context), which are user defined. NetScaler has two built-in contexts:

Geographic context, which has the following qualifier labels:

- Qualifier 1 –“Continent”
- Qualifier 2 –“Country”
- Qualifier 3 –“State”

- Qualifier 4 –“City”
- Qualifier 5 –“ISP”
- Qualifier 6 –“Organization”

Custom entries, which have the following qualifier labels:

- Qualifier 1 –“Qualifier 1”
- Qualifier 2 –“Qualifier 2”
- Qualifier 3 –“Qualifier 3”
- Qualifier 4 –“Qualifier 4”
- Qualifier 5 –“Qualifier 5”
- Qualifier 6 –“Qualifier 6”

If the geographic context is set with no Continent qualifier, Continent is derived from Country. Even the built-in qualifier labels are based on the context, and the labels can be changed. These qualifier labels specify the locations mapped with the IP addresses used to make static proximity decisions.

To perform a static proximity-based decision, the NetScaler appliance compares the location attributes (qualifiers) derived from the IP address of the local DNS server resolver with the location attributes of the participating sites. If only one site matches, the appliance returns the IP address of that site. If there are multiple matches, the site selected is the result of a round robin on the matching GSLB sites. If there is no match, the site selected is a result of a round robin on all configured sites. A site that does not have any qualifiers is considered a match.

The GEO rules for location-based policy expression allow you to check wildcard matches. This feature checks whether wildcard qualifiers match any other qualifier including non-wildcard or not. The wildcard match is done by using the `matchWildcardtoany` attribute that is added to the `set locationParameter` command.

The `matchWildcardtoany` attribute can be set to the following values:

- **Yes:** Wildcard qualifiers match any other qualifiers.
- **No:** Wildcard qualifiers do not match non-wildcard qualifiers but match other wildcard qualifiers. The default option is **No**.
- **Expression:** Wildcard qualifiers in an expression match any qualifier in an LDNS location but wildcard qualifiers in the LDNS location do not match non-wildcard qualifiers in an expression.

Example:

```
1 add dns policy1 "CLIENT.IP.SRC.MATCHES_LOCATION(\"Continent.country
 ..*.* \")" <action>
2 <!--NeedCopy-->
```

## To set the location parameters by using the CLI

At the command prompt, type:

```
1 set locationparameter -context <context> -q1label <string> [-q2label <string>] [-q3label <string>] [-q4label <string>] [-q5label <string>] [-q6label <string>] -matchWildcardtoany [Yes | No | Expression]
2 <!--NeedCopy-->
```

### Example:

```
1 set locationparameter -context custom -q1label asia -matchWildcardtoany Yes
2 <!--NeedCopy-->
```

## To set the location parameters by using the GUI

1. Navigate to **Traffic Management > GSLB > Database and Entries**.
2. Under **Settings**, click **Change Location Parameters**.
3. In the **Configure Location Parameters** page, set the location parameters.

## Configuration example (using CLI)

Consider the following network setup:

- GSLB virtual server name: gv1
- GSLB virtual server IP address: 1.1.1.2
- GSLB Service: gsvc1 bound to gv1
- Location DB file name: sample.csv
- Geolocation qualifiers: Qualifiers 1 and 2 are configured. Rest is set to match the wildcard.
  - Qualifier 1-Asia
  - Qualifier 2-IR
  - Qualifier 3-\*
  - Qualifier 4-\*
  - Qualifier 5-\*
  - Qualifier 6-\*
- DNS Policy-The policy, pol1, is set to drop the packets in if there is a match.

Set the location parameter and configure the DNS policy as follows:

```
1 set locationParameter -q2label Country_Code -q3label Subdivision_1_Name -q4label Subdivision_2_Name -q5label City
2
```

```

3 add locationFile "/var/netscaler/inbuilt_db/sample.csv"
4
5 add gslb vserver gv1 HTTP -backupLBMethod ROUNDROBIN -tolerance 0
6
7 add dns policy pol1 "CLIENT.IP.SRC.MATCHES_LOCATION(\"Asia.IR
 .*.*.**\")||CLIENT.IP.SRC.MATCHES_LOCATION(\"Asia.SY.*.*.**\")||
 CLIENT.IP.SRC.MATCHES_LOCATION(\"Asia.SD.*.*.**\")||CLIENT.IP.SRC.
 MATCHES_LOCATION(\"Asia.KP.*.*.**\")||CLIENT.IP.SRC.
 MATCHES_LOCATION(\"North America.CU.*.*.**\")||CLIENT.IP.SRC.
 MATCHES_LOCATION(\"Europe.UA.Crimea.*.*.**\")" dns_default_act_Drop
8
9 bind dns global pol1 1 -gotoPriorityExpression 65535 -type REQ_DEFAULT
10
11 add gslb service gsvc1 1.1.1.2 HTTP 80 -publicIP 1.1.1.2 -publicPort 80
 -maxClient 0 -healthMonitor NO -siteName s1 -cltTimeout 180 -
 svrTimeout 360 -downStateFlush ENABLED
12
13 bind gslb vserver gv1 -serviceName gsvc1
14
15 bind gslb vserver gv1 -domainName www.gslbnew.com -TTL 5
16 <!--NeedCopy-->

```

Add the following client entries in the location DB file. In this example, the location DB file name is sample.csv:

```

1 10.106.24.170,10.106.24.190,,,,,,8.0000,47.0000
2
3 10.102.82.170,10.102.82.190,Asia,,,,,-73.9924,40.7553
4
5 10.106.24.140,10.106.24.150,,IR,,,,,51.4231,35.6961
6 <!--NeedCopy-->

```

According to the preceding configuration, the clients between 10.106.24.170 and 10.106.24.190 do not have any wildcard qualifiers defined. The clients between 10.106.24.140 and 10.106.24.150, have qualifier 2 as IR.

Set the match wildcard qualifier to NO:

```

1 set locationparameter -matchWildcardtoany no
2 <!--NeedCopy-->

```

When the match wildcard qualifier is set to NO, the wildcard qualifiers match only the defined wildcard qualifiers. It does not match any other non-wildcard qualifier.

- The DNS queries coming 10.106.24.147 match the defined wildcard qualifier (qualifier 2 = IR). Therefore, the DNS policy comes into effect and drops the queries.

When you run the `dig @10.102.82.13 www.gslbnew.com` command on the 10.106.24.147 client, the output shows that servers were not reachable.

```

1 root@ns# dig @10.102.82.13 www.gslbnew.com

```

```

2
3 ; <<>> DiG 9.11.23 <<>> @10.102.82.13 www.gslbnew.com
4 ; (1 server found)
5 ;; global options: +cmd
6 ;; connection timed out; no servers could be reached
7 <!--NeedCopy-->

```

- The DNS queries coming from 10.106.24.180, do not match the defined qualifiers. The DNS policy does not come into effect and the queries are processed.

Run the `dig @10.102.82.13 www.gslbnew.com` command on the 10.106.24.180 client. The output shows the GSLB virtual server's IP address.

```

1 root@ns# dig @10.102.82.13 www.gslbnew.com
2
3 ; <<>> DiG 9.11.23 <<>> @10.102.82.13 www.gslbnew.com

## Specify proximity method

September 21, 2020

When you have configured the static proximity database, you are ready to specify static proximity as the GLSB method.

### To specify static proximity by using the command line interface

At the command prompt, type the following commands to configure static proximity and verify the configuration:

```
1 set gslb vserver <name> -lbMethod STATICPROXIMITY
2 show gslb vserver <name>
3 <!--NeedCopy-->
```

#### Example:

```
1 set gslb vserver Vserver-GSLB-1 -lbMethod STATICPROXIMITY
2 show gslb vserver
3 <!--NeedCopy-->
```

## To specify static proximity by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the virtual server.
2. Click the **Method** section and from the **Choose Method** drop-down list, select **STATICPROXIMITY**.

## Synchronize GSLB static proximity database

September 21, 2020

Synchronizing a global server load balancing (GSLB) static proximity database requires that one of the sites be identified as the master GSLB node. Any site in the topology can be designated as the master node. The rest of the GSLB nodes are automatically designated as slave nodes.

Synchronizing GSLB static proximity databases synchronizes the files in the `/var/netscaler/locdb` directory across the slave nodes. During the synchronization process, the master node fetches the running configuration from each of the slave nodes and compares it to the configuration on the master node. The master GSLB node uses the `rsync` program to synchronize the static proximity database across the slave nodes. To speed up the synchronization process, the `rsync` program makes only enough changes to eliminate the differences between the two files. The synchronization process cannot be rolled back.

The following example synchronizes Site2, which is a slave site, to master site Site1. The administrator enters the **sync gslb config** command on Site1:

```
1 sync gslb config -nowarn
2 Sync Time: Feb 24 2014 14:56:16
3 Retrieving local site info: ok
4 Retrieving all participating gslb sites info:
5 0 bytes in 0 blocks
6 ok
7 site1[Master]:
8 Getting Config: ok
9 site2[Slave]:
10 Syncing gslb static proximity database: ok
11 Getting Config: ok
12 Comparing config: ok
13 Applying changes: ok
14 Done
15 <!--NeedCopy-->
```

## Configure site-to-site communication

May 2, 2023

GSLB site-to-site communication is between the remote procedure call (RPC) nodes that are associated with the communicating sites. A master GSLB site establishes connections with slave sites to synchronize GSLB configuration information and to exchange site metrics.

An RPC node is created automatically when a GSLB site is created, and is assigned an internally generated user name and password. The NetScaler appliance uses this user name and password to authenticate itself to remote GSLB sites during connection establishment. No configuration steps are necessary for an RPC node, but you can specify a password of your choice, enhance security by encrypting the information that GSLB sites exchange, and specify a source IP address for the RPC node.

The appliance needs a NetScaler owned IP address to use as the source IP address when communicating with other GSLB sites. By default, the RPC nodes use either a subnet IP (SNIP) address, but you might want to specify an IP address of your choice.

The following topics describe the behavior and configuration of RPC nodes on the NetScaler appliance:

### Changing the password of an RPC node

Citrix recommends you to secure the communication between sites in your GSLB setup by changing the password of each RPC node. After you change the password for the RPC node of the local site, you must manually propagate the change to the RPC node at each of the remote sites.

The password is stored in encrypted form. You can verify that the password has changed by using the `show rpcNode` command to compare the encrypted form of the password before and after the change.

**Note:** GSLB uses internal user account. For enhanced security, Citrix recommends that you change the internal user account password as well. Internal user account password is changed through RPC node password.

### To change the password of an RPC node by using the command line interface

At the command line, type the following commands to change the password of an RPC node:

```
1 set ns rpcNode <IPAddress> {
2 -password }
3
4 show ns rpcNode
```

```
5 <!--NeedCopy-->
```

**Example:**

```
1 > set rpcNode 192.0.2.4 -password mypassword
2 Done
3 > show rpcNode
4 .
5 .
6 .
7 2) IPAddress: 192.0.2.4 Password: d336004164d4352ce39e
8 SrcIP: * Secure: OFF
9 Done
10 >
11
12 <!--NeedCopy-->
```

**To unset the password of an RPC node by using the command line interface**

To unset the password of an RPC node by using the CLI, type the `unset rpcNode` command, the IP address of the RPC node, and the `password` parameter, without a value.

**To change the password of an RPC node by using the configuration utility**

Navigate to `System > Network > RPC`, select the RPC node, and change the password.

**Encrypt the exchange of site metrics**

You can secure the information that is exchanged between GSLB sites by setting the `secure` option for the RPC nodes in the GSLB setup. With the `secure` option set, the NetScaler appliance encrypts all communication sent from the node to other RPC nodes.

**To encrypt the exchange of site metrics by using the command line interface**

At the command prompt, type the following commands to encrypt the exchange of site metrics and verify the configuration:

```
1 set ns rpcNode <IPAddress> [-secure (YES | NO)]
2 show rpcNode
3 <!--NeedCopy-->
```

**Example:**

```
1 > set rpcNode 192.0.2.4 -secure YES
2 Done
3 >
4 > show rpcNode
5 .
6 .
7 .
8 3) IPAddress: 192.0.2.4 Password: d336004164d4352ce39e SrcIP:
 192.0.2.3 Secure: ON
9 Done
10 >
11 <!--NeedCopy-->
```

### To unset the secure parameter by using the command line interface

To unset the secure parameter by using the CLI, type the `unset rpcNode` command, the IP address of the RPC node, and the secure parameter, without a value.

### To encrypt the exchange of site metrics by using the NetScaler configuration utility

1. Navigate to System > Network > RPC and double-click a RPC node.
2. Select the **Secure** option, and click **OK**.

### Configure source IP address for an RPC node

By default, the NetScaler appliance uses a NetScaler owned subnet IP (SNIP) address as the source IP address for an RPC node, but you can configure the appliance to use a specific SNIP address. If a SNIP address is not available, the GSLB site cannot communicate with other sites. In such a scenario, you must configure either the NSIP address or a virtual IP (VIP) address as the source IP address for an RPC node. A VIP address can be used as the source IP address of an RPC node only if the RPC node is a remote node. If you configure a VIP address as the source IP address and remove the VIP address, the appliance uses a SNIP address.

#### Note

From NetScaler 11.0.64.x release onwards, you can configure the appliance to use GSLB Site IP address as the source IP address for an RPC node.

### To specify a source IP address for an RPC node by using the command line interface

At the command prompt, type the following commands to change the source IP address for an RPC node and verify the configuration:

```
1 set ns rpcNode <IPAddress> [-srcIP <ip_addr|ipv6_addr|*>]
2 show ns rpcNode
3 <!--NeedCopy-->
```

**Example:**

```
1 set rpcNode 192.0.2.4 -srcIP 192.0.2.3
2 Done
3 show rpcNode
4 <!--NeedCopy-->
```

```
1 IPAddress: 192.0.2.4 Password: d336004164d4352ce39e SrcIP: 192.0.2.3
 Secure: OFF
2 Done
3 <!--NeedCopy-->
```

**To unset the source IP address parameter by using the command line interface**

To unset the source IP address parameter by using the CLI, type the `unset rpcNode` command, the IP address of the RPC node, and the `srcIP` parameter, without a value.

**To specify a source IP address for an RPC node by using the NetScaler configuration utility**

1. Navigate to System > Network > RPC and double-click a RPC node.
2. In the Source IP Address field, enter the IP address that you want the RPC node to use as the source IP address and click OK.

**Important**

The source IP address cannot be synchronized across the sites participating in GSLB because the source IP address for a RPC node is specific to each NetScaler appliance. Therefore, after you force a synchronization (using the `sync gslb config -forceSync` command or by selecting the ForceSync option in the GUI), you have to manually change the source IP addresses on the other NetScaler appliances.

## Configure metrics exchange protocol

August 18, 2023

The data centers in a GSLB setup exchange metric with each other through the metrics exchange protocol (MEP), which is a proprietary protocol for NetScaler appliance. The exchange of the metric infor-

mation begins when you create a GSLB site. These metrics comprise load, network, and persistence information.

MEP is required for health checking of data centers to ensure their availability. A connection for exchanging network metric (round-trip time) can be initiated by either of the data centers involved in the exchange, but a connection for exchanging site metrics is always initiated by the data center with the lower IP address. By default, the data center uses a subnet IP address (SNIP) to establish a connection to the IP address of a different data center. However, you can configure a specific SNIP, virtual IP (VIP) address, or the NSIP address, as the source IP address for metrics exchange. The communication process between GSLB sites uses TCP port 3011 or 3009, so this port must be open on firewalls that are between the NetScaler appliances.

Note: You can configure a SNIP or a GSLB site IP address as the source IP address for metrics exchange. For more information, see [Configure source IP address for an RPC node](#).

If the source and target sites (the site that initiates a MEP connection and the site that receives the connection request, respectively) have both private and public IP addresses configured, the sites exchange MEP information by using the public IP addresses.

You can also bind monitors to check the health of remote services as described in “[Monitoring GSLB Services](#).” When monitors are bound, metric exchange does not control the state of the remote service. If a monitor is bound to a remote service and metric exchange is enabled, the monitor controls the health status. Binding the monitors to the remote service enables the NetScaler appliance to interact with a non-NetScaler load balancing device. The NetScaler appliance can monitor non-NetScaler devices but cannot perform load balancing on them unless monitors are bound to all GSLB services and only static load balancing methods (such as the round robin, static proximity, or hash-based methods) are used.

With NetScaler release 11.1.51.x or later, to avoid unnecessary disruption of services, you can set a time delay for marking GSLB services as DOWN when a MEP connection goes DOWN.

## **MEP state in a high availability setup**

In a high availability setup, the primary node establishes connections with the remote sites and the MEP state is not synchronized from the primary node to secondary nodes. Therefore, the MEP state in secondary node remains DOWN. When the secondary node becomes primary, it establishes MEP connections with the new GSLB site and updates the MEP state accordingly.

## **Enable site metrics exchange**

Site metrics exchanged between the GSLB sites include the status of each load balancing, or content switching virtual server, the current number of connections, the current packet rate, and current bandwidth usage information.

The NetScaler appliance needs this information to perform load balancing between the sites. The site metric exchange interval is 1 second. A remote GSLB service must be bound to a local GSLB virtual server to enable the exchange of site metrics with the remote service.

### To enable or disable site metrics exchange by using the command line interface

At a command prompt, type the following commands to enable or disable site metric exchange and verify the configuration:

```
1 set gslb site <siteName> -metricExchange (ENABLED|DISABLED)
2 show gslb site** <siteName>
3 <!--NeedCopy-->
```

#### Example:

```
1 set gslb site Site-GSLB-East-Coast -metricExchange ENABLED
2 set gslb site Site-GSLB-East-Coast -metricExchange DISABLED
3 show gslb site Site-GSLB-East-Coast
4 <!--NeedCopy-->
```

### To enable or disable site metric exchange by using the GUI

1. Navigate to **Traffic Management > GSLB > Sites**, and select the site.
2. In the **Configure GSLB Site** dialog box, select the **Metric Exchange** option.

### Enable network metric exchange

If your GSLB sites use the round-trip time (RTT) load balancing method, you can enable or disable the exchange of RTT information about the client's local DNS service. This information is exchanged every 5 seconds.

For details about changing the GSLB method to a method based on RTT, see [GSLB Methods](#).

### To enable or disable network metric information exchange by using the command line interface

At the command prompt, type the following commands to enable or disable network metric information exchange and verify the configuration:

```
1 set gslb site <siteName> -nwmetricExchange (ENABLED|DISABLED)
2 show gslb site <<siteName>
3 <!--NeedCopy-->
```

**Example:**

```
1 set gslb site Site-GSLB-East-Coast -nwmetricExchange ENABLED
2 set gslb site Site-GSLB-East-Coast -nwmetricExchange DISABLED
3 show gslb site Site-GSLB-East-Coast
4 <!--NeedCopy-->
```

**To enable or disable network metric information exchange by using the GUI**

1. Navigate to **Traffic Management > GSLB > Sites**.
2. In the **Configure GSLB Site** dialog box, select the **Network Metric Exchange** option.

**Configuring a time delay for the GSLB services to be marked as DOWN when a MEP connection goes DOWN**

If the status of a MEP connection to a remote site changes to DOWN, the status of every GSLB service on that remote site is marked as DOWN, although the site might not actually be DOWN.

You can now set a delay to allow some time for reestablishment of the MEP connection before the site is marked as DOWN. If the MEP connection is back UP before the delay expires, the services are not affected.

For example, if you set the delay to 10, the GSLB services remain UP until the MEP connection has been DOWN for 10 seconds. After this duration, the GSLB services are marked as DOWN. However, if the MEP connection is back UP within the 10 seconds, the GSLB services remain in the UP state.

**Note:**

This delay is applicable only for services that are not bound to a monitor. The delay does not affect the trigger monitors.

**To set a time delay by using the command line interface**

At the command prompt, type the following command:

```
1 set gslb parameter** - GSLBSvcStateDelayTime <sec>
2 <!--NeedCopy-->
```

**Example:**

**set gslb parameter - GSLBSvcStateDelayTime 10**

**Note**

In a hierarchical deployment (parent-child topology), if you configure the GSLB service on both

the parent and child sites, set the GSLB parameter on both the parent and child sites. If you do not configure the GSLB service on the child site, set the GSLB parameter only on the parent site.

### To set a time delay by using the GUI

1. Navigate to **Configuration > Traffic Management > GSLB > Change GSLB Settings**.
2. In the **GSLB Service State Delay Time (secs)** box, type the time delay in seconds.

### Configure a learning time for GSLB services when MEP connection status comes up to avoid flaps on GSLB services

When a node reboots or during HA failover, the system is initialized. Then, the node must learn current information about the configured local and child services to communicate the service state to remote nodes through MEP. The node takes some time to learn the correct information. Meanwhile, if a peer node connects to this node and requests for an update, the node might send an incorrect service state and statistics. This incorrect information might cause service flap and other functionality related issues on the remote peer nodes. To avoid this scenario, you can now set a learning time for the local and child GSLB service.

When a learning timeout is configured, the GSLB site gets some buffer time (learning timeout) to learn the correct statistics about its local and child services. When a service is in a learning phase, the remote GSLB site gets this information in MEP update, and does not honor the primary site state and statistics received through MEP for that service.

GSLB services enter the learning phase in any of the following scenarios.

- NetScaler appliance is rebooted
- High availability failover has occurred
- Owner node in a cluster GSLB setup is changed
- MEP is enabled on a local node
- GSLB site comes out of island scenario. A GSLB Site becomes island when it is not connected to any other site.

In a parent-child deployment, the backup parent (if configured) selectively moves the adopted child site's GSLB services to the learning phase when the primary parent goes DOWN.

### To set a service state learning time by using the CLI

At the command prompt, type the following command:

```
1 set gslb parameter - SvcStateLearningTime <sec>
2 <!--NeedCopy-->
```

You can set “SvcStateLearningTime” in seconds. Default value is 0 and maximum value is 3600. This parameter is applicable only if monitors are not bound to GSLB services.

**Example:**

```
1 set gslb parameter - SvcStateLearningTime 10
2 <!--NeedCopy-->
```

**To set a service state learning time by using the GUI**

1. Navigate to **Configuration > Traffic Management > GSLB > Dashboard > Change GSLB Settings**.  
The **Set GSLB Parameters** page appears.
2. In the **GSLB Service State Learning Time (secs)** field, type the learning time in seconds.

**Enable persistence information exchange**

You can configure NetScaler appliance to provide persistent connections, so that a client transmission to any virtual server in a group can be directed to a server that has received previous transmissions from the same client.

You can enable or disable the exchange of persistence information at each site. This information is exchanged once every 5 seconds between NetScaler appliances participating in GSLB.

For details about configuring persistence, see [Configuring Persistent Connections](#).

**To enable or disable persistence information exchange by using the command line interface**

At the command prompt, type the following commands to enable or disable persistence-information exchange and verify the configuration:

```
1 set gslb site <siteName> -sessionExchange (ENABLED|DISABLED)
2 show gslb site** <siteName>
3 <!--NeedCopy-->
```

**Example:**

```
1 set gslb site Site-GSLB-East-Coast -sessionExchange ENABLED
2 set gslb site Site-GSLB-East-Coast -sessionExchange DISABLED
3 show gslb site Site-GSLB-East-Coast
4 <!--NeedCopy-->
```

### To enable or disable persistence information exchange by using the GUI

1. Navigate to **Traffic Management > GSLB > Sites**, and double-click the site.
2. In the **Configure GSLB Site** dialog box, select, or clear the **Persistence Session Entry Exchange** check box.

## Configure GSLB by using a wizard

September 21, 2020

You can now use a wizard to configure the GSLB deployment types: active-active, active-passive, and parent-child.

This wizard is available in the GUI. To access the wizard, navigate to **Configuration > Traffic Management > GSLB** and click **Get Started**.

You can also access this wizard from the GSLB dashboard. Navigate to **Configuration > Traffic Management > GSLB > Dashboard** and click **Configure GSLB**.

**Note:** You can also configure the GSLB entities individually.

- [Active-Active Site Configuration](#)
- [Active-Passive Site Configuraiton](#)
- [Parent-Child Topology Configuration](#)

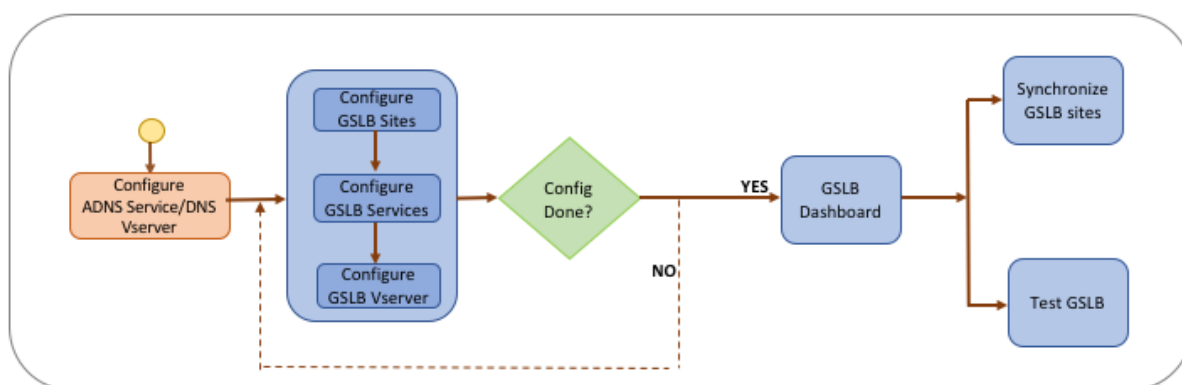

#### Important

This feature is supported in High Availability deployment and not in Admin Partition and Cluster deployments.

## Configure active-active site

May 2, 2023

The following figure shows the workflow involved in a GSLB active-active site configuration.

Before you begin configuring an active-active site, make sure you have configured a standard load balancing setup for each server farm or data center.

Also, for synchronizing the GSLB configuration across the GSLB sites in the deployment, make sure that:

- Local GLSB Sites are configured on all the appliances in the GSLB configuration.
- You have enabled management access on all the GSLB Sites in the configuration.
- You have configured the firewall to accept the auto synchronization and MEP connections.
- The master and slave NetScaler appliances are running the same NetScaler software versions.
- All the NetScaler appliances participating as sites should have the same NetScaler software version (the sites are not in a master-slave relationship).
- The RPC node password is same across all the GSLB sites in the GSLB configuration.

### To configure an active-active site by using the wizard

On the Configuration tab, do the following:

1. Navigate to **Traffic Management > GSLB**, and then click **Get Started**.
2. If you have not configured an ADNS service or a DNS virtual server for the site, you can do it now.
  - a) Click **View** and then click **Add**.
  - b) Enter the service name, IP address and select the protocol (ADNS/ADNS\_TCP) through which the data is exchanged with the service.
3. Select **Active-Active Site**.
4. Enter the fully qualified domain name and specify the time period for which the record must be cached by DNS proxies.
5. Configure the GSLB sites. Each site must be configured with a local GSLB site, and each site's configuration must include all the other sites as remote GSLB sites. There can be only one local site and all other sites are remote sites.
  - a) Enter the site details, such as the site name and site IP address.

- b) Select either REMOTE or LOCAL site type.
  - c) Optionally, change the RPC password and, if necessary, secure it.
  - d) If a monitor is to be bound to the GSLB service, select the condition under which the monitor is to monitor the service. This will be effective only after a monitor is bound to the services. The possible conditions are:
    - **ALWAYS**. Monitor the GSLB service at all times.
    - **MEP Fails**. Monitor the GSLB service only when the exchange of metrics through MEP fails.
    - **MEP Fails and Service ID Down**. Exchange of metrics through MEP is enabled but the status of the service, updated through metrics exchange, is DOWN.
6. Configure the GSLB services. To create an active-active site you must add at least two GSLB services.
- a) Enter the service details, such as service name, service type, and port number.
  - b) Associate the service with a site (local or remote) by selecting the GSLB site where the GSLB service belongs.
  - c) Select the monitor that must be bound to the service when MEP fails, if required. The service can be an existing server, or you can create a new server or a virtual server.
  - d) To associate an existing server, select the server name. The service IP address is automatically populated.
    - If the public IP address is different from the server IP, which can happen in a NAT environment, enter the public IP address and the port number of the public port.
    - To associate a new server, create a server by entering the server IP details and its public IP address and the public port number.
    - To associate a virtual server, select an already existing virtual server, or click + and add a new virtual server. This vserver is the load balancing vserver with which this GSLB service will be associated.
7. Configure the GSLB virtual servers.
- a) Enter the name of the GSLB virtual server name and select the DNS record type.
  - b) Click > in the **Select Service** box and choose the GSLB services to be bound to the GSLB virtual server.
  - c) Click > in the **Domain Binding** box to select the domain to be bound to this GSLB virtual server.
  - d) Choose the GSLB method for selecting the best-performing GSLB service. The default values for GSLB method, backup method, and dynamic weight are auto-populated, by default. You can change them if required.
    - If you choose the **Algorithm based** method, select the primary and backup methods and also specify the dynamic weight option.

- If you choose the **Static Proximity** method, select the backup method and the dynamic weight method. Also, provide the location of the database file by clicking the > icon or add a new location by clicking + in the Select a location database box.
  - If you choose the **Dynamic Proximity (RTT)** method, select the backup method and specify the dynamic weight option and the round-trip time value based on which the best-performing service is to be selected.
8. Click **Done** if the configuration is complete. The GSLB dashboard appears.
  9. If you have modified the GSLB site configuration, click **Auto Synchronize GSLB** in the dashboard to synchronize the configuration to other sites in the GSLB setup.
    - Before synchronization, make sure that the local site's configuration includes information about the remote sites. Also, for the synchronization to be successful, the local site must be configured on the other NetScaler appliances.
    - If real-time synchronization is enabled, you do not have to click **Auto Synchronize GSLB**. The synchronization happens automatically. To enable real time synchronization, do the following:
      - a) Navigate to **Traffic Management > GSLB > Dashboard** and click **Change GSLB Settings**.
      - b) Select the **Automatic Config Sync** check box.
  10. Click **Test GSLB Setup** to make sure that the ADNS services or the DNS servers are responding with the correct IP address for the domain name that is configured in the GSLB setup.

## Configure active-passive site

May 2, 2023

The following figure shows the workflow involved in the active-passive site configuration.

Before you begin configuring an active-passive site, make sure you have configured a standard load balancing setup for each server farm or data center.

Also, for synchronizing the GSLB configuration across the GSLB sites in the deployment, make sure that:

- Local GLSB Sites are configured on all the appliances in the GSLB configuration.
- You have enabled management access on all the GSLB Sites in the configuration.
- You have configured the firewall to accept the auto synchronization and MEP connections.
- The master and slave NetScaler appliances are running the same NetScaler software versions.
- All the NetScaler appliances participating as sites should have the same NetScaler software version (the sites are not in a master-slave relationship).
- The RPC node password is same across all the GSLB sites in the GSLB configuration.

### To configure an active-passive site by using the wizard

On the Configuration tab, do the following:

1. Navigate to **Traffic Management > GSLB**, and then click **Get Started**.
2. If you have not configured an ADNS service or a DNS virtual server for the site, you can do it now.
  - a) Click **View** and then click **Add**.
  - b) Enter the service name, IP address and select the protocol (ADNS/ADNS\_TCP) through which the data is exchanged with the service.
3. Select **Active-Passive Site**.
4. Enter the fully qualified domain name and specify the time period for which the record must be cached by DNS proxies.

5. Configure the GSLB sites. Each site must be configured with a local GSLB site, and each site's configuration must include all the other sites as remote GSLB sites. There can be only one local site and all other sites are remote sites.
  - a) Enter the site details, such as the site name and site IP address.
  - b) Select either REMOTE or LOCAL site type.
  - c) Optionally, change the RPC password and, if necessary, secure it.
  - d) If a monitor is to be bound to the GSLB service, select the condition under which the monitor is to monitor the service. This will be effective only after a monitor is bound to the services. The possible conditions are:
    - **ALWAYS.** Monitor the GSLB service at all times.
    - **MEP Fails.** Monitor the GSLB service only when the exchange of metrics through MEP fails.
    - **MEP Fails and Service ID Down.** Exchange of metrics through MEP is enabled but the status of the service, updated through metrics exchange, is DOWN.
6. Configure the GSLB services.
  - a) Enter the service details, such as service name, service type, and port number.
  - b) Associate the service with a site (local or remote) by selecting the GSLB site where the GSLB service belongs.
  - c) Select the monitor that must be bound to the service when MEP fails, if required. The service can be an existing server, or you can create a new server or a virtual server.
  - d) To associate an existing server, select the server name. The service IP address is automatically populated.
    - If the public IP address is different from the server IP, which can happen in a NAT environment, enter the public IP address and the port number of the public port.
    - To associate a new server, create a server by entering the server IP details and its public IP address and the public port number.
    - To associate a virtual server, select an already existing virtual server, or click **+** and add a new virtual server. This vserver is the load balancing vserver with which this GSLB service will be associated.
7. Configure the GSLB backup virtual servers. The GSLB backup virtual servers become operational only when the primary GSLB virtual servers is inaccessible or it is marked DOWN for any reason.
  - a) Enter the name of the GSLB virtual server name and select the DNS record type.
  - b) Click **>** in **Service Binding**, and choose the GSLB services that must be bound to the GSLB virtual server.
  - c) Choose the GSLB method for selecting the best-performing GSLB service. The default values for GSLB method, backup method, and dynamic weight are auto-populated, by default. You can change them if required.

- If you choose the **Algorithm based** method, select the primary and backup methods.
  - If you choose the **Static Proximity** method, select the backup method and provide the location of the database file.
  - If you choose the **Dynamic Proximity (RTT)** method, select the backup method and specify the service weight and the RTT value based on which the best-performing service is to be selected.
8. Configure the GSLB virtual servers.
- a) Enter the name of the GSLB virtual server name and select the DNS record type.
  - b) Click **>** in the **Select Service** box and choose the GSLB services to be bound to the GSLB virtual server.
  - c) Click **>** in the **Domain Binding** box to select the domain to be bound to this GSLB virtual server.
  - d) Choose the GSLB method for selecting the best-performing GSLB service. The default values for GSLB method, backup method, and dynamic weight are auto-populated, by default. You can change them if required.
    - If you choose the **Algorithm based** method, select the primary and backup methods and also specify the dynamic weight option.
    - If you choose the **Static Proximity** method, select the backup method and the dynamic weight method. Also, provide the location of the database file by clicking the **>** icon or add a new location by clicking **+** in the Select a location database box.
    - If you choose the **Dynamic Proximity (RTT)** method, select the backup method and specify the dynamic weight option and the round-trip time value based on which the best-performing service is to be selected.
9. Click **Done** if the configuration is complete. The GSLB dashboard appears.
10. If you have modified the GSLB site configuration, click **Auto Synchronize GSLB** in the dashboard to synchronize the configuration to other sites in the GSLB setup.
- Before synchronization, make sure that the local site's configuration includes information about the remote sites. Also, for the synchronization to be successful, the local site must be configured on the other NetScaler appliances.
  - If real-time synchronization is enabled, you do not have to click **Auto Synchronize GSLB**. The synchronization happens automatically. To enable real time synchronization, do the following:
    - a) Navigate to **Traffic Management > GSLB > Dashboard** and click **Change GSLB Settings**.
    - b) Select the **Automatic Config Sync** check box.
11. Click **Test GSLB Setup** to make sure that the ADNS services or the DNS servers are responding with the correct IP address for the domain name that is configured in the GSLB setup.

**Note**

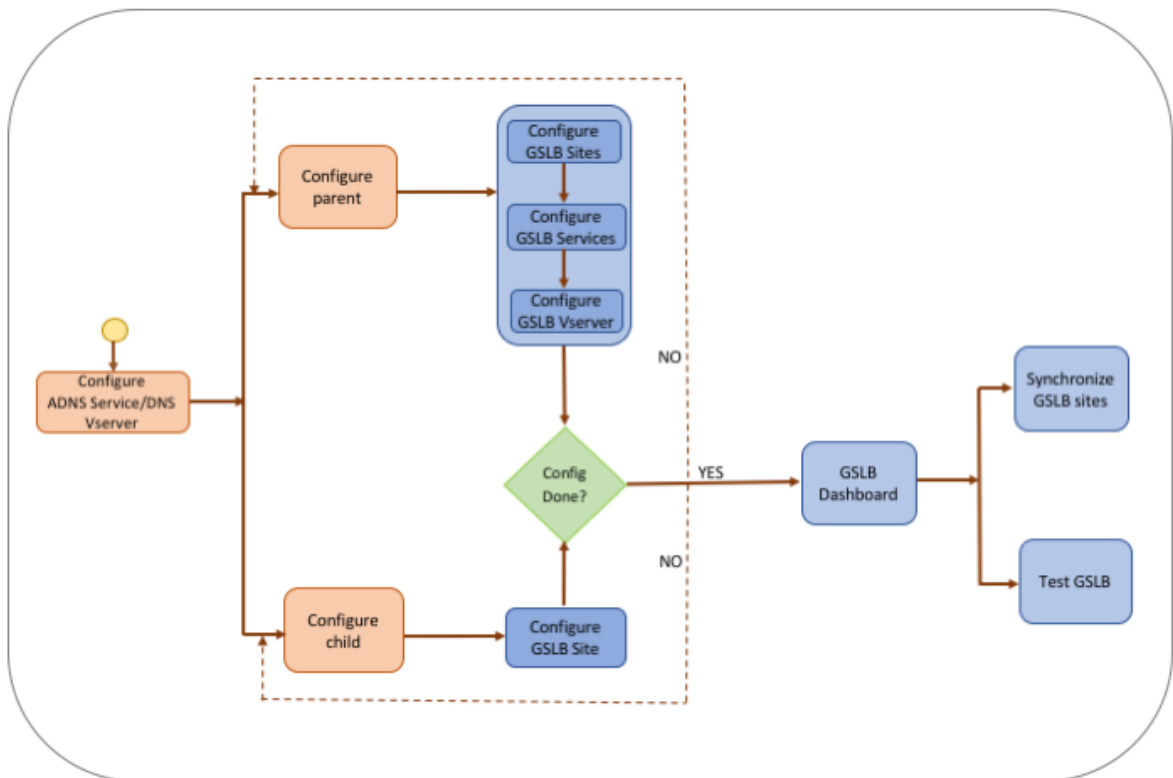

For details about configuring GSLB entities of an active-passive GSLB setup for disaster recovery, see [Configuring GSLB for Disaster Recovery](#).

## Configure parent-child topology

May 2, 2023

In a parent-child topology, at the top level are parent sites, which have peer relationships with other parents. Each parent can have multiple child sites, and each parent site exchanges health information with its child sites and with other parent sites. However, a child site communicates only with its parent site.

The following figure shows the workflow involved in a GSLB parent-child topology configuration.

Before you begin configuring the parent-child topology deployment, make sure you have configured a standard load balancing setup for each server farm or data center.

Also, for synchronizing the GSLB configuration across the GSLB sites in the deployment, make sure that:

- Local GSLB Sites are configured on all the appliances in the GSLB configuration.
- You have enabled management access on all the GSLB Sites in the configuration.
- You have configured the firewall to accept the auto synchronization and MEP connections.
- All the NetScaler appliances participating as sites should have the same NetScaler software version (the sites are not in a master-slave relationship).
- The RPC node password is same across all the GSLB sites in the GSLB configuration.

### To configure a parent-child deployment by using the wizard

On the Configuration tab, do the following:

1. Navigate to **Traffic Management > GSLB**, and then click **Get Started**.
2. If you have not configured an ADNS server or a DNS virtual server for the site, you can do it now.
  - a) Click **View** and then click **Add**.
  - b) Enter the service name, IP address and select the protocol (ADNS/ADNS\_TCP) through which the data is exchanged with the service.
3. Select **Parent-Child Topology**.
4. In the Select the site type field, choose;
  - **Parent** –When configuring the parent site, you must configure its associated child sites and also configure the other parent sites in the GSLB setup.
  - **Child** –When configuring the child site, you must configure only the child site and its parent site.

### To configure a parent site

1. Enter the fully qualified domain name and specify the time period for which the record must be cached by DNS proxies.
2. Configure the GSLB sites. Each site must be configured with a local GSLB site, and each site's configuration must include all the other sites as remote GSLB sites. There can be only one local site. All other sites are remote sites. If the specified site IP address is owned by the appliance (for example, a MIP address or SNIP address), the site is a local site. Otherwise, it is a remote site.
3. Enter the site details, such as the site name and site IP address.
  - a) Select the site type.
  - b) Optionally, change the RPC password and, if necessary, secure it.
  - c) If a monitor is to be bound to the GSLB service, select the condition under which the monitor is to monitor the service. This will be effective only after a monitor is bound to the services. The possible conditions are:

- **Always.** Monitor the GSLB service at all times.
- **MEP Fails.** Monitor the GSLB service only when the exchange of metrics through MEP fails.
- **MEP Fails and Service is DOWN.** Exchange of metrics through MEP is enabled but the status of the service, updated through metrics exchange, is DOWN.

4. Configure the GSLB services.

- a) Enter the service details such as service name, service type, and port number.
- b) Associate the service with a site (local or remote) by selecting the GSLB site to which the GSLB service belongs.
- c) Select the monitor that must be bound to the service when MEP fails, if required. The service can be an existing server, or you can create a new server or a virtual server.
  - To associate an existing server, select the server name. The service IP address is auto-populated.
  - To associate a new server, create a server by entering the server IP details and its public IP address and the public port number.
  - To associate a virtual server, select an already existing virtual server or click **+** and add a new virtual server. This vserver is the load balancing vserver to which this GSLB service will be associated. If the public IP address is different from the server IP, which can happen in a NAT environment, enter the public IP address and the public port number.

5. Configure the GSLB virtual servers.

- a) Enter the name of the GSLB virtual server name and select the DNS record type.
- b) Click **>** in the **Select Service** box and choose the GSLB services to be bound to the GSLB virtual server.
- c) Click **>** in the **Domain Binding** box to view the domain name that is bound to the GSLB virtual server.
- d) Choose the GSLB method for selecting the best-performing GSLB service. The default values for GSLB method, backup method, and dynamic weight are automatically populated by default. You can change them if required.
  - If you choose the **Algorithm based** method, select the primary and backup methods and also specify the dynamic weight option.
  - If you choose the **Static Proximity** method, select the backup method and the dynamic weight method. Also, provide the location of the database file by clicking the **>** icon or add a new location by clicking **+** in the Select a location database box.
  - If you choose the **Dynamic Proximity (RTT)** method, select the backup method and specify the service weight and the RTT value based on which the best-performing service is to be selected.

6. Click **Done** if the configuration is complete. The GSLB dashboard appears.
7. If you have modified the GSLB parent-site configuration, click **Auto Synchronize GSLB** to synchronize the configuration to the other parent sites in the GSLB setup. In a parent-child topology, synchronization for the child sites is skipped.
  - Before synchronization, make sure that the local site's configuration includes information about the remote sites.
  - If real-time synchronization is enabled, you do not have to click **Auto Synchronize GSLB**. The synchronization happens automatically. To enable real time synchronization, do the following:
    - a) Navigate to **Traffic Management > GSLB > Dashboard** and click **Change GSLB Settings**.
    - b) Select the **Automatic Config Sync** check box.
8. Click **Test GSLB Setup** to make sure that the ADNS services or the DNS servers are responding with the correct IP address for the domain name that is configured in the GSLB setup.

### To configure a child site

1. Configure the GSLB sites.
  - a) Enter the site details, such as the site name and site IP address.
  - b) Select the site type.
  - c) Optionally, change the RPC password and, if necessary, secure it. 4. If a monitor is bound to the GSLB service, select the condition under which the monitor is to monitor the service. The possible conditions are:
    - **Always**. Monitor the GSLB service at all times.
    - **MEP Fails**. Monitor the GSLB service only when the exchange of metrics through MEP fails.
    - **MEP Fails and Service is DOWN**. Exchange of metrics through MEP is enabled but the status of the service, updated through metrics exchange, is DOWN.
2. Click **Done** if the configuration is complete. The GSLB dashboard appears.
3. Click **Test GSLB Setup** to make sure that the ADNS services or the DNS servers are responding with the correct IP address for the domain name that is configured in the GSLB setup.

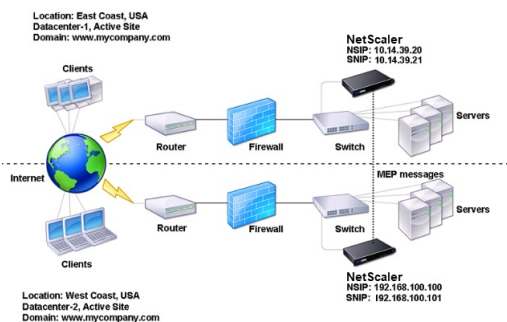

## Configure GSLB entities individually

May 2, 2023

Global server load balancing is used to manage traffic flow to a web site hosted on two separate server farms that ideally are in different geographic locations. For example, consider a Web site, `www.mycompany.com`, which is hosted on two geographically separated server farms or data centers. Both server farms use NetScaler appliances. The NetScaler appliances in these server farms are set up in one-arm mode and function as authoritative DNS servers for the `www.mycompany.com` domain. The following figure illustrates this configuration.

Figure 1. Basic GSLB Topology

To configure such a GSLB setup, you must first configure a standard load balancing setup for each server farm or data center. This enables you to balance load across the different servers in each server farm. Then, configure both NetScaler appliances as authoritative DNS (ADNS) servers. Next, create a GSLB site for each server farm, configure GSLB virtual servers for each site, create GLSB services, and bind the GSLB services to the GSLB virtual servers. Finally, bind the domain to the GSLB virtual servers. The GSLB configurations on the two appliances at the two different sites are identical, although the load-balancing configurations for each site is specific to that site.

Note: To configure a GSLB site in a NetScaler cluster setup, see [Setting Up GSLB in a Cluster](#).

## Configuring a Standard Load Balancing Setup

A load balancing virtual server balances the load across different physical servers in the data center. These servers are represented as services on the NetScaler appliance, and the services are bound to the load balancing virtual server.

For details on configuring a basic load balancing setup, see [Load Balancing](#).

## Configure an authoritative DNS service

May 2, 2023

When you configure the NetScaler appliance as an authoritative DNS server, it accepts DNS requests from the client and responds with the IP address of the data center to which the client should send requests.

Note: For the NetScaler appliance to be authoritative, you must also create SOA and NS records. For more information about SOA and NS records, see [Domain Name System](#).

### To create an ADNS service by using the command line interface

At the command prompt, type the following commands to create an ADNS service and verify the configuration:

```
1 add service <name> <IP>@ ADNS <port>
2
3 show service <name>
4 <!--NeedCopy-->
```

#### Example:

```
1 add service Service-ADNS-1 10.14.39.21 ADNS 53
2
3 show service Service-ADNS-1
4 <!--NeedCopy-->
```

### To modify an ADNS service by using the command line interface

At the command prompt, type the following command:

```
1 set service <name> <IPAddress> ADNS <port>
2 <!--NeedCopy-->
```

#### Example:

```
1 set service Service-ADNS-1 10.14.39.21 ADNS 53
2 <!--NeedCopy-->
```

### To remove an ADNS service by using the command line interface

At the command prompt, type the following command:

```
1 rm service <name>
2 <!--NeedCopy-->
```

#### Example:

```
1 rm service Service-ADNS-1
2 <!--NeedCopy-->
```

## To configure an ADNS service by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Add a new ADNS service, or select an existing service and edit its settings.

## Configure a basic GSLB site

April 2, 2024

A GSLB site is a representation of a data center in your network and is a logical grouping of GSLB virtual servers, services, and other network entities. Typically, in a GSLB setup, there are many GSLB sites that are equipped to serve the same content to a client. These are usually geographically separated to ensure that the domain is active even if one site goes down completely. All of the sites in the GSLB configuration must be configured on every NetScaler appliance hosting a GSLB site. In other words, at each site, you configure the local GSLB site and each remote GSLB site.

Once GSLB sites are created for a domain, the NetScaler sends client requests to the appropriate GSLB site as determined by the GSLB algorithms configured.

Starting from NetScaler release 14.1 build 21.x, site password parameter is added that replaces the RPC node password. If GSLB synchronization is enabled, this password is updated on all the GSLB sites.

## Create a GSLB site using the CLI

At the command prompt, type the following commands to create a GSLB site and verify the configuration:

```
1 add gslb site <siteName> <siteIPAddress>
2 show gslb site <siteName>
3 <!--NeedCopy-->
```

### Example:

```
1 add gslb site Site-GSLB-East-Coast 10.14.39.21
2 show gslb site Site-GSLB-East-Coast
3 <!--NeedCopy-->
```

## Modify or remove a GSLB Site using the CLI

- To modify a GSLB site, use the `set gslb site` command, which is just like using the `add gslb site` command, except that you enter the name of an existing GSLB Site.
- To unset a site parameter, use the `unset gslb site` command, followed by the `siteName` value and the name of the parameter to be reset to its default value.
- To remove a GSLB site, use the `rm gslb site` command, which accepts only the `<name>` argument.

## Configure a basic GSLB site using the GUI

1. Navigate to **Traffic Management > GSLB > Sites**.
2. Add a new GSLB site, or select an existing GSLB site and edit its settings.

## View the statistics of a GSLB site using the CLI

At the command prompt, type:

```
1 stat gslb site <siteName>
2 <!--NeedCopy-->
```

### Example:

```
1 stat gslb site Site-GSLB-East-Coast
2 <!--NeedCopy-->
```

## View the statistics of a GSLB site using the GUI

1. Navigate to **Traffic Management > GSLB > Sites**.
2. Select the GSLB site and click **Statistics**.

## Rename a GSLB site

Instead of deleting the sites and creating a one, you can rename the existing GSLB site and retain all the GSLB configuration entities related to the sites. Changing the name in the primary GSLB site automatically changes the GSLB name in the secondary site if the `automaticConfigSync` parameter is enabled.

**Note:** Performing multiple renaming operations for a single site leads to synchronization inconsistencies.

## Rename a GSLB site using the CLI

At the command prompt, type:

```
rename gslb site <oldName> <newName>
```

Example:

```
rename gslb site Site-GSLB-East-Coast Site-GSLB-West-Coast
```

## Rename a GSLB site using the GUI

1. Navigate to **Traffic Management > GSLB > Sites**.
2. Select the GSLB site and click Rename.

## Configure a GSLB service

September 21, 2020

A GSLB service is a representation of a load balancing or content switching virtual server. A local GSLB service represents a local load balancing or content switching virtual server. A remote GSLB service represents a load balancing or content switching virtual server configured at one of the other sites in the GSLB setup. At each site in the GSLB setup, you can create one local GSLB service and any number of remote GSLB services.

### Important

If the load balancing virtual server is either in a GSLB node itself or is in a child node (in parent-child deployment) and no monitors are bound to the GSLB service, then make sure the following:

The GLSB service IP address, port number, and protocol match the virtual server that the service is representing. Else, the service state is marked as DOWN.

## To create a GSLB service by using the command line interface

At the command prompt, type the following commands to create a GSLB service and verify the configuration:

```
1 add gslb service <serviceName> <serverName | IP> <serviceType> <port>-
 siteName <string>
2 show gslb service <serviceName>
3 <!--NeedCopy-->
```

**Example:**

```
1 add gslb service Service-GSLB-1 10.14.39.14 HTTP 80 - siteName Site-
 GSLB-East-Coast
2 show gslb service Service-GSLB-1
3 <!--NeedCopy-->
```

**To modify or remove a GSLB service by using the command line interface**

- To modify a GSLB service, use the `set gslb service <serviceName>` command. For this command, specify the name of the GSLB service whose configuration you want to modify. You can change the existing values of the parameters either specified by you or set by default. You can change the value of more than one parameter in the same command. Refer to the `add gslb service` command for details about the parameters. Example

```
1 > set gslb service SKP_GSLB_NOTCNAME_SVC2 -maxBandwidth 25 -
 maxClient 8
2 Done
3 > sh gslb service SKP_GSLB_NOTCNAME_SVC2
4 SKP_GSLB_NOTCNAME_SVC2 (21.211.21.21: 80)- HTTP
5 ...
6 Max Conn: 8 Max Bandwidth: 25 kbits
7 <!--NeedCopy-->
```

- To reset a parameter to its default value, you can use the `unset gslb service <serviceName>` command and the parameters to be unset. Example

```
1 > unset gslb service SKP_GSLB_NOTCNAME_SVC2 maxBandwidth
2 Done
3 > sh gslb service SKP_GSLB_NOTCNAME_SVC2
4 SKP_GSLB_NOTCNAME_SVC2 (21.211.21.21: 80)- HTTP
5 ...
6 Max Conn: 8 Max Bandwidth: 0 kbits
7 <!--NeedCopy-->
```

- To remove a GSLB service, use the `rm gslb service <serviceName>` command.

**To create a GSLB service by using the configuration utility**

1. Navigate to **Traffic Management > GSLB > Services**.
2. Add a new GSLB service, or select an existing service and edit its settings.

**To view the statistics of a GSLB service by using the command line interface**

At the command prompt, type:

```
1 stat gslb service <serviceName>
2 <!--NeedCopy-->
```

**Example:**

```
1 stat gslb service Service-GSLB-1
2 <!--NeedCopy-->
```

**To view the statistics of a GSLB service by using the configuration utility**

1. Navigate to **Traffic Management > GSLB > Services**.
2. Select the GSLB Service and click **Statistics**.

## Configure a GSLB service group

May 2, 2023

Service group enables you to manage a group of services as easily as a single service. If you enable or disable any option for a service group, the option gets enabled or disabled for all the members of the service group. For example, you can apply this feature to options such as Compression, Health monitoring, and Graceful shutdown.

After creating a service group, you can do any of the following:

- Bind the service group to a virtual server.
- Add services to the service group.
- Bind monitors to the service groups.

**Important**

If the load balancing virtual server is either in a GSLB node itself or is in a child node (in parent-child deployment) and no monitors are bound to the GSLB service, then make sure the following:

The GSLB service group IP address, port number, and protocol match the virtual server that the service is representing. Else, the service state is marked as DOWN.

The NetScaler supports the following types of GSLB service groups.

- IP address based service groups
- Domain name based service groups
- Domain name based autoscale service groups

## GSLB domain name based autoscale service groups

The NetScaler hybrid and multi-cloud global server load balancing (GSLB) solution enables customers to distribute application traffic across multiple data centers in hybrid clouds, multiple clouds, and on-premises. The NetScaler GSLB solution supports various load balancing solutions, such as the NetScaler load balancer, Elastic Load Balancing (ELB) for AWS, and other third-party load balancers. Also, the GSLB solution performs global load balancing even if the GSLB and load balancing layers are independently managed.

In cloud deployments, users are given a domain name as a reference when accessing the load balancing solution for management purposes. It is recommended that external entities do not use the IP addresses that these domain names resolve to. Also, the load balancing layers scale up or down based on the load, and the IP addresses are not guaranteed to be static. Therefore, it is recommended to use the domain name to refer to the load balancing endpoints instead of IP addresses. This requires the GSLB services to be referred using the domain name instead of IP addresses and it must consume all the IP addresses returned for the load balancing layer domain name and have a representation for the same in GSLB.

To use domain names instead of IP addresses when referring to the load balancing endpoints, you can use the domain name based service groups for GSLB.

## Monitor GSLB domain name based service groups

The NetScaler appliance has two built-in monitors that monitor TCP-based applications; `tcp-default` and `ping-default`. The `tcp-default` monitor is bound to all TCP services and the `ping-default` monitor is bound to all non-TCP services. The built-in monitors are bound by default to the GSLB service groups. However, it is recommended to bind an application specific monitor to the GSLB service groups.

**Recommendation for setting the trigger monitors option to MEPDOWN** The Trigger Monitors option can be used to indicate if the GSLB site must use the monitors always, or use monitors when metrics exchange protocol (MEP) is DOWN.

The Trigger Monitors option is set to ALWAYS by default.

When the Trigger Monitors option is set to ALWAYS, each GSLB node triggers the monitors independently. If each GSLB node triggers the monitors independently, then each GSLB node might operate on different set of GSLB services. This might result in discrepancies in the DNS responses for the DNS requests landing on these GSLB nodes. Also, if each GSLB node is monitoring independently, then the number of monitor probes reaching the load balancer entity increases. The persistence entries also become incompatible across the GSLB nodes.

Therefore, it is recommended that the Trigger Monitors option on the GSLB site entity is set to MEP-DOWN. When the Trigger Monitors option is set to MEPDOWN, the load balancing domain resolution and monitoring ownership lies with the local GSLB node. When the Trigger Monitors option is set to MEPDOWN, the load balancing domain resolution and subsequent monitoring is done by the local GSLB node of a GSLB service group. The results are then propagated to all other nodes participating in GSLB by using the metrics exchange protocol (MEP).

Also, whenever the set of IP addresses associated with a load balancing domain are updated, it is notified through MEP.

### Limitations of GSLB service groups

- For a load balancing domain, the IP address that is returned in the DNS response is generally the public IP address. The private IP address cannot be applied dynamically when the load balancing domain is resolved. Therefore, public IP port and private IP port for the GSLB domain name based autoscale service groups IP port bindings are the same. These parameters cannot be set explicitly for the domain name based autoscale service groups.
- Site persistence, DNS views, and clustering are not supported for GSLB service groups.

### Configure and manage GSLB service groups by using the CLI

To add a GSLB service group:

```
1 add gslb serviceGroup <serviceName>@ <serviceType> [-autoScale (
 DISABLED | DNS)] -siteName <string>
2 <!--NeedCopy-->
```

Example:

```
1 add gslb serviceGroup Service-Group-1 http -autoScale DNS -siteName
 Site1
2 <!--NeedCopy-->
```

To bind a GSLB service group to a virtual server:

```
1 bind gslb serviceGroup <serviceName> ((<IP>@ <port>) | <serverName
 >@ | (-monitorName <string>@))
2 <!--NeedCopy-->
```

Example:

```
1 bind gslb serviceGroup Service-Group-1 203.0.113.2
2 bind gslb serviceGroup Service-Group-1 S1 80
3 bind gslb serviceGroup** Service-Group-1 -monitorName Mon1
4 <!--NeedCopy-->
```

To unbind a GSLB service group to a virtual server:

```
1 unbind gslb serviceGroup <serviceName> ((<IP>@ <port>) | <
 serverName>@ | -monitorName <string>@)
2 <!--NeedCopy-->
```

Example:

```
1 unbind gslb serviceGroup Service-Group-1 -monitorName Mon1
2 <!--NeedCopy-->
```

To set parameters for a GSLB service group:

```
1 set gslb serviceGroup <serviceName>@ [(<serverName>@ <port> [-
 weight <positive_integer>] [-hashId <positive_integer>] [-publicIP <
 ip_addr|ipv6_addr|*>] [-publicPort <port>])] | -maxClient <
 positive_integer> | -cip (ENABLED | DISABLED) | <cipHeader> | -
 cltTimeout <secs> | -svrTimeout <secs> | -maxBandwidth <
 positive_integer> | -monThreshold <positive_integer> | -
 downStateFlush (ENABLED | DISABLED)] [-monitorName <string> -
 weight <positive_integer>] [-healthMonitor (YES | NO)] [-comment <
 string>] [-appflowLog (ENABLED | DISABLED)]
2 <!--NeedCopy-->
```

To unset parameters from a GSLB service group:

```
1 unset gslb serviceGroup <serviceName>@ [<serverName>@ <port> [-
 weight] [-hashId] [-publicIP] [-publicPort]] [-maxClient] [-cip] [-
 cltTimeout] [-svrTimeout] [-maxBandwidth] [-monThreshold] [-
 appflowLog] [-monitorName] [-weight] [-healthMonitor] [-cipHeader]
 [-downStateFlush] [-comment]
2 <!--NeedCopy-->
```

To enable a GSLB service group

```
1 enable gslb serviceGroup <serviceName>@ [<serverName>@ <port>]
2 <!--NeedCopy-->
```

Example:

```
1 enable gslb serviceGroup SG1 S1 80
2 <!--NeedCopy-->
```

To disable a GSLB service group

```
1 disable gslb serviceGroup <serviceName>@ [<serverName>@ <port>] [-
 delay <secs>] [-graceFul (YES /| NO)]
2 <!--NeedCopy-->
```

Example:

```
1 disable gslb serviceGroup SRG2 S1 80
2 <!--NeedCopy-->
```

**Note**

The service group that has to be disabled must be a DBS service group and not an autoscale service group.

To remove a GSLB service group:

```
1 rm gslb serviceGroup <serviceName>
2 <!--NeedCopy-->
```

Example:

```
1 rm gslb serviceGroup Service-Group-1
2 <!--NeedCopy-->
```

To view the statistics of a GSLB service group:

```
1 stat gslb serviceGroup [<serviceName>]
2 <!--NeedCopy-->
```

Example:

```
1 stat gslb serviceGroup Service-Group-1
2 <!--NeedCopy-->
```

To view the properties of a GSLB service group:

```
1 show gslb serviceGroup [<serviceName> -includeMembers]
2 <!--NeedCopy-->
```

Example:

```
1 show gslb serviceGroup SG1
2 show gslb serviceGroup -includeMembers
3 <!--NeedCopy-->
```

**Enable or disable GSLB service group members**

You can selectively enable or disable an individual member of a GSLB (DNS-based) service group instead of enabling or disabling the entire service group. This feature is available in both autoscale service groups and non-autoscale service groups. Therefore, managing a GSLB service group is made easier.

For example, you have a requirement to avoid traffic to a particular server on a GSLB site. Let's say, 10 GSLB services or servers (S1 to S10) are bound to a service group (SG1). You want to disable only service 5 (S5), that is avoid traffic to server 5. Without this feature, you have to separately bind services S1 to S4 and services S6 to S10. This process becomes tedious in a large GSLB service group where you

have to disable or enable large number of services. With this feature, you can directly disable service 5 (S5) without impacting other services in the service group.

To enable a GSLB service group member by using CLI:

```
1 enable gslb serviceGroup <serviceName>@ [<serverName>@ <port>]
2 <!--NeedCopy-->
```

**Note:**

To enable a GSLB service group, provide only the service group name. To enable a member of a service group, in addition to the GSLB service group name, provide the name of the server that hosts the service, and the port number of the service.

**Example:**

```
1 enable gslb serviceGroup http_svc_group 10.102.27.153 80
2 <!--NeedCopy-->
```

To disable a GSLB service group or a member of the GSLB service group by using CLI:

```
1 disable gslb serviceGroup <serviceName>@ [<serverName>@ <port>]
2 <!--NeedCopy-->
```

**Example:**

```
1 disable gslb serviceGroup http_svc_group 10.102.27.153 80
2 <!--NeedCopy-->
```

**Note:**

To disable a GSLB service group, provide only the service group name. To disable a member of a service group, in addition to the GSLB service group name, provide the name of the server that hosts the service, and the port number of the service.

**Changes to the existing GSLB CLI commands**

The following are the changes that are done to the existing GSLB commands after the introduction of the GSLB service groups:

- `bind gslb vservers` - The service group name is added to the bind command.

Example:

```
1 bind gslb vservers <name> ((-serviceName <string> [-weight <
 positive_integer>]) | <serviceName>@ | (-domainName <
 string> [-TTL <secs>] [-backupIP<ip_addr|ipv6_addr|*>] [-
 cookieDomain <string>] [-cookieTimeout <mins>][-sitedomainTTL
 <secs>]) | (-policyName <string>@ [-priority<positive_integer
```

```

>] [--gotoPriorityExpression <expression>] [--type REQUEST |
RESPONSE]))
2 <!--NeedCopy-->

```

- `unbind gslb vserver` - The service group is added to the unbind command.

Example:

```

1 unbind gslb vserver <name> (--serviceName <string> <
serviceGroupName> @ /(-domainName <string> [-backupIP] [-
cookieDomain]) | -policyName <string>@)
2 <!--NeedCopy-->

```

- `show gslb site` - When this command is run, the GSLB service groups are also displayed.
- `show gslb vs` - When this command is run, the GSLB service groups are displayed.
- `stat gslb vs` - When this command is run, the GSLB service groups statistics are also displayed.
- `show lb monitor bindings` - When this command is run, the GSLB service group bindings are also displayed.

### Configure GSLB service groups by using the GUI

1. Navigate to **Traffic Management > GSLB > Service Groups**.
2. Create a service group and set the AutoScale mode to DNS.

### Configure site persistence for the GSLB service groups

You can configure site persistence for the IP address based and domain name based service groups. Site persistence is not supported for domain name based autoscale service groups.

### To set site persistence based on HTTP cookies by using the CLI

- For connection proxy persistence, you do not have to set the site prefix.

At the command prompt, type:

```

1 set gslb service group <serviceGroupName> [--sitePersistence <
sitePersistence>]
2 <!--NeedCopy-->

```

- For HTTP redirect persistence, you must first set the site prefix for a member of the service group and then set the `HTTPRedirect` persistence parameter for the service group.

At the command prompt, type:

```
1 set gslb servicegroup <serviceName> <serviceGroup member
 name|Ip> <port> [-sitePrefix <string>]
2
3 set gslb servicegroup <serviceName> [-sitePersistence <
 sitePersistence>]
4 <!--NeedCopy-->
```

### Examples:

- Connection proxy persistence

```
1 set gslbservicegroup sg1 -sitePersistence connectionProxy
2 <!--NeedCopy-->
```

- HTTP Redirect persistence

```
1 set gslb servicegroup sg2 test1 80 -sitePrefix vserver-GSLB-1
2
3 set gslb servicegroup sg2 -sitePersistence HTTPRedirect
4 <!--NeedCopy-->
```

### To set site persistence based on cookies by using the GUI

1. Navigate to **Traffic Management > GSLB > Services Groups** and select the service group that you want to configure for site persistence (for example, servicegroup-GSLB-1).
2. Click the **Site Persistence** section and set the persistence that meets your requirement.

#### Tip

For deployment scenario and example configuration of GSLB service groups, see the following topics:

- [Use Case: Deployment of Domain Name Based Autoscale Service Group](#)
- [Use Case: Deployment of IP Address Based Autoscale Service Group](#)

## Configure a GSLB virtual server

May 2, 2023

A GSLB virtual server is an entity that represents one or more GSLB services and balances traffic between them. It evaluates the configured GSLB methods or algorithms to select a GSLB service to which to send the client request.

**Note**

A GSLB virtual server protocol requirement is mainly to create a relation between the virtual server and the services that are bound to the virtual server. This also keeps CLI/APIs consistent for other types of virtual servers. The Service Type parameter on a service or a virtual server is not used while serving the DNS requests. It is instead referenced during site persistence, monitoring, and for doing lookups via MEP.

**To create a GSLB virtual server by using the command line interface**

At the command prompt, type the following commands to add a GSLB virtual server and verify the configuration:

```
1 - add gslb vserver <name> <serviceType> -ipType (IPv4 | IPv6)
2 - show gslb vserver <name>
3 <!--NeedCopy-->
```

**Example:**

```
1 add gslb vserver Vserver-GSLB-1 HTTP -ipType IPv4
2 add gslb vserver Vserver-GSLB-2 HTTP -ipType IPv6
3 show gslb vserver Vserver-GSLB-1
4 show gslb vserver Vserver-GSLB-2
5 <!--NeedCopy-->
```

**To modify or remove a GSLB virtual server by using the command line interface**

- To modify a GSLB virtual server, use the `set gslb vserver` command. This command works similar to the `add gslb vserver` command, except that you enter the name of an existing GSLB virtual server.
- To reset a parameter to its default value, you can use the `unset gslb vserver` command followed by the `vserverName` value and the name of the parameter to be unset.
- To remove a GSLB virtual server, use the `rm gslb vserver` command, which accepts only the name argument.

**To configure a GSLB virtual server by using the configuration utility**

1. Navigate to **Traffic Management > GSLB > Virtual Servers**.
2. Add a new GSLB virtual server, or select an existing GSLB virtual server and edit its settings.

## To view the statistics of a GSLB virtual server by using the command line interface

At the command prompt, type:

```
1 stat gslb vserver <name>
2 <!--NeedCopy-->
```

### Example:

```
1 stat gslb vserver Vserver-GSLB-1
2 <!--NeedCopy-->
```

## To view the statistics of a GSLB virtual server by using the configuration utility

Navigate to **Traffic Management > GSLB > Virtual Servers**, select the virtual server and click **Statistics**.

### GSLB virtual server statistics

Starting from NetScaler version 12.1 build 51.xx and later, the GSLB virtual server statistics also display the following information in addition to details such as; virtual server hits, current persistence session, request bytes, response bytes, spillover threshold, spillover hits, current client established connections, and virtual server down backup hits.

- **Primary LB method failures:** Number of times the primary GSLB method has failed.
- **Backup LB method failures:** Number of times the backup GSLB method has failed.
- **Vserver persistence hits:** The number of times the request is served through the persistence sessions.

The GSLB virtual server statistics also display the statistics of the service group members bound to the virtual server.

#### Note:

The primary or the backup method can fail when the primary method is static proximity and the backup method is RTT. In this scenario, if there is no location corresponding to LDNS IP, the static proximity fails and the backup method is attempted. The statistics are updated based on the following:

- If the backup method is successful, only primary method failure statistics are incremented.
- If the RTT calculation is not successful, then the backup method also fails. In this case, both primary and backup method failure statistics are incremented.

When the backup method fails, the last resort method of round robin is used.

The following image is a sample of GSLB virtual server statistics from the CLI.

```
Gslb Vserver Summary
 Protocol State Health actSvcs inactSvc
gslbvip HTTP DOWN 0 0 0

VServer Stats:
 Rate (/s) Total
Vserver hits 0 0
Primary LB Method Failures -- 0
Backup LB Method Failures -- 0
Current Persistence Sessions -- 0
Vserver Persistence Hits -- 0
Request bytes 0 0
Response bytes 0 0
Current Client Est connections -- 0
Spill Over Threshold -- 0
Spill Over Hits -- 0
Vserver Down Backup Hits -- 0

Note: The above counters are the sum of all bound GSLB services
Done
```

The following image is a sample of GSLB virtual server statistics from the GUI.

The screenshot displays the 'GSLB Virtual Servers' configuration page for a service named 'stat'. The page title is 'GSLB Virtual Servers Statistics [ stat ]'. Under the 'Gslb Vserver Summary' section, there is a table with two columns: 'Name' and 'Vserver protocol'. The row shows 'stat' and 'HTTP'. Below the table are 'Enable' and 'Disable' buttons. The 'VServer Stats:' section lists various metrics:

Name	Vserver protocol
stat	HTTP

Buttons:

**VServer Stats:**

- Vserver hits
- Primary LB Method Failures
- Backup LB Method Failures
- Current Persistence Sessions
- Vserver Persistence Hits
- Request bytes
- Response bytes
- Current Client Est connections
- Spill Over Threshold
- Spill Over Hits
- Vserver Down Backup Hits

### GSLB service statistics

When you run the `stat gslb service` command from the command line or click the **Statistics link** from the configuration utility, the following details of the service are displayed:

- **Request bytes.** Total number of request bytes received on this service or virtual server.
- **Response bytes.** Number of response bytes received by this service or virtual server.
- **Current client established connections.** Number of client connections in ESTABLISHED state.
- **Current load on the service.** Load on the service (Calculated from the load monitor bound to the service).

The data of the number of requests and responses, and the number of current client and server connections may not be displayed or may not be synchronized with the data of the corresponding load balancing virtual server.

## Clearing the GSLB virtual server or service statistics

Note: This feature is available in NetScaler release 10.5.e.

You can now clear the statistics of a GSLB virtual server and service. NetScaler provides the following two options to clear the statistics:

- **Basic:** Clears the statistics that are specific to the virtual server but retains the statistics that are contributed by the bound GSLB service.
- **Full:** Clears both the virtual server and the bound GSLB service statistics.

### To clear the statistics of a GSLB virtual server by using the command line interface

At the command prompt, type:

```
1 stat gslb vserver <name> -clearstats <basic | full>
2 <!--NeedCopy-->
```

#### Example:

```
1 stat gslb vserver Vserver-GSLB-1 -clearstats basic
2 <!--NeedCopy-->
```

### To clear the statistics of a GSLB service by using the command line interface

At the command prompt, type:

```
1 stat gslb service <name> -clearstats <basic | full>
2 <!--NeedCopy-->
```

#### Example:

```
1 stat gslb service service-GSLB-1 -clearstats basic
2 <!--NeedCopy-->
```

### To clear the statistics of a GSLB virtual server by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Virtual Servers**.
2. Select the GSLB virtual server and, click **Statistics**, and then click **Clear**.
3. From the **Clear** drop-down list, select **Basic** or **Full**, and then click **OK**.

### To clear the statistics of a GSLB service by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Services**.

2. Select the GSLB service and, click **Statistics**, and then click **Clear**.
3. From the **Clear** drop-down list, select **Basic** or **Full**, and then click **OK**.

## Enabling and Disabling GSLB Virtual Servers

When you create a GSLB virtual server, it is enabled by default. If you disable the GSLB virtual server, upon receiving a DNS request, the NetScaler appliance does not make any GSLB decision based on the GSLB method that is configured. Instead, the response to the DNS query contains the IP addresses of all the services bound to the virtual server.

### To enable or disable a GSLB virtual server by using the command line interface

At the command prompt, type one of the following commands:

```
1 enable gslb vserver <name>@
2
3 disable gslb vserver <name>@
4 <!--NeedCopy-->
```

#### Example:

```
1 enable gslb vserver Vserver-GSLB-1
2 disable gslb vserver Vserver-GSLB-1
3 <!--NeedCopy-->
```

### To enable or disable a GSLB virtual server by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Virtual Servers**.
2. Select a virtual server and, from the **Action** list, select **enable** or **disable**.

## Use cases - GSLB virtual server

The following are some of the use cases where you can configure GSLB virtual servers:

- [Configure GSLB virtual server to protect the GSLB setup against failure](#)
- [Configure persistence in GSLB](#)
- [Configure GSLB API method](#)

## Bind GSLB services to a GSLB virtual server

September 21, 2020

Once the GSLB services and virtual server are configured, relevant GSLB services must be bound to the GSLB virtual server to activate the configuration.

### To bind a GSLB service to a GSLB virtual server by using the command line interface

At the command prompt, type the following commands to bind a GSLB service to a GSLB virtual server and verify the configuration:

```
1 bind gslb vserver <name> -serviceName <string>
2
3 show gslb vserver <name>
4 <!--NeedCopy-->
```

#### Example:

```
1 bind gslb vserver Vserver-GSLB-1 -serviceName Service-GSLB-1
2 show gslb vserver Vserver-GSLB-1
3 <!--NeedCopy-->
```

### To unbind a GSLB service from a GSLB virtual server by using the command line interface

At the command prompt, type:

```
1 unbind gslb vserver <name> -serviceName <string>
2 <!--NeedCopy-->
```

### To bind GSLB services by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Virtual Servers** and double-click a virtual server.
2. Click in the **Domains** section, and configure a domain and bind the domain.

## Bind a domain to a GSLB virtual server

May 2, 2023

To make a NetScaler appliance the authoritative DNS server for a domain, you must bind the domain to the GSLB virtual server. When you bind a domain to a GSLB virtual server, the NetScaler appliance adds an address record for the domain, containing the name of the GSLB virtual server. The start of authority (SOA) and name server (NS) records for the GSLB domain must be added manually.

For details on configuring SOA and NS records, see [Domain Name System](#).

### To bind a domain to a GSLB virtual server by using the command line interface

At the command prompt, type the following commands to bind a domain to a GSLB virtual server and verify the configuration:

```
1 bind gslb vserver <name> -domainName <string>
2 show gslb vserver <name>
3 <!--NeedCopy-->
```

#### Example:

```
1 bind gslb vserver Vserver-GSLB-1 -domainName www.mycompany.com
2 show gslb vserver Vserver-GSLB-1
3 <!--NeedCopy-->
```

### To unbind a GSLB domain from a GSLB virtual server by using the command line interface

At the command prompt, type:

```
1 unbind gslb vserver <name> -domainName <string>
2 <!--NeedCopy-->
```

### To bind a domain to a GSLB virtual server by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Virtual Servers**.
2. In GSLB Virtual Servers pane, select the GSLB Virtual Server to which you want to bind the domain (for example, Vserver-GSLB-1) and click **Open**.
3. In the Configure GSLB Virtual Server dialog box, on the Domains tab, do one of the following:
  - To create a new Domain, click **Add**.
  - To modify an existing Domain, select the domain, and then click **Open**.
4. In the Create GSLB Domain or Configure GSLB Domain dialog box, specify values for the following parameters as shown:

- Domain Name\*—domainName (for example, www.mycompany.com)

\* A required parameter

5. Click Create.
6. Click OK.

### To view the statistics of a domain by using the command line interface

At the command prompt, type:

```
1 stat gslb domain <name>
2 <!--NeedCopy-->
```

#### Example:

```
1 stat gslb domain www.mycompany.com
2 <!--NeedCopy-->
```

Note: To view statistics for a particular GSLB domain, enter the name of the domain exactly as it was added to the NetScaler appliance. If you do not specify the domain name, or if you specify an incorrect domain name, statistics for all configured GSLB domains are displayed.

### To view the statistics of a domain by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Virtual Servers**.
2. In GSLB Virtual Servers pane, select the GSLB Virtual Server (for example, Vserver-GSLB-1) and click Open.
3. In the Configure GSLB Virtual Server dialog box, on the Domains tab, select the domain, and then click **Statistics**.

### To view the configuration details of the entities bound to a GSLB domain using the command line

Note: This feature is available in NetScaler release 10.5.e.

At the command prompt, type:

```
1 show gslb domain <name>
2 <!--NeedCopy-->
```

#### Example:

```
1 show gslb domain gslb1.com
2 gslb1.com
3 gvs1 - HTTP state: DOWN
4 DNS Record Type: A
5 Configured Method: LEASTCONNECTION
6 Backup Method: ROUNDROBIN
7 Persistence Type: NONE
8 Empty Down Response: DISABLED
9 Multi IP Response: DISABLED
10 Dynamic Weights: DISABLED
11
12 gsvc1 (10.102.239.165: 80)- HTTP State: DOWN Weight: 1
13 Dynamic Weight: 0 Cumulative Weight: 1
14 Effective State: DOWN
15 Threshold : BELOW
16
17 Monitor Name : http
18 State: DOWN Weight: 1
19 Probes: 144 Failed [Total: 144 Current: 144]
20 Last response: Failure - TCP syn sent, reset
21 received.
22 Response Time: 2000 millisec
23
24 gsvc2 (10.102.239.179: 80)- HTTP State: DOWN Weight: 1
25 Dynamic Weight: 0 Cumulative Weight: 1
26 Effective State: DOWN
27 Threshold : BELOW
28
29 Monitor Name : http-ecv
30 State: DOWN Weight: 1
31 Probes: 141 Failed [Total: 141 Current: 141]
32 Last response: Failure - TCP syn sent, reset
33 received.
34 Response Time: 2000 millisec
35 Done
36 <!--NeedCopy-->
```

### To view the configuration details of the entities bound to a GSLB domain by using the configuration utility

Note: This feature is available in NetScaler release 10.5.e.

1. Navigate to **Traffic Management > GSLB > Virtual Servers** and double-click a virtual server.
2. Click the field below the **Domains** pane.
3. In the **GSLB Virtual Server Domain Binding** dialog box, select a domain, and then click **Show Bindings**.

## Example of a GSLB setup and configuration

May 2, 2023

An organization has a geographically dispersed network and has three data centers located in the United States, Mexico, and Colombia. In the configuration related to these locations, these are referred to as US, MX, and CO respectively. At each location, the company has a server farm, which provides the same content and the setup is working as expected. The NetScaler appliance at each location is configured through a virtual server with the HTTP protocol on port 80.

The organization has implemented the GSLB setup by adding a site identifier at each site. The site identifier includes a site name and an IP address that is owned by the NetScaler appliance and is used for the GSLB communications.

Each site has a site local to the appliance. Also, each site has two sites remote to the local appliance. On each site, a GSLB virtual server is created with the same name. This virtual server identifies the website of the organization globally and does not have any IP address associated with it.

The setup also has GSLB services configured that point to the load balancing virtual servers configured on each GSLB site by specifying the IP address, protocol, and port number of the respective virtual server. These services are bound to the GSLB virtual server.

**Note:** In the procedure below, the commands use private IP addresses for the GSLB sites. For public sites and GSLB services, ensure that you use public IP addresses for these sites.

The following table lists the IP addresses and locations used in the example:

IP Address	Location
10.3.1.101	Site IP of local NetScaler.
172.16.1.101	Site IP of remote location site-MX.
192.168.1.101	Site IP of remote location site-CO.
172.16.1.100	Service IP of remote location site-MX.
10.3.1.100	Service IP of local NetScaler.
192.168.1.100	Service IP of remote location site-CO.

When adding a GSLB site, if the site communicates over the internet only then use the “Public IP” field. For example, when there is no site to site VPN connectivity between the GSLB sites.

### To configure the GSLB setup with NetScaler appliances by using the CLI commands

1. Enable the GSLB feature, if not already done.

```
1 enable ns feature gslb
2 <!--NeedCopy-->
```

2. Identify a SNIP that for adding local GSLB site.
3. Add the GSLB site for the local NetScaler appliance.

```
1 add gslb site site-US 10.3.1.101
2 <!--NeedCopy-->
```

4. Add the GSLB sites for the remote NetScaler appliances.

```
1 add gslb site site-MX 172.16.1.101
2 add gslb site site-CO 192.168.1.101
3 <!--NeedCopy-->
```

5. Add the GSLB virtual server that references a service being used in the GSLB setup:

```
1 add gslb vserver gslb-lb HTTP
2 <!--NeedCopy-->
```

6. Add the GSLB services for each site participating in the GSLB setup:

```
1 add gslb service gslb_SVC30 172.16.1.100 HTTP 80 -siteName site-MX
2 add gslb service gslb_SVC10 10.3.1.100 HTTP 80 -siteName site-US
3 add gslb service gslb_SVC20 192.168.1.100 HTTP 80 -siteName site-
 CO
4 <!--NeedCopy-->
```

7. Bind the GSLB services to the GSLB virtual server:

```
1 bind gslb vserver gslb-lb -serviceName gslb_SVC10
2 bind gslb vserver gslb-lb -serviceName gslb_SVC20
3 bind gslb vserver gslb-lb -serviceName gslb_SVC30
4 <!--NeedCopy-->
```

8. Bind the domain to the GSLB virtual server.

```
1 bind gslb vserver gslb-lb -domainName www.mycompany.com -TTL 30
2 <!--NeedCopy-->
```

9. Add an ADNS service that listens to the DNS queries.

```
1 set service Service-ADNS-1 10.14.39.21 ADNS 53
2 <!--NeedCopy-->
```

## Synchronize the configuration in a GSLB setup

May 2, 2023

Typically, a GSLB setup has a few data centers with a GSLB site configured for each data center. In each NetScaler, participating in GSLB, configure one GSLB site as a local site and the others as remote sites. When you add another GSLB site at a later point, you must ensure that the configuration across all GSLB sites is identical. You can use the NetScaler's GSLB configuration synchronization option to synchronize the configuration across the GSLB sites.

The NetScaler appliance from which you use the synchronization option is referred to as the 'main site' and the GSLB sites on which the configuration is copied as the 'subordinate sites'. When you synchronize a GSLB configuration, the configurations on all the GSLB sites participating in the GSLB setup are made similar to the configuration on the main site.

Synchronization is done only on the parent sites. Synchronization does not affect GSLB child sites' configuration. This is because the parent site and the child site configurations are not identical. The child sites configuration consists only of its own and its parent site's details. Also, GSLB services are not always required to be configured in the child sites.

- The main node finds the differences between the configuration of the main node and subordinate node, and changes the configuration of the subordinate node to make it similar to the main node.

If you force a synchronization (use the 'force sync' option), the appliance deletes the GSLB configuration from the subordinate node and then configures the subordinate to make it similar to the main node.

- During synchronization, if a command fails, synchronization is not aborted and the error message are logged into a **.err** file in the **/var/netscaler/gslb** directory.
- Synchronization is done only on the parent sites. Synchronization does not affect the GSLB child sites' configuration. This is because the parent site and the child site configurations are not identical. The child sites configuration consists only of its own and its parent site's details. Also, GSLB services are not always required to be configured in the child sites.
- If you disable the internal user login, the GSLB auto sync uses the SSH keys to synchronize the configuration. But, to use GSLB auto sync in the partition environment, you must enable the internal user login and make sure that the partition user name in the local and remote GSLB sites is the same.

### Note

- On the remote GSLB site RPC node, configure the firewall to accept auto-sync connections

by specifying the remote site IP (cluster IP address for cluster setup) and port (3010 for RPC and 3008 for secure RPC). If the default route to reach the remote sites is in the management subnet, as in most cases, then NSIP is used as the source IP address.

To configure a different source IP address, you must have the GSLB site IP address and the SNIP in a different subnet. Also, you must have an explicit route defined to the remote site IP address through a GSLB site IP subnet.

For enhanced security, Citrix recommends that you change the internal user account and RPC node passwords. Internal user account password is changed through RPC node password. For details, see [Change an RPC node password](#).

If you use the saveconfig option, the sites that participate in the synchronization process automatically save their configuration, in the following way:

On the remote GSLB site RPC node, configure the firewall to accept auto-sync connections by specifying the remote site IP (cluster IP address for cluster setup) and port (3010 for RPC and 3008 for secure RPC). If the default route to reach the remote sites is in a management subnet, as in most cases, then NSIP is used as the source IP address.

To configure a different source IP address, you must have the GSLB site IP address and the SNIP in a different subnet. Also, you must have an explicit route defined to the remote site IP address through the GSLB site IP subnet. The source IP address cannot be synchronized across the sites participating in GSLB because the source IP address for an RPC node is specific to each NetScaler appliance. Therefore, after you force a synchronization (using the sync gslb config -forceSync command or by selecting the ForceSync option in the GUI), you have to manually change the source IP addresses on the other NetScaler appliances. Port 22 is also required for synchronizing the database files to the remote site.

### To improve the time taken for configuration synchronization on all GSLB sites

Configure the TCP profile settings at the command prompt as follows:

```
1 set tcpprofile nstcp_internal_apps -bufferSize 4194304 -sendBufferSize
 4194304 -tcpmode ENDPOINT
2 <!--NeedCopy-->
```

### Limitations of synchronization

- On the main site, the names of the remote GSLB sites must be identical to the names of sites configured on the NetScaler appliances hosting those sites.
- During the synchronization, traffic disruptions may occur.

- NetScaler is tested to synchronize up to 200,000 lines of the configuration.
- Synchronization may fail:
  - If the spill over method is changed from CONNECTION to DYNAMIC CONNECTION.
  - If you interchange the site prefix of the GSLB services bound to a GSLB virtual server on the main node and then try to synchronize.
  - If the RPC node passwords are different for NSIP and loopback IP address.
  - If you perform synchronization on GSLB sites that are configured in different partitions of the same NetScaler appliance.
- If you have configured the GSLB sites as High Availability (HA) pairs, the RPC node passwords of primary and secondary nodes must be the same.
- If you rename any GLSB entity that is part of your GSLB configuration (use the “show gslb runningConfig”command to display the GSLB configuration). You must use the force sync option to synchronize the configuration to other GSLB sites.

**Note:**

- In incremental synchronization, you don't have to use the force sync option to synchronize the configuration to other GSLB sites. This is applicable starting NetScaler release 13.0 build 79.x onwards.

Note: To overcome the limitations due to some settings in the GSLB configuration, you can use the force sync option. But, if you use the force sync option the GSLB entities are removed and readded to the configuration and the GSLB statistics are reset to zero. Hence the traffic is disrupted during the configuration change.

### **Points to note before starting the synchronization of a GSLB setup**

Before you start the synchronization of a GSLB setup, make sure that:

- On all the GSLB sites including the main site, management access and SSH must be enabled for the IP address of the corresponding GSLB site. The IP address of a GSLB site must be an IP address owned by the NetScaler appliance. For more information about adding the GSLB site IP addresses and enabling Management Access, see “[Configuring a Basic GSLB Site](#)”.
- The GSLB configuration on the NetScaler appliance that is considered as the main site is complete and appropriate to be copied on all the sites.
- If you are synchronizing the GSLB configuration for the first time, all the sites participating in GSLB must have the GSLB site entity of their respective local sites.
- You are not synchronizing sites that, by design, do not have the same configuration.

- The main site and the subordinate sites run the same NetScaler versions. Starting from release 12.1, build 50.x, the appliance checks for the firmware version on main and subordinate sites before initiating synchronization. If the main and the subordinate sites run different versions, the synchronization is aborted for that remote site to avoid pushing any incompatible changes across the versions. Also, an error message displaying the site details on which the synchronization aborted appears.

The following figures display sample error messages from the CLI and the GUI.

```
> sh gslb syncStatus -summary
Displaying the status summary of the manual GSLB configuration synchronization:
```

Site Name	Status	Reason
s2	Failure	Error: Different netscaler release on the remote site. Local Site: 13.0, Remote Site: 12.1
s1	Success	All Done
s3	Success	All Done

Done  
>

```
> sh gslb syncStatus -summary
Displaying the status summary of the manual GSLB configuration synchronization:
```

Site Name	Status	Reason
s2	Failure	Error: Different netscaler release on the remote site. Local Site: 13.0, Remote Site: 12.1
s1	Success	All Done
s3	Success	All Done

Done  
>

### Important

The following directories are synchronized as part of the GSLB configuration synchronization.

- /var/netscaler/locdb/
- /var/netscaler/ssl/
- /var/netscaler/inbuilt\_db/

## Manual synchronization between sites participating in GSLB

May 2, 2023

The manual synchronization of GSLB configuration across the master site and the slave sites is performed in the following manner:

- The master site detects the differences between the configuration of its own site and the slave site.
- The master site applies the difference in configuration to the slave site.
- The master site performs the configuration synchronization with all the slave sites in the GSLB setup, and completes the synchronization process.

**Important:** After a GSLB configuration is synchronized, the configuration cannot be rolled back on any of the GSLB sites. Perform the synchronization only if you are sure that the synchronization process does not overwrite the configuration on the remote site. Site synchronization is undesirable when the local and remote sites have different configurations by design, which leads to site outage. If some commands fail and some commands succeed, the successful commands are not rolled back.

### Points to note

- If you force a synchronization (use the ‘force sync’ option), the NetScaler appliance deletes the GSLB configuration from the slave site. Then, master site configures the slave site to make it similar to its own site.
- During synchronization, if a command fails, synchronization is not aborted. The error messages are logged into an .err file in the /var/netscaler/gslb directory.
- If you use the `saveconfig` option, the sites participating in the synchronization process automatically save their configuration, in the following way:
  - The master site saves its configuration immediately before it initiates the synchronization process.
  - The slave sites save their configuration after the process of synchronization is complete. A slave site saves its configuration only if the configuration difference was applied successfully on it. If synchronization fails on a slave site, you must manually investigate the cause of the failure and take corrective actions.

### To synchronize a GSLB configuration by using the CLI:

At the command prompt, type the following commands to synchronize GSLB sites and verify the configuration:

```
1 sync gslb config [-preview | -forceSync <string> | -nowarn | -
 saveconfig] [-debug]
2 show gslb syncStatus
3 <!--NeedCopy-->
```

### Example:

```
1 sync gslb config
2
3 [WARNING]: Syncing config may cause configuration loss on other site.
4
```

```
5 Please confirm whether you want to sync-config (Y/N)? [N]:y
6
7 Sync Time: Dec 9 2011 10:56:9
8
9 Retrieving local site info: ok
10
11 Retrieving all participating gslb sites info: ok
12
13 Gslb_site1[Master]:
14
15 Getting Config: ok
16
17 Gslb_site2[Slave]:
18
19 Getting Config: ok
20
21 Comparing config: ok
22
23 Applying changes: ok
24
25 Done
26 <!--NeedCopy-->
```

#### To synchronize a GSLB configuration by using the GUI:

1. Navigate to **Traffic Management > GSLB > Dashboard**.
2. Click **Auto Synchronization GSLB** and select **ForceSyn**.
3. In **GSLB Site Name**, select the GSLB sites that are to be synchronized with the master node configuration.

#### Previewing GSLB synchronization

By previewing the GSLB synchronization operation, you can see the differences between the master node and each slave node. If there are any discrepancies, you can troubleshoot before synchronizing the GSLB configuration.

#### To preview the GSLB synchronization output by using the CLI:

At the command prompt, type the following command:

```
1 sync gslb config -preview
2 <!--NeedCopy-->
```

#### To preview the GSLB synchronization output by using the GUI:

1. Navigate to **Configuration > Traffic Management > GSLB > Dashboard**.
2. Click **Auto Synchronization GSLB** and select **Preview**.
3. Click **Run**.  
A progress window displays any discrepancies in the configuration.

## Debugging the commands triggered during synchronization process

You can view the status (success or failure) of each command triggered during the synchronization process and troubleshoot accordingly.

### To debug the GSLB synchronization commands by using the CLI:

At the command prompt, type the following command:

```
1 sync gslb config -debug
2 <!--NeedCopy-->
```

### To debug the GSLB synchronization commands by using the GUI:

1. Navigate to **Configuration > Traffic Management > GSLB > Dashboard**.
2. Click **Auto Synchronization GSLB** and select **Debug**.
3. Click **Run**. A progress window displays the status of each command triggered during synchronization.

## Real-time synchronization between sites participating in GSLB

October 6, 2023

You can use the `AutomaticConfigSync` parameter to automatically synchronize the real-time GSLB configuration of the main site to all the subordinate sites. You do not have to manually trigger the `AutoSync` option to synchronize the configuration.

You can automatically synchronize GSLB configuration of the main site to all the subordinate sites by using incremental synchronization or full synchronization. The `GSLBSyncMode` parameter allows you to choose the synchronization mode.

Note:

Starting from NetScaler release 13.0 build 79.x, incremental synchronization of GSLB synchronization is supported. By default, the synchronization is performed using incremental synchronization. Incremental synchronization can be performed by enabling the `IncrementalSync` parameter. For details, see [Incremental synchronization of GSLB configuration](#).

### Best practices for using the real-time synchronization feature

- It is recommended that all the NetScaler appliances participating as sites have the same NetScaler software version.

- To change the RPC node password, first change the password on the subordinate site and then on the main site.
- Configure local GSLB sites on each site participating in GSLB.
- Enable automaticConfigSync on one of the sites where the configuration is performed. This site eventually gets synchronized to other GSLB sites.
- If there is a new configuration or changes are made to the existing configuration, make sure to check the status using the `show gslb syncStatus` command to confirm if the changes are synchronized across all sites or if there was any error.
- RSYNC port monitoring must be enabled.

### To enable real-time synchronization by using the CLI

At the command prompt, type:

```
1 set gslb parameter [- automaticConfigSync (ENABLED | DISABLED)] [-
 MEPKeepAliveTimeout <secs>] [-GSLBSyncMode (IncrementalSync |
 FullSync)] [-GSLBSyncLocFiles (ENABLED | DISABLED)] [-
 GslbConfigSyncMonitor (ENABLED | DISABLED)] [-GSLBSyncInterval <
 secs>] [-GSLBSyncSaveConfigCommand (ENABLED | DISABLED)]
2 <!--NeedCopy-->
```

#### Example:

```
1 set gslb parameter - automaticConfigSync ENABLED
2 <!--NeedCopy-->
```

The real-time synchronization provides the following configurable parameters:

- **GSLBSyncMode**—Mode in which configuration is synchronized from main site to remote sites.
  - Possible values: IncrementalSync, FullSync
  - Default value: IncrementalSync
- **GSLBSyncLocFiles**—During GSLB config synchronization, by default, the changes in the location DB files are detected and automatically synchronized. Because the location DB directories do not change often, admins can disable automatically synchronizing the location DB files. Instead, admins must manually copy the location DB files to the GSLB subordinate sites. Synchronizing location DB files takes much time. Thus, avoiding it reduces the overall synchronization time.

#### Example to disable automatically synchronizing the location DB files:

```
1 set gslb parameter -GSLBSyncMode IncrementalSync -
 GSLBSyncLocFiles DISABLED
2 <!--NeedCopy-->
```

- **GslbConfigSyncMonitor**—Enable the GSLB Config Sync Monitor parameter to monitor the state of the subordinate sites'RSYNC port which is the SSH port 22 on remote GSLB site IP address. If the monitor shows the subordinate site state as DOWN, the RSYNC operation to that site is skipped. This reduces the synchronization delays caused by attempting to connect to the remote sites that are DOWN.

**Example to enable RSYNC port monitoring in CLI:**

```
1 set gslb parameter -GSLBSyncMode IncrementalSync -
 GslbConfigSyncMonitor ENABLED
2 <!--NeedCopy-->
```

- **GSLBSyncInterval**—Set the time interval (in seconds) at which the GSLB configuration synchronization occurs. By default, the automatic GSLB configuration sync feature synchronizes the GSLB configuration automatically at every 10 seconds. You can change the time interval to any desired value. Refrain from setting this to a lower value, for example, not lesser than 5 seconds. Because synchronizing frequently might increase the management CPU consumption.

Note:

In an admin partition setup, the time interval can be set only in the default partition because it is a global parameter.

**Example to set the sync interval:**

```
1 set gslb parameter -AutomaticConfigSync ENABLED -GSLBSyncMode
 IncrementalSync -GSLBSyncInterval 7
2 <!--NeedCopy-->
```

- **GSLBSyncSaveConfigCommand**—Enable this parameter to synchronize the `save ns config` command to subordinate sites, if the `AutomaticConfigSync` option is enabled.

**Example to enable the synchronization of 'Save Config' Command:**

```
1 set gslb parameter -AutomaticConfigSync ENABLED -
 GSLBSyncSaveConfigCommand ENABLED
2 <!--NeedCopy-->
```

The `save ns config` command isn't synchronized to subordinate sites in certain scenarios as follows:

- Subordinate site is down or unreachable when config is saved on main site.
- Configuration has failed on a subordinate site.

## To enable real-time synchronization by using the GUI

1. Navigate to **Configuration > Traffic Management > GSLB > Change GSLB Settings**.

2. In the **Set GSLB Parameters** page, you can perform the following:

- To automatically synchronize the real-time GSLB configuration, select **Automatic Config-Sync**.

**Note:** This option must be enabled only in the site where the configuration is performed.

- To set the Automatic GSLB config sync interval, enter the time in seconds in the **GSLB Sync Interval** field.
- To enable RSYNC port monitoring, select the **GSLB Config Sync Monitor** check box.
- To disable automatically synchronizing the location DB files, clear the **GSLB Sync Loc Files** check box.
- To enable synchronizing of the `save ns config` command to the subordinate sites, select **Sync Save Config Command** check box.

For information on the following topics, see [Manual synchronization between sites participating in GSLB](#).

- Previewing GSLB synchronization
- Debugging the commands triggered during the synchronization process

**Points to note**

- The consolidated log file related to the real-time synchronization is stored in the `/var/netscaler/gslb/periodic_sync.log` directory.
- The default configuration file is stored in the `/var/netscaler/gslb_sync/` directory.
- The main site uses the following directory structure:
  - The main site stores all its files in the `/var/netscaler/gslb_sync/master` directory.
  - The main site stores its configuration file that must be synced to the subordinate sites, in the `/var/netscaler/gslb_sync/master/gslbconf/` directory.
  - The status files pulled from all the subordinate sites are stored in the `/var/netscaler/gslb_sync/master/status` directory.
- The subordinate site uses the following directory structure:
  - The subordinate site picks up the latest configuration file to be applied from the `/var/netscaler/gslb_sync/slave/gslbconf` directory.
  - The subordinate site stores its status file in the `/var/netscaler/gslb_sync/slave/gslbstatus` directory.
- In an admin partition setup, the same directory structure is maintained in the location: `/var/partitions/partition name/netscaler/gslb_sync`.
- The clocks on all the sites must be set accurately to a real-time standard like Coordinated Universal Time (UTC).

**Incremental synchronization of GSLB configuration**

The automatic GSLB configuration synchronization feature checks for the configuration changes on the main site at the interval of every 10 seconds, and performs a synchronization. This sync interval value is configurable.

In incremental synchronization, only the configurations that have changed on the main site between the last synchronization and the subsequent sync interval (10 secs) is synchronized across all the subordinate sites. Incremental synchronization is the default behavior. Pushing only the incremental configurations considerably reduces the configuration file size, and thus the synchronization time. If an incremental synchronization fails, the system automatically performs a full configuration synchronization.

Incremental synchronization is performed in the following manner:

- The main site pushes the configuration file comprising of only its latest changes to all the subordinate sites. The latest change refers to the configurations that has changed between the last synchronization and the subsequent sync interval (10 secs).

- Each subordinate site applies the latest change to its own site.
- Incremental synchronization is not attempted on the subordinate sites, which are in DOWN state. When the site comes back UP, again synchronization is performed.
- The subordinate site generates status logs at each step and copies them to a file at a specific location.
- The main site pulls the status log files from the specified location.
- The main site prepares a log file with logs combined from all the subordinate sites.
- This combined log file is stored in the “/var/netscaler/gslb/periodic\_sync.log” file.

For more information on the directories where the configuration files are stored, see [Points to note](#) section.

### To enable GSLB configuration incremental synchronization by using the CLI

```
1 set gslb parameter -AutomaticConfigSync (ENABLED | DISABLED) -
 GSLBSyncMode (IncrementalSync | FullSync) -GslbConfigSyncMonitor (
 ENABLED | DISABLED) -GSLBSyncInterval <secs> -GSLBSyncLocFiles (
 ENABLED | DISABLED)
2 <!--NeedCopy-->
```

#### Example:

```
1 set gslb parameter -AutomaticConfigSync ENABLED -GSLBSyncMode
 IncrementalSync
2 <!--NeedCopy-->
```

### To enable GSLB incremental synchronization by using the GUI

1. Navigate to **Traffic Management > GSLB > Dashboard > Change GSLB settings**.
2. In the **Set GSLB Parameters** page, choose **IncrementalSync** from the **GSLB Sync Mode** drop-down menu.

### Full synchronization of GSLB configuration

Whenever there is a configuration change in the main site, the complete GSLB running configuration on the main site is pushed to all the subordinate sites.

Even if incremental synchronization is configured, a full synchronization is performed when the main site does not know the configuration status of the subordinate site. Some of such scenarios are as follows:

- Enable the automatic GSLB configuration synchronization feature for the first time.
- Reboot the NetScaler appliance.

- GSLB deployment has multiple main sites, and another main site becomes the active main site.
- Add a new subordinate site to the GSLB deployment.

GSLB configuration full synchronization is performed in the following manner:

- The main site pushes its latest configuration file to all the subordinate sites.
- Each subordinate site compares its own configuration with the latest configuration file sent by the main site. The subordinate site identifies the difference in configuration, and applies the delta configuration for its own site.
- The subordinate site generates status logs at each step and copies them to a file at a specific location.
- The main site pulls the status log files from the specified location.
- The main site prepares a log file with logs combined from all the subordinate sites.
- This combined log file is stored in the “/var/netscaler/gslb/periodic\_sync.log”file.

If you attempt to manually synchronize (with the `sync gslb config` command) a site while it is being autosynchronized, a “Sync in progress”error message appears. Autosynchronization cannot be triggered for a site that is in the process of being synchronized manually.

**Note:**

Starting with NetScaler 12.1 build 49.37, SNMP traps are generated when you synchronize the GSLB configuration. In real-time synchronization, the synchronization status in the first SNMP trap is captured as failure. You can ignore this status because a second SNMP trap is automatically generated immediately after the first trap with the actual synchronization status. However, if the synchronization failed in the second attempt also, SNMP trap is not generated because the synchronization status has not changed from the previous synchronization status.

For details on configuring NetScaler appliance to generate traps, see [Configuring the NetScaler to generate SNMP traps](#).

**To enable GSLB full synchronization by using the CLI**

```
1 set gslb parameter -GSLBSyncMode (IncrementalSync | FullSync)
2 <!--NeedCopy-->
```

**Example:**

```
1 set gslb parameter -GSLBSyncMode FullSync
2 <!--NeedCopy-->
```

To enable GSLB incremental synchronization by using the GUI:

1. Navigate to **Traffic Management > GSLB > Dashboard > Change GSLB settings**.

2. In the **Set GSLB Parameters** page, choose **FullSync** from the **GSLB Sync Mode** drop-down menu.

## Multiple main sites in a GSLB deployment

The NetScaler appliance supports multiple main sites in an active-passive deployment. It is recommended to have two main sites in a GSLB deployment to cope against GSLB main site failure. Having two main sites can avoid single point of failure of GSLB configuration synchronization. At any time, only one main site can actively process the GSLB configuration from the user. If the configuration changes are performed simultaneously in more than one main site, it might lead to configuration inconsistency or configuration losses. Hence, it is recommended to perform configuration changes from only one main site at a time, and use the other main site as a backup when the active main site fails.

### Note:

When multiple main sites are used in a GSLB deployment, RSYNC monitoring must be enabled.

To make a GSLB node as one of the main sites for GSLB configuration synchronization, run the following command:

```
1 set gslb parameter -automaticConfigSync Enabled
2 <!--NeedCopy-->
```

## View GSLB synchronization status and summary

September 21, 2020

After the GSLB configuration is synchronized across the GSLB sites, you can view the detailed status and the summary of the last GSLB sync operation. This is applicable to both manual and real-time GSLB synchronization.

### To view the GSLB synchronization status or summary by using the CLI

At the command prompt, type:

```
1 show gslb sync status
2 <!--NeedCopy-->
```

or

```
1 show gslb syncStatus -summary
2 <!--NeedCopy-->
```

## Sample configuration output for GSLB manual synchronization

The following output displays the status of the manual GSLB configuration synchronization.

```
> sh gslb syncStatus
Displaying the status of the manual GSLB configuration synchronization:

gslb_site1[Master]:
 Getting Config: ok
gslb_site2[Slave]:
 Syncing gslb static proximity database: ok
 Syncing inbuilt gslb static proximity database : ok
 Getting Config: ok
 Comparing config: ok
 Applying changes: ok
gslb_natsite1[Slave]:
 Syncing gslb static proximity database: ok
 Syncing inbuilt gslb static proximity database : ok
 Getting Config: ok
 Comparing config: ok
 Applying changes: ok

Done
> █
```

The following output displays the status summary of the manual GSLB configuration synchronization.

```
> sh gslb syncStatus -summary
Displaying the status summary of the manual GSLB configuration synchronization:

 Site Name Status Reason

 gslb_site1 Success All Done
 gslb_site2 Failure Error executing command on gslb site...ERROR: Connection failed
 gslb_natsite1 Success All Done

Done
>
```

## Sample configuration output for GSLB real-time synchronization

The following output displays the status of the real-time GSLB configuration synchronization for the master site:

```
1 > sh gslb syncStatus
2 Displaying the status of the real time GSLB configuration
 synchronization as master node:
3
4 site2[Master]:
5 New GSLB configuration detected at Fri Jan 23 20:54:24
 2020
6 Fetching current configuration: Done
7 Updating default.conf file: Done
8 site1[Slave]:

 command: Done
21 Updating default.conf file: Done
22 Done
23 <!--NeedCopy-->
```

The following output displays the status of the real-time GSLB configuration synchronization for the slave site:

```
1 > sh gslb syncStatus
2 Displaying the status of the real time GSLB configuration
 synchronization as slave node:
3
4 site1 received new configuration from 10.102.217.205 in
 file 2JNSzClRHk5+pdek6szQ3g-default-10.102.217.210.
 conf
5 Firing set gslb parameter -startConfigSync ENABLED
 command: Done
6 Fetching running GSLB Config: Done
```

```

7 Comparing config: Done
8 Applying changes: Done
9 Firing set gslb parameter -startConfigSync DISABLED
 command: Done
10 Updating default.conf file: Done
11 Done
12 <!--NeedCopy-->

```

The following output displays the status summary of the real-time GSLB configuration synchronization for the master site:

```

1 > sh gslb syncStatus -summary
2 Displaying the status summary of the real time GSLB configuration
 synchronization as master node:
3
4 -----
5 Site Name Reason Status
6 -----
7 site2 All Done Success
8 site1 All Done Success
9
10 Done
11 <!--NeedCopy-->

```

The following output displays the status summary of the real-time GSLB configuration synchronization for slave site:

```

1 > sh gslb syncStatus -summary
2 Displaying the status summary of the real time GSLB configuration
 synchronization as slave node:
3
4 -----
5 Site Name Reason Status
6 -----
7 site1 All Done Success
8
9 Done
10 <!--NeedCopy-->

```

**To view the GSLB synchronization status or summary by using the GUI**

1. Navigate to **Configuration > Traffic Management > GSLB > Dashboard**.

2. Click **View Synchronization Summary** or **View Synchronization Status**, as required.

## SNMP traps for GSLB configuration synchronization

May 2, 2023

Starting with NetScaler 12.1 build 49.xx, the NetScaler appliance generates SNMP traps for both local and remote sites when you synchronize the GSLB configuration. SNMP traps are generated for both manual synchronization and real-time synchronization.

When you synchronize the GSLB configuration for the first time, SNMP traps are generated. In the subsequent synchronization attempts, the SNMP traps are generated only if there is a change in the synchronization status from the previous synchronization status. Also, the SNMP traps are generated only for sites for which the synchronization status changed from the previous state.

For example, consider that the first GSLB configuration synchronization is successful. When you synchronize the configuration for the second time and if the synchronization is successful again, then SNMP traps are not generated because the status is not changed. However, in the third attempt, if the synchronization fails for one of the sites, then SNMP trap is generated for that site alone.

In a high availability and a cluster setup, the appliance generates the SNMP traps when you synchronize the GSLB configuration from the new node irrespective of the previous synchronization status. Also, if SNMP trap option was previously disabled and then enabled, SNMP traps are generated from that point onwards irrespective of previous synchronization status.

The SNMP traps of GSLB configuration synchronization provide the following details:

- Name of the GSLB site for which the SNMP trap is sent.
- GSLB configuration synchronization status: Success or Failure.
- GSLB configuration synchronization mode: Incremental sync or Full sync.
- (Optional) Detailed information about the SNMP traps.

The SNMP traps are generated in the following scenarios:

- GSLB synchronization status for a GSLB site flips from Success to Failure, and conversely.
- GSLB synchronization mode changes from incremental synchronization to full synchronization, and conversely.

### Note:

Even when incremental synchronization is enabled, if full synchronization is performed on a GSLB site for some reason, the reason for Full sync is mentioned in the “Detailed information” section of the trap message. For example, when a new GSLB site is added to the GSLB configura-

tion.

## Sample SNMP trap messages

The following figure displays a sample SNMP trap for gslb\_site2, where the GSLB configuration synchronization is successful using the Full sync mode.

```
2021-03-18 18:18:58 <UNKNOWN> [UDP: [10.102.146.2]:3000]:
iso.3.6.1.2.1.1.3.0 = Timeticks: (667165) 1:51:11.65 iso.3.6.1.6.3.1.1.4.1.0 = OID: iso.3.6.1.4.1.5951.1.1.0.180 iso.3.6.1.4.1.5951.4.1.10.2.77.0 = STRING: "gslb_site2" iso.3.6.1.4.1.5951.4.1.10.2.78.0 = STRING: "GSLB Sync Success, Full Sync Mode, Switching to Inc Sync Mode" iso.3.6.1.4.1.5951.4.1.1.2.0 = IPAddress: 10.102.146.2
```

The following figure displays a sample SNMP trap for gslb\_site2, where the GSLB configuration synchronization is successful using the incremental sync mode.

```
2021-03-18 18:24:18 <UNKNOWN> [UDP: [10.102.146.2]:3000]:
iso.3.6.1.2.1.1.3.0 = Timeticks: (699113) 1:56:31.13 iso.3.6.1.6.3.1.1.4.1.0 = OID: iso.3.6.1.4.1.5951.1.1.0.180 iso.3.6.1.4.1.5951.4.1.10.2.77.0 = STRING: "gslb_site2" iso.3.6.1.4.1.5951.4.1.10.2.78.0 = STRING: "GSLB Sync Success, Inc Sync Mode" iso.3.6.1.4.1.5951.4.1.1.2.0 = IPAddress: 10.102.146.2
```

The following figure displays a sample SNMP trap for gslb\_site2, where the GSLB configuration synchronization using the incremental sync mode is failed. The error message indicates that you must manually fix the errors to complete the synchronization.

```
2021-03-18 18:17:34 <UNKNOWN> [UDP: [10.102.146.2]:3000]:
iso.3.6.1.2.1.1.3.0 = Timeticks: (658753) 1:49:47.53 iso.3.6.1.6.3.1.1.4.1.0 = OID: iso.3.6.1.4.1.5951.1.1.0.180 iso.3.6.1.4.1.5951.4.1.10.2.77.0 = STRING: "gslb_site2" iso.3.6.1.4.1.5951.4.1.10.2.78.0 = STRING: "GSLB Sync Failure, Inc Sync Mode, Site is not in sync, Incremental config application has failed, Switching to Full Sync Mode." iso.3.6.1.4.1.5951.4.1.1.2.0 = IPAddress: 10.102.146.2
2021-03-18 18:17:49 <UNKNOWN> [UDP: [10.102.146.2]:3000]:
iso.3.6.1.2.1.1.3.0 = Timeticks: (660256) 1:50:02.56 iso.3.6.1.6.3.1.1.4.1.0 = OID: iso.3.6.1.4.1.5951.1.1.0.180 iso.3.6.1.4.1.5951.4.1.10.2.77.0 = STRING: "gslb_site2" iso.3.6.1.4.1.5951.4.1.10.2.78.0 = STRING: "GSLB Sync Failure, Full Sync Mode, Site is not in sync, Full sync config application has failed, Please fix the errors." iso.3.6.1.4.1.5951.4.1.1.2.0 = IPAddress: 10.102.146.2
```

The following figure displays a sample SNMP trap for gslb\_site2, where the GSLB configuration synchronization using the incremental sync mode is failed. It also indicates the reason for sync failure, that is the site monitor is DOWN.

```
2021-03-18 18:21:39 <UNKNOWN> [UDP: [10.102.146.2]:3000]:
iso.3.6.1.2.1.1.3.0 = Timeticks: (683289) 1:53:52.89 iso.3.6.1.6.3.1.1.4.1.0 = OID: iso.3.6.1.4.1.5951.1.1.0.180 iso.3.6.1.4.1.5951.4.1.10.2.77.0 = STRING: "gslb_site2" iso.3.6.1.4.1.5951.4.1.10.2.78.0 = STRING: "GSLB Sync Failure, Inc Sync Mode, Syncing current configuration to gslb_site2: Skipped, Site Monitor is down" iso.3.6.1.4.1.5951.4.1.1.2.0 = IPAddress: 10.102.146.2
```

## GSLB dashboard

September 21, 2020

You can view the overall status of the GSLB sites participating in GSLB on the GSLB dashboard.

You can access the GSLB settings from the dashboard. You can also start the GSLB configuration wizard from the dashboard. Additionally, you can perform the synchronization and test the GSLB setup from the dashboard.

To access the GSLB dashboard, navigate to **Configuration > Traffic Management > GSLB > Dashboard**.

## Monitor GSLB services

May 2, 2023

When you bind a remote service to a GSLB virtual server, the GSLB sites exchange metric information, including network metric information, which is the round-trip-time and persistence information.

If a metric exchange connection is momentarily lost between any of the participating sites, the remote site is marked as DOWN and load balancing is performed on the remaining sites that are UP. When metric exchange for a site is DOWN, the remote services belonging to the site are marked DOWN as well.

The NetScaler appliance periodically evaluates the state of the remote GSLB services by using either MEP or monitors that are explicitly bound to the remote services. Binding explicit monitors to local services is not required, because the state of the local GSLB service is updated by default using the MEP. However, you can bind explicit monitors to a remote service. When monitors are explicitly bound, the state of the remote service is not controlled by the metric exchange.

By default, when you bind a monitor to a remote GSLB service, the NetScaler appliance uses the state of the service reported by the monitor. However, you can configure the NetScaler appliance to use monitors to evaluate services in the following situations:

- Always use monitors (default setting).
- Use monitors when MEP is DOWN.
- Use monitors when remote services and MEP are DOWN.

The second and third of the above settings enable the appliance to stop monitoring when MEP is UP. For example, in a hierarchical GSLB setup, a GSLB site provides the MEP information about its child sites to its parent site. Such an intermediate site may evaluate the state of the child site as DOWN because of network issues, though the actual state of the site is UP. In this case, you can bind monitors to the services of the parent site and disable MEP to determine the actual state of the remote service. This option enables you to control the manner in which the states of the remote services are determined.

To use monitors, first create them, and then bind them to GSLB services.

### Configure monitor trigger

You can configure a GSLB site to always use monitors (the default), use monitors when MEP is down, or use monitors when both the remote service and MEP are down. In the latter two cases, the NetScaler appliance stops monitoring when MEP returns to the UP state.

## To configure monitor triggering by using the command line interface

At the command prompt, type:

```
1 set gslb site <siteName> -triggerMonitor (ALWAYS | MEPDOWN |
 MEPDOWN_SVCDOWN)
2 <!--NeedCopy-->
```

### Example:

```
1 set gslb site Site-GSLB-North-America -triggerMonitor Always
2 <!--NeedCopy-->
```

## To configure monitor triggering by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Sites**, and double-click the site.
2. In the **Trigger Monitors** drop-down list, select an option for when to trigger monitoring.

## Add or remove monitors

To add a monitor, you specify the type and the port. You cannot remove a monitor that is bound to a service. You must first unbind the monitor from the service.

## To add a monitor by using the command line interface

At the command prompt, type the following commands to create a monitor and verify the configuration:

```
1 add lb monitor <monitorName> -type <monitorType> -destPort <portNumber>
2
3 show lb monitor <monitorName>
4 <!--NeedCopy-->
```

### Example:

```
1 add lb monitor monitor-HTTP-1 -type HTTP -destPort 80
2 show lb monitor monitor-HTTP-1
3 <!--NeedCopy-->
```

## To remove a monitor by using the command line interface

At the command prompt, type:

```
1 rm lb monitor <monitorName>
2 <!--NeedCopy-->
```

### To add a monitor by using the configuration utility

Navigate to

Traffic Management > Load Balancing > Monitors, and add or delete a monitor.

### Bind monitors to a GSLB service

Once you create monitors, you must bind them to GSLB services. When binding monitors to the services, you can specify a weight for the monitor. After binding one or more weighted monitors, you can configure a monitor threshold for the service. This threshold takes the service down if the sum of the bound monitor weights falls below the threshold value.

Note: In the configuration utility, you can set both the weight and the monitoring threshold at the same time that you bind the monitor. When using the command line, you must issue a separate command to set the service's monitoring threshold.

### To bind the monitor to the GSLB service by using the command line interface

At the command prompt, type:

```
1 bind monitor <name> <serviceName> [-state (Enabled | Disabled)] -
 weight <positiveInteger>
2 <!--NeedCopy-->
```

#### Example:

```
1 bind monitor monitor-HTTP-1 service-GSLB-1 -state enabled -weight 2
2 <!--NeedCopy-->
```

### To set the monitoring threshold for a GSLB service by using the command line interface

At the command prompt, type:

```
1 set gslb service <ServiceName> -monThreshold <PositiveInteger>
2 <!--NeedCopy-->
```

#### Example:

```
1 set gslb service service-GSLB-1 -monThreshold 9
2 <!--NeedCopy-->
```

### To bind the monitor to the GSLB service by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services.
2. Click the **Monitor** section and bind the monitor to the GSLB service.

### To set the monitoring threshold for a GSLB service by using the configuration utility

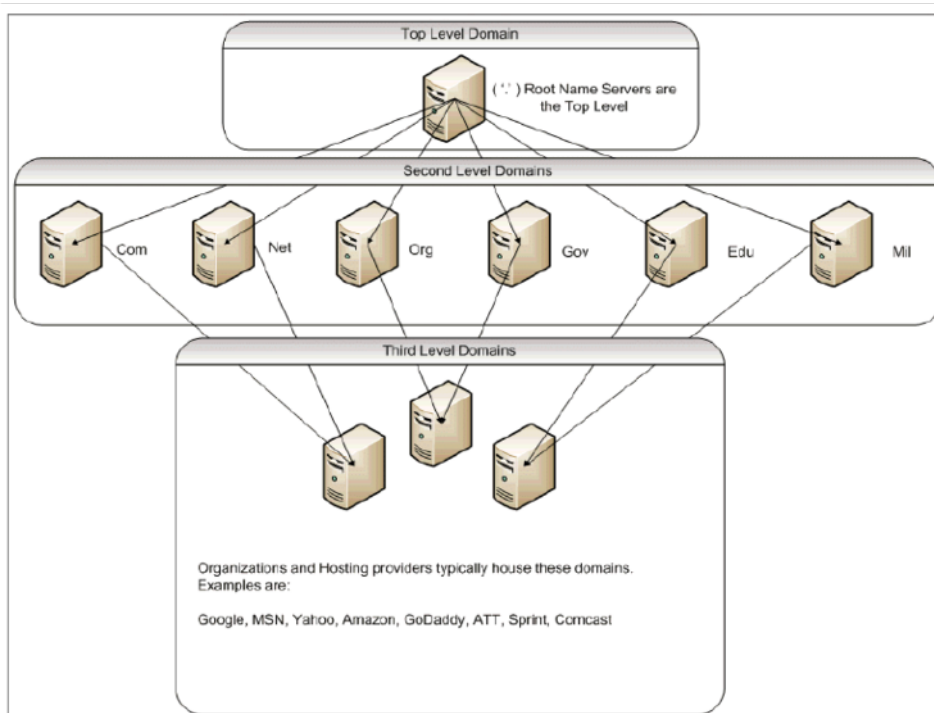

1. Navigate to Traffic Management > GSLB > Services.
2. Click the **Monitor Threshold** section and enter a threshold value.

## How domain name system supports GSLB

May 2, 2023

The domain name system (DNS) is considered as a distributed database, which uses the Client/Server architecture. Name Servers are the servers in the architecture, and the resolvers are the clients that are library routines installed on an operating system that create and send queries across the network.

The logical hierarchy of the DNS is shown in the following diagram:

Note:

The second-level root servers are responsible for maintaining Name server to Address mappings for Name server delegations within the .com, .net, .org, .gov domains, and so on. Each domain within the second-level domains is responsible for maintaining Name Server to Address mappings for the lower-level organizational domains. At the organization level, the individual host addresses are resolved for www, FTP, and other service providing hosts.

## Delegation

The main purpose of the current DNS topology is to ease the burden of maintaining all address records on one authority. This allows for delegation of an organization name space to that particular organization. The organization can then further delegate its space to subdomains within the organization. For example, under citrix.com you can create subdomains called `sales.citrix.com`, `education.citrix.com`, and `support.citrix.com`. The corresponding departments can maintain their own set of Name servers that are authoritative for their subdomain, and then maintain their own set of host name to address mappings. No single department is responsible for maintaining all of Citrix address records. Each department can change addresses and modify topologies, and not impose more work at the higher-level domain or organization.

## Benefits of the hierarchical topology

Some of the benefits of the hierarchical topology include:

- Scalability
- Adding caching functionality into Name servers at each level, where a DNS request is served by a host that is not authoritative for a particular domain but can contribute the answer to the query, and cut down on congestion and response time.
- Caching also creates redundancy and resiliency to server failure. If one name server fails, it is still possible that records can be served from other servers that have recent cached copies of the same records.

## Resolvers

Resolvers are the client component in the DNS system. Programs that are running on a host that need information from the domain name space use the resolver. The resolver handles:

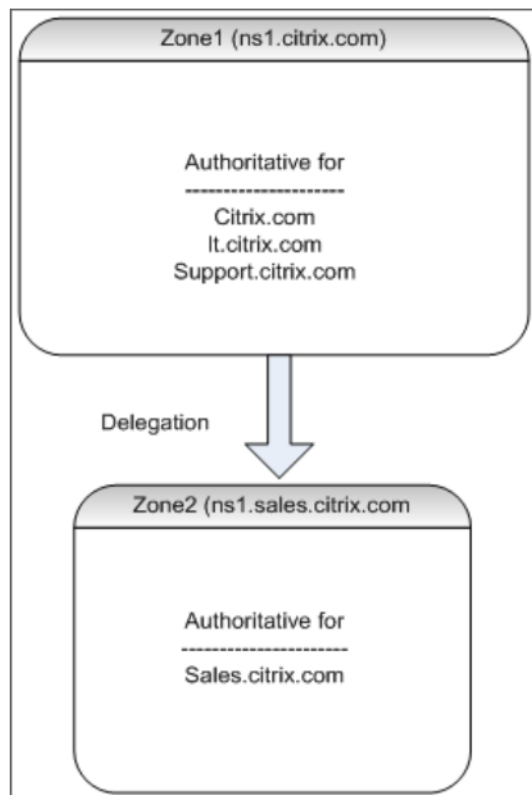

- Querying a name server.
- Interpreting responses (which might be resource records or an error).
- Returning the information to the programs that requested it.

The resolver is a set of library routines that are compiled into programs like telnet, FTP, and ping. They are not separate processes. The resolvers can put together a query, send it, and wait for an answer. And, send it again (possibly to a secondary Name Server) if it is not answered within a certain time. These types of resolvers are known as stub resolvers. Some resolvers have the added functionality to cache records, and honor time to live (TTL). In Windows, this functionality is available through the DNS Client service; viewable through the “services.msc” console.

## Name Servers

Name Servers generally store complete information about a particular part of a domain name space (called a zone). The Name Server is then said to have authority for that zone. They can also be authoritative for multiple zones.

The difference between a domain and a zone is subtle. A domain is the full set of entities including its subdomains while a zone is only the information within a domain that is not delegated to another Name Server. An example of a zone is `citrix.com`, while `sales.citrix.com` is a separate zone if that zone is delegated to another Name Server within the subdomain. In this case, the primary Citrix zone can include `citrix.com`, `it.citrix.com`, and `support.citrix.com`. Because the `sales.citrix.com` is delegated, it is not part of the zone that the `citrix.com` Name Server is authoritative over. The following diagram shows the two zones.

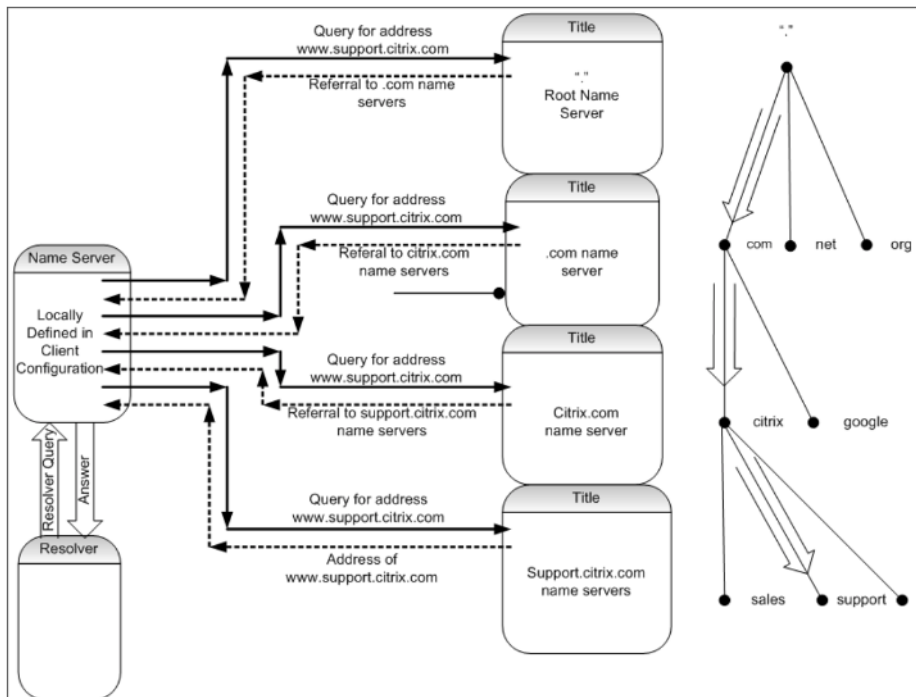

To properly delegate a subdomain, you must assign authority for the subdomain to different Name Servers. In the preceding example, the `ns1.citrix.com` does not contain information about the `sales.citrix.com` subdomain. Instead, it contains pointers to the Name servers that are authoritative for the `ns1.sales.citrix.com` subdomain.

### Root name servers and query resolution

Root Name servers know the IP addresses of all the Name servers authoritative for the second-level domains. If a Name Server does not have information about a given domain in its own data files, then it only needs to contact a root server to begin traversing the proper branch of the **DNS** tree structure to eventually get to the given domain. This involves a series of requests to multiple Name servers to help with the tree traversal to find the next authoritative Name server, which needs to be contacted for further resolution.

The following diagram shows a typical DNS request, assuming that there is no cached record for the requested name during the traversal. The following example uses a mock up of the Citrix domain.

### Recursive and non-recursive queries

The preceding example demonstrates the two types of queries that can occur.

- Recursive query: The query between the resolver and the locally configured Name server is recursive. This means that the Name server receives the query and does not respond to the

resolver until the query is fully answered, or an error is returned. If the Name Server receives a referral to the query, then the Name server follows the referral until the Name server finally receives the answer (IP address) returned.

- **Non-recursive query:** The query that the locally configured Name server makes to the subsequent authoritative domain-level Name server is non-recursive (or iterative). Each request is immediately responded with either a referral to a lower-level authoritative server or the answer to the query, if the queried Name server contains the answer in its data files or its cache.

## Caching

Although the resolution process is involved, and might potentially require small requests to several hosts, it is fast. One of the factors that increases the speed of DNS resolution is caching. Each time a Name server receives a recursive query, it might have to communicate to other servers to eventually get to the proper authoritative server for the specific request. It stores all of the information that it receives for future reference. When the next client makes a similar request, such as a different host but in the same domain, it already knows the Name server that is authoritative for that domain, and can send a request directly there instead of starting at the root Name server.

Caching can occur for negative responses also, such as the queries for hosts that do not exist. In this case, the server must not query the authoritative Name server for the requested domain to figure out that the host does not exist. To save time, the Name server simply checks the cache and responds back with the negative record.

Name servers do not cache records indefinitely, or else you can never update the IP addresses. To avoid synchronization problems, DNS responses contain a time to live (TTL). This field describes the time interval for which the cache can store a record before it must discard it and check with the authoritative Name server for any updated records. If the records have not changed, the use of TTL also allows rapid dynamic responses from devices performing GSLB.

## Resource record types

Various RFCs provide a comprehensive list of DNS resource record types and its description. The following table lists the common resource record types.

---

Resource record type	Description	RFC
A	A host address	RFC 1035
NS	An authoritative name server	RFC 1035
MD	A mail destination (Obsolete - use MX)	RFC 1035

Resource record type	Description	RFC
MF	A mail forwarder (Obsolete - use MX)	RFC 1035
CNAME	The canonical name for an alias	RFC 1035
SOA	Marks the start of a zone of authority	RFC 1035
WKS	A well known service description	RFC 1035
PTR	A domain name pointer	RFC 1035
HINFO	Host information	RFC 1035
MINFO	Mailbox or mail list information	RFC 1035
MX	Mail exchange	RFC 1035
TXT	Text strings	RFC 1035
AAAA	IP6 Address	RFC 3596
SRV	Server selection	RFC 2782]

### How GSLB supports DNS

GSLB uses algorithms and protocols that decide which IP address must be sent for a DNS query. GSLB sites are geographically distributed and there is a DNS authoritative Name server at each site running as a service on the NetScaler appliance. All Name servers at the various sites involved are authoritative for the same domain. Each of the GSLB domains is a subdomain for which a delegation is configured. Therefore, the GSLB Name servers are authoritative and can use one of the various load balancing algorithms to decide which IP address to return.

A delegation is created by adding a Name server record for the GSLB domain in the parent domain database files and a subsequent address record for the Name servers that are used for the delegation. For example, if you want to use GSLB for [www.citrix.com](http://www.citrix.com), then the following Bind SOA file can be used to delegate requests to [www.citrix.com](http://www.citrix.com) to Name Servers: Netscaler1 and Netscaler2.

```

1 #####
2 @ IN SOA citrix.com. hostmaster.citrix.com. (
3 1 ; serial
4 3h ; refresh
5 1h ; retry
6 1w ; expire
7 1h) ; negative caching TTL
8 IN NS ns1

```

```
9 IN NS ns2

23 www IN NS Netscaler2.citrix.com.
24 ###
25 IN MX 20 mail2
26 mail2 IN A 10.50.50.20
27 #####
28
29 <!--NeedCopy-->
```

Understanding BIND is not a requirement for configuring DNS. All compliant DNS server implementations have a method of creating the equivalent delegation. Microsoft DNS servers can be configured for delegation using the instructions at [Create a zone delegation](#).

What makes GSLB on NetScaler appliance different from using the standard DNS service for distributing traffic is that the NetScaler GSLB sites exchange data using a proprietary protocol called Metric Exchange Protocol (MEP). With MEP, the GSLB sites are able to maintain information about all other sites. When a DNS request is received, the MEP considers the GSLB metrics to determine information such as the following:

- Site with the least number of current connections
- Site that is closest to the LDNS server, which sent the request based on round trip times (RTT).

There are several load balancing algorithms that can be used, but GSLB is a DNS with the brain underneath telling the Name Server (hosted on the NetScaler appliance) which address must be sent based on metrics of the participating sites.

Other benefits that GSLB provides are the ability to maintain persistence (or site affinity). Responses to the incoming DNS queries can be compared with the source IP address to determine if that address was directed to a particular site in the recent past. If so, then the same address is sent in the DNS response to ensure that the client session is maintained.

Another form of persistence is obtained at the site level by using HTTP redirects, or HTTP proxying. These forms of persistence occur after the DNS response occurs. Therefore, if you get an HTTP request at a site that contains a cookie to direct the request to a different participating site, then you can either respond with a redirect or proxy the request to the appropriate site.

## Metric exchange protocol

Metric Exchange Protocol (MEP) is used to share the data used in GSLB calculations across sites. Using MEP connections, you exchange three types of data. These connections need not be secure over TCP port 3011 or can be secure using SSL over TCP port 3009.

The following three types of data are exchanged, and have their own intervals and exchange methods.

- **Site metric exchange:** This is a polling exchange model. For example, if site1 has a configuration for site2 services, then every second site1 asks site2 for the status of the GSLB services. Site2 responds with the state and other load details.
- **Network metric exchange:** This is the LDNS RTT information exchange, which is used in the dynamic proximity load balancing algorithm. This is a push exchange model. Every five seconds, each site pushes its data to other participating sites.
- **Persistency exchange:** This is for SOURCEIP persistency exchange. This is also a push exchange model. Every five seconds, each site pushes its data to other participating sites.

By default, site services are monitored over MEP based on polling information only. If you bind monitors based on monitor interval, the state is updated and you can control the frequency of the updates by setting the monitoring interval accordingly.

## Priority order for GSLB services

October 8, 2023

The priority order for services feature enables you to prioritize the order for services or service groups based on the load balancing selection preferences. You can configure the priority order when you do the following:

- Bind a service to a GSLB virtual server.
- Bind a service group to a GSLB virtual server.
- Bind a service group member to the GSLB service group.

Currently, you can configure the priority order for services using the following approaches. However, these approaches have the following limitations:

- Configuring a backup virtual server chain: The number of configuration lines is high, and you must run the `show` command several times to know the state of all the GSLB services for each virtual server.

- Configuring the preferred location: You must create location entries for all your application endpoints.

The priority order for services feature addresses the preceding limitations with fewer configuration commands, and helps you to accomplish the preferred location configuration without the need of location representation of all GSLB services' IP addresses.

## Configure priority order for GSLB services

To configure the priority order for GSLB services, the `-order <number>` parameter is added to the bind commands.

**Note:**

The lowest order number has the highest priority.

**Command:**

```
bind gslb vserver <vservname> -servicename/servicegroupname <
servicename/servicegroupname> -order <number>
```

For example, consider a set of services that are bound to a GSLB virtual server (gv1). Using the `- order <number>` parameter, you can prioritize the order of selection of services as follows:

- Set 1 (s1, s2) bound to gv1 –order 1
- Set 2 (s3, s4) bound to gv1 –order 2
- Set 3 (s5, s6) bound to gv1 –order 3

After you bind the services to gv1, and when gv1 receives the client traffic, the order of selection of services is as follows:

- The virtual server (gv1) selects the services in set 1 (s1 and s2) with order number 1, because this set is assigned the lowest order number. By default, the lowest order number has the highest priority.
- If all the services in set 1 are DOWN, gv1 selects set 2 (s3 and s4) with order number 2.
- If all the services in set 1 and set 2 are down, gv1 selects set 3 (s5 and s6) with order number 3.

## Configure priority order for GSLB services using the CLI

To configure the priority order for the GSLB services, type the following commands at the command prompt:

1. Add GSLB sites.

```
add gslb site site1 1.1.1.1
```

```
add gslb site site2 1.1.1.2
```

2. Add a GSLB virtual server.

```
add gslb vserver gv1 HTTP
```

3. Add GSLB services.

```
add gslb service gsvc1 1.1.1.3 http 80 -sitename site1
```

```
add gslb service gsvc2 1.1.1.4 http 80 -sitename site2
```

```
add gslb service gsvc3 1.1.1.5 http 80 -sitename site1
```

```
add gslb service gsvc4 1.1.1.6 http 80 -sitename site2
```

```
add gslb service gsvc5 1.1.1.7 http 80 -sitename site1
```

```
add gslb service gsvc6 1.1.1.8 http 80 -sitename site2
```

4. Set the order number and bind the services to the GSLB virtual server.

```
bind gslb vserver gv1 gsvc1 -order 1
```

```
bind gslb vserver gv1 gsvc2 -order 1
```

```
bind gslb vserver gv1 gsvc3 -order 2
```

```
bind gslb vserver gv1 gsvc4 -order 2
```

```
bind gslb vserver gv1 gsvc5 -order 3
```

```
bind gslb vserver gv1 gsvc6 -order 3
```

## Configure priority order for GSLB services using the GUI

### Prerequisites:

- You have created GSLB sites.
- You have created a GSLB virtual server.
- You have created GSLB services.

To configure the priority order for GSLB services and bind them to the GSLB virtual server, do the following:

1. Navigate to **Traffic Management > GSLB > Virtual Servers** and double-click the GSLB virtual server.
2. In **GSLB Virtual Server**, under the **GSLB Services and GSLB Service Group Binding** section, click **GSLB Virtual Server to GSLB Service Bindings**.
3. In the **GSLB Services and GSLB Service Group Binding** dialog, click **Add Binding**.

4. In the **GSLB Service Binding** dialog box, select a service.
5. Type a number in the **Order** field to set the priority order for the service.

**GSLB Service Binding**

Service Name  
site1\_gsvc1

**Binding Details**

Weight  
1 ⓘ

Dynamic Weight  
0

Cumulative Weight  
1

Order  
1

6. Click **Bind**.
7. Repeat steps 1–6 to configure different priority order number for different services.

## Configure priority order for GSLB services using LB policy commands

By default, the lowest order number has the highest priority. However, you can defer this default behavior using the new LB action and policy commands. You can configure the service selection order based on the incoming client traffic or client data.

For example, consider a set of services that are bound to a GSLB virtual server (gv1). Using the `–order <number>` parameter, you have configured the priority order for services as follows:

- Set 1 (s1, s2) bound to gv1 –order 1
- Set 2 (s3, s4) bound to gv1 –order 2
- Set 3 (s5, s6) bound to gv1 –order 3

By default, the lowest order number has the highest priority. Therefore, the default priority order of preference is 1, 2, and 3 for services in set 1, set2, and set3, respectively. However, for a specific client traffic, you want to change the priority order to 3, 1, and 2. To achieve this, you can add an LB policy and bind it to gv1.

An LB policy command consists of two elements: a rule, and an action. The rule is associated with an action, which is performed if a request matches the rule.

### Note:

The LB policy commands are common for both LB and GSLB configuration and are applicable for the requests handled by the NetScaler appliance.

**LB action****Expression:**

```
add lb action <name> <type> <string>
```

**Example:**

```
add lb action act1 -type SELECTIONORDER -value 3 2 1
```

**Parameters:**

- **name:** Name of the action.
- **type:** Type of action.
- **string:** Value for the specified action.

**LB policy****Expression:**

```
add lb policy <name> <rule> <action> <undefaction>
```

**Example:**

```
add lb policy pol1 -rule CLIENT.IP.SRC.EQ(8.8.8.8)-action act1
```

**Parameters:**

- **name:** Name of the policy.
- **rule:** A rule consists of one or more expressions. The rule is associated with an action, which is performed if the request matches the rule.
- **action:** DROP, NOLBACTION, and RESET are supported.
- **undefaction:** The NetScaler appliance generates an undefined event (UNDEF event) when a request does not match a policy. You can use the `set lb param -undefAction <action>` command to set the undefined action. You can assign these actions to an undefined event: DROP, NOLBACTION, and RESET.

Let's consider an example where you add an LB action, LB policy, and bind the policy to a GSLB virtual server (gv1) as follows:

```
add lb action act1 -type SELECTIONORDER -value 3 1 2
```

```
add lb policy pol1 -rule CLIENT.IP.SRC.EQ(8.8.8.8)-action act1
```

```
bind gslb vserver gv1 -policyName pol1 -priority 20 - gotoPriorityExpression
END -type REQUEST
```

The rule selects the client traffic that matches the IP address, 8.8.8.8, and sends that traffic to gv1. The LB action type ([SELECTIONORDER](#)) defines the service selection order. After you bind the LB policy to gv1, and when gv1 receives the client traffic from the IP address 8.8.8.8, the services are selected in the following order:

1. The virtual server (gv1) selects services in set 3 (s5 and s6) with priority order 3.
2. If all the services in set 3 are DOWN, gv1 selects set 1 (s1 and s2) with priority order 2.
3. If all the services in set 3 and set 2 are down, the gv1 selects set 1 (s1 and s2) with order 1.

### **Configure priority order for GSLB services with LB policy commands using the CLI**

To configure priority order for GSLB services using LB policy commands, type the following commands at the command prompt:

1. Add an LB action.

```
add lb action act1 -type SELECTIONORDER -value 3 1 2
```

2. Add an LB policy.

```
add lb policy pol1 -rule CLIENT.IP.SRC.EQ(8.8.8.8)-action act1
```

3. Add GSLB sites.

```
add gslb site site1 1.1.1.1
```

```
add gslb site site2 1.1.1.2
```

4. Add a GSLB virtual server.

```
add gslb vserver gv1 HTTP
```

5. Bind the LB policy to the GSLB virtual server.

```
bind gslb vserver gv1 -policyName pol1 -priority 20 - gotoPriorityExpressi
END -type REQUEST
```

6. Add GSLB services.

```
add gslb service gsvc1 1.1.1.3 http 80 -sitename site1
```

```
add gslb service gsvc2 1.1.1.4 http 80 -sitename site2
```

```
add gslb service gsvc3 1.1.1.5 http 80 -sitename site1
```

```
add gslb service gsvc4 1.1.1.6 http 80 -sitename site2
```

```
add gslb service gsvc5 1.1.1.7 http 80 -sitename site1
```

```
add gslb service gsvc6 1.1.1.8 http 80 -sitename site2
```

7. Set the order and bind the services to the GSLB virtual server.

```
bind gslb vserver gv1 gsvc1 -order 1
bind gslb vserver gv1 gsvc2 -order 1
bind gslb vserver gv1 gsvc3 -order 2
bind gslb vserver gv1 gsvc4 -order 2
bind gslb vserver gv1 gsvc5 -order 3
bind gslb vserver gv1 gsvc6 -order 3
```

## Configure priority order for GSLB services with the LB policy commands using the GUI

### Prerequisites:

- You have created GSLB sites.
- You have created a GSLB virtual server.
- You have created services.

### Step 1 - Create an LB Action:

1. Navigate to **AppExpert > LB > Actions**.
2. In **LB Actions**, click **Add**.
3. In the **Create LB Actions** dialog box, specify values for the following parameters:

- **Action Name**
- **Type**
- **Value**

**Note:**

The numbers in the **Value** field are separated by a space.

4. Click **Create**.

### Step 2 - Create an LB Policy:

1. Navigate to **AppExpert > LB > Policies**.
2. In **LB Policies**, click **Add**.
3. In the **Create LB Policies** dialog box, specify values for the following parameters:
  - **Name:** pol1
  - **Action:** act1

- **Undefined-Result Action:** NOLBACTION
- **Expression:** CLIENT.IP.SRC.EQ(8.8.8.8)

4. Click **Create**.

**Step 3 - Bind the LB policy to the GSLB virtual server:**

1. Navigate to **Traffic Management >GSLB > Virtual Servers** and double-click the GSLB virtual server.
2. In **GSLB Virtual Server**, under the **Advanced Settings** section, click **Policies**.
3. In the **Policies** section, click **GSLB Virtual Server LB Policy Binding**.
4. In the **Policy Binding** dialog box, specify values for the following parameters:
  - **Select Policy:** pol 1
  - **Priority:** 10
  - **Goto Expression:** END

5. Click **Bind**.

**Step 4 - Configure priority order for GSLB services:**

To configure priority order for GSLB, see the **Configure priority order for GSLB services using the GUI** procedure.

**Persistence settings for services**

If persistence is configured for a service, then the preference is always given to persistence, by default.

For example, consider a service with persistence configured and priority order 1. If a service with priority order 0 is UP, then preference is always given to the service with priority order 1.

However, you can override this default behavior with the following CLI command:

```
set gslb param -overridePersistencyforOrder<YES/NO>
```

Let's consider the following example:

A set of services is bound to a GSLB virtual server (gv1) with the following priority order:

- Set 1 (s1, s2) bound to gv1 – order 1
- Set 2 (s3, s4) bound to gv1 – order 2

Type the following command at the command prompt to override persistency:

```
set gslb parameter -overridePersistencyforOrder YES
```

If set 1 (services with persistence is configured) is DOWN, then set 2 services handle all the requests until set 1 services are UP. A persistence entry for priority 2 is created.

Let's assume that after some time, the set 1 services are UP. Now, both set 1 and set 2 services are UP to handle the requests. In this scenario, new load balancing decisions are made as higher order services are UP. The persistence entry is overridden with a new load balancing entry.

**Priority toggle**

With the priority toggle feature, you can toggle all the traffic to a low-priority service during version upgrade for a service with a higher priority order. You can use the following commands to toggle priority:

- `set gslb vserver -toggleorder <Ascending/Descending>`
- `set gslb vserver v1 -orderthreshold 80`

For example, let's consider that there are two services with the following priorities:

- Service 1- order 0

- Service 2 – order 1

By default, service 1 handles all the traffic. If service 1 needs to be upgraded, then the traffic needs to be rerouted to service 2.

At the command prompt, type the following commands to toggle priority:

```
set gslb vserver -toggleorder Descending
```

By default, 0 has higher priority. However, after priority toggling, 1 is considered as a higher priority. If persistence entry is present for the service, the persistence preference behavior is as explained in the **Persistence settings for services** section.

## Upgrade recommendations for GSLB deployment

May 2, 2023

This section provides recommendations on the sequence in which GSLB nodes need to be upgraded in various GSLB setups. It also addresses a few FAQs.

**Note:** The NetScaler appliance from which the GSLB synchronization is started is referred to as the ‘main site’ and the GSLB sites on which the configuration is copied as the ‘subordinate sites’.

Before you start the upgrade process, read the prerequisites mentioned in the following topics:

- [Before you begin](#)
- [Upgrade a high availability pair.](#)
- [Upgrade a cluster.](#)

### Points to note when upgrading GSLB setups

- In an HA setup, first upgrade the subordinate sites and then the main site.
- In an HA setup, service states might not propagate from an older build primary node to a newer build secondary node. However, if the builds are of different versions, but have the same HA version, the service state might still propagate.
- If GSLB is configured within a cluster, first upgrade the non-owner nodes, and then upgrade the owner node. If there is one site or multiple sites in a cluster, follow the same upgrade sequence in each of the site.
- Enable new GSLB features only after you upgrade all nodes to a newer build.
- Upgrade all GSLB nodes to the latest build. There is no functional impact on the available features when some of the GSLB nodes are using an older version and some of the GSLB nodes are upgraded to a newer version.

## FAQs

- **Are GSLB service states propagated when instances run different software versions?**

GSLB MEP is functional when instances run on different versions and GSLB service states are propagated across GSLB sites. There is no impact on the MEP communication when instances run different versions after an upgrade.

- **Is it recommended to do configuration changes during an upgrade?**

In a GSLB setup, when a main site is being upgraded, it is not recommended to do configuration changes on any other GSLB nodes.

## Use case: Deployment of domain name based autoscale service group

May 2, 2023

### Tip

For information about the GSLB service groups, see [Configuring a GSLB Service Group](#)

## Deployment scenario

Two datacenters are deployed in two AWS regions, one in Sydney and one in North Virginia. Another datacenter is deployed in Azure. An AWS ELB in each AWS region is used to load balance the application servers. ALB is used for Azure to load balancing the application server. The NetScaler appliances are configured for GSLB for the ELBs and ALB using GSLB domain name based autoscale service group.

**Important**

You must configure the required security groups in AWS and attach it to the GSLB instance. Port 53 must be allowed in the security group inbound and outbound rules. Also, ports (3009 or 3011 depending on secure MEP configuration) for MEP communication must be open. For application monitoring, the corresponding ports must be allowed in the security group outbound rules.

The configuration steps for the above deployment scenario and the corresponding CLI commands are as follows:

1. Create datacenters (represented by GSLB sites).

```
add gslb site aws-sydney 192.0.2.2
add gslb site aws-nvirginia 198.51.100.111
add gslb site alb-southindia 203.0.113.6
```

2. Add a name server with the DNS gateway IP address where the GSLB node is added. This must be done in all datacenters.

```
add dns nameServer 8.8.8.8
```

3. Add servers for ELB and ALB.

```
add server aws-sydney_server lb-sydney-1052691850.ap-southeast-2.
elb.amazonaws.com

add server aws-nvirginia_server LB-nvirginia-860559595.us-east-1.
elb.amazonaws.com

add server alb-southindia_server alb.southindia.cloudapp.azure.
com
```

4. Add GSLB autoscale service groups for each ELB and ALB and bind each server to the respective service group.

```
add gslb serviceGroup aws-nvirginia_sg HTTP -autoScale DNS -
siteName aws-nvirginia

add gslb serviceGroup aws-sydney_sg HTTP -autoScale DNS -siteName
aws-sydney

add gslb serviceGroup alb-southindia_sg HTTP -autoScale DNS -
siteName alb-southindia

bind gslb serviceGroup aws-nvirginia_sg aws-nvirginia_server 80

bind gslb serviceGroup aws-sydney_sg aws-sydney_server 80

bind gslb serviceGroup alb-southindia_sg alb-southindia_server 80
```

5. Add a GSLB virtual server and bind the application domain and the service groups to this virtual server.

```
add gslb vserver gv1 HTTP
bind gslb vserver gv1 -serviceName aws-nvirginia_sg
bind gslb vserver gv1 -serviceName aws-sydney_sg
bind gslb vserver gv1 -serviceName alb-southindia_sg
```

## Use case: Deployment of IP address based GSLB service group

March 9, 2021

### Tip

For information about the GSLB service groups, see [Configuring a GSLB Service Group](#).

### Deployment scenario

If there are multiple applications hosted on the same application server, the GSLB should probe these applications to see if the applications are responding or not. If an application is not responding, the user must be directed to the server on which the application is UP. Also, if one of the applications is DOWN, then the server should not be marked DOWN, because the other applications are UP.

In the following example, multiple applications (HTTPS) are hosted on one server in each GSLB site and hence all these applications resolve to one IP address of the respective site.

Using the GSLB service groups, you can have the same server with an IP address and port bound to multiple service groups where each service group represents a different application.

An application specific monitor is bound to the service groups that marks the service group as DOWN if the application is DOWN. Thus, whenever an application is DOWN, only that application is taken out from the setup and not the server.

```
1 ``
2 add gslb serviceGroup app1_site1 HTTP -maxClient 0 -cip DISABLED -
 cltTimeout 180 -svrTimeout 360 -siteName s1
3
4 add gslb serviceGroup app2_site1 HTTP -maxClient 0 -cip DISABLED -
 cltTimeout 180 -svrTimeout 360 -siteName s1
5
6 add gslb serviceGroup app1_site2 HTTP -maxClient 0 -cip DISABLED -
 cltTimeout 180 -svrTimeout 360 -siteName s2
7
```

```
8 add gslb serviceGroup app2_site2 HTTP -maxClient 0 -cip DISABLED -
 cltTimeout 180 -svrTimeout 360 -siteName s2
9
10 add lb monitor http_app2 HTTP -respCode 200 -httpRequest "GET /testsite
 /app2.html"
11
12 add lb monitor http_app1 HTTP -respCode 200 -httpRequest "GET /testsite
 /app1.html"
13
14 bind gslb serviceGroup app1_site1 192.0.2.140 80
15
16 bind gslb serviceGroup app1_site1 -monitorName http_app1
17
18 bind gslb serviceGroup app2_site1 192.0.2.140 80
19
20 bind gslb serviceGroup app2_site1 -monitorName http_app2
21
22 bind gslb serviceGroup app1_site2 192.0.2.142 80
23
24 bind gslb serviceGroup app1_site2 -monitorName http_app1
25
26 bind gslb serviceGroup app2_site2 192.0.2.142 80
27
28 bind gslb serviceGroup app2_site2 -monitorName http_app2
29 <!--NeedCopy--> ````
```

## How-to articles

September 21, 2020

The GSLB how-to articles contain information about some of the important GSLB configurations such as customizing GSLB configuration, configuring persistent connections, disaster recovery, and so on.

## Customize your GSLB configuration

May 2, 2023

Once your basic GSLB configuration is operational, you can customize it by modifying the bandwidth of a GSLB service, configuring CNAME based GSLB services, static proximity, dynamic RTT, persistent connections, or dynamic weights for services, or changing the GSLB Method.

You can also configure monitoring for GSLB services to determine their states.

These settings depend on your network deployment and the types of clients you expect to connect to your servers.

### Modify maximum connections or maximum bandwidth for a GSLB service

You can restrict the number of new clients that can simultaneously connect to a load balancing or content switching virtual server by configuring the maximum number of clients and/or the maximum bandwidth for the GSLB service that represents the virtual server.

#### To modify the maximum clients or bandwidth of a GSLB service by using the command line interface

At the command prompt, type the following command to modify the maximum number of client connections or the maximum bandwidth of a GSLB service and verify the configuration:

```
1 set gslb service <serviceName> [-maxClients <positive_integer>] [-
 maxBandwidth <positive_integer>]
2 show gslb service <serviceName>
3 <!--NeedCopy-->
```

#### Example:

```
1 set gslb service Service-GSLB-1 - maxBandwidth 100 - maxClients 100
2 show gslb service Service-GSLB-1
3 <!--NeedCopy-->
```

### To modify the maximum clients or bandwidth of a GSLB service by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Services**, and double-click a service.
2. Click in the **Other Settings** section and set the following parameters:
  - Max Clients—maxClients
  - Max Bandwidth—maxBandwidth

### Create CNAME-based GSLB services

To configure a GSLB service, you can use the IP address of the server or a canonical name of the server. If you want to run multiple services (like an FTP and a Web server, each running on different ports) from a single IP address or run multiple HTTP services on the same port, with different names, on the same physical host, you can use canonical names (CNAMES) for the services.

For example, you can have two entries in DNS as ftp.example.com and www.example.com for FTP services and HTTP services on the same domain, example.com. CNAME-based GSLB services are useful in a multilevel domain resolver configuration or in multilevel domain load balancing. Configuring a CNAME-based GSLB service can also help if the IP address of the physical server is likely to change.

If you configure CNAME-based GSLB services for a GSLB domain, when a query is sent for the GSLB domain, the NetScaler appliance provides a CNAME instead of an IP address. If the A record for this CNAME record is not configured, the client must query the CNAME domain for the IP address. If the A record for this CNAME record is configured, the NetScaler appliance provides the CNAME with the corresponding A record (IP address). The NetScaler appliance handles the final resolution of the DNS query, as determined by the GSLB method. The CNAME records can be maintained on a different NetScaler appliance or on a third-party system.

In an IP-address-based GSLB service, the state of a service is determined by the state of the server that it represents. However, a CNAME-based GSLB service has its state set to UP by default; the virtual server IP (VIP) address or metric exchange protocol (MEP) are not used for determining its state. If a desktop-based monitor is bound to a CNAME-based GSLB service, the state of the service is determined according to the result of the monitor probes.

You can bind a CNAME-based GSLB service only to a GSLB virtual server that has the DNS Record Type as CNAME. Also, a NetScaler appliance can contain at most one GSLB service with a given CNAME entry.

The following are some of the features supported for a CNAME-based GSLB service:

- GSLB-policy based site affinity is supported, with the CNAME as the preferred location.
- Source IP persistence is supported. The persistency entry contains the CNAME information instead of the IP address and port of the selected service.

The following are the limitations of CNAME-based GSLB services:

- Site persistence is not supported, because the service referenced by a CNAME can be present at any third-party location.
- Multiple-IP-address response is not supported because one domain cannot have multiple CNAME entries.
- Source IP Hash and Round Robin are the only load balancing methods supported. The Static Proximity method is not supported because a CNAME is not associated with an IP address and static proximity can be maintained only according to the IP addresses.

Note: The Empty-Down-Response feature should be enabled on the GSLB virtual server to which you bind the CNAME-based GSLB service. If you enable the Empty-Down-Response feature, when a GSLB virtual server is DOWN or disabled, the response to a DNS query, for the domains bound to this virtual server, contains an empty record without any IP addresses, instead of an error code.

### To create a CNAME-based GSLB service by using the command line interface

At the command prompt, type:

```
1 add gslb service <serviceName> -cnameEntry <string> -siteName <string>
2 <!--NeedCopy-->
```

#### Example:

```
1 add gslb service Service-GSLB-1 -cnameEntry transport.mycompany.com -
 siteName Site-GSLB-East-Coast
2 add gslb service Service-GSLB-2 -cnameEntry finance.mycompany.com -
 siteName Site-GSLB-West-Coast
3 <!--NeedCopy-->
```

### To create a CNAME-based GSLB service by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Services**.
2. Create a service, and set the **Type to Canonical Name Based**.

### Configure transition Out-Of-Service State (TROFS) in GSLB

When you configure persistence on a GSLB virtual server to which a service is bound, the service continues to serve requests from the client even after it is disabled, accepting new requests or connections only to honor persistence. After a configured period of time, known as the graceful shutdown period, no new requests or connections are directed to the service, and all of the existing connections are closed.

When disabling a service, you can specify a graceful shutdown period, in seconds, by using the delay argument. During the graceful shutdown period, if the service is bound to a virtual server, its state appears as Out of Service.

## **Configure dynamic weights for services**

In a typical network, there are servers that have a higher capacity for traffic than others. However, with a regular load balancing configuration, the load is evenly distributed across all services even though different services represent servers with different capacities.

To optimize your GSLB resources, you can configure dynamic weights on a GSLB virtual server. The dynamic weights can be based on either the total number of services bound to the virtual server or the sum of the weights of the individual services bound to the virtual server. Traffic distribution is then based on the weights configured for the services.

When dynamic weights are configured on the GSLB virtual server, requests are distributed according to the load balancing method, the weight of the GSLB service, and the dynamic weight. The product of the weight of the GSLB service and the dynamic weight is known as the cumulative weight. Therefore, when dynamic weight is configured on the GSLB virtual server, requests are distributed on the basis of the load balancing method and the cumulative weight.

When dynamic weight for a virtual server is disabled, the numerical value is set to 1. This ensures that the cumulative weight is a non-zero integer at all times.

Dynamic weight can be based on the total number of active services bound to load balancing virtual servers or on the weights assigned to the services.

Consider a configuration with two GSLB sites configured for a domain and each site has two services that can serve the client. If a service at either site goes down, the other server in that site has to handle twice as much traffic as a service at the other site. If dynamic weight is based on the number of active services, the site with both services active has twice the weight of the site with one service down and therefore receives twice as much traffic.

Alternatively, consider a configuration in which the services at the first site represent servers that are twice as powerful as servers at the second site. If dynamic weight is based on the weights assigned to the services, twice as much traffic can be sent to the first site as to the second.

Note: For details on assigning weights to load balancing services, see [Assigning Weights to Services](#).

As an illustration of how dynamic weight is calculated, consider a GSLB virtual server that has a GSLB service bound to it. The GSLB service represents a load balancing virtual server that in turn has two services bound to it. The weight assigned to the GSLB service is 3. The weights assigned to the two services are 1 and 2 respectively. In this example, when dynamic weight is set to:

- **Disabled:** The cumulative weight of the GSLB virtual server is the product of the dynamic weight (disabled = 1) and the weight of the GSLB service (3), so the cumulative weight is 3.
- **SERVICECOUNT:** The count is the sum of the number of services bound to the load balancing virtual servers corresponding to the GSLB service (2), and the cumulative weight is the product of the dynamic weight (2) and the weight of the GSLB service (3), which is 6.
- **SERVICEWEIGHT:** The dynamic weight is the sum of the weights of services bound to the load balancing virtual servers corresponding to the GSLB service (3), and the cumulative weight is the product of the dynamic weight (3) and the weight of the GSLB service (3), which is 9.

Note: Dynamic weights are not applicable when content switching virtual servers are configured.

### To configure a GSLB virtual server to use dynamic weights by using the command line interface

At the command prompt, type:

```
1 set gslb vserver <name> -dynamicWeight SERVICECOUNT | SERVICEWEIGHT
2 <!--NeedCopy-->
```

#### Example:

```
1 set gslb vserver vserver-GSLB-1 -dynamicWeight SERVICECOUNT
2 <!--NeedCopy-->
```

### To set GSLB virtual server to use dynamic weights by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers, double-click the GSLB virtual server whose method you want to change (for example, vserver-GSLB-1).
2. Click the **Method** section and, from the **Dynamic Weight** drop-down list, select **SERVICECOUNT** or **SERVICEWEIGHT**.

## How to configure persistence in GSLB

May 2, 2023

Persistence ensures that a series of client requests for a particular domain name is sent to the same data center instead of being load balanced. If persistence is configured for a particular domain, it takes precedence over the configured GSLB method. You can use persistence for deployments where an information related to a client transaction is stored locally on an instance, which has served the initial requests. For example, the deployments for e-commerce that uses a shopping cart, where the

server needs to maintain the state of the connection to track the transaction. The NetScaler appliance selects a data center to process a client request. With persistence enabled, it forwards the same IP address of the selected data center for all subsequent Domain Name System (DNS) requests. If a persistence session points to a data center that is DOWN, the NetScaler appliance uses the configured GSLB method to select a new data center. It then becomes persistent for subsequent requests from the client.

For persistence in GSLB, the same set of persistence identifiers (persistID) must be configured on the GSLB virtual servers in all data centers. The GSLB module uses the persistence identifier to uniquely identify a GSLB virtual server. When Source IP persistence is enabled on the GSLB virtual server, the persistence sessions are also exchanged as part of the metrics exchange. For the NetScaler appliance to support persistence across sites, persistence related configuration must be done on all the participating GSLB sites. Citrix recommends persistence in GSLB for stateful applications, which requires clients to reconnect to the same application instance for the subsequent requests.

You can achieve persistence in GSLB by the following ways:

- Persistence on GSLB virtual server
- Site persistence on GSLB services

### **Persistence on GSLB virtual server**

Persistence on GSLB virtual server is used during the DNS requests. The Source IP address of the DNS request is used to create persistence session between the client and the data center. DNS clients are generally the Local DNS (LDNS) or DNS gateways proxying a set of clients sitting behind them (in ISPs). Persistence on a GSLB virtual server is application protocol agnostic.

In general, multiple DNS gateways or Local Domain Name Servers (LDNS) are configured in the client network. Citrix recommends you to configure an appropriate persistence mask because for the subsequent DNS requests, irrespective of the upstream LDNS devices used to connect to the ADC appliance, the client is able to persist to the same data center, which had served the earlier requests. After the persistence session is created for an LDNS IP address, all the end clients connecting using that LDNS are given the same data center IP address.

### **Site persistence on GSLB services**

Site persistence becomes effective while processing the application requests. Site persistence works only for HTTP and HTTPS traffic because the persistency is achieved using HTTP cookie. As cookies are maintained on HTTP clients (browsers), it gives visibility into the clients sitting behind the DNS gateways. When you use cookies to achieve persistency for clients, no resources are consumed on the ADC appliance for each incoming client. When you bring a GSLB service DOWN with a delay time, the service goes into the transition to out of service (TROFS) state. Persistence is supported as long

as the service is in the UP or TROFS state. That is, if the same client sends a request for the same service within the specified delay time after a service is marked TROFS, the same GSLB site (data center) services the request.

If you access an application through an alias, ensure that the CNAME record is also configured on the NetScaler appliance. In a parent-child topology, site persistence does not work when you access an application through an alias.

#### Note

If the connection proxy is specified as the site persistence method and you also want to configure persistence on LB virtual servers, source IP persistence is not recommended. When the connection is proxied, an IP address owned by the ADC appliance is used, and not the actual IP address of the client.

Configure an appropriate persistence, which does not use source IP of the HTTP(S) request to identify the client, for example, cookie persistence or rule-based persistence.

## Configure persistence based on source IP address

If source IP persistence is configured on GSLB virtual server, persistence sessions are created for the source IP address of the DNS request. Depending on the Extended Client Subnet (ECS) feature, the source IP address of the DNS request is taken from any of the following:

- The source IP in the IP header of the incoming DNS request packet
- The ECS option in the DNS request For more information on ECS, see [Use the EDNS0 client subnet option for Global Server Load Balancing](#).

Persistence sessions for a client last until the persistence timeout. After the timeout period expires, existing persistence sessions are cleared. For subsequent requests, a new GSLB decision is made and a different GSLB service IP address might be selected.

The source IP persistence on GSLB virtual server and site persistence on GSLB service complements each other. If source IP persistence is disabled on GSLB virtual server, the GSLB virtual server chooses a different GSLB service each time the DNS tries to do the resolution. The client also connects to a different GSLB service and the data center which receives the application request proxy the connection to the data center which served the client first. This might add some latency. So by enabling source IP persistence on GSLB virtual server can avoid frequent such multiple hops for application requests. If the source IP persistence session has expired and the client reconnects after that, the site persistence connects the client back to the data center, which had served the client initially. Also, if the client connects back through a DNS gateway, which does not fall within the persistence mask range configured, then as well site persistence helps clients stick to the data center that served the first request.

## To configure persistence based on source IP address by using the CLI

At the command prompt, type:

```
1 set gslb vserver <name> -persistenceType (SOURCEIP|NONE) -persistenceId
 <positive_integer> [-persistMask <netmask>] - [timeout <mins>]
2 <!--NeedCopy-->
```

### Example:

```
1 set gslb vserver vserver-GSLB-1 -persistenceType SOURCEIP -
 persistenceId 23 -persistMask 255.255.255.255 - timeout 2
2 <!--NeedCopy-->
```

## To configure persistence based on source IP address by using the GUI

1. Navigate to **Traffic Management > GSLB > Virtual Servers** and double-click the GSLB virtual server whose method you want to change (for example, vserver-GSLB-1).
2. Click the **Persistence** section and, from the **Persistence** drop-down list, select **SOURCEIP** and set the following parameters:
  - Persistence Id—persistenceId
  - Time-out—timeout
  - IPv4 Netmask or IPv6 Mask length—persistMask

## Configure site persistence based on HTTP cookies

Site persistence is achieved using HTTP cookies (known as a “site cookie”) to reconnect the client to the same server. When the GSLB appliance responds to a client DNS request by sending the IP address of the selected GSLB site, the client sends an HTTP request to that GSLB site. Application endpoint in that GSLB site adds a site cookie to the HTTP header, and site persistence is in effect.

If the client sends a DNS query after the client cache is expired, the DNS request might be directed to a different GSLB site. The new GSLB site uses the site cookie present in the client request header to implement persistence. Site persistence feature becomes active under the following conditions:

- When the domain name in the host header matches one of the GSLB domains
- When site persistence is enabled on the GSLB service that represents the virtual server receiving the application traffic.

The site cookie contains information about the selected GSLB service on which the client has a persistent connection. If the GSLB service pointed by the cookie is DOWN or removed from the GSLB configuration, then the virtual server that receives the traffic continues to process the traffic. The cookie expiration is based on the cookie timeout configured on the NetScaler appliance. If the virtual server

names are not identical on all the sites, you must use the persistence identifier. Cookies inserted are compliant with RFC 2109.

NetScaler supports two types of site persistence:

- Connection Proxy
- HTTP redirect

## Connection Proxy

In the Connection Proxy mode of site persistence, the data center that receives the subsequent application request performs the following tasks to establish a connection:

1. Creates a connection to the GSLB site that inserted the site cookie.
2. Proxies the client request to the original site.

### Note:

The proxy server establishes connection with the original site using the following details:

- The SNIP of the new site is the source IP address.
- The GSLB service public IP address of the original site is the destination IP address.
- An ephemeral port is the source port and GSLB service port is the destination port.
- Uses either HTTP or HTTPS protocols depending on the GSLB service type.

3. Receives a response from the original GSLB site.
4. Relays that response back to the client.
5. Closes the connection.

## HTTP redirect

If the GSLB configuration uses HTTP redirect persistence, the new site redirects the request to the site that originally inserted the cookie. Domain name in the redirect URL is the site domain. Ensure that both cookies and SSL certificates are applicable to both GSLB domain and site domain. To apply cookies for both GSLB and site domain, the cookie domain must be the site to GSLB domain. To apply SSL certificates to both GSLB and site domain, certificate bound to the SSL virtual server must be a wildcard certificate.

Connection proxy occurs when the following conditions are satisfied:

- Requests are sent for a domain participating in GSLB. The domain is obtained from the URL/Host header.

- The local GSLB service has connection proxy enabled.
- The request includes a valid cookie that contains the IP address of an active remote GSLB service.

**Note**

In a GSLB parent-child configuration, the connection proxy works as intended even when a GSLB service is not configured on a child site. However, if you have extra configuration such as client authentication, client IP address insertion, or other SSL-specific requirement, you must add an explicit GSLB service on the site and configure it accordingly.

For more information about parent-child topology, see [Parent-Child Topology Deployment Using the MEP Protocol](#).

**To set persistence based on HTTP cookies by using the CLI**

At the command prompt, type:

```
1 set gslb service <serviceName> -sitePersistence (ConnectionProxy [-
 sitePrefix <prefix>] | HTTPRedirect -sitePrefix <prefix>)
2 <!--NeedCopy-->
```

**Example:**

```
1 set gslb service service-GSLB-1 -sitePersistence ConnectionProxy
2 set gslb service service-GSLB-1 -sitePersistence HTTPRedirect -
 sitePrefix vserver-GSLB-1
3 <!--NeedCopy-->
```

**To set persistence based on cookies by using the GUI**

1. Navigate to **Traffic Management > GSLB > Services** and select the service that you want to configure for site persistence (for example, service-GSLB-1).
2. Click the **Site Persistence** section and set persistence based on cookies.

## Manage client connections

May 2, 2023

To facilitate management of client connections, you can enable delayed cleanup of connections to the virtual server. You can then manage local DNS traffic by configuring DNS policies.

## Enable delayed cleanup of virtual server connections

The state of a virtual server depends on the states of the services bound to it, and the state of each service depends on the monitors bound to it. If a server is slow or down, the monitoring probes time out and the service that represents the server is marked as DOWN. A virtual server is marked as DOWN only when all services bound to it are marked as DOWN. You can configure services and virtual servers to either terminate all connections when they go down, or allow the connections to go through. The latter setting is for situations in which a service is marked as DOWN because of a slow server.

When you configure the down state flush option, the NetScaler appliance performs a delayed cleanup of connections to a GSLB service that is down.

### To enable delayed cleanup of virtual server connections by using the command line interface

At the command prompt, type the following commands to configure delayed connection cleanup and verify the configuration:

```
1 set gslb service <name> -downStateFlush (ENABLED | DISABLED)
2 show gslb service <name>
3 <!--NeedCopy-->
```

#### Example:

```
1 set gslb service Service-GSLB-1 -downStateFlush ENABLED
2 Done
3
4 show gslb service Service-GSLB-1
5 Done
6 <!--NeedCopy-->
```

### To enable delayed cleanup of virtual server connections by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Services** and double-click the service.
2. Click the **Other Settings** section and select the **Down State Flush** option.

## Manage local DNS traffic by using DNS policies

You can use DNS policies to implement site affinity by directing traffic from the IP address of a local DNS resolver or network to a predefined target GSLB site. This is configured by creating DNS policies with DNS expressions and binding the policies globally on the NetScaler appliance.

## DNS expressions

The NetScaler appliance provides certain predefined DNS expressions that can be used for configuring actions specific to a domain. Such actions can, for example, drop certain requests, select a specific view for a specific domain, or redirect certain requests to a specific location.

These DNS expressions (also called *rules*) are combined to create DNS policies that are then bound globally on the NetScaler appliance.

Following is the list of predefined DNS qualifiers available on the NetScaler appliance:

- CLIENT.UDP.DNS.DOMAIN.EQ(“domainname”)
- CLIENT.UDP.DNS.IS\_AREC
- CLIENT.UDP.DNS.IS\_AAAAREC
- CLIENT.UDP.DNS.IS\_SRVREC
- CLIENT.UDP.DNS.IS\_MXREC
- CLIENT.UDP.DNS.IS\_SOAREC
- CLIENT.UDP.DNS.IS\_PTRREC
- CLIENT.UDP.DNS.IS\_CNAME
- CLIENT.UDP.DNS.IS\_NSREC
- CLIENT.UDP.DNS.IS\_ANYREC

The CLIENT.UDP.DNS.DOMAIN DNS expression can be used with string expressions. If you are using domain names as part of the expression, they must end with a period (.). For example, CLIENT.UDP.DNS.DOMAIN.ENDSWITH(“abc.com.”)

### To create an expression by using the configuration utility

1. Click the icon next to the Expression text box. Click Add. (Leave the Flow Type and Protocol drop-down list boxes empty.) Follow these steps to create a rule.
2. In the Qualifier box, select a qualifier (for example, LOCATION).
3. In the Operator box, select an operator (for example, ==).
4. In the Value box, type a value (for example, Asia, Japan...).
5. Click OK. Click Create and click Close. The rule is created.
6. Click OK.

### Configure DNS actions

A DNS policy includes the name of a DNS action to be performed when the policy rule evaluates to TRUE. A DNS action can do one of the following:

- Send the client an IP address for which you have configured a DNS view. For more information about DNS views, see Adding DNS Views.

- Send the client the IP address of a GSLB service after referring to a list of preferred locations that overrides static proximity behavior. For more information about preferred locations, see [Overriding Static Proximity Behavior by Configuring Preferred Locations](#).
- Send the client a specific IP address as determined by the evaluation of the DNS query or response (DNS response rewrite).
- Forward a request to the name server without performing a lookup in the appliance's DNS cache.
- Drop a request.

You cannot create a DNS action for dropping a DNS request or for bypassing the DNS cache on the appliance. If you want to drop a DNS request, use the built-in action, `dns_default_act_Drop`. If you want to bypass the DNS cache, use the built-in action, `dns_default_act_Cachebypass`. Both actions are available along with custom actions in the Create DNS Policy and the Configure DNS Policy dialog boxes. These built-in actions cannot be modified or removed.

**To configure a DNS action by using the command line interface** At the command prompt, type the following commands to configure a DNS action and verify the configuration:

```

1 add dns action <actionName> <actionType> (-IPAddress <ip_addr |
 ipv6_addr> ... | -viewName <string> | -preferredLocList <string>
 ...) [-TTL <secs>]
2
3 show dns action [<actionName>]
4 <!--NeedCopy-->

```

**Examples Example 1: Configuring DNS Response Rewrite.** The following DNS action sends the client a preconfigured IP address when the policy to which the action is bound evaluates to true:

```

1 add dns action dns_act_response_rewrite Rewrite_Response -IPAddress
 192.0.2.20 192.0.2.56 198.51.100.10
2 Done
3
4 show dns action dns_act_response_rewrite
5 1) ActionName: dns_act_response_rewrite ActionType: Rewrite_Response
 TTL: 3600 IPAddress: 192.0.2.20 192.0.2.56
 198.51.100.10
6 Done
7 <!--NeedCopy-->

```

**Example 2: Configuring a DNS-View Based Response.** The following DNS action sends the client an IP address for which you have configured a DNS view:

```

1 add dns action send_ip_from_view_internal_ip ViewName -viewName
 view_internal_ip
2 Done
3

```

```

4 show dns action send_ip_from_view_internal_ip
5 1) ActionName: send_ip_from_view_internal_ip ActionType: ViewName
 ViewName: view_internal_ip
6 Done
7 <!--NeedCopy-->

```

**Example 3: Configuring a Response Based on a Preferred Location List.** The following DNS action sends the client the IP address that corresponds to the preferred location that it selects from the specified list of locations:

```

1 add dns action send_preferred_location GslbPrefLoc -preferredLocList NA
 .tx.ns1.*.*.* NA.tx.ns2.*.*.* NA.tx.ns3.*.*.*
2 Done
3
4 show dns action send_preferred_location
5 1) ActionName: send_preferred_location ActionType: GslbPrefLoc
 PreferredLocList: "NA.tx.ns1.*.*.*" "NA.tx.ns2.*.*.*" "NA.tx.ns3
 ..*.*"
6 Done
7 <!--NeedCopy-->

```

### To configure a DNS action by using the NetScaler configuration utility

1. Navigate to Traffic Management > DNS > Actions, create or edit a DNS action.
2. In the Create DNS Action or Configure DNS Action dialog box, set the following parameters:
  - Action Name (cannot be changed for an existing DNS action)
  - Type (cannot be changed for an existing DNS action)

To set the Type parameter, do one of the following:

  - To create a DNS action that is associated with a DNS view, select View Name. Then, from the View Name list, select the DNS view that you want to use in the action.
  - To create a DNS action with a preferred location list, select Preferred Location List. In Preferred Location, enter a location, and then click Add. Add as many DNS locations as you want.
  - To configure a DNS action for rewriting a DNS response on the basis of policy evaluation, select Rewrite Response. In IP Address, enter an IP address, and then click Add. Add as many IP addresses as you want.
  - TTL (applicable only to the Rewrite Response action type)

### Configure DNS policies

DNS policies operate on a location database that uses static and custom IP addresses. The attributes of the incoming local DNS request are defined as part of an expression, and the target site is defined

as part of a DNS policy. While defining actions and expressions, you can use a pair of single quotation marks (‘’) as a wildcard qualifier to specify more than one location. When a DNS policy is configured and a GSLB request is received, the custom IP address database is first queried for an entry that defines the location attributes for the source:

- When a DNS query comes from an LDNS, the characteristics of the LDNS are evaluated against the configured policies. If they match, an appropriate action (site affinity) is executed. If the LDNS characteristics match more than one site, the request is load balanced between the sites that match the LDNS characteristics.
- If the entry is not found in the custom database, the static IP address database is queried for an entry, and if there is a match, the above policy evaluation is repeated.
- If the entry is not found in either the custom or static databases, the best site is selected and sent in the DNS response on the basis of the configured load balancing method.

The following restrictions apply to DNS policies created on the NetScaler appliance.

- A maximum of 64 policies are supported.
- DNS policies are global to the NetScaler appliance and cannot be applied to a specific virtual server or domain.
- Domain or virtual server specific binding of policy is not supported.

You can use DNS policies to direct clients that match a certain IP address range to a specific site. For example, if you have a GSLB setup with multiple GSLB sites that are separated geographically, you can direct all clients whose IP address is within a specific range to a particular data center.

Both TCP-based and UDP-based DNS traffic can be evaluated. Policy expressions are available for UDP-based DNS traffic on the server and for both UDP-based DNS traffic and TCP-based DNS traffic on the client side. Additionally, you can configure expressions to evaluate queries and responses that involve only the following DNS question types (or QTYPE values):

- A
- AAAA
- NS
- SRV
- PTR
- CNAME
- SOA
- MX
- ANY

The following response codes (RCODE values) are also supported:

- NOERROR - No error

- FORMERR - Format error
- SERVFAIL - Server failure
- NXDOMAIN - Non-existent domain
- NOTIMP - Query type not implemented
- REFUSED - Query refused

You can configure expressions to evaluate DNS traffic. A DNS expression begins with the DNS.REQ or DNS.RES prefixes. Functions are available for evaluating the queried domain, the query type, and the carrier protocol. For more information about DNS expressions, see “Expressions for Evaluating a DNS Message and Identifying Its Carrier Protocol” in [“Policy Configuration and Reference”](#).

**To add a DNS policy by using the command line interface** At the command prompt, type the following commands to create a DNS policy and verify the configuration:

```
1 add dns policy <name> <rule> <actionName>
2 show dns policy <name>
3 <!--NeedCopy-->
```

**Example:**

```
1 > add dns policy-GSLB-1 'CLIENT.UDP.DNS.DOMAIN.EQ("domainname")'
 my_dns_action
2 Done
3 > show dns policy-GSLB-1
4 Name: policy-GSLB-1
5 Rule: CLIENT.UDP.DNS.DOMAIN.EQ("domainname")
6 Action Name: my_dns_action
7 Hits: 0
8 Undef Hits: 0
9
10 Done
11 <!--NeedCopy-->
```

**To remove a configured DNS policy by using the command line interface** At the command prompt, type:

```
1 rm dns policy <name>
2 <!--NeedCopy-->
```

**To configure a DNS policy by using the NetScaler configuration utility**

1. Navigate to Traffic Management > DNS > Policies and create a DNS policy.
2. In the Create DNS Policy or Configure DNS Policy dialog box, set the following parameters:
  - Policy Name (cannot be changed for an existing policy)

- Action
- Expression

To specify an expression, do the following:

- a) Click Add, and then, in the drop-down box that appears, select the expression element with which you want to begin the expression. A second list appears. The list contains a set of expression elements that you can use immediately after the first expression element.
  - b) In the second list, select the expression element that you want, and then enter a period.
  - c) After each selection, if you enter a period, the next set of valid expression elements appear in a list. Select expression elements and fill in arguments to functions until you have the expression you want.
3. Click Create or OK, and then click Close.

### Bind DNS policies

DNS policies are bound globally on the NetScaler appliance and are available for all configured GSLB virtual servers. Even though DNS policies are globally bound, policy execution can be limited to a specific GSLB virtual server by specifying the domain in the expression.

Note: Even though the `bind dns global` command accepts `REQ_OVERRIDE` and `RES_OVERRIDE` as valid bind points, those bind points are redundant, because DNS policies can be bound only globally. Bind your DNS policies only to the `REQ_DEFAULT` and `RES_DEFAULT` bind points.

**To bind a DNS policy globally by using the command line interface** At the command prompt, type the following commands to bind a DNS policy globally and verify the configuration:

```
1 bind dns global <policyName> <priority> [-gotoPriorityExpression <
 string>] [-type <type>]
2 show dns global -type <type>
3 <!--NeedCopy-->
```

### Example:

```
1 bind dns global policy-GSLB-1 10 -gotoPriorityExpression END
2 Done
3 show dns global -type REQ_DEFAULT
4 1) Policy Name: policy-GSLB-1
5 Priority: 10
6 GotoPriorityExpression: END
7 Done
8 <!--NeedCopy-->
```

**To bind a DNS policy globally by using the configuration utility**

1. Navigate to Traffic Management > DNS > Policies.
2. In the details pane, click Global Bindings.
3. In the Bind/Unbind DNS Policy(s) to Global dialog box, click Insert Policy.
4. In the Policy Name column, select, from the list, the policy that you want to bind. Alternatively, in the list, click New Policy, and then create a DNS policy by setting parameters in the Create DNS Policy dialog box.
5. To modify a policy that is already bound globally, click the name of the policy, and then click Modify Policy. Then, in the Configure DNS Policy dialog box, modify the policy, and then click OK.
6. To unbind a policy, click the name of the policy, and then click Unbind Policy.
7. To modify the priority assigned to a policy, double-click the priority value, and then enter a new value.
8. To regenerate assigned priorities, click Regenerate Priorities. The priority values are modified to begin at 100, with increments of 10, without affecting the order of evaluation.
9. Click OK.

**To view the global bindings of a DNS policy by using the command line interface** At the command prompt, type:

```
show dns global
```

**To view the global bindings of a DNS policy by using the configuration utility**

1. Navigate to **Traffic Management > DNS > Policies**.
2. In the details pane, click **Global Bindings**. The global bindings of all DNS policies appear in this dialog box.

**Adding DNS Views**

You can configure DNS views to identify various types of clients and provide an appropriate IP address to a group of clients who query for the same GSLB domain. DNS views are configured by using DNS policies that select the IP addresses sent back to the client.

For example, if you have configured GSLB for your company's domain and have the server hosted in your company's network, clients querying for the domain from within your company's internal network can be provided with the server's internal IP address instead of the public IP address. Clients that query DNS for the domain from the Internet, on the other hand, can be provided the domain's public IP address.

To add a DNS view, you assign it a name of up to 31 characters. The leading character must be a number or letter. The following characters are also allowed: @ \_ - . (period) : (colon) # and space ( ). After adding the view, you configure a policy to associate it with clients and a part of the network, and you bind the policy globally. To configure and bind a DNS policy, see **Managing Local DNS Traffic by Using DNS Policies**.

### To add a DNS view by using the command line interface

At the command prompt, type the following commands to create a DNS view and verify the configuration:

```
1 add dns view <viewName>
2 show dns view <viewName>
3 <!--NeedCopy-->
```

#### Example:

```
1 add dns view PrivateSubnet
2 show dns view PrivateSubnet
3 <!--NeedCopy-->
```

### To remove a DNS view by using the command line interface

At the command prompt, type:

```
1 rm dns view <viewName>
2 <!--NeedCopy-->
```

### To add a DNS view by using the configuration utility

Navigate to Traffic Management > DNS > Views and add a DNS view.

For details on how to create a DNS policy and how to bind DNS policies globally, see **Managing Local DNS Traffic by Using DNS Policies**.

## Configure GSLB for proximity

May 2, 2023

When you configure GSLB for proximity, client requests are forwarded to the closest data center. The main benefit of the proximity-based GSLB method is faster response times resulting from the selection

of the closest available data center. Such a deployment is critical for applications that require fast access to large volumes of data.

You can configure GSLB for proximity based on the round trip time (RTT), static proximity, or a combination of the two.

### **Configure dynamic round trip time (RTT) method**

Dynamic round trip time (RTT) is a measure of time or delay in the network between the client's local DNS server and a data resource. To measure dynamic RTT, the NetScaler appliance probes the client's local DNS server and gathers RTT metric information. The appliance then uses this metric to make its load balancing decision. Global server load balancing monitors the real-time status of the network and dynamically directs the client request to the data center with the lowest RTT value

To configure GSLB for proximity with dynamic method, you must first configure the basic GSLB set up and then configure dynamic RTT.

First create two GSLB sites, local and remote. Then, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Then create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server at the local site. Finally, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

For details on how to configure a basic GSLB setup, see [Configuring GSLB Entities Individually](#).

Once you have configured a basic GSLB setup, configure the dynamic RTT method.

For details on how to configure the GSLB virtual server to use the dynamic RTT method for load balancing, see [Configuring Dynamic RTT](#).

### **Configure static proximity**

The static proximity method for GSLB uses an IP address-based static proximity database to determine the proximity between the client's local DNS server and the GSLB sites. The NetScaler appliance responds with the IP address of a site that best matches the proximity criteria.

If two or more GSLB sites at different geographic locations serve the same content, the NetScaler appliance maintains a database of IP address ranges and uses the database for decisions about the GSLB sites to which to direct incoming client requests.

To configure GSLB for proximity with static proximity, you must first configure the basic GSLB set up and then configure static proximity.
