First create two GSLB sites, local and remote. Then, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Then create ADNS services and bind the

domain for which you are configuring GSLB to the GSLB virtual server at the local site. Finally, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

For details on how to configure a basic GSLB setup, see [Configuring GSLB Entities Individually](#).

Once you have configured a basic GSLB setup, configure static proximity.

For details on how to configure the GSLB virtual server to use static proximity for load balancing, see [Configuring Static Proximity](#).

## Configure static proximity and dynamic RTT

You can configure the GSLB virtual server to use a combination of static proximity and dynamic RTT when you have some clients coming from an internal network like a branch office. You can configure GSLB such that the clients coming from the branch office or any other internal network are directed to a particular GSLB site that is geographically close to the client network. For all other requests, you can use dynamic RTT.

First create two GSLB sites, local and remote. Then, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Then create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server at the local site. Finally, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

For details on how to configure a basic GSLB setup, see [Configuring GSLB Entities Individually](#).

Once you have configured a basic GSLB setup, configure the GSLB virtual server to use static proximity for all traffic originating from an internal network and then use dynamic RTT for all other traffic.

For details on how to configure static proximity, see [Configuring Static Proximity](#) and for details on how to configure dynamic RTT, see [Configuring Dynamic RTT](#).

## Protect the GSLB setup against failure

May 2, 2023

You can protect your GSLB setup against failure of a GSLB site or a GSLB virtual server by configuring the following:

- A backup GSLB virtual server
- A NetScaler appliance to respond with multiple IP addresses
- A backup IP address for a GSLB domain

You can also divert excess traffic to a backup virtual server by using spillover.

## Configure a backup GSLB virtual server

Configuring a backup entity for a GSLB virtual server ensures that DNS traffic to a site is not interrupted if the GSLB virtual server goes down. The backup entity can be another GSLB virtual server, or it can be a backup IP address. With a backup entity configured, if the primary GSLB virtual server goes down, the backup entity handles DNS requests. To specify what must happen when the primary GSLB virtual server comes back up again, you can configure the backup entity to continue handling traffic until you manually enable the primary virtual server to take over (using the `disablePrimaryOnDown` option).

Note: You can configure a single backup entity as backup for multiple GSLB virtual servers.

### To configure a backup GSLB virtual server by using the command line interface

At the command prompt, type the following commands to configure a GSLB virtual server as backup virtual server and verify the configuration:

```
1 set gslb vserver <name> -backupVServer <name> [-disablePrimaryOnDown (
 ENABLED | DISABLED)]
2
3 show gslb vserver <name>
4 <!--NeedCopy-->
```

#### Example:

```
1 set gslb vserver vserver-GSLB-1 -backupVServer vserver-GSLB-2 -
 disablePrimaryOnDown ENABLED
2 show gslb vserver vserver-GSLB-1
3 <!--NeedCopy-->
```

### To set GSLB virtual server as a backup virtual server by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Virtual Servers**, and double-click the GSLB virtual server.
2. Select the **Backup Virtual Server** section and choose the backup virtual server.

## Configure a GSLB setup to respond with multiple IP addresses

A typical DNS response contains the IP address of the best performing GSLB service. However, if you enable multiple IP responses (MIR), the NetScaler appliance sends the best GSLB service as the first record in the response and adds the remaining active services as extra records. If MIR is disabled (the default), the NetScaler appliance sends the best service as the only record in response.

### To configure a GSLB virtual server for multiple IP responses by using the command line interface

At the command prompt, type the following commands to configure a GSLB virtual server for multiple IP responses and verify the configuration:

```
1 set gslb vserver<name> -MIR (ENABLED | DISABLED)
2 - show gslb vserver <name>
3 <!--NeedCopy-->
```

#### Example:

```
1 set gslb vserver vserver-GSLB-1 -MIR ENABLED
2 show gslb vserver <vserverName>
3 <!--NeedCopy-->
```

### To set a GSLB virtual server for multiple IP responses by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Virtual Servers** and double-click the GSLB virtual server for which you want to configure a backup virtual server (for example, vserver-GSLB-1).
2. On the **Advanced** tab, under When this virtual server is “UP,”select the Send all “active”service IP in response (MIR) check box, and select **OK**.

### Configuring a GSLB Virtual Server to Respond with an Empty Address Record When DOWN

A DNS response can contain either the IP address of the requested domain or an answer stating that the IP address for the domain is not known by the DNS server, in which case the query is forwarded to another name server. These are the only possible responses to a DNS query.

When a GSLB virtual server is disabled or in a DOWN state, the response to a DNS query for the GSLB domain bound to that virtual server contains the IP addresses of all the services bound to the virtual server. However, you can configure the GSLB virtual server to in this case send an empty down response (EDR). When this option is set, a DNS response from a GSLB virtual server that is in a DOWN state does not contain IP address records, but the response code is successful. This prevents clients from attempting to connect to GSLB sites that are down.

Note: You must configure this setting for each virtual server to which you want it to apply.

### To configure a GSLB virtual server for empty down responses by using the command line interface

At the command prompt, type:

```
1 set gslb vserver<name> -EDR (ENABLED | DISABLED)
2 <!--NeedCopy-->
```

**Example:**

```
1 > set gslb vserver vserver-GSLB-1 -EDR ENABLED
2 Done
3 <!--NeedCopy-->
```

**To set a GSLB virtual server for empty down responses by using the configuration utility**

1. Navigate to **Traffic Management > GSLB > Virtual Servers** and double-click the GSLB virtual server for which you want to configure a backup virtual server (for example, vserver-GSLB-1).
2. On the Advanced tab, under When this virtual server is “Down,” select the Do not send any service’s IP address in response (EDR) check box.
3. Click **OK**.

**Configure a backup IP address for a GSLB domain**

You can configure a backup site for your GSLB configuration. With this configuration in place, if all the primary sites go DOWN, the IP address of the backup site is provided in the DNS response.

Typically, if a GSLB virtual server is active, that virtual server sends a DNS response with one of the active site IP addresses as selected by the configured GSLB method. If all the configured primary sites in the GSLB virtual server are inactive (in the DOWN state), the authoritative domain name system (ADNS) server or DNS server sends a DNS response with the backup site’s IP address.

Note: When a backup IP address is sent, persistence is not honored.

**To set a backup IP address for a domain by using the command line interface**

At the command prompt, type the following commands to set a backup IP address and verify the configuration:

```
1 set gslb vserver <name> -domainName <string> -backupIP <IPAddress>
2 show gslb vserver <name>
3 <!--NeedCopy-->
```

**Example:**

```
1 set gslb vserver vserver-GSLB-1 -domainName www.abc.com -backupIP
 10.102.29.66
2 show gslb vserver vserver-GSLB-1
3 <!--NeedCopy-->
```

**To set a backup IP address for a domain by using the configuration utility**

1. Navigate to **Traffic Management > GSLB > Virtual Servers** and double-click the GSLB virtual server to which you want to bind the backup domain (for example, vserver-GSLB-1).
2. Click the **Domains** section, configure the GSLB domain and specify the IP address of the backup domain in the **Backup IP** field.

**Divert excess traffic to a backup virtual server**

Once the number of connections to a primary GSLB virtual server exceeds the configured threshold value, you can use the spillover option to divert new connections to a backup GSLB virtual server. This threshold value can be calculated dynamically or set manually. Once the number of connections to the primary virtual server drops below the threshold, the primary GSLB virtual server resumes serving client requests.

You can configure persistence with spillover. When persistence is configured, new clients are diverted to the backup virtual server if that client is not already connected to a primary virtual server. When persistence is configured, connections that were diverted to the backup virtual server are not moved back to the primary virtual server after the number of connections to the primary virtual server drops below the threshold. Instead, the backup virtual server continues to process those connections until they are terminated by the user. Meanwhile, the primary virtual server accepts new clients.

The threshold can be measured by the number of connections, bandwidth, and health of the services.

If the backup virtual server reaches the configured threshold and is unable to take any additional load, the primary virtual server diverts all requests to the designated redirect URL. If a redirect URL is not configured on the primary virtual server, subsequent requests are dropped.

The spillover feature prevents the remote backup GSLB service (backup GSLB site) from getting flooded with client requests when the primary GSLB virtual server fails. This occurs when a monitor is bound to a remote GSLB service, and the service experiences a failure that causes its state to go DOWN. The monitor continues to keep the state of the remote GSLB service UP, however, because of the spillover feature.

As part of the resolution to this problem, two states are maintained for a GSLB service, the primary state and effective state. The primary state is the state of the primary virtual server and the effective state is the cumulative state of the virtual servers (primary and backup chain). The effective state is set to UP if any of the virtual servers in the chain of virtual servers is UP. A flag that indicates that the primary VIP has reached the threshold is also provided. The threshold can be measured by either the number of connections or the bandwidth.

A service is considered for GSLB only if its primary state is UP. Traffic is directed to the backup GSLB

service only when all the primary virtual servers are DOWN. Typically, such deployments have only one backup GSLB service.

Adding primary and effective states to a GSLB service has the following effects:

- When source IP persistence is configured, the local DNS is directed to the previously selected site only if the primary virtual server on the selected site is UP and below threshold. Persistence can be ignored in the round robin mode.
- If cookie-based persistence is configured, client requests are redirected only when the primary virtual server on the selected site is UP.
- If the primary virtual server has reached its saturation and the backup VIPs is absent or down, the effective state is set to DOWN.
- If external monitors are bound to an HTTP-HTTPS virtual server, the monitor decides the primary state.
- If there is no backup virtual server to the primary virtual server and the primary virtual server has reached its threshold, the effective state is set to DOWN.

### To configure backup GSLB virtual server by using the command line interface

At the command prompt, type the following commands to configure backup GSLB virtual server and verify the configuration:

```
1 set gslb vserver <name> -soMethod <method> -soThreshold <threshold> -
 soPersistence (**ENABLED** | **DISABLED**) -soPersistenceTimeout <
 timeout>
2 show gslb vserver <name>
3 <!--NeedCopy-->
```

#### Example:

```
1 set gslb vserver Vserver-GSLB-1 -soMethod CONNECTION -soThreshold 1000
 -soPersistence ENABLED -soPersistenceTimeout 2
2 show gslb vserver Vserver-GSLB-1
3 <!--NeedCopy-->
```

### To configure backup GSLB virtual server by using the configuration utility

1. Navigate to **Traffic Management > GSLB > Virtual Servers** and double-click the virtual server that you want to configure as backup (for example, Vserver-LB-1).
2. Click the **Spillover** section and set the following parameters:
  - Method—soMethod
  - Threshold—soThreshold
  - Persistence Time-out (min) —soPersistenceTimeout

3. Select the Persistence option and click **OK**.

## Configure GSLB for disaster recovery

May 2, 2023

Disaster recovery capability is critical, because downtime is costly. A NetScaler appliance configured for GSLB forwards traffic to the least-loaded or the best-performing data center. This configuration, referred to as an active-active setup, not only improves performance, but also provides immediate disaster recovery by routing traffic to other data centers if a data center that is part of the setup goes down. Alternatively, you can configure an active-standby GSLB setup for disaster recovery only.

### Configure GSLB for disaster recovery in an active-standby data center setup

A conventional disaster recovery setup includes an active data center and a standby data center. The standby data center is a remote site. When a failover occurs as a result of a disaster event that causes the primary active data center to be inactive, the standby data center becomes operational.

Configuring disaster recovery in an active-standby data-center setup consists of the following tasks.

- Create the active data center.
  - Add a local GSLB site.
  - Add a GSLB vserver, which represents the active data center.
  - Bind the domain to the GSLB virtual server.
  - Add gslb services and bind the services to active GSLB virtual server.
- Create the standby data center.
  - Add a remote gslb site.
  - Add a gslb vserver, which represents standby data center.
  - Add gslb services which represents standby data center and bind the services to the standby gslb vserver.
  - Designate the standby data center by configuring the standby GSLB virtual server as the backup virtual server for the active GSLB virtual server.

Once you have configured the primary data center, replicate the configuration for the backup data center and designate it as the standby GSLB site by designating a GSLB virtual server at that site as the backup virtual server.

For details on how to configure a basic GSLB setup, see [Configuring GSLB Entities Individually](#).

### To designate the standby GSLB site by using the command line interface

At both the active site and the remote site, at the command prompt, type:

```
1 set gslb vserver <name> -backupVserver <string>
2 <!--NeedCopy-->
```

#### Example:

```
1 set gslb vserver vserver-GSLB-1 -backupVServer vserver-GSLB-2
2 <!--NeedCopy-->
```

### To configure the standby site by using the configuration utility

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the GSLB virtual server for the primary site.
2. Click the **Backup Virtual Server** section and select a backup virtual server.

By default, once the primary virtual server becomes active, it starts receiving traffic. However, if you want the traffic to be directed to the backup virtual server even after the primary virtual server becomes active, use the ‘disable primary on down’ option.

### Configure for disaster recovery in an active-active data center setup

An active-active GSLB deployment, in which both GSLB sites are active, removes any risk that may arise in having a standby data center. With such a setup, web or application content can be mirrored in geographically separate locations. This ensures that data is consistently available at each distributed data center.

To configure GSLB for disaster recovery in an active-active data center set up, you must first configure the basic GSLB setup on the first data center and then configure all other data centers.

First create at least two GSLB sites. Then, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Then create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server in the local site. Finally, at the local site, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

Once you have configured the first data center, replicate the configuration for other data centers part of the setup.

For details on how to configure a basic GSLB setup, see [Configuring GSLB Entities Individually](#).

## Configuring for Disaster Recovery with Weighted Round Robin

When you configure GSLB to use the weighted round robin method, weights are added to the GSLB services and the configured percentage of incoming traffic is sent to each GSLB site. For example, you can configure your GSLB setup to forward 80 percent of the traffic to one site and 20 percent of the traffic to another. After you do this, the NetScaler appliance will send four requests to the first site for each request that it sends to the second.

To set up the weighted round robin method, first create two GSLB sites, local and remote. Next, for the local site create a GSLB virtual server and GSLB services, and bind the services to the virtual server. Configure the GSLB method as round robin. Next, create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server. Finally, create a load balancing virtual server with the same virtual server IP address as the GSLB service.

Each service that represents a physical server in the network has weights associated with it. Therefore the GSLB service is assigned a dynamic weight that is the sum of weights of all services bound to it. Traffic is then split between the GSLB services based on the ratio of the dynamic weight of the particular service to the total weight. You can also configure individual weights for each GSLB service instead of the dynamic weight.

If the services do not have weights associated with them, you can configure the GSLB virtual server to use the number of services bound to it to calculate the weight dynamically.

For details on how to configure a basic GSLB setup, see [Configuring GSLB Entities Individually](#).

Once you configure a basic GSLB setup, you must configure the weighted round robin method such that the traffic is split between the configured GSLB sites according to the weights configured for the individual services.

### To configure a virtual server to assign weights to services by using the command line interface

At the command prompt, type one of the following commands, depending upon whether you want to create a new load balancing virtual server or configure an existing one:

```
1 add lb vsrver <name>@ -weight <WeightValue> <ServiceName>
2 set lb vsrver <name>@ -weight <WeightValue> <ServiceName>
3 <!--NeedCopy-->
```

#### Example:

```
1 add lb vsrver Vserver-LB-1 -weight 4 Service-HTTP-1
2 set lb vsrver Vserver-LB-1 -weight 4 Service-HTTP-1
3 <!--NeedCopy-->
```

**To set dynamic weight by using the command line interface**

At the command prompt, type:

```
1 set gslb vserver <name> -dynamicWeight DynamicWeightType
2 <!--NeedCopy-->
```

**Example:**

```
1 set gslb vserver Vserver-GSLB-1 -dynamicWeight ServiceWeight
2 <!--NeedCopy-->
```

**To add weights to the GSLB services by using the command line interface**

At the command prompt, type:

```
1 set gslb vserver <name> -serviceName GSLBServiceName -weight
 WeightValue
2 <!--NeedCopy-->
```

**Example:**

```
1 set gslb vserver Vserver-GSLB-1 -serviceName Service-GSLB-1 -weight 1
2 <!--NeedCopy-->
```

**To configure a virtual server to assign weights to services by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Virtual Servers and double-click the virtual server (for example, Vserver-LB-1).
2. Click the Services section and set the weight of a service.

**To add weights to the GSLB services by using the configuration utility**

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the virtual server (for example, vserver-GSLB-1)
2. Click the Services section and set the weight of the service in the Weight field.

**To set dynamic weight by using the configuration utility**

1. Navigate to Traffic Management > GSLB > Virtual Servers and double-click the virtual server (for example, vserver-GSLB-1).
2. Click the **Method** section and, from the **Dynamic Weight** drop-down list select **SERVICEWEIGHT**.

## Configuring for Disaster Recovery with Data Center Persistence

Data center persistence is required for web applications that require maintaining a connection with the same server instead of having the requests load balanced. For example, in an e-commerce portal, maintaining a connection between the client and the same server is critical. For such applications, HTTP redirect persistence can be configured in an active-active setup.

To configure GSLB for disaster recovery with data center persistence, you must first configure the basic GSLB set up and then configure HTTP redirect persistence.

First create two GSLB sites, local and remote. Next, for the local site, create a GSLB virtual server and GSLB services and bind the services to the virtual server. Next, create ADNS services and bind the domain for which you are configuring GSLB to the GSLB virtual server at the local site. Next, create a load balancing virtual server with the same virtual server IP address as the GSLB service. Finally, duplicate the previous steps for the remote configuration, or configure the NetScaler appliance to autosynchronize your GSLB configuration.

For details on how to configure a basic GSLB setup, see [Configuring GSLB Entities Individually](#).

Once you have configured a basic GSLB setup, configure HTTP redirect precedence to enable data center persistence.

### To configure HTTP redirect by using the command line interface

At the command prompt, type the following commands to configure HTTP redirect and verify the configuration:

```
1 set gslb service <serviceName> -sitePersistence <sitePersistence> -
 sitePrefix <string>
2 show gslb service <serviceName>
3 <!--NeedCopy-->
```

#### Example:

```
1 set gslb service Service-GSLB-1 -sitePersistence HTTPRedirect -
 sitePrefix vserver-GSLB-1
2 show gslb service Service-GSLB-1
3 <!--NeedCopy-->
```

### To configure HTTP redirect by using the configuration utility

1. Navigate to Traffic Management > GSLB > Services and double-click the GSLB service to be configured.
2. Click the **Site Persistence** section, select the **HTTPRedirect** option, and in the **Site Prefix** text box, enter the site prefix (for example, vserver-GSLB-1).

**Note**

When site persistence is not configured and if a load balancing virtual server that is configured as a local GSLB service is DOWN, the HTTP requests are redirected to other healthy GSLB sites using a 302 redirect.

## Override static proximity behavior by configuring preferred locations

May 2, 2023

You might want to direct traffic from a local DNS (LDNS) server or network to a GSLB service other than the GSLB service that the static proximity method selects for that traffic. That is, you have a *preferred location* for that traffic. To override the static proximity method with preferred locations, you can do the following:

1. Configure a DNS action that consists of a list of preferred locations. For more information about configuring a DNS action, see [Configuring a DNS Action](#).
2. Configure a DNS policy to identify the traffic arriving from the LDNS server or network for which you want to override static proximity, and apply the action in the policy.
3. Bind the policy to the global request bind point.

In the DNS action, you can configure a list of up to 8 preferred locations. The locations must be provided in the dotted qualifier notation, which is the notation in which you add custom locations to the static proximity database. The locations can include wildcards for qualifiers that you want to omit. For information about the dotted qualifier notation for locations, see [Adding Custom Entries to a Static Proximity Database](#). When entering the preferred locations, you must enter them in the descending order of priority.

When a policy evaluates to

TRUE, the NetScaler appliance matches the preferred locations, in priority order, with the locations of GSLB services. Matches are of the following two types:

- If all the non-wildcard qualifiers in a preferred location match the corresponding qualifiers in the location of a GSLB service, the match is considered a perfect match. For example, a GSLB service location of \*.UK.\* or Europe.UK.\* is a perfect match for the preferred location \*.UK.\*.
- If only a subset of the non-wildcard qualifiers match, the match is considered a partial match. For example, a GSLB service location of Europe.EG is a partial match for the preferred location Europe.UK.

When a DNS policy evaluates to

TRUE, the following algorithm is used to select a GSLB service:

1. The appliance evaluates the preferred location that has the highest priority and moves down the priority order until a perfect match is found between a preferred location and the location of a GSLB service.

If a perfect match is found, the appliance checks whether the corresponding GSLB service is up. If it is up, it returns the IP address of the GSLB service in the DNS response. If multiple perfect matches are found (which can happen when one or more wildcards are used in a preferred location), the appliance checks the state of each of the corresponding GSLB services and load balances the GSLB services that are up.

2. If a perfect match is not found for any of the preferred locations, the appliance returns to the preferred location that has the highest priority and moves down the priority order until a partial match is found between a preferred location and the location of a GSLB service.

If a partial match is found, the appliance checks whether the corresponding GSLB service is up. If it is up, it returns the IP address of the GSLB service in the DNS response. If multiple partial matches are found, the appliance checks the state of each of the corresponding GSLB services and load balances the GSLB services that are up.

3. If none of the perfect and partial matches are up, the appliance load balances all other available GSLB services.

In this way, the appliance implements a type of site affinity for traffic that matches the DNS policy.

## Example

Consider a GSLB configuration that consists of the following eight GSLB services:

- Asia.IN
- Asia.JPN
- Asia.HK
- Europe.UK
- Europe.RU
- Europe.EG
- Africa.SD
- Africa.ZMB

Further consider the following DNS action and policy configuration:

```
1 > add dns action prefLoc11 GslbPrefLoc -preferredLocList "Asia.HK" "
 Europe.UK"
2 Done
3 > add dns policy dnsPolPrefLoc "CLIENT.IP.SRC.MATCHES_LOCATION("*.ZMB
 .*.*")" prefLoc11
```

```
4 Done
5 <!--NeedCopy-->
```

When the appliance receives a request from the location `.ZMB.*`, the preferred locations are evaluated as follows:

1. The appliance attempts to find a GSLB service whose location is a perfect match for `Asia.HK`, which is the preferred location that has the highest priority. It finds that the GSLB service at `Asia.HK` is a perfect match. If the GSLB service is up, it sends the client the IP address of the GSLB service.
2. If the GSLB service at `Asia.HK` is down, the appliance attempts to find a perfect match for the second preferred location, `Europe.UK`. It finds that the GSLB service at `Europe.UK` is a perfect match. If the GSLB service is up, it sends the client the IP address of the service.
3. If the GSLB service at `Europe.UK` is down, it returns to the preferred location that has the highest priority, `Asia.HK`, and looks for partial matches. For `Asia.HK`, it finds that `Asia.IN` and `Asia.JPN` are partial matches. If only one of the corresponding GSLB services is up, it sends the client the IP address of the service. If both locations are up, it load balances the two services.
4. If all partial matches for `Asia.HK` are down, the appliance looks for partial matches for `Europe.UK`. It finds that `Europe.RU` and `Europe.EG` are partial matches for the preferred location. If only one of the corresponding GSLB services is up, it sends the client the IP address of the service. If both locations are up, it load balances the two services.
5. If all partial matches for `Europe.UK` are down, the appliance load balances all other available GSLB services. In the current example, the appliance load balances `Africa.SD` and `Africa.ZMB` because the remaining six GSLB services have been found to be down.

## Configure GSLB service selection using content switching

September 21, 2020

In a typical GSLB deployment, you can prioritize the selection of a set of GSLB services bound to a GSLB virtual server, but you cannot do the following:

- Restrict the selection of a GSLB service from a subset of GSLB services bound to a GSLB virtual server for the given domain.
- Apply different load balancing methods on the different subsets of GSLB services in the deployment.
- Apply spillover policies on a subset of GSLB services, and you cannot have a backup for a subset of GSLB services.
- Configure a subset of GSLB services to serve different content. That is, you cannot content switch between servers in different GSLB sites. The GSLB configuration assumes that the

servers contain the same content.

- Define a subset GSLB service with different priorities and specify an order in which the services in the subset are applied to a request.

You can now configure a content switching (CS) policy to customize the GSLB deployment. First configure a set of GSLB services and bind it to a GSLB virtual server. Then, configure a CS virtual server of target type GSLB, define a CS policy and action with the GSLB virtual server as target virtual server, and bind the CS policy to CS virtual server.

#### **Important**

- Only CS policies with DNS based expressions can be bound to a CS virtual server of target type GSLB.
- If a GLSB service is bound to a CS virtual server through a GSLB virtual server, you cannot bind another GSLB virtual server bound with the same GSLB service to the CS virtual server.

#### **Example**

Consider a GLSB deployment that includes two GSLB sites. At each site, four GSLB services (S-1, S-2, S-3, and S-4) are bound to GSLB virtual server VS-1. You can configure a content switching (CS) virtual server of target type GSLB and define a CS policy and action with VS-1 as the target virtual server, so that requests for content in English are served only by S-1 and S-2, and requests for content in the local language are served only by S-3 and S-4.

You can give S-1 priority by configuring a backup virtual server to VS-1 and binding S-2 to the backup virtual server. S-1 serves the client requests. If the server S-1 represents goes down, S-2 serves the requests. If both S-1 and S-2 are down, clients receive an empty response.

#### **To configure GSLB Service Selection using Content Switching:**

1. Configure GSLB. For instructions, see [Configuring Global Server Load Balancing](#).
2. Configure a Content Switching (CS) virtual server of target type GSLB. For more information, see [Creating Content Switching Virtual Servers](#).
3. Configure Content Switching (CS) policies. For more information, see [Configuring Content Switching Policies](#).
4. Configure CS actions that designate a GSLB virtual server as the target virtual server. For more information, see [Configuring a Content Switching Action](#).
5. Bind the CS policies to the CS virtual server. For more information, see [Binding Policies to a Content Switching Virtual Server](#).
6. Bind the domain to the CS virtual server instead of the GSLB virtual server.

## Sample Configuration

The following sample configuration sends requests from the client with IP address 5.5.5.5 to SERVICE\_GSLB1 and SERVICE\_GSLB2. SERVICE\_GSLB1 has a higher priority than SERVICE\_GSLB2, and SERVICE\_GSLB2 serves the client requests only when SERVICE\_GSLB1 is down. If both SERVICE\_GSLB1 and SERVICE\_GSLB2 are down, SERVICE\_GSLB3 and service-GSLB4 are not considered, and a blank response is sent to the client.

```
1 add cs vs CSVSERVER_GSLB http -targettype GSLB
2 Done
3 add gslb vs VSERVER_GSLB1 http
4 Done
5 add gslb vs VSERVER_GSLB2 http
6 Done
7 add gslb vs VSERVER_GSLB_BACKUP1 http
8 Done
9 set gslb vs VSERVER_GSLB1 -backupvserver VSERVER_GSLB_BACKUP1
10 Done
11 add gslb service SERVICE_GSLB1 1.1.1.1 HTTP 80 -sitename site1
12 Done
13 add gslb service SERVICE_GSLB2 1.1.1.2 HTTP 80 -sitename site1
14 Done
15 add gslb service SERVICE_GSLB3 1.1.1.3 HTTP 80 -sitename site2
16 Done
17 add gslb service SERVICE_GSLB4 1.1.1.4 HTTP 80 -sitename site2
18 Done
19 bind gslb vs VSERVER_GSLB1 -servicename SERVICE_GSLB1
20 Done
21 bind gslb vs VSERVER_GSLB_BACKUP1 -servicename SERVICE_GSLB2
22 Done
23 bind gslb vs VSERVER_GSLB2 -servicename SERVICE_GSLB3
24 Done
25 bind gslb vs VSERVER_GSLB2 -servicename SERVICE_GSLB4
26 Done
27 add cs action a1 -targetvserver VSERVER_GSLB1
28 Done
29 add cs policy p1 -rule "CLIENT.IP.SRC.EQ(5.5.5.5)" -action a1
30 Done
31 bind cs vs CSVSERVER_GSLB -domainName www.abc.com
32 Done
33 bind cs vs CSVSERVER_GSLB -policyname p1 -priority 1
34 Done
35 add cs action a2 -targetvserver VSERVER_GSLB2
36 Done
37 add cs policy p2 -rule "CLIENT.IP.SRC.EQ(6.6.6.6)" -action a2
38 Done
39 bind cs vs CSVSERVER_GSLB -policyname p2 -priority 2
40 Done
41 <!--NeedCopy-->
```

## Associate a target virtual server expression to a GSLB content switching action

You can now associate a target virtual server expression to a GSLB content switching action. This allows GSLB content switching virtual server to use policy expressions to compose the target GSLB virtual server name while processing the DNS requests.

### To configure a content switching action that specifies an expression by using the CLI

At the command prompt, type the following command to configure the content switching action to retrieve the HTTP callout response.

```
1 add cs action <name> -targetVserverExpr <expression>
2 <!--NeedCopy-->
```

Example:

```
1 add cs action csact_GSLB_VServer -targetVserverExpr "SYS.HTTP_CALLOUT(
 GSLB_Method_API)"
2 <!--NeedCopy-->
```

### To configure a content switching action that specifies an expression by using the GUI

1. Navigate to **Traffic Management > Content Switching > Actions**.
2. Configure a content switching action, and specify an **Expression** that dynamically computes the name of the target load balancing virtual server.

## Configure GSLB for DNS queries with NAPTR records

May 2, 2023

In a typical Global Server Load Balancing (GSLB) deployment, the NetScaler appliance receives DNS queries for A/AAAA records, selects the most appropriate GSLB service according to the configured load balancing method, and returns the service's IP address as a reply to the DNS query. You can now configure the appliance to receive DNS queries for NAPTR records and respond with the list of services configured for a domain. The appliance also monitors the health of the services, and in the response it provides a list of only the services that are up.

### Example:

In Telco deployments, you can configure a NetScaler appliance to receive DNS queries with NAPTR records from clients such as mobile management entities (MMEs), which play the role of a DNS resolver

to discover all the services that are offered by the domain name. The appliance responds to the query with NAPTR records for all the services that are up. The MME can use this NAPTR response to run the S-NAPTR procedure to select the nodes on the basis of the service offered, colocation, topological closeness, and so on.

If multiple nodes qualify for selection, the MME can use the preference field in the NAPTR record from the NetScaler appliance to determine the node.

### **NAPTR Record Format**

While responding to a DNS query with NAPTR record, a NetScaler appliance constructs a response NAPTR record for each GSLB service.

The following table lists the files in the NAPTR record:

---

Field	
Domain	The GSLB domain
TTL	The amount of time for which the NAPTR record can be cached.
Class	The class of the record. By default, this value is set to IN.
Type	The DNS record type.
Order	Specifies the order in which the NAPTR record MUST be processed. You can specify the order in the GSLB service. Otherwise, it is set to 1.
Preference	Specifies the order in which NAPTR records with equal “order” values SHOULD be processed, low numbers being processed before high numbers. If the order is not specified in the GSLB service, it is set to 1.
Flags	Controls the aspects of the rewriting and interpretation of the fields in the record. The NetScaler appliance sets this value to A.
Service	Specifies the available service(s).
Regular Expression	Regular expressions are not supported, so this value is set to NULL.
Replacement	The domain name of the node that hosts the services.

---

## Configuration procedure

For detailed GSLB configuration instructions, see [Configuring Global Server Load Balancing \(GSLB\)](#). Make sure that you do the following:

- Set the following parameters while adding the GSLB virtual server:
  - serviceType: ANY
  - dnsRecordType: NAPTR
  - lbMethod: CUSTOMLOAD

### Example:

```
1 add gslb vserver gslb_vs ANY -dnsRecordType NAPTR -lbMethod CUSTOMLOAD
2 <!--NeedCopy-->
```

- While adding a GSLB site, set the *naptrReplacementSuffix* parameter to the domain name that you want to embed in the NAPTR records.

### Example:

```
1 add gslb site site1 10.102.218.200 -naptrReplacementSuffix example.com
2 <!--NeedCopy-->
```

- Set the following parameters while adding the GSLB service:
  - naptrreplacement
  - naptrOrder
  - naptrServices
  - naptrDomainTTL
  - naptrPreference

## Sample configuration

```
1 add gslb vserver gslb_vs ANY -dnsRecordType NAPTR -lbMethod CUSTOMLOAD
2
3 Done
4
5 add gslb site site1 10.102.218.200 -naptrReplacementSuffix example.com
6
7 Done
8
9 add gslb service sgw1 3.3.3.13 ANY * -siteName site1 -naptrreplacement
 sgw1.site1. -naptrOrder 2 -naptrServices x-3gpp-sgw:x-s5-gtp -
 naptrDomainTTL 20 -naptrPreference 200
10
11 Done
```

```
12
13 add gslb service sgw2 3.3.3.11 ANY * -siteName site1 -naptrreplacement
 sgw2.site1. -naptrOrder 5 -naptrServices x-3gpp-sgw:x-s5-gtp -
 naptrDomainTTL 20 naptrPreference 100
14
15 Done
16
17 add gslb service sgw3 3.3.3.12 ANY * -siteName site2 -naptrreplacement
 sgw3.site1. -naptrOrder 10 -naptrServices x-3gpp-sgw:x-s5-gtp -
 naptrDomainTTL 20 naptrPreference 300
18
19 bind gslb vserver gslb_vs -serviceName sgw1
20
21 Done
22
23 bind gslb vserver gslb_vs -serviceName sgw2
24
25 Done
26
27 bind gslb vserver gslb_vs -serviceName sgw3
28
29 Done
30
31 bind gslb service sgw1 -monitorName ping
32
33 Done
34
35 bind gslb service sgw2 -monitorName ping
36
37 Done
38
39 bind gslb service sgw3 -monitorName ping
40
41 Done
42
43 bind gslb vserver gslb_vs -domainName gslb.com -TTL 5
44
45 Done
46 <!--NeedCopy-->
```

**Note**

DNS queries with NAPTR records are not supported in parent-child configuration.

## Configure GSLB for wildcard domain

June 24, 2022

You can bind a wildcard DNS domain to a GSLB virtual server. Users accessing the applications behind

a wildcard domain are routed to the best optimal data center, which hosts those applications. The wildcard domain handles requests for non-existent domains and subdomains. For more information about wildcard domains, see [Supporting wildcard DNS domains](#). For information about DNS zones, see [Configure a DNS zone](#).

To configure GSLB for a wildcard domain, you must first configure the basic GSLB setup. For details on how to configure a basic GSLB setup, see [Configuring GSLB Entities Individually](#).

## To configure a GSLB setup for wildcard domain by using the CLI

Perform the following steps to configure a GSLB setup for wildcard domain:

1. Create the GSLB sites.

```
1 add gslb site site1 10.0.1.10
2 add gslb site site2 20.0.1.10
3 <!--NeedCopy-->
```

2. Add the GSLB services for each site participating in the GSLB setup.

```
1 add gslb service svc1 -sitename site1 10.0.1.10 http 80
2 add gslb service svc2 -sitename site1 10.0.1.10 http 80
3 add gslb service svc3 -sitename site2 20.0.1.10 http 80
4 add gslb service svc4 -sitename site2 20.0.1.10 http 80
5 <!--NeedCopy-->
```

3. Add the GSLB virtual server that references a service being used in the GSLB setup.

```
1 add gslb vserver gslb_vs http
2 <!--NeedCopy-->
```

4. Add an ADNS service that listens to the DNS queries.

```
1 add service adns_udp 10.14.39.21 ADNS 53
2 <!--NeedCopy-->
```

5. Bind the GSLB services to the GSLB virtual server.

```
1 bind gslb vserver gslb_vs -service svc1
2 bind gslb vserver gslb_vs -service svc2
3 bind gslb vserver gslb_vs -service svc3
4 bind gslb vserver gslb_vs -service svc4
5 <!--NeedCopy-->
```

6. Create a zone.

```
1 add dns soaRec test.com -originServer n1.test.com -contact n1.test.com
2 add dns nsrec test.com n1.test.com
3 add dns nsrec test.com n2.test.com
```

```
4 add dns zone test.com -proxymode no
5 <!--NeedCopy-->
```

7. Bind the domain name to the GSLB virtual server.

```
1 bind gslb vserver gslb_vs -domainName *.test.com
2 <!--NeedCopy-->
```

## Use the EDNS0 client subnet option for Global Server Load Balancing

May 2, 2023

EDNS Client Subnet (ECS) is a Domain Name Server (DNS) header extension that provides the client subnet details. You can use these details to improve the accuracy of NetScaler Global Server Load Balancing (GSLB) by using the client network location rather than the DNS resolver location to determine the topological closeness of the client.

### Note

NetScaler supports only EDNS0.

### Important:

Make sure that the Local Domain Name Server (LDNS) in your deployment supports the EDNS0 Client Subnet so that the incoming DNS queries contain the EDNS0 Client Subnet option and the NetScaler appliance uses the ECS address while processing the DNS query.

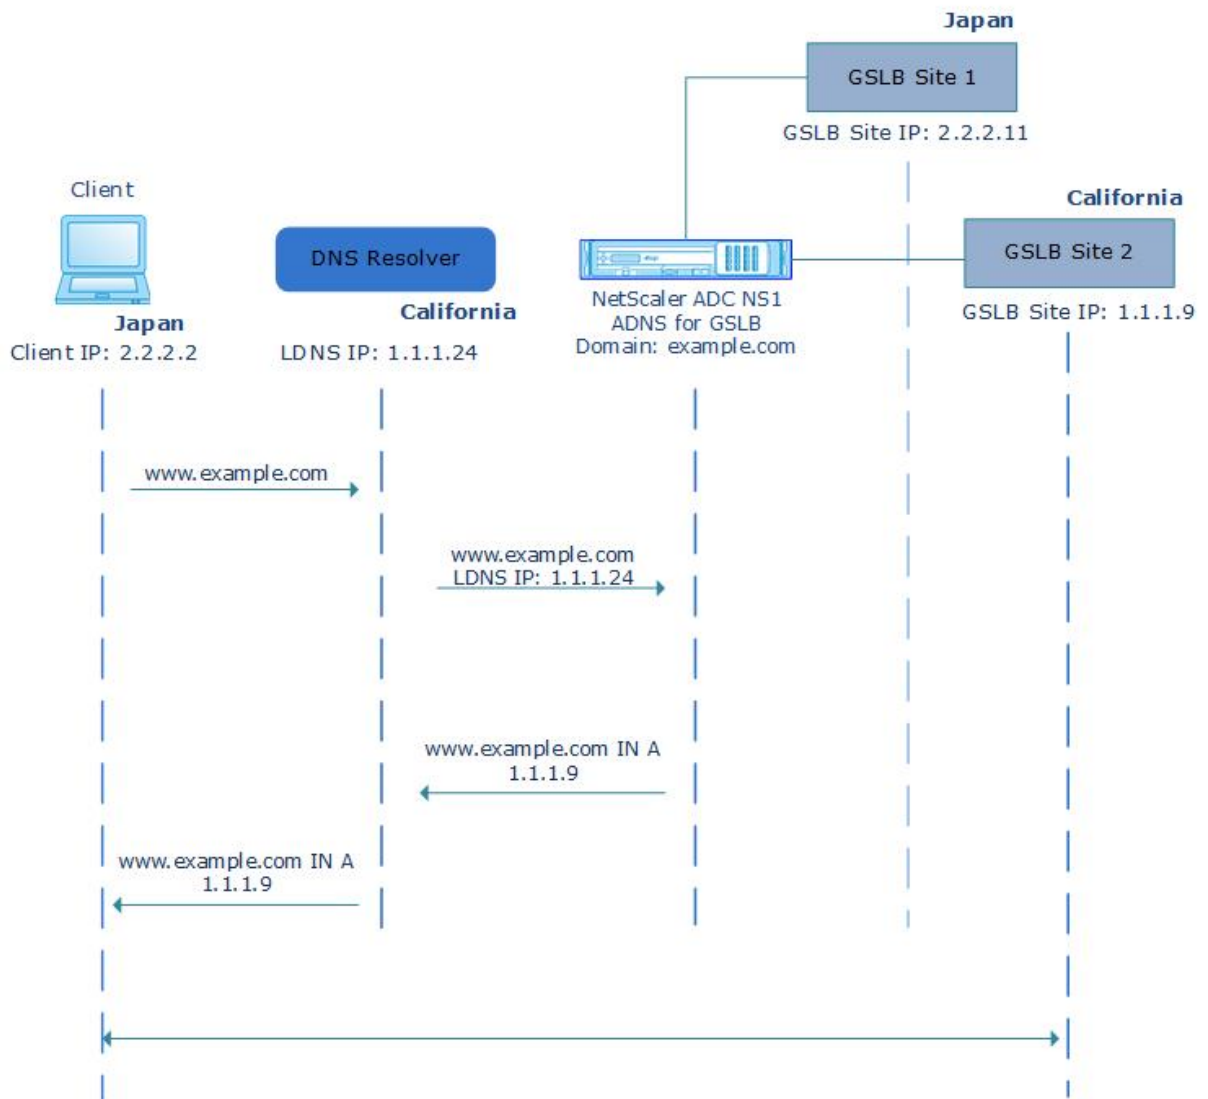

The NetScaler appliance uses the LDNS IP address for determining the topological closeness of the client and performs GSLB so, when you use proximity-based load balancing methods like static proximity or dynamic round-trip time (RTT). It happens in a typical GSLB deployment. But when a centralized DNS resolver, such as Google DNS or OpenDNS, is involved in the deployment, the NetScaler appliance sends the DNS request to a data center close to the centralized DNS resolver, which might not be close to the client. For example, in a typical NetScaler GSLB deployment using the static proximity load balancing method, an end-user request from Japan is sent to a data center in Japan and an end user request from California is sent to a data center in California. But if a centralized DNS resolver is involved, the NetScaler appliance might send a request from Japan to a data center in California.

You can use the ECS option in deployments that include the NetScaler appliance configured as an Authoritative DNS (ADNS) server for a GSLB domain. If you use static proximity as the load balancing method, you can use the IP subnet in the EDNS header instead of the LDNS IP address. This helps to determine the geographical proximity of the client. In proxy mode deployment, the NetScaler appliance forwards an ECS-enabled DNS query as-is to the back-end servers. The appliance does not cache ECS-enabled DNS responses.

**Note**

The ECS option is not applicable for all other deployment modes, such as ADNS mode for non-GSLB domains, resolver mode, and forwarder mode. The ECS option is ignored by the NetScaler appliance in the preceding mentioned modes. Also, by default, ECS is disabled for GSLB deployment.

**Without EDNS0 Client Subnet Option**

### With EDNS0 Client Subnet Option

### To enable the EDNS0 Client Subnet option by using the command line interface:

At the command prompt, type:

```

1 set gslb vserver <vserver_name> **--ECS ENABLED
2
3 set gslb vserver vserver-GSLB-1 -ECS ENABLED
4 <!--NeedCopy-->

```

### Address validation

You can configure a GSLB virtual server to verify that the address returned by the EDNS0 Client Subnet (ECS) option of the DNS query is not a private or an unroutable IP address. With address validation

enabled, the NetScaler appliance ignores the ECS address in the DNS query if it is listed in the following table, and instead uses the LDNS IP address for global server load balancing.

**Note**

By default, address validation is disabled.

Address Type	Address	Description
IPv4	10.0.0.0/8	For private use
	172.16.0.0/12	For private use
	192.168.0.0/16	For private use
	0.0.0.0/8	Refers to the host on the network
	100.64.0.0/10	Shared address space
	127.0.0.0/8	Loopback address
	169.254.0.0/16	Link Local IPv4 address as defined in RFC 3927
	192.0.0.0/24	Used for IETF protocol assignments, includes the private space 192.168.0.0/16
	192.0.2.0/24	Used for documentation purposes
	192.88.99.0/24	Used for 6to4 Relay Anycast
	198.18.0.0/15	Used in Device benchmark testing
	198.51.100.0/24	Used for documentation purposes
	203.0.113.0/24	Used for documentation purposes
	240.0.0.0/4	Used as reserved
255.255.255.255/32	Used for broadcast	
IPv6	::1/128	loopback address
	::/128	unspecified address
	::ffff:0:0/96	IPv4-mapped address

---

Address Type	Address	Description
	100::/64	discard-only address block
	2001::/23	Used for IETF protocol assignments
	2001::/32	TEREDO
	2001:2::/48	Used for benchmarking
	2001:db8::/32	Used for documentation purposes
	2001:10::/28	ORCHID
	2002::/16	Used for 6to4 Relay Anycast
	fc00::/7	Unique-local
	fe80::/10	Link-local Unicast addresses

---

### To enable address validation by using the command line interface

At the command prompt, type:

```
1 set gslb vserver <vserver_name> -ecsAddrValidation ENABLED
2
3 set gslb vserver vserver-GSLB-1 -ecsAddrValidation ENABLED
4 <!--NeedCopy-->
```

## Example of a complete parent-child configuration using the metrics exchange protocol

April 27, 2021

Consider the following parent-child topology in which the GSLB sites are distributed globally.

- Site1 and Site2 are the parent sites.
- Site1\_child1 and Site1\_child2 are the child sites of Site1.
- Site2\_child1 and Site2\_child2 are the child sites of Site2.

The following commands illustrate the complete configuration of the parent-child topology.

### site1

```

1 add gslb site site1 10.102.82.164 -publicIP 10.102.82.164
2
3 add gslb site site2 10.106.24.164 -publicIP 10.106.24.164
4
5 add gslb site site1_child1 10.102.82.131 -publicIP 10.102.82.131 -
 nwMetricExchange DISABLED -sessionExchange DISABLED -parentSite
 site1
6
7 add gslb site site1_child2 10.102.82.67 -publicIP 10.102.82.67 -
 nwMetricExchange DISABLED -sessionExchange DISABLED -parentSite
 site1
8
9 add gslb site site2_child1 10.106.24.132 -publicIP 10.106.24.132 -
 nwMetricExchange DISABLED -sessionExchange DISABLED -parentSite
 site2
10
11 add gslb site site2_child2 10.106.24.67 -publicIP 10.106.24.67 -
 nwMetricExchange DISABLED -sessionExchange DISABLED -parentSite
 site2
12
13 add gslb service site1_child1_http_gsvc1 10.102.82.132 HTTP 80 -
 publicIP 10.102.82.132 -publicPort 80 -maxClient 0 -siteName
 site1_child1 -cltTimeout 180 -svrTimeout 360 -downStateFlush ENABLED
14

```

```

15 add gslb service site1_child2_http_gsvc1 10.102.82.68 HTTP 80 -publicIP
 10.102.82.68 -publicPort 80 -maxClient 0 -siteName site1_child2 -
 cltTimeout 180 -svrTimeout 360 -downStateFlush ENABLED
16
17 add gslb service site2_child1_http_gsvc1 10.106.24.134 HTTP 80 -
 publicIP 10.106.24.134 -publicPort 80 -maxClient 0 -siteName
 site2_child1 -cltTimeout 180 -svrTimeout 360 -downStateFlush ENABLED
18
19 add gslb service site2_child2_http_gsvc1 10.106.24.68 HTTP 80 -publicIP
 10.106.24.68 -publicPort 80 -maxClient 0 -siteName site2_child2 -
 cltTimeout 180 -svrTimeout 360 -downStateFlush ENABLED
20
21 add gslb vserver gv1 HTTP -backupLBMethod ROUNDROBIN -tolerance 0 -
 appflowLog DISABLED
22
23 bind gslb vserver gv1 -serviceName site1_child1_http_gsvc1
24
25 bind gslb vserver gv1 -serviceName site1_child2_http_gsvc1
26
27 bind gslb vserver gv1 -serviceName site2_child2_http_gsvc1
28
29 bind gslb vserver gv1 -serviceName site2_child1_http_gsvc1
30
31 bind gslb vserver gv1 -domainName www.gslb.com -TTL 5
32 <!--NeedCopy-->

```

### site1\_child1

```

1 add gslb site site1 10.102.82.164 -publicIP 10.102.82.164
2
3 add gslb site site1_child1 10.102.82.131 -publicIP 10.102.82.131 -
 nwMetricExchange DISABLED -sessionExchange DISABLED -parentSite
 site1
4 <!--NeedCopy-->

```

You can add the following commands for load balancing configuration:

```

1 add service svc1 10.102.82.25 HTTP 80 -gslb NONE -maxClient 0 -maxReq 0
 -cip DISABLED -usip NO -useproxyport YES -sp ON -cltTimeout 180 -
 svrTimeout 360 -CKA NO -TCPB NO -CMP NO
2
3 add lb vserver lb1 HTTP 10.102.82.132 80 -persistenceType NONE -

 svrTimeout 360 -CKA NO -TCPB NO -CMP NO
2
3 add lb vserver lb1 HTTP 10.106.24.68 80 -persistenceType NONE -
 cltTimeout 180
4
5 bind lb vserver lb1 svc1
6 <!--NeedCopy-->
```

## Link load balancing

May 2, 2023

Link load balancing (LLB) balances outbound traffic across multiple Internet connections provided by different service providers. LLB enables the NetScaler appliance to monitor and control traffic so that packets are transmitted seamlessly over the best possible link. Unlike with server load balancing, where a service represents a server, with LLB, a service represents a router or the next hop. A link is a connection between the NetScaler appliance and the router.

To configure link load balancing, many users begin by configuring a basic setup with default settings. A basic setup involves services, virtual servers, monitors, routes, an LLB method, and persistence (optional). Once a basic setup is operational, you can customize it for your environment.

Load balancing methods that are applicable to LLB are round robin, destination IP hash, least bandwidth, and least packets. You can optionally configure persistence for connections to be sustained on a specific link. The available persistence types are source IP address-based, destination IP address-based, and source IP and destination IP address-based. PING is the default monitor but configuring a transparent monitor is recommended.

You can customize your setup by configuring reverse NAT (RNAT) and backup links.

## Configuring a Basic LLB Setup

May 2, 2023

To configure LLB, you first create services representing each router to the Internet Service Providers (ISPs). A PING monitor is bound by default to each service. Binding a transparent monitor is optional but recommended. Then, you create a virtual server, bind the services to the virtual server, and configure a route for the virtual server. The route identifies the virtual server as the gateway to the physical

routers represented by the services. The virtual server selects a router by using the load balancing method that you specify. Optionally, you can configure persistence to make sure that all traffic for a particular session is sent over a specific link.

To configure a basic LLB setup, do the following:

- [Configure services](#)
- [Configure an LLB virtual server and binding a service](#)
- [Configure the LLB method and persistence](#)
- [Configure an LLB route](#)
- [Create and bind a transparent monitor](#)

## Configure services

A default monitor (PING) is automatically bound to a service type of ANY when the service is created, but you can replace the default monitor with a transparent monitor, as described in [Creating and Binding a Transparent Monitor](#).

### To create a service by using the command line interface

At the command prompt, type:

```
1 add service <name> <IP> <serviceType> <port>
2
3 show service <name>
4 <!--NeedCopy-->
```

### Example:

```
1 add service ISP1R_svc_any 10.10.10.254 any *
2 show service ISP1R_svc_any
3 ISP1R_svc_any (10.10.10.254:*) - ANY
4 State: DOWN
5 Last state change was at Tue Aug 31 04:31:13 2010
6 Time since last state change: 2 days, 05:34:18.600
7 Server Name: 10.10.10.254
8 Server ID : 0 Monitor Threshold : 0
9 Max Conn: 0 Max Req: 0 Max Bandwidth: 0 kbits
10 Use Source IP: NO
11 Client Keepalive(CKA): NO
12 Access Down Service: NO
13 TCP Buffering(TCPB): YES
14 HTTP Compression(CMP): NO
15 Idle timeout: Client: 120 sec Server: 120 sec
16 Client IP: DISABLED
```

```
17 Cacheable: NO
18 SC: OFF
19 SP: OFF
20 Down state flush: ENABLED
21
22 1) Monitor Name: ping
23 State: UP Weight: 1
24 Probes: 244705 Failed [Total: 0 Current: 0]
25 Last response: Success - ICMP echo reply received.
26 Response Time: 1.322 millisec
27 Done
28 <!--NeedCopy-->
```

### To create services by using the configuration utility

Navigate to Traffic Management > Load Balancing > Services, and create a service.

### To create services by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Create Service dialog box, specify values for the following parameters:
  - Service Name\*—name
  - Server—IP
  - Protocol\*—serviceType (Select ANY from the drop-down list.)
  - Port\*—port

A required parameter

1. Click Create.
2. Repeat Steps 2-4 to create another service.
3. Click Close.
4. In the Services pane, select the services that you just configured and verify that the settings displayed at the bottom of the screen are correct.

### Configure an LLB virtual server and bind a service

After you create a service, create a virtual server and bind services to the virtual server. The default LB method of least connections is not supported in LLB. For information about changing the LB method, see [Configuring the LLB Method and Persistence](#).

## To create a link load balancing virtual server and bind a service by using the command line interface

At the command prompt, type:

```
1 add lb vserver <name> <serviceType>
2
3 bind lb vserver < name> <serviceName>
4
5 show lb vserver < name>
6 <!--NeedCopy-->
```

### Example:

```
1 add lb vserver LLB-vip any
2 bind lb vserver LLB-vip ISP1R_svc_any
3 sh lb vserver LLB-vip
4 LLB-vip (0.0.0.0:0) - ANY Type: ADDRESS
5 State: DOWN
6 Last state change was at Thu Sep 2 10:51:32 2010
7 Time since last state change: 0 days, 17:51:46.770
8 Effective State: DOWN
9 Client Idle Timeout: 120 sec
10 Down state flush: ENABLED
11 Disable Primary Vserver On Down : DISABLED
12 No. of Bound Services : 1 (Total) 0 (Active)
13 Configured Method: ROUNDROBIN
14 Mode: IP
15 Persistence: NONE
16 Connection Failover: DISABLED
17
18 1) ISP1R_svc_any (10.10.10.254: *) - ANY State: DOWN Weight: 1
19 Done
20 <!--NeedCopy-->
```

## To create a link load balancing virtual server and bind a service by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and create a virtual server for link load balancing. Specify **ANY** in the **Protocol** field.
2. In the **IP Address Type** drop-down list, select the desired option. Select **Non Addressable** to create a virtual server that is not directly accessible.
3. Under the **Services** tab, in the **Active** column, select the check box for the service that you want to bind to the virtual server.

## Configure the LLB method and persistence

By default, the NetScaler appliance uses the least connections method to select the service for redirecting each client request, but you should set the LLB method to one of the supported methods. You can also configure persistence, so that different transmissions from the same client are directed to the same server.

### To configure the LLB method and/or persistence by using the command line interface

At the command prompt, type the following command:

```
1 set lb vserver <name> -lbMethod <lbMethod> -persistenceType <
 persistenceType>
2
3 show lb vserver <name>
4 <!--NeedCopy-->
```

#### Example:

```
1 set lb vserver LLB-vip -lbmethod ROUNDROBIN -persistencetype SOURCEIP
2
3 show lb vserver LLB-vip
4 LLB-vip (0.0.0.0:0) - ANY Type: ADDRESS
5 State: DOWN
6 Last state change was at Fri Sep 3 04:46:48 2010
7 Time since last state change: 0 days, 00:52:21.200
8 Effective State: DOWN
9 Client Idle Timeout: 120 sec
10 Down state flush: ENABLED
11 Disable Primary Vserver On Down : DISABLED
12 No. of Bound Services : 0 (Total) 0 (Active)
13 Configured Method: ROUNDROBIN
14 Mode: IP
15 Persistence: SOURCEIP
16 Persistence Mask: 255.255.255.255 Persistence v6MaskLength:
17 128 Persistence Timeout: 2 min
18 Connection Failover: DISABLED
19 <!--NeedCopy-->
```

### To configure the link load balancing method and/or persistence by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers and select the virtual server for which you want to configure the load balancing method and/or persistence settings.
2. In the **Advanced Settings** section, select Method and configure the load balancing method.
3. In the **Advanced Settings** section, select **Persistence** and configure the persistence parameters.

## Configure an LLB route

After configuring the IPv4 or IPv6 services, virtual servers, LLB methods, and persistence, you configure an IPv4 or IPv6 LLB route for the network specifying the LLB virtual server as the gateway. A route is a collection of links that are load balanced. Requests are sent to the LLB virtual server IP address that acts as the gateway for all outbound traffic and selects the router based on the LLB method configured.

### To configure an IPv4 LLB route by using the command line interface

At the command prompt, type:

```
1 add lb route <network> <netmask> <gatewayName>
2
3 show lb route [<network> <netmask>]
4 <!--NeedCopy-->
```

#### Example:

```
1 add lb route 0.0.0.0 0.0.0.0 LLB-vip
2 show lb route 0.0.0.0 0.0.0.0
3 Network Netmask Gateway/VIP Flags
4 ----- -
5 1) 0.0.0.0 0.0.0.0 LLB-vip UP
6 <!--NeedCopy-->
```

### To configure an IPv6 LLB route by using the command line interface

At the command prompt, type:

```
1 add lb route6 <network> <gatewayName>
2
3 show lb route6
4 <!--NeedCopy-->
```

#### Example:

```
1 add lb route6 ::/0 llb6_vs show lb route6 Network VIP Flags -----
2 <!--NeedCopy-->
----- 1) ::/0 llb6_vs UP
```

### To configure an LLB route by using the configuration utility

Navigate to System > Network > Routes, and select **LLB**, and configure the LLB route.

**Note:** Select LLBV6 to configure an IPV6 route.

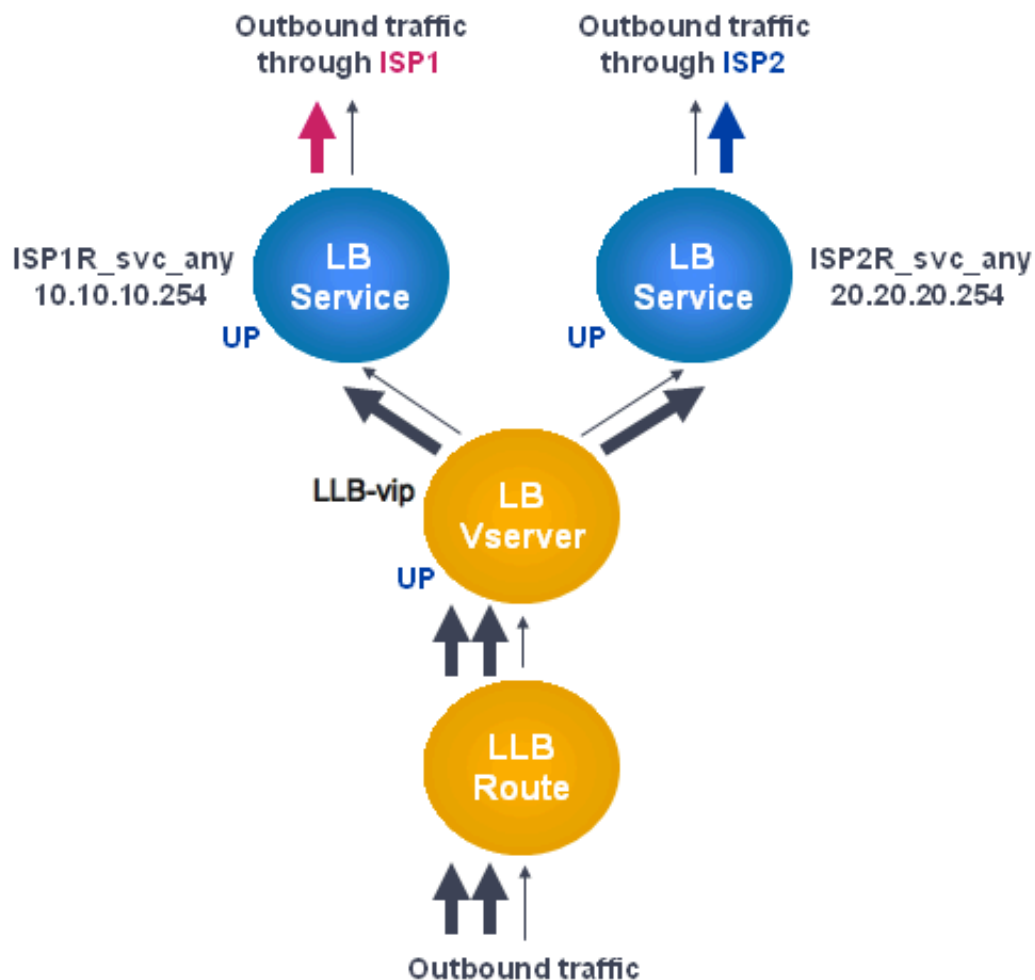

### To configure an LLB route by using the configuration utility

1. Navigate to System > Network > Routes.
2. In the details pane, select one of the following:
  - Click LLB to configure an IPv4 route.
  - Click LLB6 to configure an IPv6 route.
3. In the Create LB Route or Create LB IPV6 Routedialog box, set the following parameters:
  - Network\*
  - Netmask\*—Required for IPV4 routes.
  - Gateway Name\*—gatewayName

\*A required parameter
4. Click Create, and then click Close. The route that you just created appears on the LLB or the LLB6 tab in the Routes pane.

The following diagram shows a basic LLB setup. A service is configured for each of the two links (ISPs) and PING monitors are bound by default to these services. A link is selected based on the LLB method configured.

Figure 1. Basic LLB Setup

**Note**  
 If your Internet service provider has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the above figure.

**Create and bind a transparent monitor**

You create a transparent monitor to monitor the health of upstream devices, such as routers. You can then bind the transparent monitor to services. The default PING monitor monitors the connectivity only between the NetScaler appliance and the upstream device. The transparent monitor monitors all the devices existing in the path from the appliance to the device that owns the destination IP address specified in the monitor. If a transparent monitor is not configured and the status of the router is UP but one of the next hop devices from that router is down, the appliance includes the router while performing load balancing and forwards the packet to the router. However, the packet is not delivered to the final destination because one of the next hop devices is down. By binding a transparent monitor,

if any of the devices (including the router) are down, the service is marked as DOWN and the router is not included when the appliance performs link load balancing.

### To create a transparent monitor by using the command line interface

At the command prompt, type:

```
1 add lb monitor <monitorName> <type> -destIP <ip_addr|*> -transparent
 YES
2
3 show lb monitor [<monitorName>]
4 <!--NeedCopy-->
```

### Example:

```
1 add lb monitor monitor-1 PING -destIP 10.10.10.11 -transparent YES
2 > show lb monitor monitor-1
3 1) Name.....: monitor-1 Type.....: PING State.....:
 ENABLED
4 Standard parameters:
5 Interval.....: 5 sec Retries.....:
 3
6 Response timeout.: 2 sec Down time.....:
 30 sec
7 Reverse.....: NO Transparent.....:
 YES
8 Secure.....: NO LRTM.....:
 ENABLED
9 Action.....: Not applicable Deviation.....:
 0 sec
10 Destination IP...: 10.10.10.11
11 Destination port.: Bound service
12 Iptunnel.....: NO
13 TOS.....: NO TOS ID.....:
 0
14 SNMP Alert Retries: 0 Success Retries...:
 1
15 Failure Retries...: 0
16 <!--NeedCopy-->
```

### To create a transparent monitor by using the configuration utility

Navigate to Traffic Management > Load Balancing > Monitors and configure a transparent monitor.

### To create a transparent monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.

2. In the Monitors pane, click Add.
3. In the Create Monitor dialog box, set the following parameters:
  - Name\*
  - Type\*
  - Destination IP
  - Transparent

\*A required parameter
4. Click Create, and then click Close.
5. In the Monitors pane, select the monitor that you just configured and verify that the settings displayed in the Details pane are correct.

### To bind a monitor to a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. On the **Monitors** tab, under **Available**, select the monitor that you want to bind to the service, and then click **Add**.

### To bind a monitor to a service by using the command line interface

At the command prompt, type:

```
1 bind lb monitor <monitorName> <serviceName>
2
3 show service <name>
4 <!--NeedCopy-->
```

#### Example:

```
1 bind lb monitor monitor-HTTP-1 ISP1R_svc_any
2 Done
3 > show service ISP1R_svc_any
4 ISP1R_svc_any (10.10.10.254:*) - ANY
5 State: UP
6 Last state change was at Thu Sep 2 10:51:07 2010
7 Time since last state change: 0 days, 18:41:55.130
8 Server Name: 10.10.10.254
9 Server ID : 0 Monitor Threshold : 0
10 Max Conn: 0 Max Req: 0 Max Bandwidth: 0 kbits
11 Use Source IP: NO
12 Client Keepalive(CKA): NO
13 Access Down Service: NO
14 TCP Buffering(TCPB): YES
```

```
15 HTTP Compression(CMP): NO
16 Idle timeout: Client: 120 sec Server: 120 sec
17 Client IP: DISABLED
18 Cacheable: NO
19 SC: OFF
20 SP: OFF
21 Down state flush: ENABLED
22
23 1) Monitor Name: monitor-HTTP-1
24 State: UP Weight: 1
25 Probes: 1256 Failed [Total: 0 Current: 0]
26 Last response: Success - ICMP echo reply received.
27 Response Time: 1.322 millisec
28 Done
29 <!--NeedCopy-->
```

### To bind a monitor to a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select a service to which you want to bind a monitor, and then click Open.
3. In the Configure Service dialog box, on the Monitors tab, under Available, select the monitor that you want to bind to the service, and then click Add.
4. Click OK.
5. In the Services pane, select the service that you just configured and verify that the settings displayed in the Details pane are correct.

## Configure RNAT with LLB

May 2, 2023

You can configure an LLB setup for reverse network address translation (RNAT) for outbound traffic. It ensures that the return network traffic for a specific flow is routed through the same path. First configure basic LLB, as described in [Configuring a Basic LLB Setup](#), and then configure RNAT as described in [Configure RNAT](#). Then enable “use subnet IP (USNIP)” mode.

In the following diagram, the NetScaler appliance uses LLB to route outbound traffic to different links. During the RNAT operation, the ADC appliance replaces the source IP addresses of the outbound traffic with the public NAT IP address (198.141.23.1) to route the traffic through ISP-1. Similarly, the ADC appliance replaces the source IP addresses with 198.140.23.1 to route the traffic through ISP-2.

### To add SNIPs for ISP routers by using the CLI

At the command prompt, type:

```

1 add NS IP <subnet of first ISP in the IP router> <subnet mask> -type
 SNIP
2
3 add NS IP <subnet of second ISP in the IP router> <subnet mask> -type
 SNIP
4 <!--NeedCopy-->

```

#### Example:

```

1 add ns ip 198.140.23.1 255.255.255.0 -type snip
2
3 add ns ip 198.141.23.1 255.255.255.0 -type snip
4 <!--NeedCopy-->

```

### To configure RNAT by using the CLI

At the command prompt, type:

```

1 add rnat <name> (<network> | (<aclname> [-redirectPort <port>]))
2
3 bind rnat <name> <natIP>@ ...
4
5 show rnat <name>
6 <!--NeedCopy-->

```

#### Example:

```

1 add rnat RNAT-1 192.0.2.0 255.255.255.0
2 bind rnat RNAT-1 -natIP 198.140.23.1
3 bind rnat RNAT-1 -natIP 198.141.23.1

```

```

4
5 > show rnat RNAT-1
6 1) RNAT Name: RNAT-1 Network: 192.0.2.0 Netmask:
 255.255.255.0 Traffic Domain: 0
7 UseProxyPort: ENABLED
8
9 NatIP: 198.140.23.1
10 NatIP: 198.141.23.1
11 <!--NeedCopy-->

```

### To configure RNAT by using the GUI

1. Navigate to **System > Network > NATs**.
2. On the **RNAT** tab, click **Configure RNAT**.
3. Specify the network on which to perform RNAT.

**Note**

You can also configure RNAT by using Access Control Lists (ACLs). Refer [Configuring RNAT](#) for details.

### To enable Use Subnet IP mode by using the CLI

At the command prompt, type:

```

1 enable ns mode USNIP
2
3 show ns mode
4 <!--NeedCopy-->

```

**Example:**

```

1 enable ns mode USNIP
2
3 show ns mode
4 Mode Acronym Status
5 ----- -
6 1) Fast Ramp FR ON
7 2) ...
8 8) Use Subnet IP USNIP ON
9 9) ...
10 <!--NeedCopy-->

```

### To enable Use Subnet IP mode by using the GUI

1. Navigate to **System > Settings** and, under **Modes and Features**, click **Configure Modes**.

2. In the **Configure Modes** dialog box, select **Use Subnet IP**, and then click **OK**.

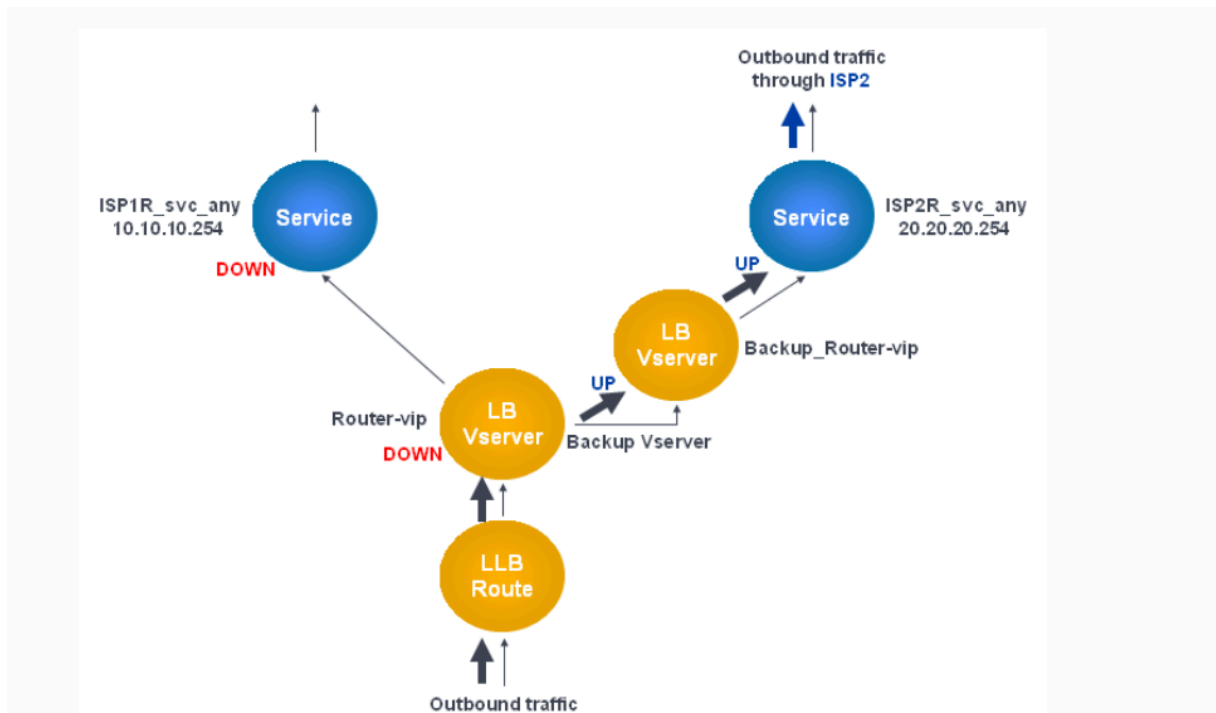

## Configure a backup route

May 2, 2023

To prevent disruption in services when the primary route is down, you can configure a backup route. Once the backup route is configured, the NetScaler appliance automatically uses it when the primary route fails. First create a primary virtual server as described in [Configuring an LLB Virtual Server and Binding a Service](#). To configure a backup route, create a secondary virtual server similar to a primary virtual server and then designate this virtual server as a backup virtual server (route).

In the following diagram, **Router-vip** is the primary virtual server, and **Backup\_Router-vip** is the secondary virtual server designated as the backup virtual server.

Figure 1. Backup Route Setup

**Note:** If your ISP has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the preceding figure.

By default, all traffic is sent through the primary route. However, when the primary route fails, all traffic is diverted to the backup route as shown in the following diagram.

Figure 2. Back up Routing in Operation

**Note:** If your ISP has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the preceding figure.

### To set the secondary virtual server as the backup virtual server by using the command line interface

At the command prompt, type:

```
1 set lb vserver <name> -backupVserver <string>
2 <!--NeedCopy-->
```

#### Example:

```
1 set lb vserver Router-vip -backupVServer Backup_Router-vip
2 > show lb vserver Router-vip
3 Router-vip (0.0.0.0:0) - ANY Type: ADDRESS
4 State: UP
5 Last state change was at Fri Sep 3 04:46:48 2010
6 Time since last state change: 0 days, 03:09:45.600
7 Effective State: UP
8 Client Idle Timeout: 120 sec
9 Down state flush: ENABLED
10 Disable Primary Vserver On Down : DISABLED
11 No. of Bound Services : 1 (Total) 1 (Active)
12 Configured Method: ROUNDROBIN
13 Mode: IP
```

```
14 Persistence: DESTIP Persistence Mask: 255.255.255.255
 Persistence v6MaskLength: 128 Persistence Timeout: 2
 min
15 Backup: Router2-vip
16 Connection Failover: DISABLED
17 Done
18 <!--NeedCopy-->
```

### To set the secondary virtual server as the backup virtual server by using the configuration utility

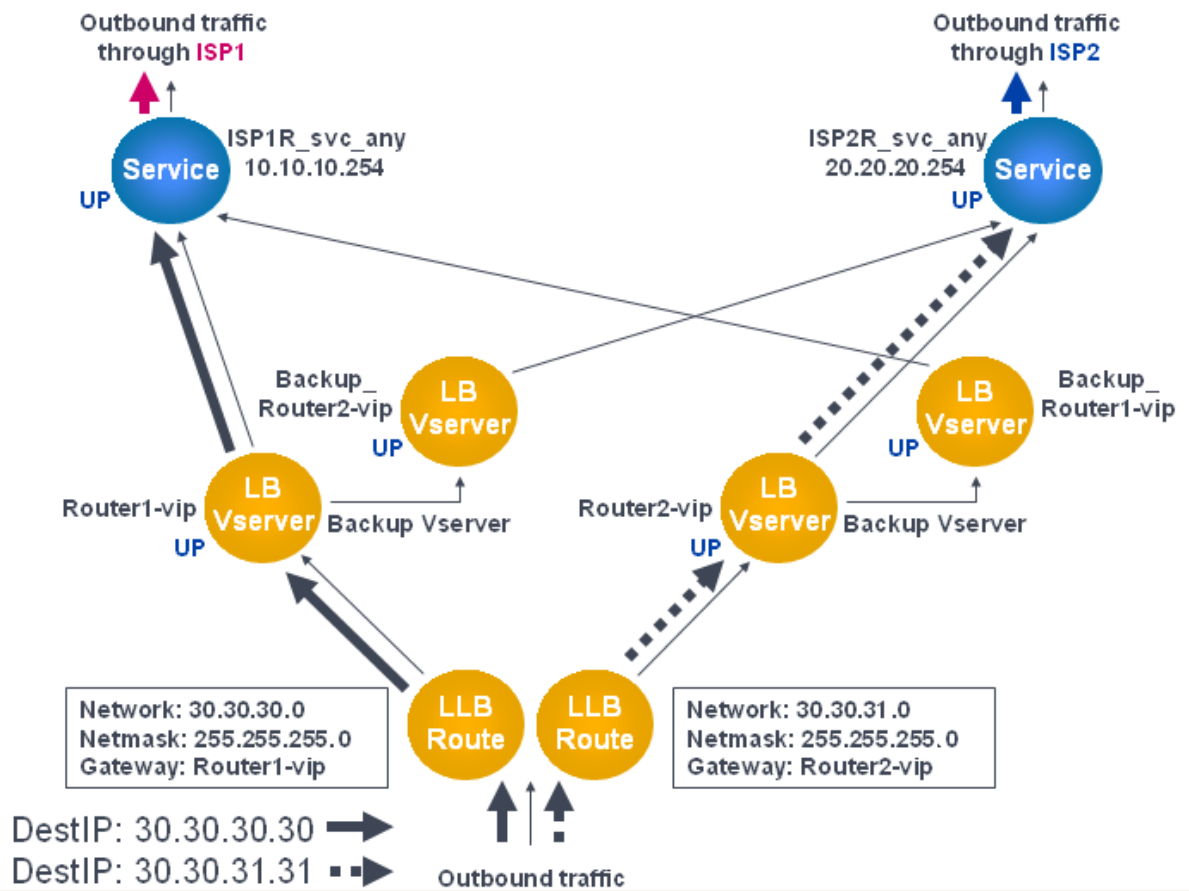

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers** and select the secondary virtual server for which you want to configure the backup virtual server.
2. In the **Load Balancing Virtual Server** dialog box, under **Advanced**, select **Protection**.
3. In the **Backup Virtual Server** drop-down list, select the secondary backup virtual server, and then click **OK**.

## Resilient LLB deployment scenario

January 7, 2021

In the following diagram, there are two networks: 30.30.30.0 and 30.30.31.0. Link load balancing is configured based on the destination IP address. Two routes are configured with gateways **Router1-vip** and **Router2-vip**, respectively. **Router1-vip** is configured as a backup to **Router2-vip** and the opposite way. All traffic with the destination IP specified as 30.30.30.30 is sent through **Router1-vip** and traffic with the destination IP specified as 30.30.31.31 is sent through **Router2-vip**.

Figure 1. Resilient LLB Deployment Setup

Note: If your ISP has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the preceding figure.

However, if any one of the gateways (**Router1-vip** or **Router2-vip**) is DOWN, traffic is routed through the backup router. In the following diagram, **Router1-vip** for ISP1 is DOWN, so all traffic with the destination IP specified as 30.30.30.30 is also sent through ISP2.

Figure 2. Resilient LLB Deployment Scenario

**Note:** If your ISP has provided an IPv6 address, replace the IPv4 service with an IPv6 service in the preceding figure.

## Monitor an LLB setup

May 2, 2023

After the configuration is up and running, you can view the statistics for each service and virtual server to check for possible problems.

### View the statistics of a virtual server

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on the NetScaler appliance. You can display a summary of statistics for all the virtual servers. You can also specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name

- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of hits

### Display virtual server statistics by using the CLI

To display a summary of the statistics for all the virtual servers currently configured on the NetScaler, or for a single virtual server, at the command prompt, type:

```
1 stat lb vserver -detail] [<name>]
2 <!--NeedCopy-->
```

#### Example:

```
1 stat lb vserver -detail
2 Virtual Server(s) Summary
3
4 vsvrIP port Protocol State Req/s
5 Hits/s
6 One * 80 HTTP UP 5/s
7 0/s
8 Two * 0 TCP DOWN 0/s
9 0/s
10 Three * 2598 TCP DOWN 0/s
11 0/s
12 dnsVirtualNS 10.102.29.90 53 DNS DOWN 0/s
13 0/s
14 BRVSRV 10.10.1.1 80 HTTP DOWN 0/s
15 0/s
16 LBVIP 10.102.29.66 80 HTTP UP 0/s
17 0/s
18 Done
19 <!--NeedCopy-->
```

### Display virtual server statistics by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers > Statistics**.
2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server, and click Statistics.

## View the statistics of a service

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in the surge queue, current server connections, and so forth using the service statistics.

### View the statistics of a service by using the CLI

At the command prompt, type:

```
1 stat service <name>
2 <!--NeedCopy-->
```

#### Example:

```
1 stat service Service-HTTP-1
2 <!--NeedCopy-->
```

### View the statistics of a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services > Statistics**.
2. If you want to display the statistics for only one service, select the service, and click Statistics.

## Load Balancing

May 2, 2023

The load balancing feature distributes user requests for webpages and other protected applications across multiple servers that all host (or mirror) the same content. You use load balancing primarily to manage user requests to heavily used applications, preventing poor performance and outages and ensuring that users can access your protected applications. Load balancing also provides fault tolerance. When one server that hosts a protected application becomes unavailable, the feature distributes user requests to the other servers that host the same application.

You can configure the load balancing feature to;

- Distribute all requests for a specific protected website, application, or resource between two or more identically configured servers.
- Use any of several different algorithms to determine which server must receive each incoming user request, basing the decision on different factors, such as which server has the fewest current user connections or which server has the lightest load.

The load balancing feature is a core feature of the NetScaler appliance. Most users first set up a working basic configuration and then customize various settings, including persistence for connections. In addition, you can configure features for protecting the configuration against failure, managing client traffic, managing and monitoring servers, and managing a large scale deployment.

## How load balancing works

May 2, 2023

In a basic load balancing setup, clients send their requests to the IP address of a virtual server configured on the NetScaler appliance. The virtual server distributes them to the load-balanced application servers according to a preset pattern, called the load balancing algorithm. Sometimes, you might want to assign the load balancing virtual server a wildcard address instead of a specific IP address. For instructions about specifying a global HTTP port on the appliance, see **Global HTTP Ports**.

### Load balancing basics

A load balancing setup includes a load-balancing virtual server and multiple load-balanced application servers. The virtual server receives incoming client requests, uses the load balancing algorithm to select an application server, and forwards the requests to the selected application server. The following conceptual drawing illustrates a typical load balancing deployment. Another variation involves assigning a global HTTP port.

Figure 1. Load Balancing Architecture

The load balancing virtual server can use several algorithms (or methods) to determine how to distribute load among the load-balanced servers that it manages. The default load balancing method is the least connection method, in which the NetScaler appliance forwards each incoming client connection to whichever load-balanced application server currently has the fewest active user connections.

The entities that you configure in a typical NetScaler load balancing setup are:

- **Load balancing virtual server.** The IP address, port, and protocol combination to which a client sends connection requests for a particular load-balanced website or application. If the application is accessible from the Internet, the virtual server IP (VIP) address is a public IP address. If the application is accessible only from the LAN or WAN, the VIP is usually a private (ICANN non-routable) IP address.
- **Service.** The IP address, port, and protocol combination used to route requests to a specific load-balanced application server. A service can be a logical representation of the application server itself, or of an application running on a server that hosts multiple applications. After creating a service, you bind it to a load balancing virtual server.
- **Server object.** A virtual entity that enables you to assign a name to a physical server instead of identifying the server by its IP address. If you create a server object, you can specify its name instead of the server's IP address when you create a service. Otherwise, you must specify the server's IP address when you create a service, and the IP address becomes the name of the

server.

- **Monitor.** An entity on the NetScaler appliance that tracks a service and ensures that it is operating correctly. The monitor periodically probes (or performs a health check on) each service to which you assign it. If the service does not respond within the time specified by the time-out, and a specified number of health checks fail, that service is marked DOWN. The NetScaler appliance then skips that service when performing load balancing, until the issues that caused the service to quit responding are fixed.

The virtual server, services, and load balanced application servers in a load balancing setup can use either Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6) IP addresses. You can mix IPv4 and IPv6 addresses in a single load balancing setup.

For variations in the load balancing setup, see the following use cases:

- [Configuring Load Balancing in Direct Server Return Mode](#)
- [Configuring LINUX Servers in DSR Mode](#)
- [Configuring DSR Mode When Using TOS](#)
- [Configuring Load Balancing in DSR Mode by Using IP Over IP](#)
- [Configuring Load Balancing in One-arm Mode](#)
- [Configuring Load Balancing in the Inline Mode](#)
- [Load Balancing of Intrusion Detection System Servers](#)
- [Load balance remote desktop protocol servers](#)

## Understanding the topology

In a load balancing setup, the load balancing server is logically located between the client and the server farm, and manages traffic flow to the servers in the server farm. On the NetScaler appliance, the application servers are represented by virtual entities called services. The following diagram shows the topology of a basic load balancing configuration.

Figure 2. Basic Load Balancing Topology

In the diagram, load balancing is used to manage traffic flow to the servers. The virtual server selects the service and assigns it to serve client requests. Consider a scenario where the services Service-HTTP-1 and Service-HTTP-2 are created and bound to the virtual server named Vserver-LB-1. Vserver-LB-1 forwards the client request to either Service-HTTP-1 or Service-HTTP-2. The NetScaler appliance uses the least connection load balancing method to select the service for each request. The following table lists the names and values of the basic entities that must be configured on the appliance.

Entity	Name	IPAddress	Port	Protocol
Virtual server	Vserver-LB-1	10.102.29.60	80	HTTP
Services	Service-HTTP-1	10.102.29.5	80	HTTP
	Service-HTTP-2	10.102.29.6	80	HTTP
Monitors	Default	None	None	None

The following diagram shows the load balancing sample values and mandatory parameters that are described in the preceding table.

Figure 3. Load Balancing Entity Model

## Use of wildcards instead of IP addresses and ports

Sometimes you might need to use a wildcard for the IP address or the port of a virtual server or for the port of a service. The following cases might require using a wildcard:

- If the NetScaler appliance is configured as a transparent pass through, which must accept all traffic that is sent to it regardless of the IP or port to which it is sent.
- If one or more services listen on ports that are not well known.
- If one or more services, over time, change the ports that they listen on.
- If you reach the limit for the number of IP addresses and ports that you can configure on a single NetScaler appliance.
- If you want to create virtual servers that listen for all traffic on a specific virtual LAN.

When a wildcard-configured virtual server or service receives traffic, the NetScaler appliance determines the actual IP address or port and creates records for the service and associated load balanced application server. These dynamically created records are called dynamically learned server and service records.

For example, a firewall load balancing configuration can use wildcards for both the IP address and

port. If you bind a wildcard TCP service to this type of load balancing virtual server, the virtual server receives and processes all TCP traffic that does not match any other service or virtual server.

The following table describes some of the different types of wildcard configurations and when each must be used.

IP	Port	Protocol	Description
*	*	TCP	A general wildcard virtual server that accepts traffic sent to any IP address and port on the NetScaler appliance. When using a wildcard virtual server, the appliance dynamically learns the IP and port of each service and creates the necessary records as it processes traffic.
*	*	TCP	A firewall load balancing virtual server. You can bind firewall services to this virtual server, and the NetScaler appliance passes traffic through the firewall to the destination.
IP Address	*	TCP, UDP, and ANY	A virtual server that accepts all traffic that is sent to the specified IP address, regardless of the port. You must explicitly bind to this type of virtual server the services to which it will redirect traffic. It does not learn them dynamically.

IP	Port	Protocol	Description
*	port	SSL, SSL_TCP	A virtual server that accepts all traffic sent to any IP address on a specific port. Used for global transparent SSL offloading. All SSL, HTTP, and TCP processing that usually is performed for a service of the same protocol type is applied to traffic that is directed to this specific port. The appliance uses the port to dynamically learn the IP of the service it must use. If cleartext is not specified, the NetScaler appliance uses end-to-end SSL.
*	port	Not applicable	All other virtual servers that can accept traffic to the port. You do not bind services to these virtual servers. The NetScaler appliance learns them dynamically.

Note: If you have configured your NetScaler appliance as a transparent pass through that uses global (wildcard) ports, you might want to turn on Edge mode.

For more information, see [“Configuring Edge Mode.”](#)

The NetScaler appliance attempts to locate virtual servers and services by first attempting an exact match. If none is found, it continues to search for a match based on wildcards, in the following or-

der:

1. Specific IP address and specific port number
2. Specific IP address and a \* (wildcard) port
3. • (wildcard) IP address and a specific port
4. • (wildcard) IP address and a \* (wildcard) port

If the appliance is unable to select a virtual server by IP address or port number, it searches for a virtual server based on the protocol used in the request, in the following order:

1. HTTP
2. TCP
3. ANY

## Configuring global HTTP ports

You do not configure services or virtual servers for a global HTTP port. Instead, you configure a specific port by using the `set ns param` command. After configuring this port, the NetScaler appliance accepts all traffic that matches the port number, and processes it as HTTP traffic, dynamically learning and creating services for that traffic.

You can configure more than one port number as a global HTTP port. If you are specifying more than one port number in a single `set ns param` command, separate the port numbers by a single white space. If one or more ports have already been specified as global HTTP ports, and you want to add one or more ports without removing the ports that are currently configured, you must specify all the port numbers, current and new, in the command. Before you add port numbers, use the `show ns param` command to view the ports that are currently configured.

### To configure a global HTTP port by using the command line interface

At the command prompt, type the following commands to configure a global HTTP port and verify the configuration:

```
1 set ns param -httpPort <port>
2
3 show ns param
4 <!--NeedCopy-->
```

**Example 1: Configuring a port as a global HTTP port** In this example, port 80 is configured as a global HTTP port.

```
1 set ns param -httpPort 80
2 Done
```

```
3 show ns param
4 Global configuration settings:
5 HTTP port(s): 80
6 Max connections: 0
7 Max requests per connection: 0
8 Client IP insertion: DISABLED
9 Cookie version: 0
10 Persistence Cookie Secure Flag: ENABLED
11 ...
12 ...
13 <!--NeedCopy-->
```

**Example 2: Adding ports when one or more global HTTP ports are already configured\*\*** In this example, port 8888 is added to the global HTTP port list. Port 80 is already configured as a global HTTP port.

```
1 > show ns param
2 Global configuration settings:
3 HTTP port(s): 80
4 Max connections: 0
5 Max requests per connection: 0
6 Client IP insertion: DISABLED
7 Cookie version: 0
8 Persistence Cookie Secure Flag: ENABLED
9 Min Path MTU: 576
10 ...
11 ...
12 Done
13 > set ns param -httpPort 80 8888
14 Done
15 > show ns param
16
17 Global configuration settings:
18 HTTP port(s): 80,8888
19 Max connections: 0
20 Max requests per connection: 0
21 Client IP insertion: DISABLED
22 Cookie version: 0
23 Persistence Cookie Secure Flag: ENABLED
24 Min Path MTU: 576
25
26 ...
27 ...
28 Done
29 >
30 <!--NeedCopy-->
```

### To configure a global HTTP port by using the configuration utility

1. Navigate to **System > Settings > Change HTTP Parameters**, and then add an HTTP port number.

## Set up basic load balancing

March 20, 2024

Before configuring your initial load balancing setup, enable the load balancing feature. Then begin by creating at least one service for each server in the load balancing group. With the services configured, you are ready to create a load balancing virtual server, and bind each service to the virtual server. That completes the initial setup. Before proceeding with further configuration, verify your configuration to make sure that each element was configured properly and is operating as expected.

### Enable load balancing

You can configure load balancing entities such as services and virtual servers when the load balancing feature is disabled, but they will not function until you enable the feature.

### To enable load balancing by using the CLI

At the command prompt, type the following command to enable load balancing and verify the configuration:

- enable ns feature LB
- show ns feature

### Example

```
1 > enable ns feature LoadBalancing
2
3 Done
4
5 > show ns feature
6
7
8
9 Feature Acronym Status
10
```

```
11 -----
12
13 1) Web Logging WL OFF
14
15 2) Surge Protection SP ON
16
17 3) Load Balancing LB ON
18
19 .
20
21 .
22
23 .
24
25 24) NetScaler Push push OFF
26
27 Done
28 <!--NeedCopy-->
```

### To enable load balancing by using the GUI

Navigate to **System > Settings** and, in **Configure Basic Features**, select **Load Balancing**.

### Configure a server object

Create an entry for your server on the NetScaler appliance. The NetScaler appliance supports IP address based servers and domain-based servers. If you create an IP address based server, you can specify the name of the server instead of its IP address when you create a service. For information about setting up DNS for a domain-based server, see [Domain Name System](#).

### To create a server object by using the CLI

At the command prompt, type:

```
1 add server `<name>`@ `<IPAddress>`@ | `<domain>`
2 <!--NeedCopy-->
```

#### Example for adding IP address-based name server:

```
1 add server web_serv 10.102.27.150
2 <!--NeedCopy-->
```

#### Example for adding domain-based server:

```
1 add server web_serv test.com
2 <!--NeedCopy-->
```

## To create a server object by using the GUI

Navigate to **Traffic Management > Load Balancing > Servers**, and add a server object.

## Configure services

After you enable the load balancing feature, you must create at least one service for each application server that is to be included in your load balancing setup. The services that you configure provide the connections between the NetScaler appliance and the load balanced servers. Each service has a name and specifies an IP address, a port, and the type of data that is served.

If you create a service without first creating a server object, the IP address of the service is also the name of the server that hosts the service. If you prefer to identify servers by name rather than IP address, you can create server objects and then specify a server's name instead of its IP address when you create a service.

When you create a service that uses UDP as the transport layer protocol, a ping monitor is automatically bound to the service. A ping monitor is the most basic of the built-in monitors. When you create a service that uses TCP as the transport layer protocol, a TCP\_default monitor is automatically bound to the service. When you develop a strategy for managing your load balancing setup, you might decide to bind a different type of monitor, or multiple monitors, to the service.

## Create a Service

Before you create a service, you need to understand the different service types and how each is used. The following list describes the types of services supported on the NetScaler appliance.

- **HTTP**

Used for load-balanced servers that accept HTTP traffic, such as standard websites and web applications. The HTTP service type enables the NetScaler appliance to provide compression, content filtering, caching, and client keep-alive support for your Layer 7 web servers. This service type also supports virtual server IP port insertion, redirect port rewriting, Web 2.0 Push, and URL redirection support.

Because HTTP is a TCP-based application protocol, you can also use the TCP service type for web servers. If you do so, however, the NetScaler appliance is able to perform only Layer 4 load balancing. It cannot provide any of the Layer 7 supports described earlier.

- **SSL**

Used for servers that accept HTTPS traffic, such as ecommerce websites and shopping cart applications. The SSL service type enables the NetScaler appliance to encrypt and decrypt SSL traffic

(perform SSL offloading) for your secure web applications. It also supports HTTP persistence, content switching, rewrite, virtual server IP port insertion, Web 2.0 Push, and URL redirection.

You can also use the SSL\_BRIDGE, SSL\_TCP, or TCP service types. If you do so, however, the appliance performs only Layer 4 load balancing. It cannot provide SSL offloading or any of the Layer 7 supports described.

- **FTP**

Used for servers that accept FTP traffic. The FTP service type enables the NetScaler appliance to support specific details of the FTP protocol.

You can also use TCP or ANY service type for FTP servers.

- **TCP**

Used for servers that accept many different types of TCP traffic, or that accept a type of TCP traffic for which a more specific type of service is not available.

You can also use the ANY service type for these servers.

- **SSL\_TCP**

Used for servers that accept non-HTTP-based SSL traffic, to support SSL offloading.

You can also use the TCP service type for these services. If you do so, the NetScaler appliance performs both the Layer 4 load balancing and SSL offloading.

- **UDP**

Used for servers that accept UDP traffic. You can also use the ANY service type.

- **SSL\_BRIDGE**

Used for servers that accept SSL traffic when you do not want the NetScaler appliance to perform SSL offloading. Alternatively, you can use the SSL\_TCP service type.

- **NNTP**

Used for servers that accept Network News Transfer Protocol (NNTP) traffic, typically Usenet sites.

- **DNS**

Used for servers that accept DNS traffic, typically nameservers. With the DNS service type, the NetScaler appliance validates the packet format of each DNS request and response. It can also cache DNS responses. You can apply DNS policies to DNS services.

You can also use the UDP service type for these services. If you do, however, the NetScaler appliance can only perform Layer 4 load balancing. It cannot provide support for DNS-specific features.

- **ANY**

Used for servers that accept any type of TCP, UDP, or ICMP traffic. The ANY parameter is used primarily with firewall load balancing and link load balancing.

- **SIP-UDP**

Used for servers that accept UDP-based Session Initiation Protocol (SIP) traffic. SIP initiates, manages, and terminates multimedia communications sessions, and has emerged as the standard for Internet telephony (VoIP).

You can also use the UDP service type for these services. If you do, however, the NetScaler appliance performs only Layer 4 load balancing. It cannot provide support for SIP-specific features.

- **DNS-TCP**

Used for servers that accept DNS traffic, where the NetScaler appliance acts as a proxy for TCP traffic sent to DNS servers. With services of the DNS-TCP service type, the NetScaler appliance validates the packet format of each DNS request and response and can cache DNS responses, as with the DNS service type.

You can also use the TCP service type for these services. If you do, however, the NetScaler appliance only performs Layer 4 load balancing of external DNS name servers. It cannot provide support for any DNS-specific features.

- **RTSP**

Used for servers that accept Real Time Streaming Protocol (RTSP) traffic. RTSP provides delivery of multimedia and other streaming data. Select this type to support audio, video, and other types of streamed media.

You can also use the TCP service type for these services. If you do, however, the NetScaler appliance performs only Layer 4 load balancing. It cannot parse the RTSP stream or provide support for RTSPID persistence or RTSP NAT.

- **DHCPRA**

Used for servers that accept DHCP traffic. The DHCPRA service type can be used to relay DHCP requests and responses between VLANs.

- **DIAMETER**

Used for load balancing Diameter traffic among multiple Diameter servers. Diameter uses message-based load balancing.

- **SSL\_DIAMETER**

Used for load balancing Diameter traffic over SSL.

Services are designated as DISABLED until the NetScaler appliance connects to the associated load-balanced server and verifies that it is operational. At that point, the service is designated

as ENABLED. Thereafter, the NetScaler appliance periodically monitors the status of the servers, and places any that fail to respond to monitoring probes (called health checks) back in the DISABLED state until they respond.

**Note:**

You can create a range of services from a single CLI command or the same dialog box. The names in the range vary by a number used as a suffix/prefix. For example, service1, service2, and so on. From the GUI, you can specify a range only in the last octet of the IP address, which is the fourth in case of an IPv4 address and the eighth in an IPv6 address. From the command line, you can specify the range in any octet of the IP address.

**• QUIC**

Used by load balancing servers that accept UDP based QUIC video traffic. The service enables the NetScaler appliance to optimize encrypted ABR video traffic over the UDP protocol.

**• DNS over TLS (DOT)**

Used for the servers that accept DNS traffic. With the DOT service type, NetScaler validates the packet format of each DNS request, encrypts it, and responds to the client. It can also cache the encrypted DNS responses.

**To create a service by using the CLI**

At the command prompt, type:

```
1 add service <name> <serverName> <serviceType> <port>
2
3 add service Service-HTTP-1 192.0.2.5 HTTP 80
4 <!--NeedCopy-->
```

**To create a service by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. In the details pane, click **Add**.
3. In the Create Service dialog box, specify values for the following parameters:
  - Service Name—name
  - Server—serverName
  - Protocol—serviceType
  - Port—port
4. Click **Create**, and then click **Close**. The service you created appears in the Services pane.

## Create a virtual Server

After you create your services, you must create a virtual server to accept traffic for the load balanced websites, applications, or servers. Once load balancing is configured, users connect to the load-balanced website, application, or server through the virtual server's IP address or FQDN.

### Notes:

- Virtual server names prefixed with “app\_” do not appear in the GUI though they are present in the ns.conf file and are displayed when you run the show command. However, virtual server names prefixed with “app” are displayed in the GUI.
- The virtual server is designated as DOWN until you bind the services that you created to it, and until the NetScaler connects to those services and verifies that they are operational. After the verification, the virtual server is designated as UP.
- If you want the virtual server to listen to all the ports, use a wildcard (\*) character instead of the specific port.

**Example:** `add lb vserver v1 TCP 1.11.1.1 *`

## To create a virtual server by using the CLI

At the command prompt, type:

```
1 add lb vserver <name> <serviceType> <ip> <port>
2
3 add lb vserver Vserver-LB-1 HTTP 10.102.29.60 80
4 <!--NeedCopy-->
```

## To create a virtual server by using the GUI

Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and then create a virtual server.

## Bind services to the virtual server

### Note:

A service can be bound to a maximum of 500 virtual servers.

After you have created services and a virtual server, you must bind the services to the virtual server. Usually, services are bound to virtual servers of the same type, but you can bind certain types of services to certain different types of virtual servers, as shown below.

---

Virtual Server Type	Service Type	Comment
HTTP	SSL	You would normally bind an SSL service to an HTTP virtual server to do encryption.
SSL	HTTP	You would normally bind an HTTP service to an SSL virtual server to do SSL offloading.
SSL_TCP	TCP	You would normally bind a TCP service to an SSL_TCP virtual server to do SSL offloading for other TCP (SSL decryption without content awareness).

---

The state of the services bound to a virtual server determines the state of the virtual server: if all of the bound services are DOWN, the virtual server is marked DOWN, and if any of the bound services is UP or OUT OF SERVICE, the state of the virtual server is UP.

### To bind a service to a load balancing virtual server by using the CLI

At the command prompt, type:

```
1 bind lb vserver <name> <serviceName>
2
3 bind lb vserver Vserver-LB-1 Service-HTTP-1
4 <!--NeedCopy-->
```

### To bind a service to a load balancing virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and select a virtual server.
2. Click in the **Service** section, and select a service to bind.

Note: You can bind a service to multiple virtual servers.

### Verify the configuration

After finishing your basic configuration, you can view the properties of each service and load balancing virtual server in your load balancing setup to verify that each is configured correctly. After the

configuration is up and running, you can view the statistics for each service and load balancing virtual server to check for possible problems.

### View the properties of a server object

You can view properties such as the name, state, and IP address of any server object in your NetScaler appliance configuration.

**To view the properties of server objects by using the CLI** At the command prompt, type:

```
1 show server <serverName>
2
3 show server server-1
4 <!--NeedCopy-->
```

**To view the properties of server objects by using the GUI** Navigate to **Traffic Management > Load Balancing > Servers**. The parameter values of the available servers appear in the details pane.

### View the properties of a virtual server

You can view properties such as the name, state, effective state, IP address, port, protocol, method, and number of bound services for your virtual servers. If you have configured more than the basic load balancing settings, you can view the persistence settings for your virtual servers, any policies that are bound to them, and any cache redirection and content switching virtual servers that have been bound to the virtual servers.

**To view the properties of a load balancing virtual server by using the CLI** At the command prompt, type:

```
1 show lb vservice <name>
2
3 show lb vservice Vservice-LB-1
4 <!--NeedCopy-->
```

### To view the properties of a load balancing virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, click a virtual server to display its properties at the bottom of the details pane.

3. To view the cache redirection and content switching virtual servers that are bound to this virtual server, click **Show CS/CR Bindings**.

### View the properties of a service

You can view the name, state, IP address, port, protocol, maximum client connection, maximum requests per connection, and server type of the configured services, and use this information to troubleshoot any mistake in the service configuration.

**To view the properties of services by using the CLI** At the command prompt, type:

```
1 show service <name>
2
3 show service Service-HTTP-1
4 <!--NeedCopy-->
```

**To view the properties of services by using the GUI** Navigate to **Traffic Management > Load Balancing > Services**. The details of the available services appear on the Services pane.

### View the bindings of a service

You can view the list of virtual servers to which the service is bound. The binding information also provides the name, IP address, port, and state of the virtual servers to which the services are bound. You can use the binding information to troubleshoot any problem with binding the services to virtual servers.

**To view the bindings of a service by using the CLI** At the command prompt, type:

```
1 show service bindings <name>
2
3 show service bindings Service-HTTP-1
4 <!--NeedCopy-->
```

### To view the bindings of a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. In the details pane, select the service whose binding information you want to view.
3. In the **Action** tab, click **Show Bindings**.

**View the statistics of a virtual server**

To evaluate the performance of virtual servers or to troubleshoot problems, you can display details of the virtual servers configured on NetScaler. You can display a summary of statistics for all the virtual servers, or you can specify the name of a virtual server to display the statistics only for that virtual server. You can display the following details:

- Name
- IP address
- Port
- Protocol
- State of the virtual server
- Rate of requests received
- Rate of hits

**To display virtual server statistics by using the CLI** To display a summary of the statistics for all the virtual servers currently configured on the appliance, or for a single virtual server, at the command prompt, type:

```
1 stat lb vserver [`<name>`]
2 <!--NeedCopy-->
```

**Example:**

```
1 stat lb vserver server-1
2 <!--NeedCopy-->
```

The following figure displays a sample statistic.

```
> stat lbvserver
```

```
[
```

```
Virtual Server(s) Summary

test124	0.0.0.0	0	SSL	DOWN	0/s
testssl	0.0.0.0	0	SSL	DOWN	0/s

### To display virtual server statistics by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. If you want to display the statistics for only one virtual server, in the details pane, select the virtual server whose statistics you want to display.
3. In the details pane, click **Statistics**.

### View the statistics of a service

You can view the rate of requests, responses, request bytes, response bytes, current client connections, requests in the surge queue, current server connections, and so forth using the service statistics.

**To view the statistics of a service by using the CLI** At the command prompt, type:

```
1 stat service <name>
2 <!--NeedCopy-->
```

#### Example:

```
1 stat service Service-HTTP-1
2 <!--NeedCopy-->
```

### To view the statistics of a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. In the details pane, select the service whose statistics you want to view (for example, Service-HTTP-1).
3. Click **Statistics**. The statistics appear in a new window.

## Load balance virtual server and service states

April 5, 2021

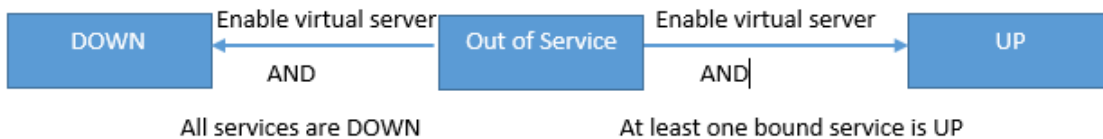

A load balancing virtual server that does not have a backup virtual server can take the following states, depending on the states of the services bound to it and whether it is administratively disabled:

- **UP**: At least one of the services bound to the virtual server is UP.
- **DOWN**: All the services bound to the virtual server are DOWN, or the load balancing feature is not enabled.

- **Out of Service (OFS):** If you administratively disable the virtual server, it enters the OFS state but its effective state is DOWN. Administrator can control the transitioning to the OFS state from the DOWN or UP state, or to the DOWN or UP state from the OFS state.

The state and effective state of a virtual server are the same if a backup virtual server is not configured. However, if a backup virtual server or a chain of backup virtual servers is configured, the effective state is derived from the states of the services that are bound to the primary virtual server and the backup virtual servers. If any of the backup virtual servers in the chain is UP, the effective state of the primary virtual server is UP, even if all the services bound to the primary virtual server are DOWN.

The following diagrams show the conditions under which a virtual server transitions from one state to another.

A service can take the following states:

- **UP:** If probes from all the monitors bound to the service are successful.
- **DOWN:** If monitoring probes to the service are not answered within the configured time limit.
- **OUT OF SERVICE:** If you administratively disable the service, or if you gracefully shut down the service and there are no active transactions to the service
- **GOING OUT OF SERVICE (TROFS):** If you administratively disable the service with delay, or gracefully shut down the service and there are active transactions to the service. For more in-

formation, see [Graceful Shut down of Services](#).

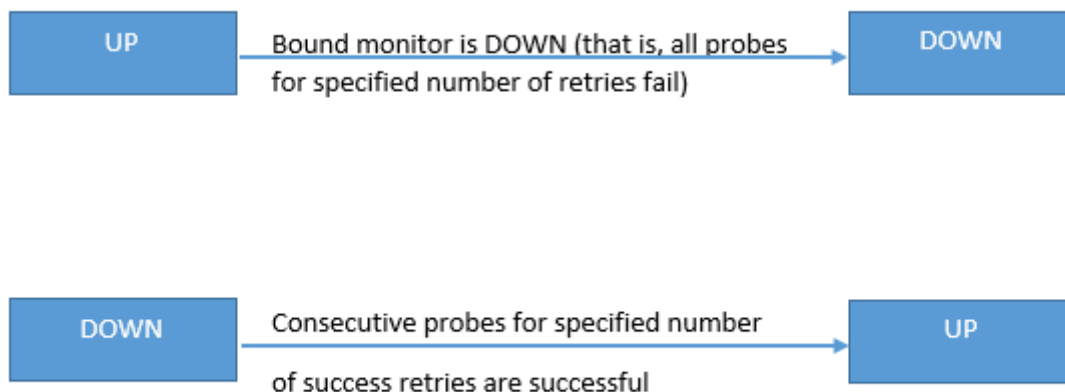

- **DOWN WHEN GOING OUT OF SERVICE (TROFS\_DOWN)[[]]** A monitoring probe fails while the service is in the GOING OUT OF SERVICE state.

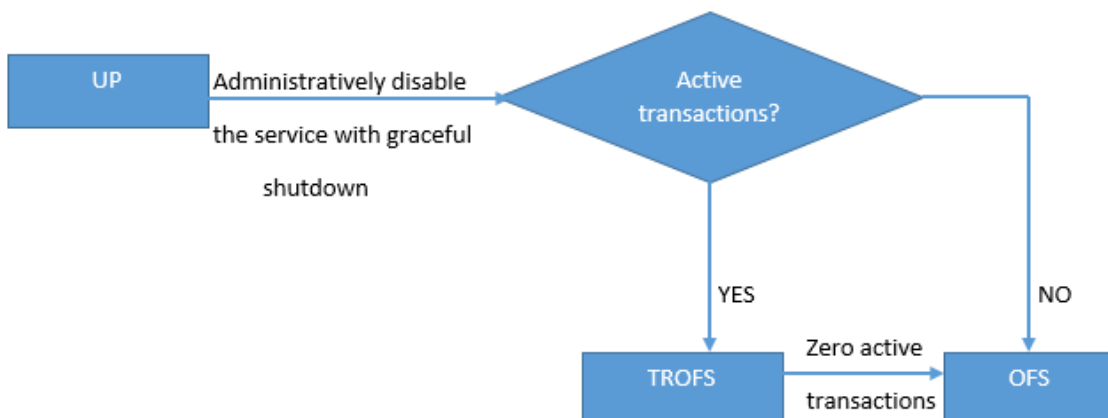

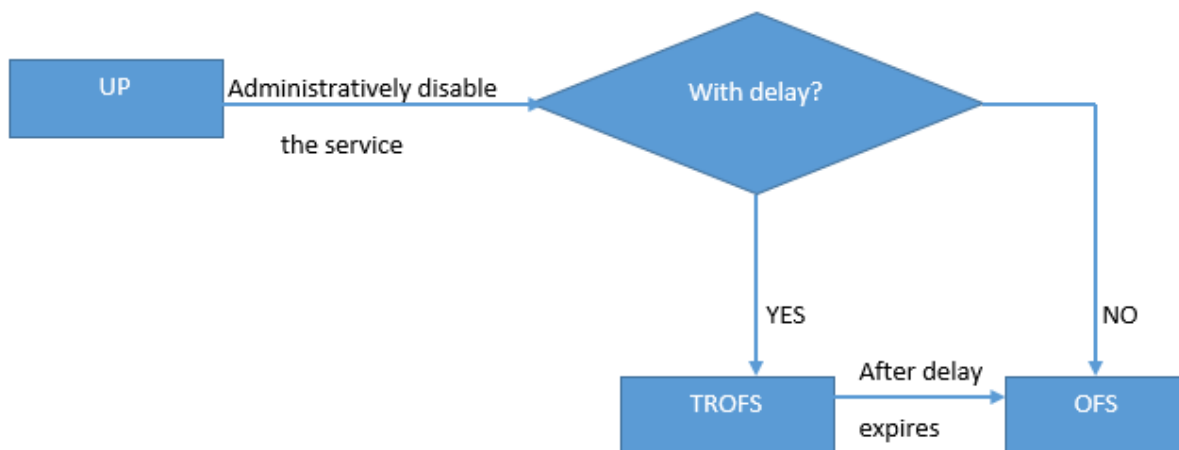

A service in the process of transitioning from UP to OFS is in the GOING OUT OF SERVICE state. A service transitioning from DOWN to OFS is in the DOWN WHEN GOING OUT OF SERVICE state. For example, if a service is DOWN and you disable it with delay, the service transitions to DOWN WHEN GOING OUT OF SERVICE and then to the OUT OF SERVICE state. If a service is UP and you disable it with delay, the service transitions to GOING OUT OF SERVICE. During this time, if a monitoring probe to the server fails, the service transitions to DOWN WHEN GOING OUT OF SERVICE and, after the delay time expires, enters the OFS state.

**Note**

You can configure spillover to a backup virtual server by setting the “healthThreshold” parameter to a non-zero positive value. Then, if a single service bound to the primary virtual server transitions to the DOWN WHEN GOING OUT OF SERVICE state and the health threshold is not reached, the primary virtual server is marked DOWN and new connections are directed to the backup virtual server.

The following diagrams show the conditions under which a service transitions from one state to another.

## Support for load balancing profile

June 12, 2023

A load balancing configuration has many parameters, so setting the same parameters on several virtual servers can become tedious. From release 11.1, a load balancing (LB) profile makes this task

easier. You can now set load balancing parameters in a profile and associate this profile with virtual servers, instead of setting these parameters on each virtual server.

The following parameters are presently supported in an LB profile:

- `HTTPOnlyFlag`—Include the `HttpOnly` attribute in persistence cookies. The `HttpOnly` attribute limits the scope of a cookie to HTTP requests and helps mitigate the risk of cross-site scripting attacks.
- `UseSecuredPersistenceCookie`—Encrypt the persistence cookie values by using the SHA2 hash algorithm.
- `Cookiepassphrase`—Specify the passphrase used to generate a secured persistence cookie value.
- `DBS_LB`—Enable database specific load balancing for MySQL and MSSQL service types.
- `Cl_process_local`—Packets destined to a virtual server in a cluster are not steered. Enable the option for single packet request response mode or when the upstream device is performing a proper RSS for connection based distribution.
- `lbHashAlgorithm`—Specify the hashing algorithm to be used for the following hash-based load balancing methods:
  - URL hash method
  - Domain hash method
  - Destination IP hash method
  - Source IP hash method
  - Source IP Destination IP hash method
  - Source IP Source Port hash method
  - Call ID hash method
  - Token method

Possible values: DEFAULT, PRAC, JARH

Default value: DEFAULT

- `lbHashFingers`—Specify the number of fingers to be used in PRAC and JARH algorithms for hash-based LB methods. Increasing the number of fingers provides better distribution of traffic at the expense of additional memory.

Default value: 256

Minimum value: 1

Maximum value: 1024

- `proximityFromSelf`—Enable to use the Netscaler's loopback IP address instead of the client's IP address to fetch the closest server location for static proximity load balancing or GSLB decision.

**Note**

You can set DBS\_LB and Cl\_process\_local parameters on a virtual server and in the profile. If you enable these parameters on a virtual server and then set a profile to this virtual server, the parameters appear as disabled in the output of the `"show lb vserver"` command for that virtual server. Check the profile to see the actual status of these parameters. In addition, if you set and then unset a profile to a virtual server, the parameters are set with default values for that virtual server.

**To create an LB profile by using the CLI**

At the command prompt, type:

```
1 add lb profile <lbprofilename> -dbsLb (ENABLED | DISABLED) -
 processLocal (ENABLED | DISABLED) -httpOnlyCookieFlag (ENABLED |
 DISABLED) -cookiePassphrase -useSecuredPersistenceCookie (ENABLED |
 DISABLED) -lbHashAlgorithm <lbHashAlgorithm> -lbHashFingers <
 positive_integer>- proximityFromSelf <NO/YES>
2 <!--NeedCopy-->
```

**Example:**

```
1 > sh lb profile p1
2 LB Profile name: p1
3 DBS LB : DISABLED Process Local: DISABLED
4 Persistence Cookie HttpOnly Flag: ENABLED
5 Use Encrypted Persistence Cookie: DISABLED
6 Proximity From Self: ENABLED
7 No of vservers bound: 0
8 Store MQTT clientid and username in transactional logs: NO
9 Hash LB algorithm used in LB decision: DEFAULT
10 Number of fingers for Hash LB algorithm: 256
11 Done
12
13 <!--NeedCopy-->
```

**To create an LB profile by using the GUI**

Navigate to **System > Profiles > LB Profile**, and add a profile.

**To associate an LB profile with an LB virtual server by using the CLI**

At the command prompt, type:

```
1 set lb vserver <name> -lbprofilename <string>
2 <!--NeedCopy-->
```

### Example

```
1 set lbvserver lbvip1 -lbprofile p1
2
3 Done
4
5 sh lb vserver lbvip1
6
7 lbvip1 (203.0.113.1:80) - HTTP Type: ADDRESS
8 State: UP
9 Last state change was at Wed May 25 12:36:20 2016
10 Time since last state change: 0 days, 00:01:26.140
11 Effective State: UP ARP:DISABLED
12 Client Idle Timeout: 180 sec
13 Down state flush: ENABLED
14 Disable Primary Vserver On Down : DISABLED
15 Appflow logging: ENABLED
16 Port Rewrite : DISABLED
17 No. of Bound Services : 2 (Total) 2 (Active)
18 Configured Method: LEASTCONNECTION BackupMethod: ROUNDROBIN
19 Mode: IP
20 Persistence: NONE
21 Vserver IP and Port insertion: OFF
22 Push: DISABLED Push VServer:
23 Push Multi Clients: NO
24 Push Label Rule: none
25 L2Conn: OFF
26 Skip Persistency: None
27 Listen Policy: NONE
28 IcmpResponse: PASSIVE
29 RHlstate: PASSIVE
30 New Service Startup Request Rate: 0 PER_SECOND, Increment Interval: 0
31 Mac mode Retain Vlan: DISABLED
32 DBS_LB: DISABLED
33 Process Local: DISABLED
34 Traffic Domain: 0
35 LB Profile: p1
36 Done
37 <!--NeedCopy-->
```

### To associate an LB profile with an LB virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Select a virtual server, and click **Edit**.
3. In **Advanced Settings**, click **Profiles**.
4. In the **LB Profile** list, select the profile to associate with this virtual server.

## To configure the Proximity from Self parameter in the load balancing profile by using the GUI

Configure the Proximity from Self parameter in the profile so that when the profile is attached to the entity the parameter is enabled for the entity.

1. Navigate to **System > Profile > LB Profile**.
2. Click **Add**.
3. Select **Proximity from Self**.
4. Click **OK**.

## Load balancing algorithms

January 11, 2024

The load balancing algorithm defines the criteria that the NetScaler appliance uses to select the service to which to redirect each client request. Different load balancing algorithms use different criteria. For example, the least connection algorithm selects the service with the fewest active connections, while the round robin algorithm maintains a running queue of active services, distributes each connection to the next service in the queue, and then sends that service to the end of the queue.

Some load balancing algorithms are best suited to handling traffic on websites, others to managing traffic to DNS servers, and others to handling complex web applications used in e-commerce or on company LANs or WANs. The following table lists each load balancing algorithm that the NetScaler appliance supports, with a brief description of how each operates.

---

Name	Server selection based on
LEASTCONNECTION	Which service currently has the fewest client connections. This is the default load balancing algorithm.
ROUNDROBIN	Which service is at the top of a list of services. After that service is selected for a connection, it moves to the bottom of the list.
LEASTRESPONSETIME	Which load balanced server currently has the quickest response time.
URLHASH	A hash of the destination URL.
DOMAINHASH	A hash of the destination domain.
DESTINATIONIPHASH	A hash of the destination IP address.

Name	Server selection based on
SOURCEIPHASH	A hash of the source IP address.
SRCIPDESTIPHASH	A hash of the source and destination IP addresses.
CALLIDHASH	A hash of the call ID in the SIP header.
SRCIPSRCPORHASH	A hash of the client's IP address and port.
LEASTBANDWIDTH	Which service currently has the fewest bandwidth constraints.
LEASTPACKETS	Which service currently is receiving the fewest packets.
CUSTOMLOAD	Data from a load monitor.
TOKEN	The configured token.
LRTM	Fewest active connections and the lowest average response time.
Static Proximity	The service that best matches the proximity criteria.
Least Request	Which service currently has the fewest client request.

Depending on the protocol of the service that it is load balancing, the NetScaler appliance sets up each connection between client and server to last for a different time interval. This is called load balancing granularity, of which are three types: request-based, connection-based, and time-based granularity. The following table describes each type of granularity and when each is used.

Granularity	Types of Load Balanced Service	Specifies
Request -based	HTTP or HTTPS	A new service is chosen for each HTTP request, independent of TCP connections. As with all HTTP requests, after the Web server fulfills the request, the connection is closed.

---

Granularity	Types of Load Balanced Service	Specifies
Connection-based	TCP and TCP-based protocols other than HTTP	A service is chosen for every new TCP connection. The connection persists until terminated by either the service or the client.
Time-based	UDP and other IP protocols	A new service is chosen for each UDP packet. Upon selection of a service, a session is created between the service and a client for a specified period. When the time expires, the session is deleted and a new service is chosen for any additional packets, even if those packets come from the same client.

---

During startup of a virtual server, or whenever the state of a virtual server changes, the virtual server can initially use the round robin method to distribute the client requests among the physical servers. This type of distribution, referred to as *startup round robin*, helps prevent unnecessary load on a single server as the initial requests are served. After using the round robin method at the startup, the virtual server switches to the load balancing method specified on the virtual server.

The Startup RR Factor works in the following manner:

- If the Startup RR Factor is set to zero, the appliance switches to the specified load balancing method depending on the request rate.
- If the Startup RR Factor is any number other than zero, the appliance uses the round robin method for the specified number of requests before switching to the specified load balancing method.
- By default, the Startup RR Factor is set to zero.

Note: You cannot set the startup RR Factor for an individual virtual server. The value you specify applies to all the virtual servers on the NetScaler appliance.

### **To set the startup round-robin factor by using the CLI**

At the command prompt, type:

```
set lb parameter -startupRRFactor <positive_integer>
```

Example

```
set lb parameter -startupRRFactor 25000
```

### To set the startup round-robin factor by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Configure Load Balancing Parameters**, and set the Startup RR Factor.

## Least connection method

January 11, 2024

When a virtual server is configured to use the least connection load balancing algorithm (or method), it selects the service with the fewest active connections. This is the default method, because, in most circumstances, it provides the best performance.

For TCP, HTTP, HTTPS, and SSL\_TCP services, the NetScaler appliance includes the following connection types in its list of existing connections:

- **Active connections to a service.** Connections representing requests that a client has sent to the virtual server and that the virtual server has forwarded to a service. For HTTP and HTTPS services, active connections represent only those HTTP or HTTPS requests that have not yet received a response.
- **Waiting connections in the surge queue.** Any connections to the virtual server that are waiting in a surge queue and have not yet been forwarded to a service. Connections can build up in the surge queue at any time, for any of the following reasons:
  - Your services have connection limits, and all services in your load balancing configuration are at that limit.
  - The surge protection feature is configured and has been activated by a surge in requests to the virtual server.
  - The load-balanced server has reached an internal limit and therefore does not open any new connections. (For example, an Apache server's connection limit is reached.)

When a virtual server uses the least connection method, it considers the waiting connections as belonging to the specific service. Therefore, it does not open new connections to those services.

For UDP services, the connections that the least connection algorithm considers include all sessions between the client and a service. These sessions are logical, time-based entities. When the first UDP

packet in a session arrives, the NetScaler appliance creates a session between the source IP address and port and the destination IP address and port.

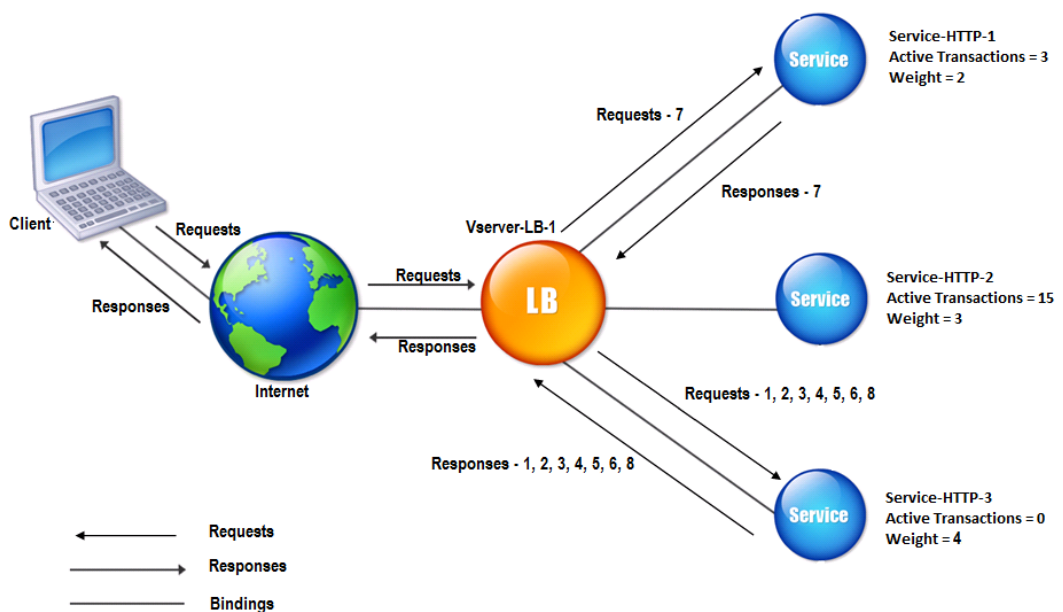

For Real-Time Streaming Protocol (RTSP) connections, the NetScaler appliance uses the number of active control connections to determine the lowest number of connections to an RTSP service.

The following example shows how a virtual server selects a service for load balancing by using the least connection method. Consider the following three services:

- Service-HTTP-1 is handling 3 active transactions.
- Service-HTTP-2 is handling 15 active transactions.
- Service-HTTP-3 is not handling any active transactions.

The following diagram illustrates how the NetScaler appliance forwards incoming requests when using the least connection method.

Figure 1. Mechanism of the Least Connections Load Balancing Method

In this diagram, the virtual server selects the service for each incoming connection by choosing the server with the fewest active transactions.

Connections are forwarded as follows:

- Service-HTTP-3 receives the first request, because it is not handling any active transactions.

Note: The service with no active transaction is selected first.

- Service-HTTP-3 receives the second and third requests because the service has the next least number of active transactions.
- Service-HTTP-1 receives the fourth request because Service-HTTP-1 and Service-HTTP-3 have the same number of active transactions, the virtual server uses the round robin method to choose between them.
- Service-HTTP-3 receives the fifth request.
- Service-HTTP-1 receives the sixth request, and so on, until both Service-HTTP-1 and Service-HTTP-3 are handling the same number of requests as Service-HTTP-2. Then, the NetScaler appliance starts forwarding requests to Service-HTTP-2 when it is the least loaded service or its turn comes up in the round robin queue.

**Note:**

If connections to Service-HTTP-2 close, it might get new connections before each of the other two services has 15 active transactions.

The following table explains how connections are distributed in the three-service load balancing setup described earlier.

Incoming Connection	Service Selected	Current Number of Active Connections	Remarks
Request-1	Service-HTTP-3; (N = 0)	1	Service-HTTP-3 has the fewest active connections.
Request-2	Service-HTTP-3; (N = 1)	2	Service-HTTP-3 has the fewest active connections.
Request-3	Service-HTTP-3; (N = 2)	3	-
Request-4	Service-HTTP-1; (N = 3)	4	Service-HTTP-1 and Service-HTTP-3 have the same number of active connections.
Request-5	Service-HTTP-3; (N = 3)	4	Service-HTTP-1 and Service-HTTP-3 have the same number of active connections.
Request-6	Service-HTTP-1; (N = 4)	5	-
Request-7	Service-HTTP-3; (N = 4)	5	-
Request-8	Service-HTTP-1; (N = 5)	6	-

Service-HTTP-2 is selected for load balancing when it completes its active transactions and the current connections to it close, or when the other services (Service-HTTP-1 and Service-HTTP-3) have 15 or more connections each.

The NetScaler appliance can also use the least connection method when weights are assigned to services. It selects a service by using the value (Nw) of the following expression:

$$Nw = (\text{Number of active transactions}) * (10000 / \text{weight})$$

The following example shows how the NetScaler appliance selects a service for load balancing by using the least connection method when weights are assigned to services. In the preceding example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4. Connections are forwarded as follows:

- Service-HTTP-3 receives the first because the service is not handling any active transactions.  
 Note: If the services are not handling any active transactions, the NetScaler appliance uses the round robin method regardless of the weights assigned to each of the services.
- Service-HTTP-3 receives the second, third, fourth, fifth, and sixth requests because the service has the lowest Nw value.
- Service-HTTP-1 receives the seventh request. Because Service-HTTP-1 and Service-HTTP-3 now have the same Nw value, the appliance performs load balancing in a round robin manner. Therefore, Service-HTTP-3 receives the eighth request.

The following table explains how connections are distributed on the three-service load balancing setup that is described earlier.

Request Received	Service Selected	Current Nw (Number of active transactions) * (10000 / weight) value	Remarks
Request-1	Service-HTTP-3; (Nw = 0)	Nw = 2500	Service-HTTP-3 has the lowest Nw value.
Request-2	Service-HTTP-3; (Nw = 2500)	Nw = 5000	
Request-3	Service-HTTP-3; (Nw = 5000)	Nw = 7500	
Request-4	Service-HTTP-3; (Nw = 7500)	Nw = 10000	
Request-5	Service-HTTP-3; (Nw = 10000)	Nw = 12500	

Request Received	Service Selected	Current Nw (Number of active transactions) * (10000 / weight) value	Remarks
Request-6	Service-HTTP-3; (Nw = 12500)	Nw = 15000	
Request-7	Service-HTTP-1; (Nw = 15000)	Nw = 20000	Service-HTTP-1 and Service-HTTP-3 have the same Nw values
Request-8	Service-HTTP-3; (Nw = 15000)	Nw = 17500	

Service-HTTP-2 is selected for load balancing when it completes its active transactions or when the Nw value of other services (Service-HTTP-1 and Service-HTTP-3) is equal to 50000.

The following diagram illustrates how the NetScaler appliance uses the least connection method when weights are assigned to the services.

Figure 2. Mechanism of the Least Connections Load Balancing Method when Weights are Assigned

To configure the least connection method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

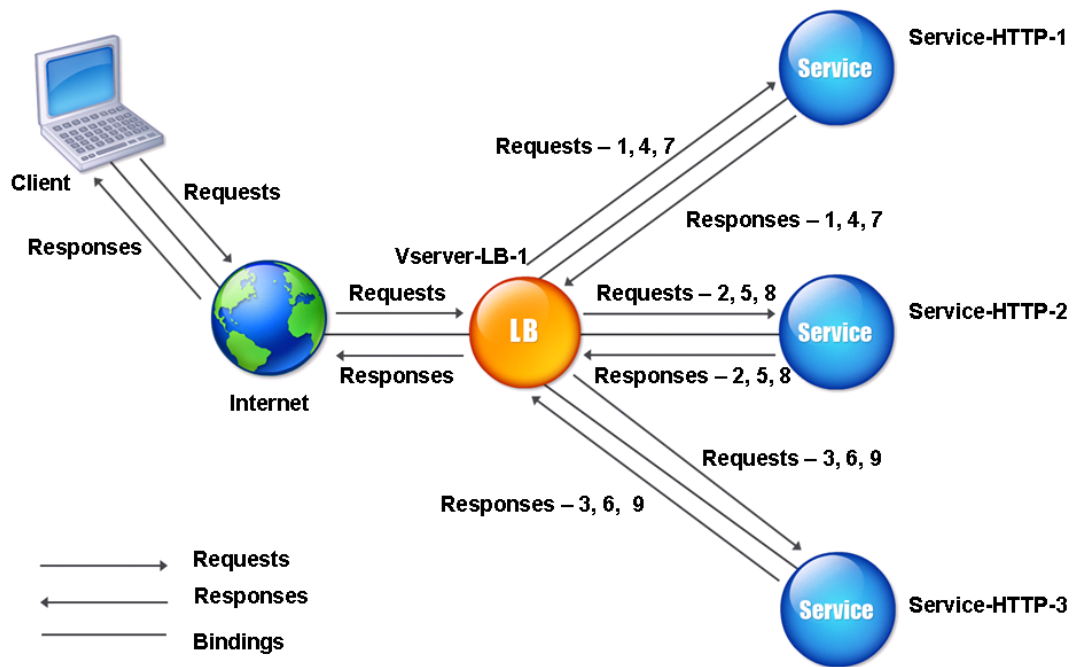

## Round robin method

May 2, 2023

When a load balancing virtual server is configured to use the round robin method, it continuously rotates a list of the services that are bound to it. When the virtual server receives a request, it assigns the connection to the first service in the list, and then moves that service to the bottom of the list.

The following diagram illustrates how the NetScaler appliance uses the round robin method with a load balancing setup that contains three load-balanced servers and their associated services.

Figure 1. How the Round Robin Load Balancing Method Works

If you assign a different weight to each service, the NetScaler appliance performs the weighted round robin distribution of incoming connections. It does this by skipping the lower-weighted services at appropriate intervals.

For example, assume that you have a load balancing setup with three services. You set Service-HTTP-1 to a weight of 2, Service-HTTP-2 to a weight of 3, and Service-HTTP-3 to a weight of 4. The services are bound to Vserver-LB-1, which is configured to use the round robin method. With this setup, incoming requests are delivered as follows:

- Service-HTTP-1 receives the first request.
- Service-HTTP-2 receives the second request.
- Service-HTTP-3 receives the third request.
- Service-HTTP-1 receives the fourth request.
- Service-HTTP-2 receives the fifth request.
- Service-HTTP-3 receives the sixth request.
- Service-HTTP-2 receives the seventh request.
- Service-HTTP-3 receives both the eighth and the ninth requests.

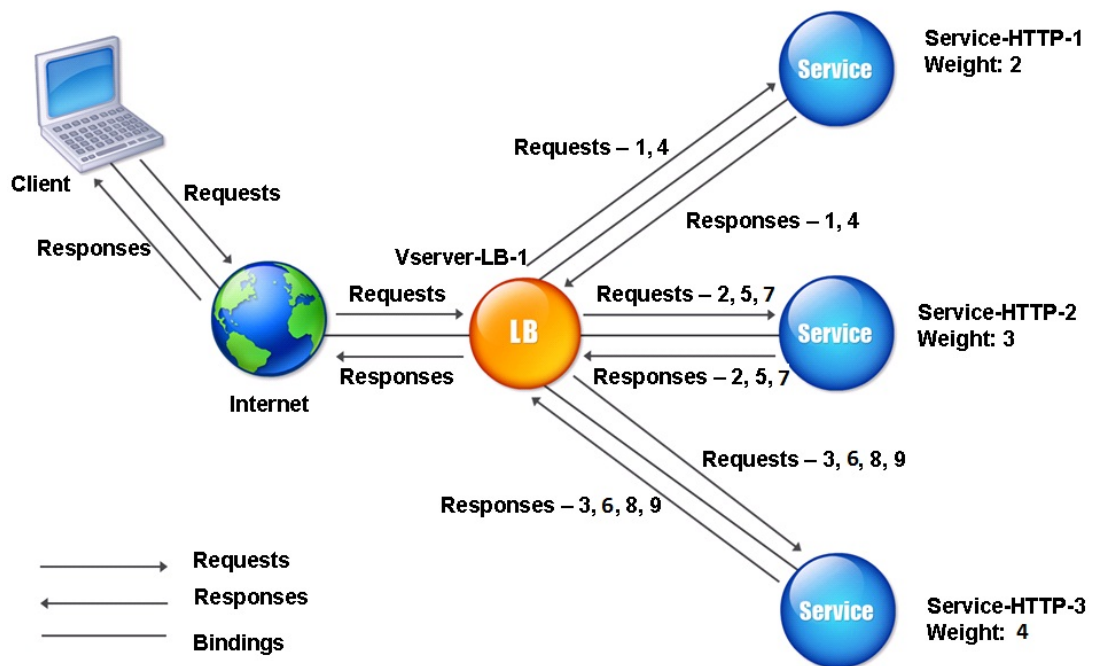

**Note:**

You can also configure weights on services to prevent multiple services from using the same server and overloading the server.

A new cycle then begins, using the same pattern.

The following diagram illustrates the weighted round robin method.

Figure 2. How the Round Robin Load Balancing Method supports Weighted Services

To configure the round robin method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

## Least response time method

May 2, 2023

When the load balancing virtual server is configured to use the least response time method, it selects the service with the fewest active connections and the lowest average response time. You can configure this method for HTTP and Secure Sockets Layer (SSL) load balancing virtual servers only. The response time (also called Time to First Byte, or TTFB) is the time interval between sending a request packet to a service and receiving the first response packet from the service. The NetScaler appliance uses response code 200 to calculate TTFB.

The following example shows how a virtual server selects a service for load balancing by using the least response time method. Consider the following three services:

- Service-HTTP-1 is handling three active transactions and TTFB is two seconds.
- Service-HTTP-2 is handling seven active transactions and TTFB is one second.
- Service-HTTP-3 is not handling any active transactions and TTFB is two seconds.

The following diagram illustrates how the NetScaler appliance uses the least response time method to forward the connections.

Figure 1. How the Least Response Time Load Balancing Method Works

The virtual server selects a service by multiplying the number of active transactions by the TTFB for each service and then selecting the service with the lowest result. For the example shown above, the virtual server forwards requests as follows:

- Service-HTTP-3 receives the first request, because the service is not handling any active transactions.
- Service-HTTP-3 also receives the second and third requests, because the result is the lowest of the three services.
- Service-HTTP-1 receives the fourth request. Since Service-HTTP-1 and Service-HTTP-3 have the same result, the NetScaler appliance chooses between them by applying the Round Robin method.
- Service-HTTP-3 receives the fifth request.
- Service-HTTP-2 receives the sixth request, because at this point it has the lowest result.
- Because Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 all have the same result at this point, the appliance switches to the round robin method, and continues to distribute connections using that method.

The following table explains how connections are distributed in the three-service load balancing setup described earlier.

Request Received	Service Selected	Current N Value (Number of Active Transactions * TTFB)	Remarks
Request-1	Service-HTTP-3;(N = 0)	N = 2	Service-HTTP-3 has the lowest N value.
Request-2	Service-HTTP-3; (N = 2)	N = 4	Service-HTTP-3 has the lowest N value.
Request-3	Service-HTTP-3; (N = 4)	N = 6	Service-HTTP-3 has the lowest N value.
Request-4	Service-HTTP-1; (N = 6)	N = 8	Service-HTTP-1 and Service-HTTP-3 have the same N values. The appliance uses the round robin method to distribute the requests.
Request-5	Service-HTTP-3; (N = 6)	N = 8	Service-HTTP-1 and Service-HTTP-3 have the same N values.
Request-6	Service-HTTP-2; (N = 7)	N = 8	Service-HTTP-2 has the lowest N value.
Request-7	Service-HTTP-3; (N = 8)	N = 10	Service-HTTP-1, Service-HTTP-2 and Service-HTTP-3 have the same N values. The NetScaler appliance uses the round robin method to distribute the requests.
Request-8	Service-HTTP-1; (N = 8)	N = 10	Service-HTTP-1 and Service-HTTP-2 have the same N values, the appliance uses the round robin method to distribute the requests.

Service-HTTP-1 is again selected for load balancing when it completes its active transactions or when its N value is less than the other services (Service-HTTP-2 and Service-HTTP-3).

## Selection of services when weights are assigned

The following diagram illustrates how the NetScaler appliance uses the least response time method when weights are assigned.

Figure 2. How the Least Response Time Load Balancing Method Works When Weights Are Assigned

The virtual server selects a service by using the value (Nw) in the following expression:

$$Nw = (N) * (10000 / \text{weight}), \text{ where } N = (\text{number of active transactions} * \text{TTFB})$$

Suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned weight of 3, and Service-HTTP-3 is assigned weight of 4.

The NetScaler appliance distributes requests as follows:

- Service-HTTP-3 receives the first request, because it is not handling any active transactions.  
If the services are not handling any active transactions, the appliance selects them regardless of the weights assigned to them.
- Service-HTTP-3 receives the second, third, fourth, and fifth requests, because this service has the lowest Nw value.
- Service-HTTP-2 receives the sixth request, because this service has the lowest Nw value.

- Service-HTTP-3 receives the seventh request, because this service has the lowest Nw value.
- Service-HTTP-2 receives the eighth request, because this service has the lowest Nw value.

Service-HTTP-1 has the lowest weight and therefore the highest Nw value, so the virtual server does not select it for load balancing.

The following table explains how connections are distributed in the three-service load balancing setup described earlier.

Request Received	Service Selected	Current Nw Value = (N) * (10000 / Weight)	Remarks
Request-1	Service-HTTP-3; (Nw = 0)	Nw = 5000	Service-HTTP-3 has the lowest Nw value.
Request-2	Service-HTTP-3; (Nw = 5000)	Nw = 10000	Service-HTTP-3 has the lowest Nw value.
Request-3	Service-HTTP-3; (Nw = 10000)	Nw = 15000	Service-HTTP-3 has the lowest Nw value.
Request-4	Service-HTTP-3; (Nw = 15000)	Nw = 20000	Service-HTTP-3 has the lowest Nw value.
Request-5	Service-HTTP-3; (Nw = 20000)	Nw = 25000	Service-HTTP-3 has the lowest Nw value.
Request-6	Service-HTTP-2; (Nw = 23333.34)	Nw = 26666.67	Service-HTTP-2 has the lowest Nw value.
Request-7	Service-HTTP-3; (Nw = 25000)	Nw = 30000	Service-HTTP-3 has the lowest Nw value.
Request-8	Service-HTTP-2; (Nw = 26666.67)	Nw = 30000	Service-HTTP-2 has the lowest Nw value.

Service-HTTP-1 is selected for load balancing when it completes its active transactions or when its Nw value is less than other services (Service-HTTP-2 and Service-HTTP-3).

**To configure the least response time load balancing method by using the CLI**

At the command prompt type;

```
1 set lb vserver <name> -lbMethod LEASTRESPONSETIME
2 <!--NeedCopy-->
```

**Example:**

```
1 set lb vserver Vserver-LB-1 -lbMethod LEASTRESPONSETIME
2 <!--NeedCopy-->
```

**To configure the least response time load balancing method by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In Advanced Settings, select **LEASTRESPONSETIME**.

For more information about configuring monitors, see [Configuring Monitors in a Load Balancing Setup](#).

**LRTM method**

May 2, 2023

**Note:** LRTM stands for Least response time method using monitors (LRTM).

When a load balancing virtual server is configured to use the LRTM method, it uses the existing monitoring infrastructure to get the fastest response time. The load balancing virtual server then selects the service with the smallest number of active transactions and lowest response time. Before you use the LRTM method, you must bind application-specific monitors to each service and enable LRTM mode on these monitors. The NetScaler appliance then makes load balancing decisions based on the response times it calculates from monitoring probes.

You can use the LRTM method to load balance non-HTTP and non-HTTPS services also. You can also use this method when several monitors are bound to a service. Each monitor determines the response time by using the protocol that it measures for the service that it is bound to. The virtual server then calculates an average response time for that service by averaging the results.

The following table summarizes how response times are calculated for the various monitors.

---

Monitor	Response time calculation
PING	Time difference between the ICMP ECHO request and the ICMP ECHO response.
TCP	Time difference between the SYN request and the SYN+ACK response.
HTTP	Time difference between the HTTP request (after the TCP connection is established) and the HTTP response.

Monitor	Response time calculation
TCP-ECV	Time difference between the time the data send string is sent and the data receive string is returned. A TCP-ECV monitor without the send and receive strings is considered to have an incorrect configuration.
HTTP-ECV	Time difference between the HTTP request and the HTTP response.
UDP-ECV	Time difference between the UDP's send string and the receive string. A UDP-ECV monitor without the receive string is considered to have an incorrect configuration.
DNS	Time difference between a DNS query and the DNS response.
TCPS	Time difference between a SYN request and the SSL handshake completion.
FTP	Time difference between the sending of the user name and the completion of user authentication.
HTTPS (monitors HTTPS requests)	Time difference is the same as for the HTTP monitor.
HTTPS-ECV (monitors HTTPS requests)	Time difference is the same as for the HTTP-ECV monitor
USER	Time difference between the time when a request is sent to the dispatcher and the time when the dispatcher response is received.

The following example shows how the NetScaler appliance selects a service for load balancing by using the LRTM method. Consider the following three services:

- Service-HTTP-1 is handling 3 active transactions and the response time is five seconds.
- Service-HTTP-2 is handling 7 active transactions and the response time is one second.
- Service-HTTP-3 is not handling any active transactions and the response time is two seconds.

The following diagram illustrates the process that the NetScaler appliance follows when it forwards requests.

Figure 1. How the LRTM Method Works

The virtual server selects a service by using the value (N) in the following expression:

$$N = (\text{Number of active transactions} * \text{Response time that is determined by the monitor})$$

The virtual server delivers requests as follows:

- Service-HTTP-3 receives the first request, because this service is not handling any active transaction.
- Service-HTTP-3 receives the second, third, and fourth requests, because this service has the lowest N value.
- Service-HTTP-2 receives the fifth request, because this service has the lowest N value.
- Since both Service-HTTP-2 and Service-HTTP-3 currently have the same N value, the NetScaler appliance switches to the round robin method. Therefore, Service-HTTP-3 receives the sixth request.
- Service-HTTP-2 receives the seventh and eighth requests, because this service has the lowest N value.

Service-HTTP-1 is not considered for load balancing, because it is more heavily loaded (has the highest N value) when compared to the other two services. However, if Service-HTTP-1 completes its active transactions, the NetScaler appliance again considers that service for load balancing.

The following table summarizes how N is calculated for the services.

Request Received	Service Selected	Current N Value (Number of Active Transactions * TTFB)	Remarks
Request-1	Service-HTTP-3;(N = 0)	N = 2	Service-HTTP-3 has the lowest N value.
Request-2	Service-HTTP-3; (N = 2)	N = 4	Service-HTTP-3 has the lowest N value.
Request-3	Service-HTTP-3; (N = 4)	N = 6	Service-HTTP-3 has the lowest N value.
Request-4	Service-HTTP-3; (N = 6)	N = 8	Service-HTTP-3 has the lowest N value.
Request-5	Service-HTTP-2; (N = 7)	N = 8	Service-HTTP-2 has the lowest N value.
Request-6	Service-HTTP-3; (N = 8)	N = 10	Service-HTTP-2 and Service-HTTP-3 have the same N values. NetScaler appliance switches to the round robin method and selects Service-HTTP-3
Request-7	Service-HTTP-2; (N = 8)	N = 9	Service-HTTP-2 has the lowest N value.
Request-8	Service-HTTP-2; (N = 9)	N = 10	Service-HTTP-2 has the lowest N value.

Service-HTTP-1 is again selected for load balancing when it completes its active transactions or when its N value is less than the other services (Service-HTTP-2 and Service-HTTP-3).

### Selection of services when weights are assigned

The NetScaler appliance also performs load balancing by using the number of active transactions, response time, and weights if different weights are assigned to services. The NetScaler appliance selects the service by using the value (Nw) in the following expression:

$$Nw = (N) * (10000 / \text{weight})$$

Where N = (Number of active transactions \* Response time that is determined by the monitor)

The following diagram illustrates how the virtual server uses the LRTM method when weights are assigned.

Figure 2. How the Least Response Time Load Balancing Method Works When Weights Are Assigned

In this example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4.

The NetScaler appliance delivers requests as follows:

- Service-HTTP-3 receives the first request, because it is not handling any active transactions.
- Service-HTTP-3 receives the second, third, fourth, and fifth requests, because this service has the lowest Nw value.
- Service-HTTP-2 receives the sixth request, because this service has the lowest Nw value.
- Service-HTTP-3 receives the seventh request, because this service has the lowest Nw value.
- Service-HTTP-2 receives the eighth requests, because this service has the lowest Nw value.

Service-HTTP-1 has the lowest weight and the highest Nw value, so the NetScaler appliance does not select it for load balancing.

The following table summarizes how Nw is calculated for various monitors.

Request Received	Service Selected	Current Nw Value (N) * (10000 / Weight)	Remarks
Request-1	Service-HTTP-3; (Nw = 0)	Nw = 5000	Service-HTTP-3 has the lowest Nw value.
Request-2	Service-HTTP-3; (Nw = 5000)	Nw = 10000	Service-HTTP-3 has the lowest Nw value.
Request-3	Service-HTTP-3; (Nw = 10000)	Nw = 15000	Service-HTTP-3 has the lowest Nw value.
Request-4	Service-HTTP-3; (Nw = 15000)	Nw = 20000	Service-HTTP-3 has the lowest Nw value.
Request-5	Service-HTTP-3; (Nw = 20000)	Nw = 25000	Service-HTTP-3 has the lowest Nw value.
Request-6	Service-HTTP-2; (Nw = 23333.34)	Nw = 26666.67	Service-HTTP-2 has the lowest Nw value.
Request-7	Service-HTTP-3; (Nw = 25000)	Nw= 30000	Service-HTTP-3 has the lowest Nw value.
Request-8	Service-HTTP-2; (Nw = 26666.67)	Nw = 30000	Service-HTTP-2 has the lowest Nw value.

Service-HTTP-1 is selected for load balancing when it completes its active transactions or when its Nw value is less than other services (Service-HTTP-2 and Service-HTTP-3).

### To configure the LRTM load balancing method by using the CLI

At the command prompt type;

```
1 set lb vsriver <name> [-lbMethod <lbMethod>]
2 <!--NeedCopy-->
```

#### Example:

```
1 set lb vsriver Vserver-LB-1 -lbMethod LRTM
2 <!--NeedCopy-->
```

### To configure the LRTM load balancing method by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In Advanced Settings, select **LRTM**.

### To enable the LRTM option in monitors by using the CLI

At the command prompt type;

```
1 set lb monitor <monitorName> <type> [-LRTM (ENABLED | DISABLED)]
2 <!--NeedCopy-->
```

#### Example:

```
1 set lb monitor monitor-HTTP-1 HTTP -LRTM ENABLED
2 <!--NeedCopy-->
```

### To enable the LRTM option in monitors by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors**, and open a monitor.
2. In Advanced Parameters, select **LRTM (Least Response Time using Monitoring)**.

For more information about configuring monitors, see [Configuring Monitors in a Load Balancing Setup](#).

## Hashing methods

May 2, 2023

Load balancing methods based on hashes of certain connection information or header information constitute most the NetScaler appliance's load balancing methods. Hashes are shorter and easier to use than the information that they are based on, while retaining enough information to ensure that no two different pieces of information generate the same hash and are therefore confused with one another.

You can use the hashing load balancing methods in an environment where a cache serves a wide range of content from the Internet or specified origin servers. Caching requests reduces request and response latency, and ensures better resource (CPU) utilization, making caching popular on heavily used websites and application servers. Since these sites also benefit from load balancing, hashing load balancing methods are widely useful.

The NetScaler appliance provides the following hashing methods:

- URL hash method
- Domain hash method
- Destination IP hash method
- Source IP hash method

- Source IP Destination IP hash method
- Source IP Source Port hash method
- Call ID hash method
- Token method

Most of the hashing algorithms calculate two hash values:

- A hash of the service's IP address and port.
- A hash of the incoming URL, the domain name, the source IP address, the destination IP address, or the source and destination IP addresses, depending on the configured hash method.

The NetScaler appliance then generates a new hash value by using both of those hash values. Finally, it forwards the request to the service with the highest hash value. As the appliance computes a hash value for each request and selects the service that processes the request, it populates a cache. Subsequent requests with the same hash value are sent to the same service. The following flow chart illustrates this process.

Note

Starting from NetScaler release 13.0 build 79.x, Prime Re-Shuffled Assisted CARP (PRAC) and Jump table Assisted Ring Hash (JARH) consistent hashing algorithms are supported. The consistent hashing algorithms ensure minimal disruption when services are added to or deleted from your load balancing setup, or during a service flap event in load balancing setup. For more details, see [Consistent hashing algorithms](#).

Figure 1. How the Hashing Methods Distribute Requests

Hashing methods can be applied to IPv4 and IPv6 addresses.

Consider a scenario where three services (Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3) are bound to a virtual server, any hash method is configured, and the hash value is Hash1. When the configured services are UP, the request is sent to Service-HTTP-1. If Service-HTTP-1 is down, the NetScaler appliance calculates the hash value for the last log of the number of services. The appliance then selects the service with the highest hash value, such as Service-HTTP-2. The following diagram illustrates this process.

Figure 2. Entity Model for Hashing Methods

Note

If the NetScaler appliance fails to select a service by using a hashing method, it defaults to the least connection method to select a service for the incoming request. Adjust server pools by removing services during periods of low traffic to enable the caches to repopulate without affecting performance on your load balancing setup.

### Consistent hashing algorithms

The consistent hashing algorithms are used to achieve stateless persistency. The hash-based LB methods use one of the following three consistent hashing algorithms:

- **Cache Array Routing Protocol (CARP)**

The CARP algorithm is used in load-balancing HTTP requests across multiple proxy cache servers. This algorithm is enabled by default.

- **Prime Re-Shuffled Assisted CARP (PRAC)**

The NetScaler appliance uses the proprietary PRAC algorithm to provide uniform traffic distribution.

- **Jump table Assisted Ring Hash (JARH)**

The NetScaler appliance uses the proprietary JARH algorithm to provide consistency and uniform distribution of the traffic. This algorithm uses hash fingers. Higher number of fingers provide better distribution of traffic. However, increasing the number of fingers increases the memory usage as well.

### To choose the consistent hashing algorithm by using CLI

```
1 set lb parameter [-lbHashAlgorithm [DEFAULT|JARH|PRAC] [-lbHashFingers
 <positive_integer>]
2 <!--NeedCopy-->
```

#### Example:

```
1 set lb parameter -lbHashAlgorithm JARH -lbHashFingers 10
2 <!--NeedCopy-->
```

#### ARGUMENTS:

- **lbHashAlgorithm**-Specify the hashing algorithm to be used for the following hash-based load balancing methods:
  - URL hash method
  - Domain hash method
  - Destination IP hash method
  - Source IP hash method
  - Source IP Destination IP hash method
  - Source IP Source Port hash method
  - Call ID hash method
  - Token method

Possible values: DEFAULT, PRAC, JARH

Default value: DEFAULT

- **lbHashFingers**-Specify the number of fingers to be used in PRAC and JARH algorithms for hash-based LB methods. Increasing the number of fingers provides better distribution of traffic at the expense of extra memory.

Default value: 256  
Minimum value: 1  
Maximum value: 1024

**To choose the consistent hashing algorithm by using GUI**

1. Navigate to **Traffic Management > Load Balancing > Change Load Balancing parameters.**
2. In the **Configure Load Balancing Parameters** pane, enter appropriate values for the following fields based on your requirement:
  - LB Hash Fingers
  - In the **LB Hash Algorithm** field, choose the consistent hashing algorithm from the drop-down menu.

← Configure Load Balancing Parameters

**The URL Hash Method**

When you configure the NetScaler appliance to use the URL hash method for load balancing the services, for selecting a service, the appliance generates a hash value of the HTTP URL present in the

incoming request. If the service selected by the hash value is DOWN, the algorithm has a method to select another service from the list of active services. The appliance caches the hashed value of the URL, and when it receives subsequent requests that use the same URL, it forwards them to the same service. If the appliance cannot parse an incoming request, it uses the round robin method for load balancing instead of the URL hash method.

For generating the hash value, the appliance uses a specific algorithm and considers a part of the URL. By default, the appliance considers the first 80 bytes of the URL. If the URL is of less than 80 bytes, the complete URL is used. You can specify a different length. The hash length can be from 1 byte to 4096 bytes. Generally, if long URLs are used where only a few characters are different, it is a good idea to make the hash length as high as possible to try to ensure a more even load distribution.

Consider a scenario where three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3, are bound to a virtual server, and the load balancing method configured on the virtual server is the URL hash method. The virtual server receives a request and the hash value of the URL is U1. Appliance selects Service-HTTP-1. If Service-HTTP-1 is DOWN, the appliance selects Service-HTTP-2.

The following diagram illustrates this process.

Figure 3. How URL Hashing Operates

If both Service-HTTP-1 and Service-HTTP-2 are DOWN, the appliance sends requests with hash value

U1 to Service-HTTP-3.

If Service-HTTP-1 and Service-HTTP-2 are down, requests that generate the hash URL1 are sent to Service-HTTP-3. If these services are UP, the requests that generate the hash URL1 are distributed in the following manner:

- If the Service-HTTP-2 is up, the request is sent to Service-HTTP-2.
- If the Service-HTTP-1 is up, the request is sent to Service-HTTP-1.
- If Service-HTTP-1 and Service-HTTP-2 are up at the same time, the request is sent to Service-HTTP-1.

To configure the URL hash method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#). Select the load balancing method as URL Hash, and set the hash length to the number of bytes to be used for generating the hash value.

## The Domain Hash Method

A load balancing virtual server configured to use the domain hash method uses the hashed value of the domain name in the HTTP request to select a service. The domain name is taken from either the incoming URL or the Host header of the HTTP request. If the domain name appears in both the URL and the Host header, the appliance gives preference to the URL.

If you configure domain name hashing, and an incoming HTTP request does not contain a domain name, the NetScaler appliance defaults to the round robin method for that request.

The hash-value calculation uses the name length or hash length value, whichever is smaller. By default, the NetScaler appliance calculates the hash value from the first 80 bytes of the domain name. To specify a different number of bytes in the domain name when calculating the hash value, you can set the hashLength parameter (Hash Length in the configuration utility) to a value of from 1 to 4096 (bytes).

To configure the domain hash method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

## The Destination IP Hash Method

A load balancing virtual server configured to use the destination IP hash method uses the hashed value of the destination IP address to select a server. You can mask the destination IP address to specify which part of it to use in the hash value calculation, so that requests that are from different networks but destined for the same subnet are all directed to the same server. This method supports IPv4 and IPv6-based destination servers.

This load balancing method is appropriate for use with the cache redirection feature.

To configure the destination IP hash method for an IPv4 destination server, you set the netMask parameter. To configure this method for an IPv6 destination server, you use the v6NetMaskLen parameter. In the configuration utility, text boxes for setting these parameters appear when you select the **Destination IP Hash method**.

To configure the destination IP hash method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

### **The Source IP Hash Method**

A load balancing virtual server configured to use the source IP hash method uses the hashed value of the client IPv4 or IPv6 address to select a service. To direct all requests from source IP addresses that belong to a particular network to a specific destination server, you must mask the source IP address. For IPv4 addresses, use the netMask parameter. For IPv6 addresses, use the v6NetMaskLength parameter.

To configure the source IP hash method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

### **The Source IP Destination IP Hash Method**

A load balancing virtual server configured to use the source IP destination IP hash method uses the hashed value of the source and destination IP addresses (either IPv4 or IPv6) to select a service. Hashing is symmetric. The hash value is the same regardless of the order of the source and destination IPs. This ensures that all packets flowing from a particular client to the same destination are directed to the same server.

To direct all requests that belong to a particular network to a specific destination server, you must mask the source IP address. For IPv4 addresses, use the netMask parameter. For IPv6 addresses, use the v6NetMaskLength parameter.

To configure the source IP destination IP hash method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

### **The Source IP Source Port Hash Method**

A load balancing virtual server configured to use the source IP source port hash method uses the hash value of the source IP (either IPv4 or IPv6) and the source port to select a service. This ensures that all packets on a particular connection are directed to the same service.

This method is used in connection mirroring and firewall load balancing. For more information about connection mirroring, see [Connection Failover](#).

To direct all requests that belong to a particular network to a specific destination server, you must mask the source IP address. For IPv4 addresses, use the `netMask` parameter. For IPv6 addresses, use the `v6NetMaskLength` parameter.

To configure the source IP source port hash method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

## The Call ID Hash Method

A load balancing virtual server configured to use the call ID hash method uses the hash value of the call ID in the SIP header to select a service. Packets for a particular SIP session are therefore always directed to the same proxy server.

This method is applicable to SIP load balancing. For more information about SIP load balancing, see [Monitoring SIP Services](#).

To configure the call ID hash method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

## Least bandwidth method

May 2, 2023

A load balancing virtual server configured to use the least bandwidth method selects the service that is currently serving the least amount of traffic, measured in megabits per second (Mbps). The following example shows how the virtual server selects a service for load balancing by using the least bandwidth method.

Consider three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3.

- Service-HTTP-1 has 3 Mbps bandwidth.
- Service-HTTP-2 has 5 Mbps bandwidth.
- Service-HTTP-3 has 2 Mbps bandwidth.

The following diagram illustrates how the virtual server uses the least bandwidth method to forward requests to the three services.

Figure 1. How the Least Bandwidth Load Balancing Method Works

The virtual server selects the service by using the bandwidth value (N), which is the sum of the number of bytes transmitted and received over the previous 14 seconds. If each request requires 1 Mbps bandwidth, the NetScaler appliance delivers requests as follows:

- Service-HTTP-3 receives the first request, because this service has the lowest N value.
- Because Service-HTTP-1 and Service-HTTP-3 now have the same N value, the virtual server switches to the round robin method for these servers, alternating between them. Service-HTTP-1 receives the second request, Service-HTTP-3 receives the third request, Service-HTTP-1 receives the fourth request, Service-HTTP-3 receives the fifth request, and Service-HTTP-1 receives the sixth request.
- Since Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 now all have the same N value, the virtual server includes Service-HTTP-2 in the round robin list. Therefore, Service-HTTP-2 receives the seventh request, Service-HTTP-3 receives the eighth request, and so on.

The following table summarizes how N is calculated.

Request Received	Service Selected	Current N Value	Remarks
Request-1	Service-HTTP-3; (N = 2)	N = 3	Service-HTTP-3 has the lowest N value.

Request Received	Service Selected	Current N Value	Remarks
Request-2	Service-HTTP-1; (N = 3)	N = 4	Service-HTTP-1 and Service-HTTP-3 have the same N values.
Request-3	Service-HTTP-3;(N = 3)	N = 4	Service-HTTP-1 and Service-HTTP-3 have the same N values.
Request-4	Service-HTTP-1; (N = 4)	N = 5	-
Request-5	Service-HTTP-3; (N = 4)	N = 5	-
Request-6	Service-HTTP-1; (N = 5)	N = 6	Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 have the same N values.
Request-7	Service-HTTP-2; (N = 5)	N = 6	Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 have the same N values.
Request-8	Service-HTTP-3; (N = 5)	N = 6	-

Note: If you enable the RTSP NAT option on the virtual server, the NetScaler appliance uses the number of data and control bytes exchanged to determine the bandwidth usage for RTSP services. For more information about the RTSP NAT option, see [Managing RTSP Connections](#).

The NetScaler appliance also performs load balancing by using the bandwidth and weights if different weights are assigned to the services. It selects a service by using the value (Nw) in the following expression:

$$Nw = (N) * (10000 / \text{weight})$$

As in the preceding example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4. The NetScaler appliance delivers requests as follows:

- Service-HTTP-3 receives the first second, third, fourth, and fifth requests, because this service has the lowest Nw value.
- Service-HTTP-1 receives the sixth request, because this service has the lowest Nw value.
- Service-HTTP-3 receives the seventh request, because this service has the lowest Nw value.
- Service-HTTP-2 receives the eighth request, because this service has the lowest Nw value.

The following table summarizes how Nw is calculated.

Request Received	Service Selected	Current Nw Value (Number of Active Transactions) * (10000 / Weight)	Remarks
Request-1	Service-HTTP-3; (Nw = 5000)	Nw = 5000	Service-HTTP-3 has the lowest Nw value.
Request-2	Service-HTTP-3; (Nw = 5000)	Nw = 7500	-
Request-3	Service-HTTP-3; (Nw = 7500)	Nw = 10000	-
Request-4	Service-HTTP-3; (Nw = 10000)	Nw = 12500	-
Request-5	Service-HTTP-3; (Nw = 12500)	Nw = 15000	-
Request-6	Service-HTTP-1; (Nw = 15000)	Nw = 20000	Service-HTTP-1 and Service-HTTP-3 have the same Nw value.
Request-7	Service-HTTP-3; (Nw = 15000)	Nw = 17500	Service-HTTP-1 and Service-HTTP-3 have the same Nw value.
Request-8	Service-HTTP-2; (Nw = 16666.67)	Nw = 20000	Service-HTTP-2 has the lowest Nw value.

The following diagram illustrates how the virtual server uses the least bandwidth method when weights are assigned to the services.

Figure 2. How the Least Bandwidth Load Balancing Method Works When Weights Are Assigned

To configure the least bandwidth method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

## Least packets method

May 2, 2023

A load balancing virtual server configured to use the least packets method selects the service that has received the fewest packets in the last 14 seconds.

For example, consider three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3.

- Service-HTTP-1 has handled three packets in the last 14 seconds.
- Service-HTTP-2 has handled five packets in the last 14 seconds.
- Service-HTTP-3 has handled two packets in the last 14 seconds.

The following diagram illustrates how the NetScaler appliance uses the least packets method to choose a service for each request that it receives.

Figure 1. How the Least Packets Load Balancing Method Works

The NetScaler appliance selects a service by using the number of packets (N) transmitted and received by each service in the last 14 seconds. Using this method, it delivers requests as follows:

- Service-HTTP-3 receives the first request, because this service has the lowest N value.
- Since Service-HTTP-1 and Service-HTTP-3 now have the same N value, the virtual server switches to the round robin method. Service-HTTP-1 therefore receives the second request, Service-HTTP-3 receives the third request, Service-HTTP-1 receives the fourth request, Service-HTTP-3 receives the fifth request, and Service-HTTP-1 receives the sixth request.
- Since Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 all now have the same N value, the virtual server switches to the round robin method for Service-HTTP-2 as well, including it in the round robin list. Therefore, Service-HTTP-2 receives the seventh request, Service-HTTP-3 receives the eighth request, and so on.

The following table summarizes how N is calculated.

Request Received	Service Selected	Current N Value	Remarks
Request-1	Service-HTTP-3; (N = 2)	N = 3	Service-HTTP-3 has the lowest N value.

Request Received	Service Selected	Current N Value	Remarks
Request-2	Service-HTTP-1; (N = 3)	N = 4	Service-HTTP-1 and Service-HTTP-3 have the same N values.
Request-3	Service-HTTP-3; (N = 3)	N = 4	Service-HTTP-1 and Service-HTTP-3 have the same N values.
Request-4	Service-HTTP-1; (N = 4)	N = 5	-
Request-5	Service-HTTP-3; (N = 4)	N = 5	-
Request-6	Service-HTTP-1; (N = 5)	N = 6	Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 have the same N values.
Request-7	Service-HTTP-2; (N = 5)	N = 6	Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 have the same N values.
Request-8	Service-HTTP-3; (N = 5)	N = 6	-

Note: If you enable the RTSP NAT option on the virtual server, the appliance uses the number of data and control packets to calculate the number of packets for RTSP services. For more information about the RTSP NAT option, see [Managing RTSP Connections](#).

The NetScaler appliance also performs load balancing by using the number of packets and weights when a different weight is assigned to each service. It selects a service by using the value (Nw) in the following expression:

$$Nw = (N) * (10000 / \text{weight})$$

As in the preceding example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4. The NetScaler appliance delivers requests as follows:

- Service-HTTP-3 receives the first second, third, fourth, and fifth requests, because this service has the lowest Nw value.
- Service-HTTP-1 receives the sixth request, because this service has the lowest Nw value.
- Service-HTTP-3 receives the seventh request, because this service has the lowest Nw value.
- Service-HTTP-2 receives the eighth request, because this service has the lowest Nw value.

The following table summarizes how Nw is calculated.

Request Received	Service Selected	Current Nw Value (Number of Active Transactions) * (10000 / weight)	Remarks
Request-1	Service-HTTP-3; (Nw = 5000)	Nw = 5000	Service-HTTP-3 has the lowest Nw value.
Request-2	Service-HTTP-3; (Nw = 5000)	Nw = 7500	-
Request-3	Service-HTTP-3; (Nw = 7500)	Nw = 10000	-
Request-4	Service-HTTP-3; (Nw = 10000)	Nw = 12500	-
Request-5	Service-HTTP-3; (Nw = 12500)	Nw = 15000	-
Request-6	Service-HTTP-1; (Nw = 15000)	Nw = 20000	Service-HTTP-1 and Service-HTTP-3 have the same Nw value.
Request-7	Service-HTTP-3; (Nw = 15000)	Nw = 17500	Service-HTTP-1 and Service-HTTP-3 have the same Nw value.
Request-8	Service-HTTP-2; (Nw = 16666.67)	Nw = 20000	Service-HTTP-2 has the lowest Nw value.

The following diagram illustrates how the virtual server uses the least packets method when weights are assigned.

Figure 2. How the Least Packets Method Works When Weights Are Assigned

To configure the least packets method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

## Custom load method

May 2, 2023

Custom load balancing is performed on server parameters such as CPU usage, memory, and response time. When using the custom load method, the NetScaler appliance usually selects a service that is not handling any active transactions. If all the services in the load balancing setup are handling active transactions, the appliance selects the service with the smallest load. A special type of monitor, known as a load monitor, calculates the load on each service in the network. The load monitors do not mark the state of a service, but they do take services out of the load balancing decision when those services are not UP.

For more information about load monitors, see [Understanding Load Monitors](#). The following diagram illustrates how a load monitor operates.

Figure 1. How Load Monitors Operate

The load monitor uses SNMP probes to calculate the load on each service by sending an SNMP GET request to the service. This request contains one or more object IDs (OIDs). The service responds with an SNMP GET response, with metrics corresponding to the SNMP OIDs. The load monitor uses the response metrics to calculate the load on the service.

The load monitor calculates the load on a service by using the following parameters:

- Metrics values retrieved through SNMP probes that exist as tables in the NetScaler appliance.
- Threshold value set for each metric.
- Weight assigned to each metric.

For example, consider three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3.

- Service-HTTP-1 is using 20 MB of memory.
- Service-HTTP-2 is using 70 MB of memory.
- Service-HTTP-3 is using 80 MB of memory.

The load balanced servers can export metrics such as CPU and memory usage to the services, which can in turn provide them to the load monitor. The load monitor sends an SNMP GET request containing the OIDs 1.3.6.1.4.1.5951.4.1.1.41.1.5, 1.3.6.1.4.1.5951.4.1.1.41.1.4, and 1.3.6.1.4.1.5951.4.1.1.41.1.3 to the services. SNMP OIDs of type STRING are not supported, because you cannot calculate the load by

using a STRING OID. Loads can be calculated by using other data types, such as INT and gauge32. The three services respond to the request. The NetScaler appliance compares the exported metrics, and then selects Service-HTTP-1 because it has more available memory. The following diagram illustrates this process.

Figure 2. How the Custom Load Method Works

If each request uses 10 MB memory, the NetScaler appliance delivers requests as follows:

- Service-HTTP-1 receives the first, second, third, fourth, and fifth requests, because this service has the lowest N value.
- Service-HTTP-1 and Service-HTTP-2 now have the same load, so the virtual server reverts to the round robin method for these servers. Therefore, Service-HTTP-2 receives the sixth request, and Service-HTTP-1 receives the seventh request.
- Since Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 all now have the same load, the virtual server reverts to the round robin method for Service-HTTP-3 as well. Therefore, Service-HTTP-3 receives the eighth request.

The following table summarizes how N is calculated.

Request received	Service selected	Current N Value (Number of Active Transactions)	Remarks
Request-1	Service-HTTP-1; (N = 20)	N = 30	Service-HTTP-3 has the lowest N value.
Request-2	Service-HTTP-1; (N = 30)	N = 40	-
Request-3	Service-HTTP-1; (N = 40)	N = 50	-
Request-4	Service-HTTP-1; (N = 50)	N = 60	-
Request-5	Service-HTTP-1; (N = 60)	N = 70	-
Request-6	Service-HTTP-1; (N = 70)	N = 80	Service-HTTP-2 and Service-HTTP-3 have the same N values.
Request-7	Service-HTTP-2; (N = 70)	N = 80	Service-HTTP-3 have the same N values.
Request-8	Service-HTTP-1; (N = 80)	N = 90	Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 have the same N values.

If different weights are assigned to the services, the custom load algorithm considers both the load on each service and the weight assigned to each service. It selects a service by using the value (Nw) in the following expression:

$$Nw = (N) * (10000 / \text{weight})$$

As in the preceding example, suppose Service-HTTP-1 is assigned a weight of 4, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 2. If each request uses 10 MB memory, the NetScaler appliance delivers requests as follows:

- Service-HTTP-1 receives the first, second, third, fourth, fifth, sixth, seventh, and eighth requests, because this service has the lowest Nw value.
- Service-HTTP-2 receives the ninth request, because this service has the lowest Nw value.

Service-HTTP-3 has the highest Nw value, and is therefore not considered for load balancing.

The following table summarizes how Nw is calculated.

Request received	Service selected	Current Nw Value (Number of Active Transactions) * (10000 / Weight)	Remarks
Request-1	Service-HTTP-1; (Nw = 50000)	Nw = 75000	Service-HTTP-1 has the lowest Nw value.
Request-2	Service-HTTP-1; (Nw = 5000)	Nw = 100000	-
Request-3	Service-HTTP-1; (Nw = 15000)	Nw = 125000	-
Request-4	Service-HTTP-1; (Nw = 20000)	Nw = 150000	-
Request-5	Service-HTTP-1; (Nw = 23333.34)	Nw = 175000	-
Request-6	Service-HTTP-1; (Nw = 25000)	Nw = 200000	-
Request-7	Service-HTTP-1; (Nw = 23333.34)	Nw = 225000	-
Request-8	Service-HTTP-1; (Nw = 25000)	Nw = 250000	-
Request-9	Service-HTTP-2; (Nw = 233333.34)	Nw = 266666.67	Service-HTTP-2 has the lowest Nw value.

Service-HTTP-1 is selected for load balancing when it completes its active transactions or when the Nw value of other services (Service-HTTP-2 and Service-HTTP-3) is equal to 400,000.

The following diagram illustrates how the NetScaler appliance uses the custom load method when weights are assigned.

Figure 3. How the Custom Load Method Works When Weights Are Assigned

To configure the custom load method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

## Static proximity method

June 12, 2023

When a virtual server is configured to use the static proximity method, it selects the service that best matches the proximity criteria.

For the static proximity method to work, you must either configure the NetScaler appliance to use an existing static proximity database populated through a location file or add custom entries to the static proximity database. After adding custom entries, you can set their location qualifiers. After configuring the database, you are ready to specify static proximity as the load balancing method.

For more details, see the following topics.

- [Adding a Location File to Create a Static Proximity Database](#)
- [Adding Custom Entries to a Static Proximity Database](#)

- [Setting the Location Qualifiers](#)
- Specifying the Static Proximity method

## Specifying the Proximity Method

When you have configured the static proximity database, you are ready to specify static proximity as the GLSB method.

### To specify static proximity by using the command line interface

At the command prompt, type the following commands to configure static proximity and verify the configuration:

```
1 set lb vserver <name> -lbMethod STATICPROXIMITY
2
3 show lb vserver <name>
4 <!--NeedCopy-->
```

#### Example:

```
1 set lb vserver Vserver-LB-1 -lbMethod STATICPROXIMITY
2
3 show lb vserver
4 <!--NeedCopy-->
```

### To specify static proximity by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers** and select the virtual server.
2. Click **Edit** and expand the **Method** section.
3. In the **Load Balancing Method** list, select **STATICPROXIMITY**.

#### Note

Enable the proximityFromSelf parameter to use the Netscaler's loopback IP address instead of the client's IP address to fetch the closest server location for static proximity load balancing or GSLB decision.

## Token method

May 2, 2023

A load balancing virtual server configured to use the token method bases its selection of a service on the value of a data segment extracted from the client request. The data segment is called the token. You configure the location and size of the token. For subsequent requests with the same token, the virtual server chooses the same service that handled the initial request.

This method is content aware. It operates differently for TCP, HTTP, and HTTPS connections. For HTTP or HTTPS services, the token is found in the HTTP headers, the URL, or the BODY. To locate the token, you specify or create a classic or advanced expression. For more information on classic or advanced expressions, see [Policy Configuration and Reference](#).

For HTTP services, the virtual server searches for the configured token in the first 24 kilobytes (KB) of the TCP payload. For non-HTTP (TCP, SSL, and SSL\_TCP) services, the virtual server searches for the configured token in the first 16 packets if the total size of the 16 packets is less than 24 KB. But if the total size of the 16 packets is greater than 24 KB, the appliance searches for the token in the first 24 KB of payload. You can use this load balancing method across virtual servers of different types to make sure that requests presenting the same token are directed to appropriate services, regardless of the protocol used.

For example, consider a load balancing setup consisting of servers that contain Web content. You want to configure the NetScaler appliance to search for a specific string (the token) inside the URL query portion of the request. Server-1 has two services, Service-HTTP-1 and Service-TCP-1, and Server-2 has two services, Service-HTTP-2 and Service-TCP-2. The TCP services are bound to Vserver-LB-2, and the HTTP services are bound to Vserver-LB-1.

If Vserver-LB-1 receives a request with the token AA, it selects the service Service-HTTP-1 (bound to server-1) to process the request. If Vserver-LB-2 receives a different request with the same token (AA), it directs this request to the service Service-TCP-1. The following diagram illustrates this process.

Figure 1. How the Token Method Works

### To configure the Token load balancing method by using the command line interface

At the command prompt, type the following commands to configure the token load balancing method and verify the configuration:

```

1 set lb vserver <name> -lbMethod TOKEN -rule <rule> -datalength <length>
 -dataoffset <offset>
2
3 show lb vserver <name>
4 <!--NeedCopy-->

```

#### Example:

```

1 set lb vserver LB-VServer-1 -lbMethod TOKEN -rule 'AA' -datalength 2 -
 dataoffset 25
2
3 show lb vserver LB-VServer-1
4 <!--NeedCopy-->

```

## To configure the token load balancing method by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In Advanced Settings, click Method
3. In the Load Balancing Method list, select Token, and specify an expression.

## Least requests method

January 16, 2024

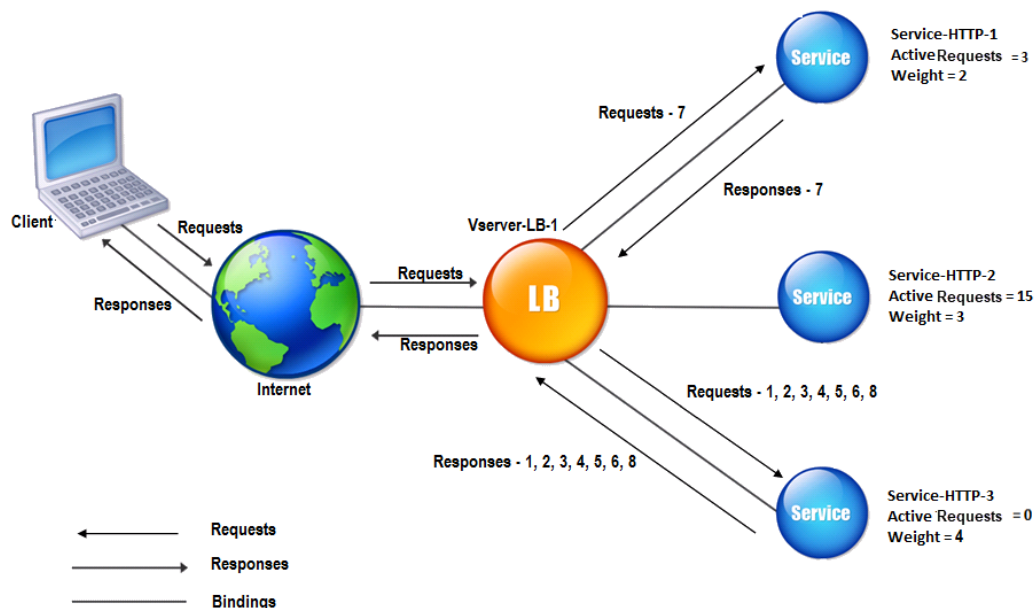

A load balancing virtual server configured to use the least request method selects the service that has received the fewest requests.

For example, consider three services, Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3.

- Service-HTTP-1 is handling 3 requests.
- Service-HTTP-2 is handling 15 requests.
- Service-HTTP-3 is not handling any requests.

The following diagram illustrates how NetScaler uses the least requests method to choose a service for each request that it receives.

Figure 1. How the Least Request Load Balancing Method Works

In this example, the virtual server selects the service for each incoming request by choosing the server with the fewest requests.

Requests are forwarded as follows:

- Service-HTTP-3 receives the first request, because it is not handling any request.  
Note: The service with no request is selected first.
- Service-HTTP-3 receives the second and third requests because the service has the next least number of requests.
- Service-HTTP-1 receives the fourth request because Service-HTTP-1 and Service-HTTP-3 have the same number of requests, the virtual server uses the round robin method to choose between them.
- Service-HTTP-3 receives the fifth request.
- Service-HTTP-1 receives the sixth request, and so on, until both Service-HTTP-1 and Service-HTTP-3 are handling the same number of requests as Service-HTTP-2. Then, NetScaler starts forwarding requests to Service-HTTP-2 when it is the least loaded service or its turn comes up in the round robin queue.

**Note:**

If requests to Service-HTTP-2 is completed, it might get new request before each of the other two

services has 15 requests.

The following table explains how requests are distributed among the services in the load balancing setup.

Incoming requests	Service selected	Current number of requests	Remarks
Request-1	Service-HTTP-3; (N = 0)	1	Service-HTTP-3 has the fewest requests.
Request-2	Service-HTTP-3; (N = 1)	2	Service-HTTP-3 has the fewest requests.
Request-3	Service-HTTP-3; (N = 2)	3	-
Request-4	Service-HTTP-1; (N = 3)	4	Service-HTTP-1 and Service-HTTP-3 have the same number of requests.
Request-5	Service-HTTP-3; (N = 3)	4	Service-HTTP-1 and Service-HTTP-3 have the same number of requests.
Request-6	Service-HTTP-1;(N = 4)	5	-
Request-7	Service-HTTP-3; (N = 4)	5	-
Request-8	Service-HTTP-1; (N = 5)	6	-

Service-HTTP-2 is selected for load balancing when it completes all the requests, or when the other services (Service-HTTP-1 and Service-HTTP-3) have 15 or more requests each.

NetScaler can also use the least request method when weights are assigned to services. It selects a service by using the value (Nw) of the following expression:

$$Nw = (\text{Number of active requests}) * (10000 / \text{weight})$$

The following example shows how NetScaler selects a service for load balancing by using the least request method when weights are assigned to services. In the preceding example, suppose Service-HTTP-1 is assigned a weight of 2, Service-HTTP-2 is assigned a weight of 3, and Service-HTTP-3 is assigned a weight of 4. Requests are forwarded as follows:

- Service-HTTP-3 receives the first request because the service is not handling any requests.

Note: If the services are not handling any requests, NetScaler uses the round robin method regardless of the weights assigned to each of the services.

- Service-HTTP-3 receives the second, third, fourth, fifth, and sixth requests because the service has the lowest Nw value.
- Service-HTTP-1 receives the seventh request. Because Service-HTTP-1 and Service-HTTP-3 now have the same Nw value, the appliance performs load balancing in a round robin manner. Therefore, Service-HTTP-3 receives the eighth request.

The following table explains how requests are distributed on the three-service load balancing setup that is described earlier.

Request Received	Service Selected	Current Nw (Number of requests) * (10000 / weight) value	Remarks
Request-1	Service-HTTP-3; (Nw = 0)	Nw = 2500	Service-HTTP-3 has the lowest Nw value.
Request-2	Service-HTTP-3; (Nw = 2500)	Nw = 5000	
Request-3	Service-HTTP-3; (Nw = 5000)	Nw = 7500	
Request-4	Service-HTTP-3; (Nw = 7500)	Nw = 10000	
Request-5	Service-HTTP-3; (Nw = 10000)	Nw = 12500	
Request-6	Service-HTTP-3; (Nw = 12500)	Nw = 15000	
Request-7	Service-HTTP-1; (Nw = 15000)	Nw = 20000	Service-HTTP-1 and Service-HTTP-3 have the same Nw values
Request-8	Service-HTTP-3; (Nw = 15000)	Nw = 17500	

Service-HTTP-2 is selected for load balancing when it completes its requests or when the Nw value of other services (Service-HTTP-1 and Service-HTTP-3) is equal to 50000.

The following diagram illustrates how NetScaler uses the least request method when weights are assigned to the services.

Figure 2. Mechanism of the Least Requests Load Balancing Method when Weights are Assigned

To configure the least request method, see [Configuring a Load Balancing Method that Does Not Include a Policy](#).

## Configure a load balancing method that does not include a policy

May 2, 2023

After you select a load balancing algorithm for your load balancing setup, you must configure the NetScaler appliance to use that algorithm. You can configure it by using the CLI or by using the configuration utility.

Note:

The token method is policy based and requires more configuration than is described here. To configure the token method, see [Token method](#).

For some hash-based methods, you can mask an IP address to direct requests belonging to the same subnet to the same server. For more information, see [Hashing methods](#).

### To set the load balancing method by using the command line interface

At the command prompt, type:

```
1 set lb vserver <name> -lbMethod <method>
2 <!--NeedCopy-->
```

**Example:**

```
1 set lb vserver Vserver-LB-1 -lbMethod LeastConnection
2 <!--NeedCopy-->
```

**To set the load balancing method by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In Advanced Settings, click **Method**, and in the Load Balancing Method list, select a method.

**Persistence and persistent connections**

May 2, 2023

A load balancing stateless protocol, such as HTTP, disrupts the maintenance of state information about client connections if persistence is not configured. Different transmissions from the same client might be directed to different servers even though all the transmissions are part of the same session. You can configure persistence on a load balancing virtual server that handles certain types of Web applications, such as shopping cart applications.

Before you can configure persistence, you need to understand the different types of persistence, how they are used, and what their implications are. You then need to configure the NetScaler appliance to provide persistent connections for those websites and Web applications that require them.

You can also configure backup persistence, which takes effect if the primary type of persistence configured for a load balancing virtual server fails. You can configure persistence groups, so that a client transmission to any virtual server in a group can be directed to a server that has received previous transmissions from the same client.

For information about persistence with RADIUS load balancing, see [Configuring RADIUS Load Balancing with Persistence](#).

**About Persistence**

May 2, 2023

You can choose from among any of several types of persistence for a given load balancing virtual server, which then routes to the same service all connections from the same user to your shopping cart application, web-based email, or other network application. The persistence session remains in effect for the time which you specify.

If a server participating in a persistence session goes DOWN, the load balancing virtual server uses the configured load balancing method to select a new service, and establishes a new persistence session with the server represented by that service. If the server goes OUT OF SERVICE, it continues to process existing persistence sessions, but the virtual server does not direct any new traffic to it. After the shutdown period elapses, the virtual server ceases to direct connections from existing clients to the service, closes existing connections, and redirects those clients to new services if necessary.

Depending on the persistence type you configure, the NetScaler appliance might examine the source IPs, destination IPs, SSL session IDs, Host or URL headers, or some combination of these things to place each connection in the proper persistence session. It might also base persistence on a cookie issued by the Web server, on an arbitrarily assigned token, or on a logical rule. Almost anything that allows the appliance to match connections with the proper persistence session and is used as the basis for persistence.

The following table summarizes the persistence types available on the NetScaler appliance.

---

Persistence Type	Description
Source IP	SOURCEIP. Connections from the same client IP address are parts of the same persistence session.
HTTP Cookie	COOKIEINSERT. Connections that have the same HTTP Cookie header are parts of the same persistence session.
SSL Session ID	SSLSESSION. Connections that have the same SSL Session ID are parts of the same persistence session.
URL Passive	URLPASSIVE. Connections to the same URL are treated as parts of the same persistence session.
Custom Server ID	CUSTOMSERVERID. Connections with the same HTTP HOST header are treated as parts of the same persistence session.
Destination IP	DESTIP. Connections to the same destination IP are treated as parts of the same persistence session.

Persistence Type	Description
Source and Destination IPs	SRCIPDESTIP. Connections that are both from the same source IP and to the same destination IP are treated as parts of the same persistence session.
SIP Call ID	CALLID. Connections that have the same call ID in the SIP header are treated as parts of the same persistence session.
RTSP Session ID	RTSPSID. Connections that have the same RTSP Session ID are treated as parts of the same persistence session.
User-Defined Rule	RULE. Connections that match a user-defined rule are treated as parts of the same persistence session.

Table 1. Types of Persistence

Depending on the type of persistence that you have configured, the virtual server can support either 250,000 simultaneous persistent connections or any number of persistent connections up to the limits imposed by the amount of RAM on your NetScaler appliance. The following table shows which types of persistence fall into each category.

Persistence Type	Number of Simultaneous Persistent Connections Supported
Source IP, SSL Session ID, Rule, destination IP, source IP/destination IP, SIP Call ID, RTSP Session ID	250 K
Cookie, URL Server ID, Custom Server ID	Memory limit. In CookieInsert, if timeout is not 0, the number of connections is limited by memory.

Table 2. Persistence Types and Numbers of Simultaneous Connections Supported

Some types of persistence are specific to particular types of virtual server. The following table lists each type of persistence and indicates which types of persistence are supported on which types of virtual server.

Persistence								
Type	HTTP	HTTPS	TCP	UDP/IP	SSL_Bridge	SSL_TCP	RTSP	SIP_UDP
<b>SOURCEIP</b>	YES	YES	YES	YES	YES	YES	NO	NO
<b>COOKIEINSERT</b>	YES	YES	NO	NO	NO	NO	NO	NO
<b>SSLSESSION</b>	NO	YES	NO	NO	YES	YES	NO	NO
<b>URLPASSIVE</b>	YES	YES	NO	NO	NO	NO	NO	NO
<b>CUSTOMSERVERID</b>	YES	YES	NO	NO	NO	NO	NO	NO
<b>RULE</b>	YES	YES	YES	NO	NO		NO	NO
<b>SRCIPDESTIPS</b>	YES	YES	YES	YES	YES	YES	NO	NO
<b>DESTIP</b>	YES	YES	YES	YES	YES	YES	NO	NO
<b>CALLID</b>	NO	NO	NO	NO	NO	NO	NO	YES
<b>RTSPID</b>	NO	NO	NO	NO	NO	NO	YES	NO

Table 3. Relationship of Persistence Type to Virtual Server Type

## Source IP address persistence

May 2, 2023

When source IP persistence is configured, the load balancing virtual server uses the configured load balancing method to select a service for the initial request, and then uses the source IP address (client IP address) to identify subsequent requests from that client and send them to the same service. You can set a time-out value, which specifies the maximum inactivity period for the session. When the time-out value expires, the session is discarded, and the configured load balancing algorithm is used to select a new server.

**Caution:** In some circumstances, using persistence based on source IP address can overload your servers. All requests to a single website or application are routed through the single gateway to the NetScaler appliance, even though they are then redirected to multiple locations. In multiple proxy environments, client requests frequently have different source IP addresses even when they are sent from the same client, resulting in rapid multiplication of persistence sessions where a single session must be created. This issue is called the “Mega Proxy problem.” You can use HTTP cookie-based persistence instead of Source IP-based persistence to prevent this from happening.

To configure persistence based on Source IP Address, see [Configuring Persistence Types That Do Not Require a Rule](#).

**Note:** If all incoming traffic comes from behind a Network Address Translation (NAT) device or proxy, the traffic appears to the NetScaler appliance to come from a single source IP address. This prevents Source IP persistence from functioning properly. Where this is the case, you must select a different persistence type.

## HTTP cookie persistence

May 2, 2023

When HTTP cookie persistence is configured, the NetScaler appliance sets a cookie in the HTTP headers of the initial client request. The cookie contains the IP address and port of the service selected by the load balancing algorithm. As with any HTTP connection, the client then includes that cookie with any subsequent requests.

When the NetScaler appliance detects the cookie, it forwards the request to the service IP and port in the cookie, maintaining persistence for the connection. You can use this type of persistence with virtual servers of type HTTP or HTTPS. This persistence type does not consume any appliance resources and therefore can accommodate an unlimited number of persistent clients.

**Note:** If the client's Web browser is configured to refuse cookies, HTTP cookie-based persistence does not work. It might be advisable to configure a cookie check on the website, and warn clients that do not appear to be storing cookies properly that they need to enable cookies for the website if they want to use it.

The format of the cookie that the NetScaler appliance inserts is:

```
NSC_XXXX=<ServiceIP ><ServicePort>
```

Where:

- NSC\_XXXX is the virtual server ID that is derived from the virtual server name.
- ServiceIP and ServicePort are encoded representations of the service IP address and service port, respectively. The IP address and port are encoded separately.

You can set a time-out value for this type of persistence to specify an inactivity period for the session. When the connection has been inactive for the specified period, the NetScaler appliance discards the persistence session. Any subsequent connection from the same client results in a new server being selected based on the configured load balancing method, and a new persistence session being established.

**Note:** If you set the time-out value to 0, the NetScaler appliance does not specify an expiration time, but sets a session cookie that is not saved when the client's browser is shut down.

By default, the NetScaler appliance sets HTTP version 0 cookies for maximum compatibility with client browsers. (Only certain HTTP proxies understand version 1 cookies; most commonly used browsers do not.) You can configure the appliance to set HTTP version 1 cookies, for compliance with RFC2109. For HTTP version 0 cookies, the appliance inserts the cookie expiration date and time as an absolute Coordinated Universal Time (GMT). It calculates this value as the sum of the current GMT time on the appliance and the time-out value. For HTTP version 1 cookies, the appliance inserts a relative expiration time by setting the “Max-Age” attribute of the HTTP cookie. In this case, the client’s browser calculates the actual expiration time.

To configure persistence based on a cookie inserted by the appliance, see [Configuring Persistence Types That Do Not Require a Rule](#).

In the HTTP cookie, the appliance by default sets the `HTTPOnly` flag to indicate that the cookie is nonscriptable and must not be revealed to the client application. Therefore, a client-side script cannot access the cookie, and the client is not susceptible to cross-site scripting.

Certain browsers, however, do not support the `HTTPOnly` flag and, therefore, might not return the cookie. As a result, persistence is broken. For browsers that do not support the flag, you can omit the `HTTPOnly` flag in the persistence cookie.

### To change the `HTTPOnly` flag setting by using the CLI

At the command prompt, type:

```
1 set lb parameter -httpOnlyCookieFlag (ENABLED|DISABLED)
2 <!--NeedCopy-->
```

#### Example:

```
1 > set lb parameter -httpOnlyCookieFlag disabled
2 Done
3 > show lb parameter
4 Global LB parameters:
5 Persistence Cookie HttpOnly Flag: DISABLED
6 Use port for hash LB: YES
7 Done
8 <!--NeedCopy-->
```

### To change the `HTTPOnly` flag setting by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Configure Load Balancing Parameters**, and select or clear the **Persistence Cookie HTTPOnly** flag.

## Encrypting the Cookie

From release 10.5 build 55.8, you can encrypt the cookie in addition to any SSL encryption.

### To encrypt the cookie by using the command line interface, at the command prompt, type

```
1 set lb parameter -UseEncryptedPersistenceCookie ENABLED -
 cookiePassphrase test
2 <!--NeedCopy-->
```

### To encrypt the cookie by using the configuration utility

1. Navigate to **Traffic Management > Change Load Balancing Parameters**, and select **Encode Persistence Cookie Values** and enter a passphrase in **Cookie Passphrase**.

## SSL session ID persistence

May 2, 2023

When SSL session ID persistence is configured, the NetScaler appliance uses the SSL session ID, which is part of the SSL handshake process, to create a persistence session before the initial request is directed to a service. The load balancing virtual server directs subsequent requests that have the same SSL session ID to the same service. This type of persistence is used for SSL bridge services.

### Note:

There are two issues that users must consider before choosing this type of persistence. First, this type of persistence consumes resources on the NetScaler appliance, which limits the number of concurrent persistence sessions that it can support. If you expect to support multiple persistence sessions, you might want to choose another type of persistence.

Second, if the client and the load-balanced server must renegotiate the session ID during their transactions, persistence is not maintained, and a new persistence session is created when the client's next request is received. This might result in the client's activity on the website being interrupted and the client might be asked to reauthenticate or restart the session. It might also result in large numbers of abandoned sessions if the timeout is set to too large a value.

To configure persistence based on SSL session ID, see [Configuring Persistence Types That Do Not Require a Rule](#).

**Note**

SSL session ID persistence is not supported with session tickets.

**Back up persistence support for SSL session ID**

From NetScaler release 12.0 build 56.20, source IP persistence is supported as a backup persistence type for SSL session ID persistence. If the client and load-balanced server renegotiate the session, and source IP persistence is configured as the backup persistence, client requests are forwarded to the same server.

To support backup persistence for SSL session ID, the NetScaler appliance creates session entries for both source IP and SSL session ID when a client request is received for the first time. For the subsequent requests containing the same session ID, the SSL session ID is used. However, when the client and the load-balanced server renegotiate the session, the client request is forwarded to the same server by using the Source IP persistence and a new SSL Session ID persistence entry is created.

For information about configuring backup persistence, see [Configuring Backup Persistence](#).

**Diameter AVP number persistence**

May 2, 2023

You can use persistence based on the Attribute-Value Pair (AVP) number of a Diameter message to create persistent Diameter sessions. When the NetScaler appliance finds the AVP in the Diameter message, it creates a persistence session based on the value of the AVP. All subsequent messages that match the value of the AVP are directed to the previously selected server. If the value of the AVP does not match the persistence session, a new session is created for the new value.

Note: If the AVP number is not defined in Diameter base-protocol RFC 6733, and if the number is nested inside a grouped AVP, you must define a sequence of AVP numbers (maximum of 3) in parent-to-child order. For example, if the persist AVP number X is nested inside AVP Y, which is nested in Z, define the list as Z Y X.

**To configure Diameter-based persistence on a virtual server by using the command line interface**

At the command prompt, type the following command:

```
1 set lb vserver <name> -PersistenceType <type-> persistAVPno <
 positive_integer>
```

```
2 <!--NeedCopy-->
```

**Example:**

```
1 set lb vserver diameter_vs -persistenceType DIAMETER -persistAVPno 263
2 <!--NeedCopy-->
```

## Custom server ID persistence

May 2, 2023

In the Custom Server ID persistence method, the Server ID specified in the client request is used to maintain persistence. For this type of persistence to work, you must first set a server ID on the services. The NetScaler appliance checks the URL of the client request and connects to the server associated with the specified server ID. The service provider must make sure that the users are aware of the server IDs to be provided in their requests for specific services.

For example, if your site provides different types of data, such as images, text, and multimedia, from different servers, you can assign each server a server ID. On the NetScaler appliance, you specify those server IDs for the corresponding services, and you configure custom server ID persistence on the corresponding load balancing virtual server. When sending a request, the client inserts the server ID into the URL indicating the required type of data.

To configure custom server ID persistence:

- In your load balancing setup, assign a server ID to each service for which you want to use the user-defined server ID to maintain persistence. Alphanumeric server IDs are allowed.
- Specify rules, in the default-syntax expression language, to examine the URL queries for the server ID and forward traffic to the corresponding server.
- Configure custom server ID persistence.

**Note:** The persistence time-out value does not affect the Custom Server ID persistence type. There is no limit on the maximum number of persistent clients because this persistence type does not store any client information.

**Example:**

In a load balancing setup with two services, assign server ID 2345-photo-56789 to Service-1, and server ID 2345-drawing-abb123 to Service-2. Bind these services to a virtual server named Web11.

```
1 set service Service-1 10.102.29.5 -CustomServerID 2345-photo-56789
2
3 set service Service-2 10.102.29.6 -CustomServerID 2345-drawing-abb123
4 <!--NeedCopy-->
```

On virtual server Web11, enable Custom Server ID persistence.

Create the following expression so that all URL queries containing the string “sid=” are examined.

HTTP.REQ.URL.AFTER\_STR(“sid=”)

**Example:**

```
1 set lb vserver Web11 -persistenceType customserverID -rule "HTTP.REQ.
 URL.AFTER_STR("sid=")"
2
3 bind lb vserver Web11 Service-[1-2]
4 <!--NeedCopy-->
```

When a client sends a request with the following URL to the IP address of Web11, the appliance directs the request to Service-2 and honors persistence.

**Example:**

<http://www.example.com/index.asp?&sid=2345-drawing-abb123>

For more information about default-syntax policy expressions, see the [Policy Configuration and Reference](#).

### To configure custom server ID persistence by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Open the service and set a server ID.
3. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
4. In Advanced Settings, select Persistence.
5. Select CUSTOMESERVERID, and specify an expression.

## IP address persistence

May 2, 2023

You can base persistence on Destination IP addresses, or on both Source IP and Destination IP Addresses.

### Persistence Based on Destination IP Addresses

With destination IP address-based persistence, when the NetScaler appliance receives a request from a new client, it creates a persistence session based on the IP address of the service selected by the

virtual server (the destination IP address). Later, it directs requests to the same destination IP to the same service. This type of persistence is used with link load balancing. For more information about link load balancing, see [Link Load Balancing](#).

The time-out value for destination IP persistence is the same as that for source IP persistence, described in [Persistence Based on Source IP Address](#).

To configure persistence based on the destination IP address, see [Configuring Persistence Types That Do Not Require a Rule](#).

## **Persistence Based on Source and Destination IP Addresses**

With source and destination IP address-based persistence, when the NetScaler appliance receives a request, it creates a persistence session based on both the IP address of the client (the source IP address) and the IP address of the service selected by the virtual server (the destination IP address). Later, it directs requests from the same source IP and to the same destination IP to the same service.

The time-out value for destination IP persistence is the same as that for source IP persistence, described in [Persistence Based on Source IP Address](#).

To configure persistence based on both source and destination IP addresses, see [Configuring Persistence Types That Do Not Require a Rule](#).

## **SIP Call ID persistence**

May 2, 2023

With SIP Call ID persistence, the NetScaler appliance chooses a service based on the call ID in the SIP header. This enables it to direct packets for a particular SIP session to the same service and, therefore, to the same load balanced server. This persistence type is applicable specifically to SIP load balancing. For more information about SIP load balancing, see [Monitoring SIP Services](#).

To configure persistence based on SIP Call ID, see [Configuring Persistence Types That Do Not Require a Rule](#).

## **RTSP session ID persistence**

May 2, 2023

With RTSP Session ID persistence, when the NetScaler appliance receives a request from a new client, it creates a persistence session based on the Real-Time Streaming Protocol (RTSP) session ID in the RTSP packet header, and then directs the request to the RTSP service selected by the configured load balancing method. It directs subsequent requests that contain the same session ID to the same service. This persistence type is applicable specifically to SIP load balancing. For more information about SIP load balancing, see [Monitoring SIP Services](#).

**Note:** RTSP Session ID persistence is configured by default on RTSP virtual servers, and you cannot modify that setting.

Sometimes different RTSP servers issue the same session IDs. When this happens, unique sessions cannot be created between the client and the RTSP server by using only the RTSP session ID. If you have multiple RTSP servers that might issue the same session IDs, you can configure the appliance to append the server IP address and port to the session ID, creating a unique token that can be used to establish persistence. This is called session ID mapping.

To configure persistence based on RTSP Session IDs, see [Configuring Persistence Types That Do Not Require a Rule](#).

**Important:** If you need to use session ID mapping, you must set the following parameter when configuring each service within the load balancing setup. Also, make sure that no non-persistent connections are routed through the RTSP virtual server.

## Configure URL passive persistence

October 8, 2023

With URL Passive persistence, when the NetScaler appliance receives a request from a client, it extracts the server IP address-port information (expressed as a single hexadecimal number) from the client request.

URL passive persistence requires configuring an advanced expression that specifies the query element that contains the server IP address-port information. For more information about classic and advanced policy expressions, see [Policies and Expressions](#).

The following expression configures the appliance to examine requests for URL queries that contain the string “urlp=”, extract the server IP address-port information, convert it from a hexadecimal string to an IP and port number, and forward the request to the service configured with this IP address and port number.

```
HTTP.REQ.URL.AFTER_STR(“urlp=“)
```

If URL passive persistence is enabled and the previous expression is configured, a request with the following URL and server IP address-port string is directed to 10.102.29.10:80.

`http://www.example.com/index.asp?urlp=0A661D0A0050`

The persistence time-out value does not affect this persistence type. Persistence is maintained as long as the server IP address-port information can be extracted from client requests. This persistence type does not consume any appliance resources, so it can accommodate an unlimited number of persistent clients.

To configure URL passive persistence, you first configure persistence as described in [Configuring Persistence Types That Do Not Require a Rule](#). You set the persistence type to URLPASSIVE. You then perform the following procedures.

### To configure URL passive persistence by using the CLI

At the command prompt, type:

```
1 set lb vserver <vserverName> [-persistenceType <persistenceType>] [-
 rule <expression>]
2 <!--NeedCopy-->
```

#### Example:

```
1 set lb vserver LB-VServer-1 -persistenceType URLPASSIVE - rule HTTP.REQ
 .URL.AFTER_STR(" urlp= ")
2 <!--NeedCopy-->
```

### To configure persistence on a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
2. In the Persistence section, choose the persistence type that meets your requirement. The most suitable persistence type for the virtual server is available as option buttons. Other persistence types that are applicable to the specific virtual server type can be selected from the Others list.

#### Note:

Prior to NetScaler release 12.0 build 56.20, all persistence types are available in a single Persistence drop-down list without any option buttons.

## Configure persistence based on user-defined rules

October 8, 2023

**Warning:**

The use of classic expressions for the persistence rule in the load balancing feature is removed and no longer available for the filter rule on the NetScaler appliance release 13.1 onwards. Citrix recommends that you do not use these policy expressions through the NetScaler command line interface, NetScaler GUI, or Nitro automation. For more information, see Table 1 and Table 2 in the [Classic Policy Deprecation FAQ](#) page.

When rule based persistence is configured, the NetScaler appliance creates a persistence session based on the contents of the matched rule before directing the request to the service selected by the configured load balancing method. Later, it directs all requests that match the rule to the same service. You can configure rule based persistence for services of type HTTP, SSL, RADIUS, ANY, TCP, and SSL\_TCP.

Rule based persistence requires a classic or Advanced policy expression. You can use a classic expression to evaluate request headers, or you can use a Advanced policy expression to evaluate request headers, Web form data in a request, response headers, or response bodies. For example, you can use a classic expression to configure persistence based on the contents of the HTTP Host header. You can also use a Advanced policy expression to configure persistence based on application session information in a response cookie or custom header. For more information on creating and using classic and Advanced policy expressions, see [Policies and Expressions](#).

The expressions that you can configure depend on the type of service for which you are configuring rule based persistence. For example, certain RADIUS-specific expressions are not allowed for protocols other than RADIUS, and TCP-option based expressions are not allowed for service types other than the ANY type. For TCP and SSL\_TCP service types, you can use expressions that evaluate TCP/IP protocol data, Layer 2 data, TCP options, and TCP payloads.

**Note:** For a use case that involves configuring rule based persistence based on Financial Information eXchange (“FIX”) Protocol data transmitted over TCP, see [Configuring Rule Based Persistence Based on a Name-Value Pair in a TCP Byte Stream](#).

Rule based persistence can be used for maintaining persistence with entities such as Citrix SD-WAN appliances, Citrix SD-WAN plug-ins, cache servers, and application servers.

**Note:** On an ANY virtual server, you cannot configure rule-based persistence for the responses.

To configure persistence based on a user-defined rule, you first configure persistence as described in [Configuring Persistence Types That Do Not Require a Rule](#), and set the persistence type to RULE. You can then perform the following procedures. You can configure rule based persistence by using the configuration utility or the CLI.

## To configure persistence based on user-defined rules by using the CLI

At the command prompt, type:

```
1 set lb vserver <vserverName> [-rule <expression>][-resRule <expression
>]
2 <!--NeedCopy-->
```

### Example:

```
1 set lb vserver vsvr_name - rule http.req.header("cookie").value(0).
typecast_nvlist_t('=', ';').value("server")
2
3 set lb vserver vsvr_name - resrule http.res.header("set-cookie").value
(0).typecast_nvlist_t('=', ';').value("server")
4
5 <!--NeedCopy-->
```

## To configure persistence based on user-defined rules by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
2. In the Persistence section, choose the persistence type that meets your requirement. The most suitable persistence type for the virtual server is available as option buttons. Other persistence types that are applicable to the specific virtual server type can be selected from the Others list.

### Note

Prior to NetScaler release 12.0 build 56.20, all persistence types are available in a single Persistence drop-down list without any option buttons.

### Example: Classic Expression for a Request Payload

The following classic expression creates a persistence session based on the presence of a User-Agent HTTP header that contains the string, “MyBrowser”, and directs any subsequent client requests that contain this header and string to the same server that was selected for the initial request.

```
1 http header User-Agent contains MyBrowser
2 <!--NeedCopy-->
```

### Example: Advanced policy Expression for a Request Header

The following Advanced policy expression does the same thing as the previous classic expression. HTTP.REQ.HEADER(“User-Agent”).CONTAINS ( “MyBrowser”)

**Example: Advanced policy Expression for a Response Cookie**

The following expression examines responses for “server” cookies, and then directs any requests that contain that cookie to the same server that was selected for the initial request.

```
HTTP.RES.HEADER("SET-COOKIE").VALUE(0).TYPECAST_NVLIST_T('=',';').VALUE("server")
```

**Configure persistence types that do not require a rule**

October 8, 2023

To configure persistence, you must first set up a load balancing virtual server, as described in [Setting Up Basic Load Balancing](#). You then configure persistence on the virtual server.

**To configure persistence on a virtual server by using the CLI**

At the command prompt, type the following commands to configure persistence and verify the configuration:

```
1 set lb vserver <name> -PersistenceType <type> [-timeout <integer>]
2
3 show lb vserver
4 <!--NeedCopy-->
```

**Example:**

```
1 set lb vserver Vserver-LB-1 -persistenceType SOURCEIP -timeout 60
2
3 show lb vserver
4 <!--NeedCopy-->
```

Timeout is the time period for which a persistence session is in effect. The timeout default and minimum values (in minutes) vary based on the persistence type as listed in the following table.

persistence type	Default value	Minimum value	Maximum value
Cookie insert/group cookie insert	2	0	1440
Other persistence types	2	2	1440

#### Note

- Group cookie insert persistence type can be set on the load balancing group.
- For IP-based persistence, you can also set the persistMask parameter.
- The persistence type by default is set to NONE.

### To configure persistence on a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
2. In the Persistence section, choose the persistence type that meets your requirement. The most suitable persistence type for the virtual server is available as option buttons. Other persistence types that are applicable to the specific virtual server type can be selected from the **Others** list.

**Note** Prior to NetScaler release 12.0 build 56.20, all persistence types are available in a single Persistence drop-down list without any option buttons.

## Configure backup persistence

April 19, 2021

You can configure a virtual server to use the source IP persistence type when the primary persistence type fails.

The following table describes the combinations of primary and secondary backup persistence types, and the conditions when the backup persistence is used.

Primary persistence	Backup persistence	When the primary persistence lookup fails...
Cookie Insert	Source IP	The appliance falls back to source-IP based persistence only when the client browser does not return any cookie in the request. However, if the browser returns a cookie (not necessarily the persistence cookie) it is assumed that the browser supports cookies and hence backup persistence is not triggered.
Rule	Source IP	The appliance uses source-IP based persistence when the parameter specified in the rule is missing in the incoming request.

**Note**

- If the primary persistence type is HTTP-cookie based persistence, and the backup persistence type is Source IP-based, you can set a timeout value for backup persistence. For instructions, see [Setting a Timeout Value for Idle Client Connections](#).
- You cannot set a timeout value for backup persistence when the primary persistence is rule based, because in that case the timeout value for secondary persistence must be the same as for the primary persistence. Therefore, the primary and secondary expire at the same time.

**To set backup persistence for a virtual server by using the command line interface**

At the command prompt, type:

```
1 set lb vserver <name> -persistenceType <PersistenceType> -
 persistenceBackup <BackupPersistenceType>
2 <!--NeedCopy-->
```

**Example:**

```
1 set lb vserver Vserver-LB-1 -persistenceType CookieInsert -
 persistenceBackup SourceIP
```

```
2
3 set lb vserver Vserver-LB-1 -persistenceType sslsession -
 persistenceBackup SourceIP
4
5 set lb vserver Vserver-LB-1 -persistenceType RULE -rule http.req.
 header("User-Agent").value(0).contains("MyBrowser") -
 persistenceBackup SOURCEIP
6
7 set lb vserver Vserver-LB-1 -persistenceType sslsession -
 persistenceBackup SourceIP
8 <!--NeedCopy-->
```

## To set backup persistence for a virtual server by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
2. In **Advanced Settings**, select **Persistence**, and specify a backup persistence type.

**Note:** The primary persistence must be set to COOKIEINSERT, RULE, or SSLSESSION.

## Configure persistence groups

September 21, 2020

When you have load-balanced servers that handle several different types of connections (such as Web servers that host multimedia), you can configure a virtual server group to handle these connections. To create a virtual server group, you bind different types of virtual servers, one for each type of connection that your load balanced servers accept, into a single group. You then configure a persistence type for the entire group.

You can configure either source IP-based persistence or HTTP cookie-based persistence for persistence groups. After you set persistence for the entire group, you cannot change it for individual virtual servers in the group. If you configure persistence on a group and then add a new virtual server to the group, the persistence of the new virtual server is changed to match the persistence setting of the group.

When persistence is configured on a group of virtual servers, persistence sessions are created for initial requests, and subsequent requests are directed to the same service as initial request, regardless of the virtual server in the group that receives each client request.

When you add a virtual server that has persistence sessions to a load balancing group with a different persistence type, the existing persistent sessions specific to an old persistence type are deleted. The

persistent sessions decide whether the traffic must go to the same virtual server or to a different server. Therefore, existing established connections are not impacted.

The persistence type of a load balancing group is applied to all the virtual servers bound to that group, irrespective of the virtual servers' protocol type. A load balancing group supports the following persistence types:

- SourceIP
- CookieInsert
- Rule

Some virtual servers support only certain persistence types. For example, a virtual server of type SSL\_BRIDGE can use only SourceIP persistence type for an LB group.

If you configure HTTP cookie-based persistence, the domain attribute of the HTTP cookie is set. This setting causes the client software to add the HTTP cookie into client requests if different virtual servers have different public host names. For more information about CookieInsert persistence type, see [Persistence Based on HTTP Cookies](#).

### To create a virtual server persistency group by using the command line interface

At the command prompt, type:

```
1 bind lb group <vServerGroupName> <vServerName> -persistenceType <
 PersistenceType>
2 <!--NeedCopy-->
```

#### Example:

```
1 bind lb group Vserver-Group-1 Vserver-LB-1 -persistenceType
 CookieInsert
2 <!--NeedCopy-->
```

### To modify a virtual server group by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Persistency Groups**, create a persistency group, and specify the virtual servers that must be part of this group.

### To modify a virtual server group by using the command line interface

At the command prompt, type:

```
1 set lb group <vServerGroupName> -PersistenceBackup <
 BackupPersistenceType> -persistMask <SubnetMaskAddress>
2 <!--NeedCopy-->
```

**Example:**

```
1 set lb group vserver-Group-1 -PersistenceBackup SourceIP -persistMask
 255.255.255.255
2 <!--NeedCopy-->
```

## Share persistent sessions between virtual servers

May 2, 2023

In some customer environments (telecom and ISP), a single server handles both control and data traffic. For a given client IP address, both control and data traffic have to be directed to the same back-end server. For this, one virtual server is required for handling client authentication traffic, and usually rule based persistency is configured on it. For example, `Radius.req.avp(8).value.typecast_text_t`. The second virtual server for handling data traffic. Usually, SourceIP persistence is configured on it.

Previously, persistence entries were local to the virtual server. If you had to apply persistence across multiple virtual servers, you had to add the virtual server to a load balancing group and then apply a common persistence type to the group. This requirement cannot be achieved, because all the virtual servers bound to a load balancing group inherited the persistency configured on the group.

With the persistency sharing between virtual server feature, you can set the new `useVserverPersistency` parameter for a load balancing group to allow the virtual server in the group to use their own persistency parameters instead of inheriting them from the group settings. You can configure separate rule-based persistency on each virtual server.

Optionally, you can also designate one of the virtual servers in the group as a main virtual server. When a virtual server is designated as a main virtual server, only that virtual server creates the persistence entries, which are used by all the virtual server in the group. If the main virtual server is down, the NetScaler appliance does not create any persistence entries.

**Note:** Persistence sharing across the virtual servers is supported only for rule based persistency methods. Configure compatible rule based persistence parameters on the member virtual servers.

**Example:**

Assume v1 and v2 are bound to a load balancing group, v1 is a RADIUS type virtual server and v2 is an HTTP type virtual server. `Radius.req.avp(8).value.typecast_text_t` persistency is configured on v1 and `client.ip.src` is configured on v2.

When traffic flows through the RADIUS virtual server v1, it creates a persistent entry based on the evaluated rule string. Later, when traffic reaches the HTTP type virtual server v2, v2 checks for the persistence entries on the load balancing group and uses the same persistence session to direct traffic to the same back-end server.

## Configuring Sharing of Persistent Sessions

To share persistency parameters across the virtual server in a load balancing group, you must first enable the `useVserverPersistency` parameter and then designate one of the virtual servers in the group as a main server.

### To enable the `useVserverPersistency` parameter by using the command line interface

At the command prompt, type:

```
1 set lb group <name> -useVserverPersistency (ENABLED)
2 <!--NeedCopy-->
```

#### Example:

```
1 set lb group lb_grp1 -useVserverPersistency ENABLED
2 <!--NeedCopy-->
```

### To enable the `useVserverPersistency` parameter by using the GUI

1. Navigate to **Configuration > Traffic Management > Load Balancing > Persistency Groups**.
2. Click **Add** to add a new group or select an existing group and click **Edit**.
3. Select **Use Vserver Persistence**.

### To designate a virtual server as a main virtual server by using the command line interface

At the command prompt, type:

```
1 set lb group <name> -useVserverPersistency (ENABLED) -masterVserver <
 string>
2 <!--NeedCopy-->
```

#### Example:

```
1 set lb group lb_grp1 -useVserverPersistency ENABLED -masterVserver vs1
2 <!--NeedCopy-->
```

### To designate a virtual server as a main virtual server by using the GUI

1. Navigate to **Configuration > Traffic Management > Load Balancing > Persistency Groups**.
2. Click **Add** to add a new group or select an existing group and click **Edit**.

3. Select **Use Vserver Persistence**.
4. In the **Virtual Server Name** box, click **+** to add the virtual server to the group. You can select the available virtual server or create a virtual server.
5. Click **Create** if you are adding a new group or **Close** if you are modifying an existing group.
6. Select the group for which you have enabled the useVserverPersistence parameter and click **Edit** to set a virtual server as a main to create persistence entries.
7. From the **Master vServer** list, select the virtual server that has to be designated as a main virtual server.

## Arguments

### useVserverPersistence

Allow the virtual servers in a group to use their own persistency parameters to create persistent sessions, instead of inheriting the persistency settings from the group settings. When this parameter is enabled, persistence cannot be set on the load balancing group.

When this parameter is disabled, the group's virtual servers inherit the persistency parameters from the group settings.

When this parameter is toggled on the load balancing group, the NetScaler appliance flushes all the corresponding persistence entries of the group and the member virtual servers.

Possible values: ENABLED, DISABLED

Default: DISABLED

#### Example:

```
1 set lb group lb_grp1 -useVserverPersistence ENABLED
2 <!--NeedCopy-->
```

### masterVserver

Designate a virtual server as a main virtual server in its load balancing group. Once designated, only the main virtual server can create the persistent entries used by the group.

**Note:** This parameter can be set only if the useVserverPersistence parameter is enabled.

#### Example:

```
1 set lb group lb_grp1 -masterVserver vs1
2 <!--NeedCopy-->
```

## Example Configuration of Sharing Persistent Sessions by Using the Command Line Interface

The virtual servers are created

```
1 add lb vs vs1 http 10.1.10.11 80 -persistence rule -rule 'client.ip.
 src '
2
3 add lb vs vs2 radius 10.2.2.2 1812 -persistenceType rule -rule '
 Radius.req.avp(8).value.typecast_text_t '
4 <!--NeedCopy-->
```

The groups are created.

```
1 add lb group lb_grp1 -persistenceType NONE -useVserverPersistency
 ENABLED
2 <!--NeedCopy-->
```

A virtual server in a group is designated as the main virtual server.

```
1 set lb group lb_grp1 -masterVserver vs1
2 <!--NeedCopy-->
```

The virtual servers are bound to the group.

```
1 bind lb group lb_grp1 vs1
2 bind lb group lb_grp1 vs2
3 <!--NeedCopy-->
```

For more details, see [Setting Up Basic Load Balancing](#) and [Configuring Persistence Groups](#).

## Configure RADIUS load balancing with persistence

May 2, 2023

Today's complex networking environment often requires coordinating a high-volume, high-capacity load balancing configuration with robust authentication and authorization. Application users might connect to a VPN through mobile access points such as consumer-grade DSL or Cable connections, WiFi, or even dial-up nodes. Those connections usually use dynamic IPs, which can change during the connection.

If you configure RADIUS load balancing on the NetScaler appliance to support persistent client connections to RADIUS authentication servers, the appliance uses the user logon or the specified RADIUS attribute instead of the client IP as the session ID, directing all connections and records associated with that user session to the same RADIUS server. Users are therefore able to log on to your VPN from mobile access locations without experiencing disconnections when the client IP or WiFi access point changes.

To configure RADIUS load balancing with persistence, you must first configure RADIUS authentication for your VPN. For information and instructions, see the Authentication, Authorization, Auditing (AAA) chapter in [AAA Application Traffic](#). Also choose either the Load Balancing or Content Switching feature as the basis for your configuration, and make sure that the feature you chose is enabled. The configuration process with either feature is almost the same.

Then, you configure either two load balancing, or two content switching, virtual servers, one to handle RADIUS authentication traffic and the other to handle RADIUS accounting traffic. Next, you configure two services, one for each load balancing virtual server, and bind each load balancing virtual server to its service. Finally, you create a load balancing persistency group and set the persistency type to RULE.

### Enabling the Load Balancing or Content Switching Feature

To use the Load Balancing or Content Switching feature, you must first ensure that the feature is enabled. If you are configuring a new NetScaler appliance that has not previously been configured, both of these features are already enabled, so you can skip to the next section. If you are configuring a NetScaler appliance with a previous configuration on it, and you are not certain that the feature you use is enabled, you must do that now.

- For instructions on enabling the load balancing feature, see [Enabling Load Balancing](#).
- For instructions on enabling the content switching feature, see [Enabling Content Switching](#)

### Configuring Virtual Servers

After enabling the load balancing or content switching feature, you must next configure two virtual servers to support RADIUS authentication:

- **RADIUS authentication virtual server.** This virtual server and its associated service handles authentication traffic to your RADIUS server. Authentication traffic consists of connections associated with users logging onto your protected application or virtual private network (VPN).
- **RADIUS accounting virtual server.** This virtual server and its associated service handles accounting connections to your RADIUS server. Accounting traffic consists of connections that track an authenticated user's activities on your protected application or VPN.

**Important:** You must create either a pair of load balancing virtual servers or a pair of content switching virtual servers to use in your RADIUS persistence configuration. You cannot mix virtual server types.

**To configure a load balancing virtual server by using the command line interface**

At the command prompt type the following commands to create a load balancing virtual server and verify the configuration:

```
1 add lb vserver <name> RADIUS <IP address> <port> -lbmethod TOKEN -rule
 <rule>
2
3 show lb vserver <name>
4 <!--NeedCopy-->
```

To configure an existing load balancing virtual server, replace the preceding `add lb virtual server` command with the `set lb vserver` command, which takes the same arguments.

**To configure a content switching virtual server by using the command line interface**

At the command prompt type the following commands to create a content switching virtual server and verify the configuration:

```
1 add cs vserver <name> RADIUS <IP address> <port> -lbmethod TOKEN -rule
 <rule>
2
3 show cs vserver <name>
4 <!--NeedCopy-->
```

To configure an existing content switching virtual server, replace the preceding `add cs vserver` command with the `set cs vserver` command, which takes the same arguments.

**Example:**

```
1 add lb vserver radius_auth_vs1 RADIUS 192.168.46.33 1812 -lbmethod
 TOKEN -rule CLIENT.UDP.RADIUS.USERNAME
2
3 add lb vserver radius_acct_vs1 RADIUS 192.168.46.34 1813 -lbmethod
 TOKEN -rule CLIENT.UDP.RADIUS.USERNAME
4
5 set lb vserver radius_auth_vs1 RADIUS 192.168.46.33 1812 -lbmethod
 TOKEN -rule CLIENT.UDP.RADIUS.USERNAME
6
7 set lb vserver radius_auth_vs1 RADIUS 192.168.46.34 1813 -lbmethod
 TOKEN -rule CLIENT.UDP.RADIUS.USERNAME
8 <!--NeedCopy-->
```

**To configure a load balancing or content switching virtual server by using the configuration utility**

Navigate to **Traffic Management > Load Balancing > Virtual Servers** or navigate to **Traffic Management > Content Switching > Virtual Servers**, and configure a virtual server.

## Configuring Services

After configuring your virtual servers, you must next configure two services, one for each of the virtual servers that you created.

Note: Once configured, these services are in the DISABLED state until the NetScaler appliance can connect to your RADIUS server's authentication and accounting IPs and monitor their status. For instructions, see [Configuring Services](#).

## Binding Virtual Servers to Services

After configuring your services, you must next bind each of the virtual servers that you created to the appropriate service. For instructions, see [Binding Services to the Virtual Server](#).

## Configuring a Persistency Group for Radius

After binding your load balancing virtual servers to the corresponding services, you must set up your RADIUS load balancing configuration to support persistence. To do so, you configure a load balancing persistency group that contains your RADIUS load balancing virtual servers and services, and configure that load balancing persistency group to use rule-based persistence. A persistency group is required because the authentication and accounting virtual servers are different and both the authentication & accounting message for a single user should reach the same RADIUS server. Persistency group enables to use the same session for both virtual servers. For instructions, see [Configuring Persistence Groups](#).

## Configuring RADIUS Shared Secret

From release 12.0, a NetScaler appliance supports RADIUS shared secret. A RADIUS client and server communicate with each other by using a shared secret that is configured on the client and on the server. Transactions between a RADIUS client and server are authenticated by using a shared secret. This secret is also used to encrypt some of the information in the RADIUS packet.

### RADIUS shared secret key validation scenarios

The validation of the **RADIUS shared secret** key happens in the following scenarios:

- **RADIUS shared secret key is configured for both the radius client and the radius server:**  
The NetScaler appliance uses the RADIUS secret key for both the client side and the server side. If the verification succeeds, the appliance allows the RADIUS message to go through. Otherwise, it drops the RADIUS message.

- **RADIUS shared secret key is not configured for either the radius client or the radius server:** The NetScaler appliance drops the RADIUS message, because shared-secret-key validation cannot be performed on a node that has no radkey configured.
- **RADIUS shared secret key is not configured for both the RADIUS client and the RADIUS server:** The NetScaler appliance bypasses the RADIUS secret key validation and allows the RADIUS messages to go through.

You can configure a default RADIUS shared secret or configure on a per client or a subnet basis. It is recommended to add a RADIUS shared secret key for all deployments with RADIUS policy configured. The appliance uses the source IP address of the RADIUS packet to decide which shared secret to use. You might configure a RADIUS client and server and the corresponding shared secret as follows:

At the CLI prompt, type:

```
1 add radiusNode <clientPrefix/Subnet> -radKey <Shared_secret_key>
2 <!--NeedCopy-->
```

## Arguments

**IPaddress** IP address or subnet of the RADIUS client in CIDR format. The appliance uses the source IP address of an incoming request packet to match the client IP address. Instead of configuring a client IP address, you can configure the client network address. Longest prefix is matched to identify the shared secret for an incoming client request.

**Radkey** Shared secret between the client, NetScaler appliance, and the server. Maximum length: 31.

```
1 add lb vserver radius_auth_vs1 RADIUS 192.168.46.33 1812 -lbmethod
 TOKEN -rule CLIENT.UDP.RADIUS.USERNAME
2
3 add lb vserver radius_acct_vs1 RADIUS 192.168.46.34 1813 -lbmethod
 TOKEN -rule CLIENT.UDP.RADIUS.USERNAME
4
5 add service radius_auth_service1 192.168.41.68 RADIUS 1812
6
7 add service radius_acct_service1 192.168.41.70 RADIUS 1813
8
9 bind lb vserver radius_auth_vs1 radius_auth_service1
10
11 bind lb vserver radius_acct_vs1 radius_acct_service[1-3]
12
13 add radiusNode 192.168.41.0/24 -radKey serverkey123
14
15 add radiusNode 203.0.113.0/24 -radkey clientkey123
16 <!--NeedCopy-->
```

A shared secret must be configured both for a RADIUS client and server. The command is the same. The subnet determines whether the shared secret is for a client or for a server.

For example, if the subnet specified is a client subnet, the shared secret is for the client. If the subnet specified is a server subnet (192.168.41.0/24 in the earlier example), the shared secret is for the server.

A subnet of 0.0.0.0/0 implies that it is the default shared secret for all clients and servers.

**Note:**

Only the PAP and CHAP authentication methods are supported with RADIUS shared secret.

## View persistence sessions

May 2, 2023

You can view the different persistence sessions that are in effect globally or for a particular virtual server.

**Note:** A NetScaler nCore appliance uses multiple CPU cores for packet handling. The CPU core owns every session on the appliance. If the appliance receives a request for which a session does not exist, a session is created, and one of the cores is designated as the owner of that session.

Subsequent requests that belong to that session might not always arrive at and be handled by the owner core. In that case, inter-core messaging ensures that the session information on the owner core is always current.

However, when a core receives a request that belongs to a persistence session owned by another core, the inter-core messaging does not refresh the timeout value for the persistence session.

Therefore, in the output of successively run `show lb persistentSessions` commands, which display timeout values from owner cores only, the timeout value for a persistence session might diminish to 0 (zero), even if the persistence session remains active.

### To view persistence sessions by using the command line interface

At the command prompt, to view persistence sessions related to all virtual servers, type:

```
1 show lb persistentSessions [<vServer>]
2 <!--NeedCopy-->
```

At the command prompt, to view persistence sessions related a virtual server, type:

```
1 show lb persistentSessions <vServername>
2 <!--NeedCopy-->
```

**Example:**

```
1 show lb persistentSessions myVserver
2 <!--NeedCopy-->
```

**To view persistence sessions by using the GUI**

Navigate to **Traffic Management > Virtual server persistent sessions**.

**Clear persistence sessions**

May 2, 2023

You might need to clear persistence sessions from the NetScaler appliance if sessions fail to time out. You can do one of the following:

- Clear all sessions for all virtual servers at once.
- Clear all sessions for a given virtual server at once.
- Clear a particular session that is associated with a given virtual server.

**To clear a persistence session by using the command line interface**

At the command prompt, type the following commands to clear persistence sessions and verify the configuration:

```
1 clear lb persistentSessions [<vServer> [-persistenceParam <string>]]
2
3 show persistentSessions <vServer>
4 <!--NeedCopy-->
```

**Examples:**

Example 1 clears all persistence sessions for load balancing virtual server lbvip1.

Example 2 first displays the persistence sessions for load balancing virtual server lbvip1, clears the session with the persistence parameter xls, and then displays the persistence sessions to verify that the session was cleared.

**Example 1:**

```

1 > clear persistentSessions lbvip1
2 Done
3 > show persistentSessions
4 Done
5 >
6 <!--NeedCopy-->

```

**Example 2:**

```

1 > show persistentSessions lbvip1
2 Type SRC-IP ... PERSISTENCE-PARAMETER
3 RULE 0.0.0.0 ... xls
4 RULE 0.0.0.0 ... txt
5 RULE 0.0.0.0 ... html
6 Done
7 > clear persistentSessions lbvip1 -persistenceParam xls
8 Done
9 > show persistentSessions lbvip1
10 Type SRC-IP ... PERSISTENCE-PARAMETER
11 RULE 0.0.0.0 ... txt
12 RULE 0.0.0.0 ... html
13 Done
14 >
15 <!--NeedCopy-->

```

**To clear persistence sessions by using the configuration utility**

1. Navigate to **Traffic Management > Clear Persistent Sessions**.

**Override persistence settings for overloaded services**

May 2, 2023

When a service is loaded or is otherwise unavailable, service to clients is degraded. In this case, you might have to configure the NetScaler appliance to temporarily forward to other services the requests that would otherwise be included in the persistence session that is associated with the overloaded service. In other words, you might have to override the persistence setting that is configured for the load balancing virtual server. You can achieve this functionality by setting the `skippersistency` parameter. When this `skippersistency` parameter is set, and if the virtual server receives new connections for an overloaded service, the following happens.

- The virtual server disregards any existing persistence sessions that are associated with that service, until the service returns to a state at which it can accept requests.
- Persistence sessions associated with other services are not affected.

This functionality is available for only virtual servers whose type is ANY or UDP.

In Branch Repeater load balancing configurations, you must also configure a load monitor and bind it to the service. The monitor takes the service out of subsequent load balancing decisions until the load on the service is brought below the configured threshold. For information about configuring a load monitor for your virtual server, see [Understanding Load Monitors](#).

You can configure the virtual server to perform one of the following actions with the requests that would otherwise form a part of the persistence session:

- **Send each request to one of the other services.** The virtual server takes a load balancing decision and sends each request to one of the other services based on the load balancing method. If all the services are overloaded, requests are dropped until a service becomes available.

Both wildcard and IP address–based virtual servers support this option. This action is appropriate for all deployments, including deployments in which the virtual server is load balancing Branch Repeater appliances or firewalls.

- **Bypass the virtual server-service configuration.** The virtual server does not take a load balancing decision. Instead, it simply bridges each request through to a physical server based on the destination IP address in the request.

Only wildcard virtual servers of type ANY and UDP support the bypass option. Wildcard virtual servers have a : IP and port combination. This action is appropriate for deployments in which you are using the virtual server to load balance Branch Repeater appliances or firewalls. In these deployments, the NetScaler appliance first forwards a request to a Branch Repeater appliance or firewall, and then forwards the processed response to a physical server. The virtual server sends requests directly to their destination IP addresses in the following conditions.

- You configure the virtual server to bypass the virtual server–service configuration for overloaded services.
- The Branch Repeater appliance or firewall gets overloaded.

The virtual server sends requests directly to their destination IP addresses until the Branch Repeater appliance or firewall can accept requests.

## To override persistence settings for overloaded services by using the CLI

At the command prompt, type the following commands to override persistence settings for overloaded services and verify the configuration:

```
1 set lb vserver <name> -skippersistency <skippersistency>
2
3 show lb vserver <name>
4 <!--NeedCopy-->
```

**Example**

```
1 > set lb vserver mylbvserver -skippersistency ReLb
2 Done
3 > show lb vserver mylbvserver
4 mylbvserver (*:*) - ANY Type: ADDRESS
5 . . .
6 . . .
7 Skip Persistency: ReLb
8 . . .
9 Done
10 >
11 <!--NeedCopy-->
```

**To override persistence settings for overloaded services by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers** and select the virtual server of type UDP or ANY.
2. In the Advanced Settings pane, select Traffic Settings, and specify the type of Skip Persistency.

**Troubleshooting**

May 2, 2023

- **The statistics from the NetScaler VPX appliance indicate that the appliance has reached the session persistence limit. As a result, persistence sessions are failing. Is possible to increase the session persistence limit?**

**Cause:** The NetScaler appliance has the system limit of 250,000 persistence session for a core.

**Resolution:** To resolve this issue, you can perform any of the following tasks:

- Reduce the time-out value for persistence
  - Increase the number of cores for the appliance
- **After configuring Cookie Insert persistence on the NetScaler appliance, the users report that the connections work fine for some time, but then start getting disconnected. What best practice should I follow when configuring persistence?**

**Cause:** By default, the time-out value for Cookie Insert persistence is 120 seconds.

**Resolution:** When you configure persistence for applications for which idle time cannot be determined, set the Cookie Insert persistence time-out value to 0. With this setting, the connection does not time out.

- **After configuring an HTTP virtual server on the NetScaler appliance, I need to make sure that a user always connects to the same server for the requested content, so I configured SourceIP persistence. Now, increasing the time-out value for persistence introduces latency. How can I increase the timeout value without affecting performance?**

**Resolution:** Consider using Cookie Insert persistence with the time-out value set to 0. This setting enables long-duration persistence settings, because the appliance does not specify a time for expiring the cookie.

- **After configuring Cookie Insert persistence on the NetScaler appliance, it works as expected when clients from the same time zone access the content. However, when a client from another time zone makes an attempt to connect, the connection is immediately timed out.**

**Cause:** Time based Cookie Insert persistence works as expected when a client from the same time zone makes a connection. However, when the client machine and NetScaler appliance are in different time zones, the cookie is not valid. For example, when a client in the EST time zone sends a cookie at 11:00 AM EST to a NetScaler appliance in the PST time zone, the appliance receives the cookie at 2:00 PM PST. As a result of the difference in time, the cookie is not valid, and the connection is immediately timed-out.

**Resolution:** Set the time-out value for Cookie Insert persistence to 0.

- **A NetScaler appliance is used to load balance application servers, such as Oracle Weblogic server. To make sure that clients get persistent connections to these servers, SourceIP persistence is configured. It works as expected when a connection is made from a computer. However, when thin clients attempt a connection through a terminal server and, as a result, the appliance receives requests from multiple clients from the same IP address (the terminal server IP address). Therefore, the connections from all thin clients are directed to the same application server. Is it possible to configure persistency for requests from individual thin clients based on the client IP address?**

**Cause:** The NetScaler appliance receives requests from the terminal server and the source IP address of the request remains the same. As a result, the appliance cannot distinguish among the requests received from the thin clients and provide persistence according to the requests from thin clients.

**Resolution:** To avoid this problem, you can configure Rule persistence based on some unique parameter value for each thin client.

- **The NetScaler appliance is used to load balance Web Interface servers. When accessing the servers, the user receives the “State Error” error message. Additionally, when one of the Web Interface servers is shut down or not available, some of the users receive an error message.**

**Cause:** Lack of persistence to the Web Interface servers can result in error messages when a user attempts to connect to the server.

**Resolution:** Citrix recommends that you specify the Cookie Insert persistence method on the NetScaler appliance when load balancing Web Interface servers.

## Insert cookie attributes to ADC generated cookies

October 8, 2023

The web administrators can insert other cookie attributes to the cookies generated by the NetScaler appliance. These additional cookie attributes help in enforcing the required policies for the ADC generated cookies based on the application access pattern.

The following features use the ADC generated cookies to achieve persistency.

- Load balancing cookie persistence
- Load balancing group cookie persistence
- GSLB site persistence
- Content switching cookie persistence

You can insert other cookie attributes to the ADC generated cookies using the following parameters:

- **LiteralADCCookieAttribute:** Append other cookie attributes to the ADC generated cookie, as a string.
- **ComputedADCCookieAttribute:** Use an ADC ns variable to conditionally append cookie attributes to the ADC generated cookie, based on the client or server attributes, for example, user agent version.

### Note

You cannot configure both Literal ADC Cookie Attribute and Computed ADC Cookie Attribute, simultaneously on the load balancing parameter or in a single load balancing profile.

### Use case: Configure SameSite cookie attribute

Every cookie has a domain associated with it. When a cookie's domain matches the website domain in the user's address bar, this is considered a same-site (or first party) context. If the domain associated with a cookie matches an external service and not the website in the user's address bar, this is considered a cross-site (or third party) context.

The **SameSite** attribute indicates the browser whether the cookie can be used for cross-site context or only for same-site context. Also, if an application intends to be accessed in the cross-site context then it can do so only via the HTTPS connection. For details, see [RFC6265](#).

Until Feb 2020, the **SameSite** property was not explicitly set in NetScaler. The browser took the default value as None, and did not impact the NetScaler deployments.

However with certain browsers upgrade, such as Google Chrome 80, there is a change in the default cross-domain behavior of cookies. The **SameSite** attribute can be set to one of the following values. Default value for Google Chrome is set to Lax.

- **None:** Indicates the browser to use a cookie in cross-site context only on secure connections.
- **Lax:** Indicates the browser to use a cookie for requests in the same-site context. In the cross-site context, only safe HTTP methods like GET request can use the cookie.
- **Strict:** Use the cookie only in the same-site context.

If there is no SameSite attribute in the cookie, the Google Chrome assumes the functionality of SameSite=Lax.

#### Note

For certain version of other browsers, the default value for the SameSite attribute might be set to **None**. In some browser versions, “SameSite = none” can be treated differently. For example, the following browsers reject a cookie with “SameSite = none”:

- Versions of Chrome from Chrome 51 to Chrome 66 (inclusive on both ends)
- Versions of UC browser on Android earlier to version 12.13.2

## Configure ADC generated cookies

To configure ADC generated cookie attributes, you must perform the following:

1. Create a load balancing virtual server
2. Set the ADC Cookie attributes for the load balancing virtual server, either through LB parameters or LB profile.
3. If you use an LB profile, set the LB profile to a load balancing virtual server.
4. If you choose to use the Computed ADC Cookie Attribute, configure the related rewrite policy.

#### Note

If an LB profile is bound to an LB virtual server, then the profile parameter configuration is considered instead of the global LB parameter configuration.

You can set the ADC generated cookie attributes by the following methods:

- Setting the ADC cookie attributes in load balancing parameters

- Setting the ADC cookie attributes in the load balancing profile

### Setting the ADC cookie attributes in the load balancing parameters by using the CLI

To apply a policy uniformly to ADC generated cookies of all applications configured on the NetScaler appliance, you can set the ADC cookie attribute in the global LB parameters.

The **Literal ADC Cookie Attribute** setting allows you to unconditionally insert the cookie attributes to the ADC generated cookie.

At the command prompt, type:

```
1 set lb parameter -LiteralADCCookieAttribute <string>
2 <!--NeedCopy-->
```

Example:

```
1 set lb parameter -LiteralADCCookieAttribute SameSite=None
2 <!--NeedCopy-->
```

The **Computed ADC Cookie Attribute** setting allows you to conditionally insert the cookie attributes, based on the client or server attributes, to the ADC generated cookie.

At the command prompt, type:

```
1 set lb parameter -ComputedADCCookieAttribute <ns variable>
2 <!--NeedCopy-->
```

Example:

```
1 add ns variable cookieattribute_var -type "text(100)" -scope
 transaction
2 set lb parameter -ComputedADCCookieAttribute "$cookieattribute_var"
3 add ns assignment samesiteassign -variable "$cookieattribute_var" -set
 "\"SameSite=None\""
4
5 add policy expression pol_iphone "(HTTP.REQ.HEADER(\"User-Agent\").
 CONTAINS(\"iP\") && (HTTP.REQ.HEADER(\"User-Agent\").REGEX_SELECT(re
 /OS \\d+_/.).REGEX_SELECT(re/\\d+/.).TYPECAST_NUM_T(DECIMAL).EQ(12).
 typecast_text_t ALT \"false\").eq(\"true\"))"
6 add policy expression pol_chrome "(HTTP.REQ.HEADER(\"User-Agent\").
 CONTAINS(\"Chrom\") && (HTTP.REQ.HEADER(\"User-Agent\").REGEX_SELECT
 (re/Chrom.*\\d+/.).REGEX_SELECT(re/\\d+/.).TYPECAST_NUM_T(DECIMAL).
 BETWEEN(51,66).typecast_text_t ALT \"false\").eq(\"true\"))"
7 add rewrite policy exception_samesite_attribute "pol_iphone ||
 pol_chrome " NOREWRITE
8 add rewrite policy append_samesite_attribute true samesiteassign
9
10 bind rewrite global exception_samesite_attribute 90 110 -type
 RES_OVERRIDE
```

```
11 bind rewrite global append_samesite_attribute 100 110 -type
 RES_OVERRIDE
12 <!--NeedCopy-->
```

### Configure variables by using the GUI

1. Navigate to **AppExpert > Variables**, and click **Add**.
2. In the **Create Variable** page, select **Scope** as **Transaction** and **Type** as **text** from the drop-down menu.

## ← Create Variable

Name\*

Comments

**Create** **Close**

3. Enter other details, and click **Create**.

## Create an assignment by using the GUI

After configuring a variable, you can assign a value or specify the operation to be performed on the variable by creating an assignment.

1. Navigate to **AppExpert > Assignments**, and click **Add**.
2. In the **Create Assignment** page, enter the details, and click **Create**.

## Setting the ADC cookie attributes in load balancing parameters by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Change Load Balancing parameters**.

**Load Balancing**

The load balancing feature distributes user requests for applications among multiple servers that all host (or mirror) the same content. You use load balancing primarily to manage user requests to heavily used applications, preventing poor performance and outages, and ensuring that users can seamlessly access your applications. Load balancing also provides fault tolerance: when a server that hosts an application becomes unavailable, the feature distributes user requests to the other servers that host the same application.

To set up load balancing:

- Configure a virtual server.
- Configure a service representing the application running on the server.
- Bind the service to the virtual server.
- Optionally, configure a monitor and bind it to the service.
- Optionally, configure persistence and a load balancing method.

**Settings**

- [Change SIP settings](#)
- [Change Load Balancing parameters](#)
- [Change SMPP Parameters](#)

**Configuration Summary**

- No Load Balancing Virtual Server
- No Service
- No Service Group
- 28 Monitors
- 6 Metric Tables
- No Server
- No Persistency Group

2. In the **Configure Load Balancing Parameters** pane, enter appropriate values for either one of the fields based on your requirement:

- **Literal ADC Cookie Attribute**
- **Computed ADC Cookie Attribute**

## ← Configure Load Balancing Parameters

### Setting the ADC cookie attributes in the load balancing profile by using the CLI

To apply a policy for a specific application that is configured on the NetScaler appliance, you can set the cookie attribute parameters in the LB profile bound to the application-specific LB virtual server.

The **Literal ADC Cookie Attribute** setting in the LB profile allows you to unconditionally insert the cookie attributes to the ADC generated cookie that is specific to a virtual server.

At the command prompt, type:

```
1 add lb profile <profile name> -LiteralADCCookieAttribute <string>
2 <!--NeedCopy-->
```

Example:

```
1 add lb profile LB-Vserver-Profile-1 -LiteralADCCookieAttribute SameSite
 =None
2 add lb vserver LB-VServer-1 SSL 10.102.148.37 443 -persistenceType
 COOKIEINSERT -lbprofilename LB-Vserver-Profile-1
3 <!--NeedCopy-->
```

The **Computed ADC Cookie Attribute** setting in the LB profile allows you to conditionally insert the cookie attributes based on the client or server attributes, to the ADC generated cookie. Then, set this LB profile to an LB virtual server.

At the command prompt, type:

```
1 add lb profile <profile name> -ComputedADCCookieAttribute <ns variable>
2 <!--NeedCopy-->
```

Example:

```
1 add ns variable cookieattribute_var -type "text(100)" -scope
 transaction
2 add ns assignment samesiteassign -variable "$cookieattribute_var" -set
 "\"SameSite=None\""
3 add lb profile LB-Vserver-Profile-1 -ComputedADCCookieAttributeE "
 $cookieattribute_var"
4
5 add policy expression pol_iphone "(HTTP.REQ.HEADER(\"User-Agent\").
 CONTAINS(\"iP\") && (HTTP.REQ.HEADER(\"User-Agent\").REGEX_SELECT(re
 /OS \\d+_/.).REGEX_SELECT(re/\\d+/.).TYPECAST_NUM_T(DECIMAL).EQ(12).
 typecast_text_t ALT \"false\").eq(\"true\"))"
6 add policy expression pol_chrome "(HTTP.REQ.HEADER(\"User-Agent\").
 CONTAINS(\"Chrom\") && (HTTP.REQ.HEADER(\"User-Agent\").REGEX_SELECT
 (re/Chrom.*\\d+/.).REGEX_SELECT(re/\\d+/.).TYPECAST_NUM_T(DECIMAL).
 BETWEEN(51,66).typecast_text_t ALT \"false\").eq(\"true\"))"
7 add rewrite policy exception_samesite_attribute "pol_iphone ||
 pol_chrome " NOREWRITE
```

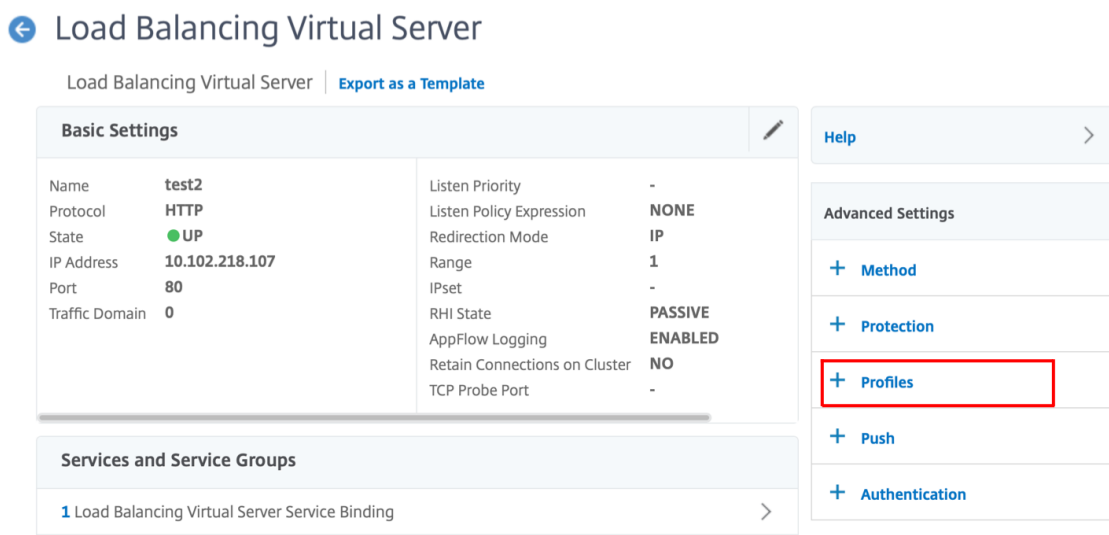

```

8 add rewrite policy append_samesite_attribute true samesiteassign
9
10 add lb vserver LB-VServer-1 SSL 10.102.148.37 443 -persistenceType
 COOKIEINSERT -lbprofilename LB-Vserver-Profile-1
11 bind lb vserver LB-VServer-1 -policyName exception_samesite_attribute -
 priority 90 -gotoPriorityExpression 110 -type RESPONSE
12 bind lb vserver LB-VServer-1 -policyName append_samesite_attribute -
 priority 100 -gotoPriorityExpression 110 -type RESPONSE
13 <!--NeedCopy-->

```

### Setting the ADC Cookie attributes in the load balancing profile by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual servers**.
2. Select a virtual server and click **Edit**.
3. Under **Advanced Settings** section, click **Add profiles**.

4. In the **Profiles** section, click **Add** to create an LB Profile.  
If you have already created a profile, choose it from the **LB Profile** drop-down menu.

**Profiles** ✕

A profile is a collection of settings that can be applied to a Citrix ADC entity, such as a virtual server or service. You can apply the same profile to multiple entities of the same type.

Net Profile <input type="text"/> ▾	<input type="button" value="Add"/>	<input type="button" value="Edit"/>
TCP Profile <input type="text"/> ▾	<input type="button" value="Add"/>	<input type="button" value="Edit"/>
LB Profile <input type="text"/> ▾	<input type="button" value="Add"/>	<input type="button" value="Edit"/>

HTTP Profile <input type="text"/> ▾	<input type="button" value="Add"/>	<input type="button" value="Edit"/>
DB Profile <input type="text"/> ▾	<input type="button" value="Add"/>	<input type="button" value="Edit"/>
DNS Profile Name <input type="text"/> ▾	<input type="button" value="Add"/>	<input type="button" value="Edit"/>
adfsProxy Profile Name <input type="text"/> ▾	<input type="button" value="Add"/>	<input type="button" value="Edit"/>

5. In the **LB Profile** pane, enter appropriate values for either one of the fields based on your requirement:

- **Literal ADC Cookie Attribute**
- **Computed ADC Cookie Attribute**

The screenshot shows the 'LB Profile' configuration page in the NetScaler GUI. The page has a dark header with 'Dashboard', 'Configuration', and 'Rep' tabs. Below the header is a breadcrumb trail with a back arrow and the text 'LB Profile'. The main content area contains several configuration fields:

- LB Profile Name:** A text input field containing 'lbprof1'.
- DBS LB:** A checkbox that is unchecked.
- Process Local:** A checkbox that is unchecked.
- Persistence Cookie HttpOnly Flag:** A checkbox that is unchecked.
- Encode Persistence Cookie Values:** A checkbox that is unchecked.
- Cookie Passphrase:** A text input field that is empty.
- Literal ADC Cookie Attribute:** A text input field that is empty, highlighted with a red rectangular box.
- Computed ADC Cookie Attribute:** A text input field containing 'Sibvar'.

At the bottom of the form are two buttons: 'OK' (a blue button) and 'Close' (a white button with a grey border).

1. Click **OK**.
2. Set the created LB profile to the LB virtual server created in **Step 1**.

### Verify ns variable configuration

To verify that the ADC ns variable is configured appropriately in LB parameters or LB profile, use the show lb parameter or show lb profile commands.

The following table lists the various warning messages and its cause, when the ns variable is not correctly configured.

Warning message	Reasons
NS Variable is not configured. Configure it with type text() and scope transaction for variable	NS variable is not yet configured.
Scope of configured NS variable is not transaction.	Variable is configured but scope is not set to "transaction."
Type of variable is not Text().	Variable is configured but type is not set to "Text".
Configured value-max-size for the NS Variable is greater than 255.	The value configured for the NS variable is greater than 255 characters. <b>Note:</b> A maximum length of 255 characters can be appended to an ADC generated cookie. The characters that exceed the maximum length are truncated.

### Sample output

In the following example, the warning message is displayed when the ns variable is not configured.

```

1 set lb parameter -ComputedADCCookieAttribute "$lbvar"
2
3 Warning: NS Variable is not configured. Please configure it with type
 text() and scope transaction
4 Done
5 <!--NeedCopy-->
```

The warning message is displayed in the following output of the `show lb parameter` command.

```

1 show lb parameter
2
3 Global LB parameters:
4 Persistence Cookie HttpOnly Flag: ENABLED
5 Use Encrypted Persistence Cookie: DISABLED
6 Use Port For Hash LB: YES
7 Prefer direct route: YES
8 Retain Service State: OFF
9 Start RR Factor: 0
10 Skip Maxclient for Monitoring: DISABLED
11 Monitor Connection Close: FIN
12 Use consolidated stats for LeastConnection: YES
13 Allow mac mode based vserver to pick the return traffic from services:
 DISABLED
14 Allow bound service removal: ENABLED
15 TTL for Domain Based Server: 0 secs
16
17 NetScaler Cookie Variable Name: $lbvar(NS Variable is not configured.
 Please configure it with type text() and scope transaction)
```

```

18
19 Done
20 <!--NeedCopy-->

```

## Sample configuration for inserting cookie attributes in GSLB deployment

The following sample configuration applies to site persistence configured on GSLB services corresponding to an LB virtual server. To append some additional cookie attributes to the GSLB cookies, perform the following configuration.

- Set the ADC cookie attributes in the LB profile (LB-Vserver-Profile-1).
- Set the Literal ADC Cookie Attribute value, for example “SameSite=None”, in the LB profile.
- Set the LB profile to the load balancing virtual server (LB-VServer-1), which represents the GSLB service.

```

1 add gslb vserver GSLB-VServer-1 SSL -backupLBMethod ROUNDROBIN -
 tolerance 0 -appflowLog DISABLED
2 add gslb site site1 10.102.148.4 -publicIP 10.102.148.4
3 add gslb service site1_gsvc1 10.102.148.35 SSL 443 -publicIP

14 <!--NeedCopy-->

```

### Note

You can also conditionally insert the cookie attributes using the Computed ADC Cookie Attribute.

## Sample configuration for inserting cookie attribute in content switching deployment

The following sample configuration applies when multiple applications are hosted behind a content switching virtual server. To apply the same policy to all the applications, bind the rewrite policies to content switching virtual server instead of LB virtual server, as follows:

- Set the ADC cookie attributes in the LB parameters.

**Note:**

You can set the ADC cookie attributes in the LB profile as well.

- Configure the ns variable (cookieattribute\_var) of Type set to Text and Scope set to Transaction.
- Set the Computed ADC Cookie Attribute in the global LB parameters using the ns variable.
- Set the rewrite policies (exception\_samesite\_attribute and append\_samesite\_attribute) to the content switching virtual servers for inserting the cookie attributes.

```

1 add ns variable cookieattribute_var -type "text(100)" -scope
 transaction
2 set lb parameter -ComputedADCCookieAttribute "$cookieattribute_var"
3 add ns assignment samesiteassign -variable "$cookieattribute_var" -set
 "\"SameSite=None\""
4
5 add policy expression pol_iphone "(HTTP.REQ.HEADER(\"User-Agent\").
 CONTAINS(\"iP\") && (HTTP.REQ.HEADER(\"User-Agent\").REGEX_SELECT(re
 /OS \\d+_/.).REGEX_SELECT(re/\\d+/.).TYPECAST_NUM_T(DECIMAL).EQ(12).
 typecast_text_t ALT \"false\").eq(\"true\"))"
6 add policy expression pol_chrome "(HTTP.REQ.HEADER(\"User-Agent\").
 CONTAINS(\"Chrom\") && (HTTP.REQ.HEADER(\"User-Agent\").REGEX_SELECT
 (re/Chrom.*\\d+/.).REGEX_SELECT(re/\\d+/.).TYPECAST_NUM_T(DECIMAL).
 BETWEEN(51,66).typecast_text_t ALT \"false\").eq(\"true\"))"
7 add rewrite policy exception_samesite_attribute "pol_iphone ||
 pol_chrome " NOREWRITE
8 add rewrite policy append_samesite_attribute true samesiteassign

## Customize a load balancing configuration

May 2, 2023

After you configure a basic load balancing setup, you can make several modifications to it so that it distributes the load exactly as you need. The load balancing feature is complex. You can modify the basic elements by doing one or more of the following:

- Changing the load balancing algorithm
- Configuring load balancing groups and using them to create your load balancing configuration
- Configuring persistent client-server connections
- Configuring the redirection mode
- Assigning different weights to different services that have different capacities.

The default load balancing algorithm on the NetScaler appliance is the least connection method. In the least connection method, the appliance sends each incoming connection to the service that is currently handling the fewest connections. You can specify different load balancing algorithms, each of which is suited to different conditions.

To accommodate applications such as shopping carts, which require that all requests from the same user be directed to the same server, you can configure the appliance to maintain persistent connections between clients and servers. You can also specify persistence for a group of virtual servers. Persistence lets the appliance to direct individual client requests to the same service regardless of which virtual server in the group receives the client request.

You can enable and configure the redirection mode that the appliance uses when redirecting user requests, choosing between IP-based and MAC-based forwarding. You can also assign weights to different services, specifying what percentage of incoming load must be directed to each service. Assigning weights enable you to include servers with different capacities in the same load balancing setup without;

- overloading the lower-capacity servers or
- allowing the higher-capacity servers to sit idle.

## Customize the hash algorithm for persistence across virtual servers

May 2, 2023

The NetScaler appliance uses hash-based algorithms for maintaining persistence across virtual servers. By default, the hash-based load balancing method uses a hash value of the IP address and

port number of the service. If a service is made available at different ports on the same server, the algorithm generates different hash values. Therefore, different load balancing virtual servers might send requests for the same application to different services, breaking the pseudo-persistence.

As an alternative to using the port number to generate the hash value, you can specify a unique hash identifier for each service. For a service, the same hash identifier value must be specified on all the virtual servers. If a physical server serves more than one type of application, each application type should have a unique hash identifier.

The algorithm for computing the hash value for a service works as follows:

- By default, a global setting specifies the use of port number in a hash calculation.
- If you configure a hash identifier for a service, it is used, and the port number is not, regardless of the global setting.
- If you do not configure a hash identifier, but change the default value of the global setting so that it does not specify use of the port number, the hash value is based only on the IP address of the service.
- If you do not configure a hash identifier or change the default value of the global setting to use the port number, the hash value is based on the IP address and the port number of the service.

You can also specify hash identifiers when using the CLI to bind services to a service group. In the configuration utility, you can open a service group and add hash identifiers on the Members tab.

### To change the use-port-number global setting by using the CLI

At the command prompt, type:

---

```
set lb parameter -usePortForHashLb (YES NO)
```

---

#### Example:

```
1 > set lb parameter -usePortForHashLb NO
2 Done
3 >show lb parameter
4 Global LB parameters:
5 Persistence Cookie HttpOnly Flag: DISABLED
6 Use port for hash LB: NO
7 Done
8 <!--NeedCopy-->
```

### To change the use-port-number global setting by using the GUI

1. Navigate to Traffic Management > Load Balancing > Configure Load Balancing parameters.
2. Select or clear Use Port for Hash Based LB Methods.

## To create a new service and specify a hash identifier for a service by using the CLI

At the command prompt, type the following commands to set the hash ID and verify the setting:

```
add service < name > (< ip > < serverName >) < serviceType > < port > -hashId
 < positive_integer >
```

```
1 show service <name>
2 <!--NeedCopy-->
```

### Example:

```
1 > add service flbkng 10.101.10.1 http 80 -hashId 12345
2 Done
3 >show service flbkng
4 flbkng (10.101.10.1:80) - HTTP
5 State: DOWN
6 Last state change was at Thu Nov 4 10:14:52 2010
7 Time since last state change: 0 days, 00:00:15.990
8 Server Name: 10.101.10.1
9 Server ID : 0 Monitor Threshold : 0
10
11 Down state flush: ENABLED
12 Hash Id: 12345
13
14 1) Monitor Name: tcp-default
15 State: DOWN Weight: 1
16
17 Done
18 <!--NeedCopy-->
```

## To specify a hash identifier for an existing service by using the CLI

Type the set service command, the name of the service, and **-hashID** followed by the ID value.

## To specify a hash identifier while adding a service group member

To specify a hash identifier for each member to be added to the group and verify the setting, at the command prompt, type the following commands (Be sure to specify a unique hashID for each member.):

```
1 bind servicegroup <serviceGroupName> <memberName> <port> -hashId <
 positive_integer>
2
3 show servicegroup <serviceGroupName>
4 <!--NeedCopy-->
```

**Example:**

```
1 bind servicegroup http_svc_group 10.102.27.153 80 -hashId 2222222
2
3 >show servicegroup SRV
4 SRV - HTTP
5 State: ENABLED Monitor Threshold : 0
6 ...
7
8 1) 1.1.1.1:80 State: DOWN Server Name: 1.1.1.1
9 Server ID: 123 Weight: 1
10 Hash Id: 32211
11
12 Monitor Name: tcp-default State: DOWN
13 ...
14 2) 2.2.2.2:80 State: DOWN Server Name: 2.2.2.2
15 Server ID: 123 Weight: 1
16 Hash Id: 12345
17
18 Monitor Name: tcp-default State: DOWN
19 ...
19 Done
20
21 <!--NeedCopy-->
```

**To specify a hash identifier for a service by using the GUI**

1. Navigate to Traffic Management > Load Balancing > Services.
2. Create a new service, or open an existing service and specify the hash ID.

**To specify a hash identifier for an already configured service group member by using the GUI**

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Open a member and type a unique hash ID.

**Configure the redirection mode**

May 2, 2023

The redirection mode configures the method used by a virtual server to determine where to forward incoming traffic. The NetScaler appliance supports the following redirection modes. Before forwarding the request to a server, the redirection modes function as follows:

- IP-Based forwarding (the default): The destination IP address is changed to the server's IP address.
- MAC-Based forwarding: The destination MAC address is changed to the server's MAC address. However, the destination IP address is not changed. MAC-based redirection mode is used mostly in firewall load balancing deployments.
- IP TUNNEL Based: An IP-in-IP encapsulation is performed for the client IP packets. In the outer IP headers, the destination IP address is set to the IP address of the server and the source IP address is set to the subnet IP (SNIP). The client IP packets are not modified. This is applicable to both IPv4 and IPv6 packets.
- TOS ID Based: The virtual server's TOS ID is encoded in the TOS field of the IP header.

You can use either the IP TUNNEL or the TOS option to implement Direct Server Return (DSR). For more information see:

- [Configure DSR mode when using TOS](#)
- [Configure load balancing in DSR mode for IPv6 networks by using the TOS field](#)
- [Configure load balancing in DSR mode by using IP Over IP](#)

You can configure MAC-Based forwarding on networks that use DSR topology, link load balancing, or firewall load balancing. For more information on MAC-Based forwarding for load balancing, see [Configure MBF for load balancing configuration](#).

## To configure the redirection mode by using the CLI

At the command prompt, type:

```
1 set lb vserver <name> -m <RedirectionMode>
2 <!--NeedCopy-->
```

### Example:

```
1 set lb vserver Vserver-LB-1 -m MAC
2 <!--NeedCopy-->
```

#### Note

For a service that is bound to a virtual server on which the `-m MAC` option is enabled, you must bind a non-user monitor.

## To configure the redirection mode by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open a virtual server and select the redirection mode.

## Configure per-VLAN wildcarded virtual servers

September 21, 2020

If you want to configure load balancing for traffic on a specific virtual local area network (VLAN), you can create a wildcarded virtual server with a listen policy that restricts it to processing traffic only on the specified VLAN.

### To configure a wildcarded virtual server that listens to a specific VLAN by using the CLI

At the command prompt, type the following commands to configure a wildcarded virtual server that listens to a specific VLAN and verify the configuration:

```
1 add lb vserver <name> <serviceType> IPAddress * Port * -listenpolicy <
 expression> [-listenpriority <positive_integer>]
2
3 show vserver
4 <!--NeedCopy-->
```

#### Example:

```
1 add lb vserver Vserver-LB-vlan1 ANY -listenpolicy "CLIENT.VLAN.ID.EQ(2)
 " -listenpriority 10
2
3 show vserver Vserver-LB-vlan1
4 <!--NeedCopy-->
```

### To configure a wildcarded virtual server that listens to a specific VLAN by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Create a new virtual server or open an existing virtual server.
3. Specify a listen policy priority and expression.

After you have created this virtual server, you bind it to one or more services as described in [Setting Up Basic Load Balancing](#).

## Assign weights to services

January 16, 2024

In a load balancing configuration, you assign weights to services to indicate the percentage of traffic that should be sent to each service. Services with higher weights can handle more requests; services with lower weights can handle fewer requests. Assigning weights to services allows the NetScaler appliance to determine how much traffic each load balanced server can handle, and therefore more effectively balance load.

Note: If you use a load balancing method that supports weighting of services (for example, the round robin method), you can assign a weight to the service.

The following table describes the load balancing methods that support weighting, and briefly describes the manner in which weighting affects how a service is selected for each one.

---

Load Balancing Methods	Service Selection with Weights
Round Robin	The virtual server prioritizes the queue of available services such that services with the highest weights come to the front of the queue more frequently than those with the lowest weights and receive proportionately more traffic. For a complete description, see <a href="#">The Round Robin Method</a> .
Least Connection	The virtual server selects the service with the best combination of fewest active transactions and highest weight. For a complete description, see <a href="#">The Least Connection Method</a> .
Least Response Time and Least Response Time Method using Monitors	The virtual server selects the service with the best combination of fewest active transactions and fastest average response time. For a complete description, see <a href="#">The Least Response Time Method</a> .
Least Bandwidth	The virtual server selects the service with the best combination of least traffic and highest bandwidth. For a complete description, see <a href="#">The Least Bandwidth Method</a> .
Least Packets	The virtual server selects the service with the best combination of fewest packets and highest weight. For a complete description, see <a href="#">The Least Packets Method</a> .
Custom Load	The virtual server selects the service with the best combination of lowest load and highest weight. For a complete description, see <a href="#">The Custom Load Method</a> .

---

**Load Balancing Methods****Service Selection with Weights**

---

Hashing methods, Static proximity and Token method

Weighting is not supported by these load balancing methods.

Least Request

The virtual server selects the service with the combination of fewest active requests and highest weight. For a complete description, see [The Least Request Method](#).

---

**To configure a virtual server to assign weights to services by using the CLI**

At the command prompt, type:

```
1 set lb vserver <name> -weight <Value> <ServiceName>
2 <!--NeedCopy-->
```

**Example:**

```
1 set lb vserver Vserver-LB-1 -weight 10 Service-HTTP-1
2 <!--NeedCopy-->
```

**To configure a virtual server to assign weights to services by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open the virtual server, and then click in the **Services** section.
3. In the weight column for the service, assign a weight to the service.

**Configure the MySQL and Microsoft SQL server version setting**

September 21, 2020

You can specify the version of Microsoft® SQL Server® and the MySQL server for a load balancing virtual server that is of type MSSQL and MySQL respectively. The version setting is recommended if you expect some clients to not be running the same version as your MySQL or Microsoft SQL Server product. The version setting provides compatibility between the client-side and server-side connections by ensuring that all communication conforms to the server's version.

**To set the Microsoft SQL server version parameter by using the CLI**

At the command prompt, type the following commands to set the Microsoft SQL Server version parameter for a load balancing virtual server and verify the configuration:

```
1 set lb vserver <name> -mssqlServerVersion <mssqlServerVersion>
2
3 show lb vserver <name>
4 <!--NeedCopy-->
```

**Example**

```
1 > set lb vserver myMSSQLvip -mssqlServerVersion 2008R2
2 Done
3 > show lb vserver myMSSQLvip
4 myMSSQLvip (190.0.2.12:1433) - MSSQL Type: ADDRESS
5 . . .
6 . . .
7 Mssql Server Version: 2008R2
8 . . .
9 . . .
10 Done
11 >
12 <!--NeedCopy-->
```

**To set the MySQL server version parameter by using the CLI**

At the command prompt, type the following commands to set the MySQL Server version parameter for a load balancing virtual server and verify the configuration:

```
1 set lb vserver <name> -mysqlServerVersion <string>
2
3 show lb vserver <name>
4 <!--NeedCopy-->
```

**Example**

```
1 > set lb vserver mysqlsvr -mysqlserverversion 5.5.30
2 Done
3 > sh lb vserver mysqlsvr
4 mysqlsvr (2.22.2.222:3306) - MYSQL Type: ADDRESS
5 . . .
6 . . .
7 Mysql Server Version: 5.5.30
8 . . .
9 . . .
```

```
10 Done
11 >
12 <!--NeedCopy-->
```

## To set the MySQL or Microsoft SQL server version parameter by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open a virtual server of type MySQL or MSSQL, and set the server version.

## Multi-IP virtual servers

May 2, 2023

The NetScaler supports creating a single load balancing virtual server with multiple non-consecutive/consecutive IPv4 and IPv6 addresses of type VIP. Each VIP address bound to a virtual server is treated as an individual virtual server. These virtual servers have the same protocol and other virtual server level settings. A virtual server with multiple VIP addresses is also called multi-IP virtual server.

The following are some advantages of using multi-IP virtual servers:

- A multi-IP virtual server offloads the work of creating many virtual servers with the same settings and service bindings.
- Multi-IP virtual servers effectively reduces the possibility of reaching the maximum limit on virtual server entities.
- One multi-IP virtual server can be used for clients in different subnets to connect to the same set of servers.
- Only one multi-IP virtual server can be used for IPv6 and IPv4 clients to connect to the same set of servers.

## Configure a multi-IP virtual server

Configuring a multi-IP virtual server consists of the following tasks:

- Create an IPset and bind multiple IP addresses to it.
- Bind the IPset to load balancing virtual servers.

Note the following points related to IPset configuration:

- An IPset can have:

- non-consecutive/consecutive IPv4 addresses and IPv6 addresses
  - combinations of IPv4 and IPv6 addresses.
- All IPv4/IPv6 addresses to be associated with virtual servers using IPset must be of type VIP.
  - A single IPset can be bound to multiple virtual servers.
  - IPv4/IPv6 addresses can be bound/unbound to/from IPset irrespective any existing IPset bindings to virtual servers.
  - You must unset the IPset binding to a virtual server before binding a new IPset to it.

### To add an IPset and bind multiple VIP addresses to it by using the CLI

At the command prompt, type:

```
1 add ipset <name>
2
3 bind ipset <name> <IPaddress1 ...>
4
5 bind ipset <name> <IPaddress2...>
6
7 show ipset <name>
8 <!--NeedCopy-->
```

### To bind the IPset to a virtual server by using the CLI

At the command prompt, type:

```
1 set lb vsrver <name> -ipset <ipset name>
2
3 show lb vsrver <name>
4 <!--NeedCopy-->
```

### To add an IPset and bind multiple VIP addresses to it by using the GUI

Navigate to **System > Network > IPsets**, and create an IPset with multiple VIP addresses.

### To bind the IPset to a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server to which you want to bind the created IPset.
2. In **Basic Settings**, set the **IPset** parameter to the name of the created IPset.

```
1 > add ipset IPSET-1
2
```

```
3
4 Done
5
6 > bind ipset IPSET-1 9.9.9.10
7
8
9 Done
10
11 > bind ipset IPSET-1 1000::20
12
13
14 Done
15
16 > add lb vserver LBVS-1 HTTP 8.8.8.10 80 -ipset IPSET-1
17
18
19 Done
20
21 > add service SVC-1 3.3.3.10 HTTP 80
22
23
24 Done
25
26 > add service SVC-2 3.3.3.100 HTTP 80
27
28
29 Done
30
31 > bind lb vserver LBVS-1 SVC-1
32
33
34 Done
35
36 > bind lb vserver LBVS-1 SVC-2
37
38
39 Done
```

## GSLB support for multi-IP virtual servers

Floating IP addresses are required for the high availability deployments. Cloud deployments do not support floating IP addresses. So, the IP set feature helps you support high availability in cloud deployments. With the IP set feature, you can associate a private IP address to each of the primary and secondary instances. One of the private IP addresses is added when creating the virtual server. The other IP address is bound to an IP set. The IP set is then associated with the virtual server. Typically a public IP address is mapped to one of the private IP addresses based on which appliance is taking the traffic. During failover, this mapping changes dynamically to route the traffic to the new primary.

In GSLB deployments, the GSLB service represents the virtual server and it requires both the private

and public IP address of the virtual server. In cloud deployments, there are multiple private IP addresses represented as an IP set but the GSLB service can accept only one private IP address. So while configuring the GSLB service it is recommended to give the IP address that is configured while adding the virtual server or one of the IP addresses in the IP set. You need not configure the IP set feature on the GSLB service. The IP set configured on the load balancing virtual server associated with the GSLB service is sufficient.

In GSLB Parent-child topology, the load balancing virtual servers on the child sites can have the IP set associated with it. The GSLB service corresponding to this topology carries the public IP address and one of the private IP addresses. The private IP address can be an IP address in the IP set or the one configured while adding the virtual server on the child site. Communication between the parent and the child sites is always using the public IP address and the public port of the GSLB service.

Also, with IP set support, you can have a single virtual server endpoint for both IPv4 and IPv6 traffic. Previously, you had to configure different virtual servers for IPv4 and IPv6 traffic. With IP set support, you can associate IPv4 and IPv6 IP addresses to the same IP set. You can add different GSLB services representing the IPv4 and IPv6 endpoints.

## Limit the number of concurrent requests on a client connection

May 2, 2023

You can limit the number of concurrent requests on a single client connection. You can protect the servers from security vulnerabilities by limiting the number of concurrent requests. When the client connection reaches the specified maximum limit, the NetScaler appliance drops subsequent requests on the connection until the outstanding request count goes below the limit.

You can configure the `maxPipelineNat` parameter to limit the number of concurrent requests on a single client connection. This parameter is applicable only to the following service types and when “`svrTimeout`” is set to zero:

- ANY
- All UDP service types except DNS

The default value of `maxPipelineNat` parameter is 255. A value of zero (0) applies no limit to the number of concurrent requests. When no limit is set, the NetScaler appliance executes all requests.

### Note

If you set `MaxpipelineNAT` to a higher value, then the probability of spoofing attack can be higher. Hence, it is recommended to set `MaxpipelineNAT` to a lower value.

## To limit the number of concurrent connections for a client by using the CLI

At the command prompt, type:

```
1 set lb parameter -maxPipelineNat <positive_integer>
2 <!--NeedCopy-->
```

### Example:

```
1 set lb parameter -maxPipelineNat 199
2 <!--NeedCopy-->
```

## To limit the number of concurrent connections for a client by using the GUI

Navigate to **Traffic Management > Load Balancing > Configure Load Balancing Parameters**, specify a value for Max Pipeline NAT requests.

## Configure diameter load balancing

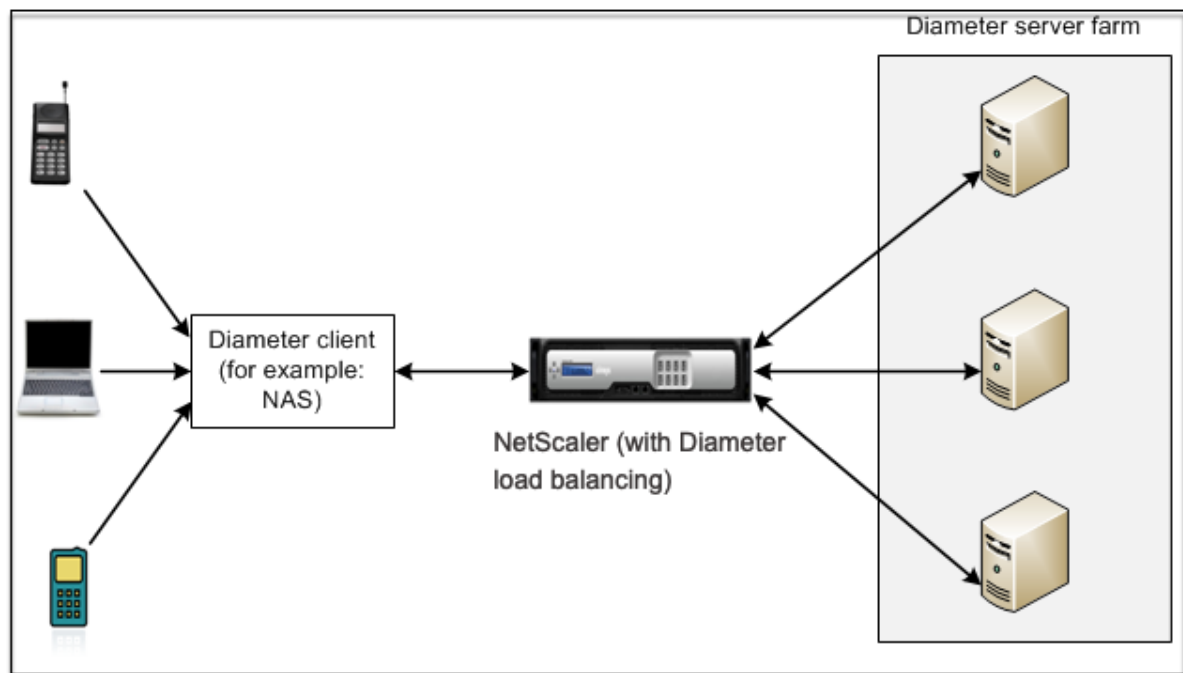

September 27, 2023

The Diameter protocol is a next generation Authentication, Authorization, and Accounting (AAA) signaling protocol used mainly on mobile devices such as laptops and mobile phones. It is a peer-to-peer protocol, as opposed to the traditional client-server model used by most other protocols. However, in most Diameter deployments, the clients originates the request and the server responds to the request.

When Diameter messages are exchanged, the Diameter server usually does much more processing than does the Diameter client. With the increase in control plane signaling volume, the Diameter server becomes a bottleneck. Therefore, Diameter messages must be load balanced to multiple servers. A virtual server performing load balancing of Diameter messages provides the following benefits:

- Lighter load on Diameter servers, which translates to faster response time to end users.
- Server health monitoring and better failover capabilities.
- Better scalability in terms of server addition without changing client configuration.
- High availability.
- SSL-Diameter offloading.

The following figure shows a Diameter system in a NetScaler deployment:

A Diameter system has the following components:

- **Diameter client.** Supports Diameter client applications in addition to the base protocol. Diameter clients are often implemented in devices at the edge of a network and provide access control services for that network. Typical examples of Diameter clients are a Network Access Server (NAS) and the Mobile IP Foreign Agent (FA).
- **Diameter agent.** Provides relay, proxy, redirect, or translation services. The NetScaler appliance (configured with a Diameter load balancing virtual server) plays the role of a Diameter agent.
- **Diameter server.** Handles the authentication, authorization, and accounting requests for a particular realm. A Diameter server must support Diameter server applications in addition to the base protocol.

In a typical Diameter topology, when an end-user device (such as a mobile phone) needs a service, it sends a request to a Diameter client. Each Diameter client establishes a single connection (TCP connection—SCTP is not yet supported) with a Diameter server as specified by the Diameter base-protocol RFC 6733. The connection is long-lived and all messages between the two Diameter nodes (client and server) are exchanged over this connection. The NetScaler uses message based load balancing.

**Example:**

A mobile service provider uses Diameter for its billing system. When a subscriber uses a prepaid number, the Diameter client repeatedly sends requests to the server to check the available balance. The Diameter protocol establishes a connection between the client and the server, and all requests are exchanged over that connection. Connection based load balancing would be pointless, because there

is only one connection. However, with the large number of messages on the connection, message based load balancing expedites the process of billing the prepaid mobile subscriber.

### **How diameter load balancing works**

A Diameter client opens a connection to the NetScaler appliance and sends a Diameter Capability Exchange Request (CER) message. The NetScaler selects a diameter server, opens a connection to the server, and forwards the CER message to the server. The server reads the client identity and determines that it is directly connected to the client.

The Diameter server prepares the Diameter handshake reply and sends it to the NetScaler appliance. The appliance modifies the handshake and inserts its own identity. At this point, the Diameter client determines that it is directly connected to the NetScaler (the agent).

**Note:**

All Diameter request messages from the client are queued on the selected server until the Diameter handshake is complete. The packets are forwarded to the server when the handshake is complete.

### **Load balancing diameter traffic**

When a client sends a request to the NetScaler appliance, the appliance parses the request and contextually load balances it to a Diameter server based on a persist AVP. The appliance has advertised the client identity to the server, so it does not add route entries, because the server is expecting messages directly from client.

Server initiated requests are not as frequent as client requests. Server initiated requests are similar to client initiated requests, except:

- Since messages are received from multiple servers, the appliance maintains the transaction state by adding a unique Hop by Hop (HbyH) number to each forwarded request message. When the message response arrives (with same HbyH number), the appliance translates this HbyH number to the HbyH number that was received on the server when the request arrived.
- The NetScaler appliance adds a route entry by putting its identity, because the client sees the appliance as a relay agent.

Note: If a Diameter message spans more than one packet, the appliance accumulates the packets in an incomplete header queue and forwards them to the server when the full message is accumulated. Similarly, if a single packet contains more than one Diameter message, the appliance splits the packet and forwards the messages to servers as determined by the load balancing virtual server.

## Disconnect a session

A Disconnect Peer Request (DPR) indicates the peer's intention of closing the connection, with the reason for closing the connection. The peer replies with a DPA (TCP always provides successful DPA).

- When the NetScaler appliance receives a DPR from the client, it broadcasts the DPR to all servers and immediately replies with a DPA to the client. The servers reply with DPAs, but the appliance ignores them. The client sends a FIN, which the appliance broadcasts to all servers.
- When the appliance receives a DPR from the server, it replies with a DPA to that server alone, and does not remove the server from the reuse pool. When the server sends a FIN, the appliance replies with FIN/ACK and removes connections from the reuse pool.
- If the appliance receives a FIN from the client, it sends the client a FIN/ACK, broadcasts the FIN, and immediately removes the server connection from the reuse pool.
- If the appliance receives a FIN from the server, it sends a FIN/ACK and removes it from reuse pool. Any new message for this server is sent on a new connection.

## Configure load balancing for diameter traffic

To configure the NetScaler appliance to load balance diameter traffic, you must first set the Diameter parameters on the appliance, then add the diameter monitor, add the diameter services, bind the services to the monitor, add the diameter load balancing virtual server, and bind the services to the virtual server.

### To configure load balancing for diameter traffic by using the command line interface

Configure the diameter parameters.

```
1 set ns diameter -identity <string> -realm <string> -
 serverClosePropagation <YES|NO>
2 <!--NeedCopy-->
```

#### Example:

```
1 set ns diameter -identity mydomain.org -realm org -
 serverClosePropagation YES
2 <!--NeedCopy-->
```

Add a Diameter monitor.

```
1 add lb monitor <monitorName> DIAMETER -originHost <string> -originRealm
 <string>
2 <!--NeedCopy-->
```

#### Example:

```

1 add lb monitor diameter_mon DIAMETER -originHost mydomain.org -
 originRealm org
2 <!--NeedCopy-->

```

Create the Diameter services.

```

1 add service <name> <IP> DIAMETER <port>
2 <!--NeedCopy-->

```

**Example:**

```

1 add service diameter_svc0 10.102.82.86 DIAMETER 3868
2
3 add service diameter_svc1 10.102.82.87 DIAMETER 3868
4
5 add service diameter_svc2 10.102.82.88 DIAMETER 3868
6
7 add service diameter_svc3 10.102.82.89 DIAMETER 3868
8 <!--NeedCopy-->

```

Bind the Diameter services to the Diameter monitor.

```

1 bind service <name>@ monitorName <monitorName>
2 <!--NeedCopy-->

```

**Example:**

```

1 bind service diameter_svc0 -monitorName diameter_mon
2
3 bind service diameter_svc1 -monitorName diameter_mon
4
5 bind service diameter_svc2 -monitorName diameter_mon
6
7 bind service diameter_svc3 -monitorName diameter_mon
8 <!--NeedCopy-->

```

Add a Diameter load balancing virtual server with Diameter persistence.

```

1 add lb vserver <name> DIAMETER <IPAddress> <port> -persistenceType
 DIAMETER -persistAVPno <positive_integer>
2 <!--NeedCopy-->

```

**Example:**

```

1 add lb vserver diameter_vs DIAMETER 10.102.112.152 3868 -
 persistenceType DIAMETER -persistAVPno 263
2 <!--NeedCopy-->

```

Bind the Diameter services to the Diameter load balancing virtual server.

```

1 bind lb vserver <name> <serviceName>
2 <!--NeedCopy-->

```

**Example:**

```
1 bind lb vserver diameter_vs diameter_svc0
2
3 bind lb vserver diameter_vs diameter_svc1
4
5 bind lb vserver diameter_vs diameter_svc2
6
7 bind lb vserver diameter_vs diameter_svc3
8 <!--NeedCopy-->
```

Save the configuration.

```
1 save ns config
2 <!--NeedCopy-->
```

**Note:** You can also configure load balancing of Diameter traffic over SSL by using the **SSL\_DIAMETER** service type.

**To configure load balancing for Diameter traffic by using the configuration utility**

1. Navigate to **System > Settings > Change Diameter Parameters** and set the diameter parameters.
2. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and create a load balancing virtual server of type Diameter.
3. Create a service of type Diameter.
4. Create a monitor of type Diameter. In Special parameters, set the origin host and origin realm.
5. Bind the monitor to the service, and bind the service to the Diameter virtual server.
6. In Advanced Settings, click **Persistence**, specify the diameter, and enter a persistence AVP number.
7. Click **Save**, and click **Done**.

**Configure FIX load balancing**

May 2, 2023

Financial Information eXchange (FIX) protocol is an open message standard used in the financial industry for electronic exchange of information related to securities transaction between trading partners. FIX/SSL\_FIX protocol is used extensively by buy-side and sell-side firms, trading platforms, and regulators for communicating trade information.

This feature enables you to configure a FIX or SSL\_FIX load balancing virtual server to distribute incoming FIX messages and provide security in FIX messaging. NetScaler supports FIX message based

load balancing (MLB) for FIX 4.1, FIX 4.2, FIX 4.3, and FIX 4.4 versions.

FIX MBLB on a NetScaler appliance provides the following benefits:

1. Efficient management of FIX or SSL\_FIX servers with superior HA and health monitoring.
2. SYN protection to all FIX or SSL\_FIX servers.
3. FIX session persistence.

## How FIX load balancing works

A FIX MBLB setup includes a FIX load-balancing virtual server and multiple load-balanced FIX servers. The FIX virtual server receives incoming client traffic, parses the incoming traffic into FIX messages, selects a FIX server for each FIX message, and forwards the message to the selected FIX server. The following conceptual drawing illustrates a typical FIX load balancing setup.

In a basic FIX MBLB setup, the FIX virtual server distributes FIX messages coming from clients to the load-balanced FIX servers using the round robin load-balancing method. With persistence of type FIXSESSION enabled, the FIX virtual server selects the same server for different FIX messages belonging to the same FIX session. The FIX session is determined based on the values of the **FIX** fields Sender-CompID (tag 49) and TargetCompID (tag 56).

## Configure and monitor load balancing for FIX traffic

Following are the configurations that you must do to load balance FIX message traffic:

1. Configuring FIX load balancing virtual server
2. Configuring SSL\_FIX load balancing virtual server
3. Configuring FIX load balancing service
4. Configuring SSL\_FIX load balancing service
5. Configuring FIXSESSION persistence
6. Setting persistence timeout
7. Displaying FIX/SSL\_FIX stats
8. Monitoring FIX/SSL\_FIX persistent sessions

### To configure a FIX load balancing server by using the command line interface

At the command prompt, type:

```
1 add lb vserver <name> FIX <IP> <PORT>
2 <!--NeedCopy-->
```

Example

```
1 add lb vserver vs1 FIX 10.102.82.86 3868
2 <!--NeedCopy-->
```

### To configure a SSL\_FIX load balancing virtual server by using the command line interface

At the command prompt, type:

```
1 add lb vserver <name> SSL_FIX <IP> <PORT>
2 <!--NeedCopy-->
```

Example

```
1 add lb vserver vs1 SSL_FIX 10.102.82.86 3868
2 <!--NeedCopy-->
```

### To configure a FIX service by using the command line interface

At the command prompt, type:

```
1 add service <name> <ip-addr> FIX <port>
2 <!--NeedCopy-->
```

Example

```
1 add service_svc1 10.102.82.86 FIX 3868
2 <!--NeedCopy-->
```

**To configure a SSL\_FIX service by using the command line interface**

At the command prompt, type:

```
1 add service <name> <ip-addr> SSL_FIX <port>
2 <!--NeedCopy-->
```

Example

```
1 add service svc1 10.102.82.86 SSL_FIX 3868
2 <!--NeedCopy-->
```

**To configure FIXSESSION persistence by using the command line interface**

At the command prompt, type:

```
1 set lb vserver <name> -persistenceType FIXSESSION
2 <!--NeedCopy-->
```

Example

```
1 set lb vserver vs1 -persistenceType FIXSESSION
2 <!--NeedCopy-->
```

**To set persistence timeout by using the command line interface**

At the command prompt, type:

```
1 set lb vserver <name> -timeout <value>
2 <!--NeedCopy-->
```

Example

```
1 set lb vserver vs1 -timeout 2
2 <!--NeedCopy-->
```

**To display FIX stats by using the command line interface**

At the command prompt, type:

```
1 stat lb vserver <name>
2 <!--NeedCopy-->
```

Example

```
1 stat lb vserver_svc1
2 <!--NeedCopy-->
```

### To bind FIX service to FIX virtual server by using the command line interface

At the command prompt, type:

```
1 bind lb vserver <name> <service name>
2 <!--NeedCopy-->
```

Example

```
1 bind lb vserver vs1 svc1
2 <!--NeedCopy-->
```

### To display FIX persistent sessions by using the command line interface

At the command prompt, type:

```
1 show lb persistentSessions <name>
2 <!--NeedCopy-->
```

Example

```
1 show lb persistentSessions vs1
2 <!--NeedCopy-->
```

#### Note

Note: You can now configure the load balancing of FIX traffic over SSL by using the SSL\_FIX service type. This service provides secured communication for FIX messages.

### To configure FIX load balancing virtual server by using the GUI

1. Navigate to the **Configuration > Traffic Management > Load Balancing > Virtual Servers** page and click **Add** to create a FIX Load Balancing virtual server.
2. On the **Load Balancing Virtual Server** page, set the server parameters:
  - a) Virtual Server Name
  - b) Protocol type as “FIX”
  - c) Server IP Address Type
  - d) Server IP Address
  - e) Server Port Number
3. Click **OK** and **Continue** to set other parameters.
4. In the **Services** section, select or add a new FIX load balancing virtual service, and bind it to the FIX server.
5. In the **Persistence** section, set the following parameters:

- a) Persistence type as 'FIXSESSION'
  - b) Time-out interval
6. Click **OK** and then **Done**.

### **To edit a FIX load balancing virtual server by using the GUI**

Navigate to **Configuration > Traffic Management > Load Balancing > Virtual Servers** page, select a FIX server and click **Edit**.

### **To delete a FIX load balancing virtual server by using the GUI**

Navigate to **Configuration > Traffic Management > Load Balancing > Virtual Servers** page, select a FIX server, and click **Delete**.

### **To configure FIX Load Balancing Virtual Service by using the GUI**

1. Navigate to **Configuration > Traffic Management > Load Balancing > Services** page and click **Add** to create a FIX Load Balancing virtual service.
2. On the **Services** page, set the following parameters. You can click the 'More' arrow to set other parameters such as Traffic Domain, Hash ID, Server ID, Cache Type, and Number of Active Connections.
  - a) Service Name –FIX Virtual Service Name
  - b) Choose Virtual Server type as (New or Existing)
  - c) Protocol –Protocol Type as 'FIX'
  - d) Server –Virtual Server IP address
  - e) Port –Server Port Number
3. Click **OK** and **Continue** to set other parameters such as Monitors, Threshold & Timeout, Profiles, and Policies.
4. Click **OK** and then **Done**.

### **To edit a FIX load balancing virtual service by using the GUI**

Navigate to **Configuration > Traffic Management > Load Balancing > Services** page, select a **FIX service** and click **Edit**.

### **To delete a FIX load balancing virtual service by using the GUI**

Navigate to **Configuration > Traffic Management > Load Balancing > Services** page, select a FIX service, and click **Delete**.

### **To display FIX load balancing server statistics**

Navigate to **Configuration > Traffic Management > Load Balancing > Virtual Servers** page and then click **Statistics** to display the FIX server statistics.

### **To display Persistent sessions for a FIX server by using the GUI**

Navigate to **Configuration > Traffic Management** page and, under **Monitor Sessions** click **Virtual Server Persistent Sessions**.

### **To clear Persistent sessions for a FIX server by using the GUI**

1. Navigate to **Configuration > Traffic Management** page and, under **Monitor Sessions** click **Clear Persistent Sessions**.
2. On the **Clear Persistent Sessions** page, set the following parameters:
  - a) Virtual Server –Choose a FIX virtual server
  - b) Persistence Parameter –Choose a FIX persistence parameter
3. Click **OK**.

## **MQTT load balancing**

May 2, 2023

The Message Queuing Telemetry Transport (MQTT) is an OASIS standard messaging protocol for the Internet of Things (IoT). MQTT is a flexible and easy-to-use technology that provides effective communication within an IoT system. MQTT is a broker-based protocol and is widely used to facilitate the exchange of messages between clients and broker.

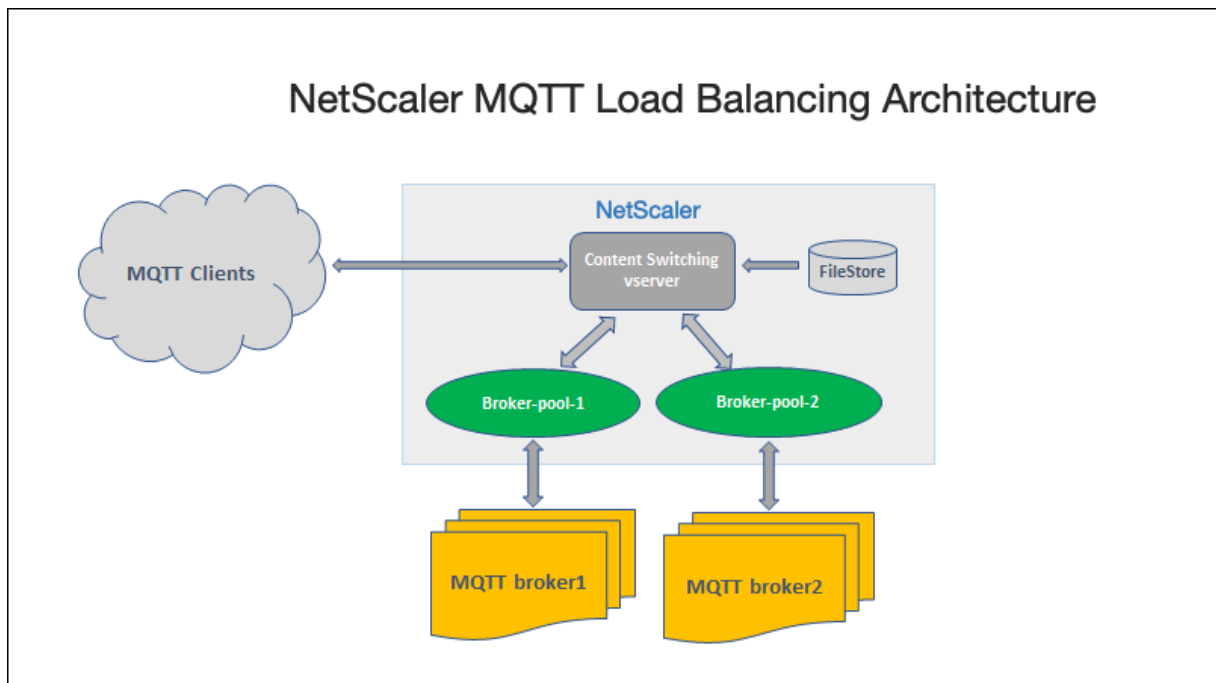

The following key benefits of MQTT make it a well-suited option for your IoT device:

- Reliability
- Fast response time
- Capability to support unlimited devices

- Publish/subscribe messaging that is perfect for many-to-many communication

IoT is the network of interconnected devices that are embedded with sensors, software, network connectivity, and necessary electronics. The embedded components enable IoT devices to collect and exchange data. The increase in use of IoT devices brings in multiple challenges for network infrastructure, with Scale being the prominent one. In a large scale deployment of IoT devices, the data generated by each IoT device needs to be analyzed swiftly. To achieve the scale requirement and efficient usage of resources, the load on the broker pool must be distributed evenly. With the support of the MQTT protocol, you can use the NetScaler appliance in IoT deployments to load balance the MQTT traffic.

The following figure depicts the MQTT architecture using a NetScaler appliance to load balance the MQTT traffic.

An IoT deployment with MQTT protocol has the following components:

- **MQTT broker.** A server that receives all messages from the clients and then routes the messages to the appropriate destination clients. The broker is responsible for receiving all messages, filtering the messages, determining who is subscribed to each message, and sending the message to these subscribed clients. The broker is the central hub through which every message must pass.
- **MQTT client.** Any device, from a micro controller up to a full-fledged server, which runs an MQTT library and connects to an MQTT broker over a network. Both publishers and subscribers are MQTT clients. The publisher and subscriber labels refer to whether the client is publishing messages or subscribed to receive messages.

- **MQTT load balancer.** The NetScaler appliance is configured with an MQTT load balancing virtual server to load balance MQTT traffic.

In a typical IoT deployment, the broker (cluster of servers) manages the group of IoT devices (IoT clients). The NetScaler appliance load balances the MQTT traffic to the brokers based on various parameters, such as Client ID, topic, and user name.

## Configure load balancing for MQTT traffic

For the NetScaler appliance to load balance MQTT traffic, perform the following configuration tasks:

1. Configure MQTT/MQTT\_TLS services or service groups.
2. Configure MQTT/MQTT\_TLS load balancing virtual server.
3. Bind the MQTT/MQTT\_TLS services to the MQTT/MQTT\_TLS load balancing virtual server.
4. Configure MQTT/MQTT\_TLS content switching virtual server.
5. Configure a content switching action that specifies the target load balancing virtual server
6. Configure a content switching policy.
7. Bind the content switching policy to a content switching virtual server that is already configured to redirect to the specific load balancing virtual server.
8. Save the configuration.

### To configure load balancing for MQTT traffic by using the CLI

Configure MQTT/MQTT\_TLS services or service groups.

```
1 add service <name> <IP> <protocol> <port>
2 add servicegroup <ServiceGroupName> <Protocol>
3 bind servicegroup <serviceGroupName> <IP> <port>
4 <!--NeedCopy-->
```

#### Example:

```
1 add service srvcl 10.106.163.3 MQTT 1883
2 add servicegroup srvcg1 MQTT
3 bind servicegroup srvcg1 10.106.163.3 1883
4 <!--NeedCopy-->
```

Configure MQTT/MQTT\_TLS load balancing virtual server.

```
1 add lb vserver <name> <protocol> <IPAddress> <port>
2 <!--NeedCopy-->
```

#### Example:

```
1 add lb vserver lb1 MQTT 10.106.163.9 1883
2 <!--NeedCopy-->
```

Bind the MQTT/MQTT\_TLS services or service groups to the MQTT load balancing virtual server.

```
1 bind lb vserver <name> <serviceName>
2 bind lb vserver <name> <servicegroupName>
3 <!--NeedCopy-->
```

**Example:**

```
1 bind lb vserver lb1 srvc1
2 bind lb vserver lb1 srvcg1
3 <!--NeedCopy-->
```

Configure MQTT/MQTT\_TLS content switching virtual server.

```
1 add cs vserver <name> <protocol> <IPAddress> <port>
2 <!--NeedCopy-->
```

**Example:**

```
1 add cs vserver cs1 MQTT 10.106.163.13 1883
2 <!--NeedCopy-->
```

Configure a content switching action that specifies the target load balancing virtual server.

```
1 add cs action <name> -targetLBvserver <string> [-comment <string>]
2 <!--NeedCopy-->
```

**Example:**

```
1 add cs action act1 -targetlbvserver lbv1
2 <!--NeedCopy-->
```

Configure a content switching policy.

```
1 add cs policy <policyName> [-url <string> | -rule <expression>] -
 action <actName>
2 <!--NeedCopy-->
```

**Example:**

```
1 add cs policy cspol1 -rule "MQTT.COMMAND.EQ(CONNECT) && MQTT.CONNECT
 .FLAGS.QOS.eq(2)" -action act1
2 <!--NeedCopy-->
```

Bind the content switching policy to a content switching virtual server that is already configured to redirect to the specific load balancing virtual server.

```
1 bind cs vserver <virtualServerName> -policyName <policyName> -priority
 <positiveInteger>
2 <!--NeedCopy-->
```

**Example:**

```
1 bind cs vserver cs1 -policyName cspol1 -priority 20
2 <!--NeedCopy-->
```

Save the configuration.

```
1 save ns config
2 <!--NeedCopy-->
```

### To configure load balancing for MQTT traffic by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and create a load balancing virtual server of type **MQTT** or **MQTT\_TLS**.
2. Create a service or service group of type MQTT.
3. Bind the service to the MQTT virtual server.
4. Click **Save**.

### MQTT message length limit

The NetScaler appliance treats the messages with message length greater than 65536 bytes as jumbo packets, and discard them by default. The `dropmqttjumbomessage lb` parameter decides whether to process the jumbo packets or not. This parameter is by default set to **YES**, which implies that the jumbo MQTT packets are dropped by default. If this parameter is set to **NO**, the ADC appliance handles even the packets with message length greater than 65536 bytes.

To configure the ADC appliance to handle jumbo packets by using CLI:

```
1 Set lb parameter -dropMqttJumboMessage [YES | NO]
2 <!--NeedCopy-->
```

#### Example:

```
1 set lb parameter -dropMqttJumboMessage no
2 <!--NeedCopy-->
```

### Protect a load balancing configuration against failure

May 2, 2023

When a load balancing virtual server fails, or when the virtual server is unable to handle excessive traffic, the load balancing setup can fail. You can protect your load balancing setup against failure by configuring;

- the NetScaler appliance to redirect excess traffic to an alternate URL,
- a backup load balancing virtual server, and
- a stateful connection failover.

## Redirect client requests to an alternate URL

October 8, 2023

You can redirect requests to an alternate URL by using an HTTP 302 redirect if a load balancing virtual server of type HTTP or HTTPS goes DOWN or is disabled. The alternate URL can provide information about the status of the server. The configured redirect URL is specified in the location header of the HTTP response. The exact URL specified in the response depends on the following configuration options:

- If the configured redirect URL contains only the domain name, such as <http://www.sample1.example.com>, the redirect URL specified in the HTTP response appends the Uniform Resource Identifier (URI). It is specified in the HTTP request to the configured domain name. For example, if the request contains the GET [http://www.sample2.example.com/images/site\\_nav.png](http://www.sample2.example.com/images/site_nav.png) header, then the location header in the redirect response specifies the location: [http://www.sample1.example.com/images/site\\_nav.png](http://www.sample1.example.com/images/site_nav.png) header.

**Note**

The domain names in the request and response can differ. In this topic, the two domains are referred to as [sample1.example.com](http://www.sample1.example.com) and [sample2.example.com](http://www.sample2.example.com) to explain the concept.

- If the configured redirect URL contains a complete path, then the redirect response specifies the complete configured URL, irrespective of the URI in the request. For example, the following are such URLs:
  - Requested URL - <http://www.redirect.com/en/index.html>
  - Redirect URL - [http://www.redirect.com/en/site\\_down.html](http://www.redirect.com/en/site_down.html)

The following table lists the preceding configuration options:

Configured Redirect URL	URL in HTTP Request	Header
<a href="http://www.sample1.example.com">http://www.sample1.example.com</a>	<a href="http://www.sample2.example.com/en/index.html">http://www.sample2.example.com/en/index.html</a>	<a href="http://www.sample1.example.com/en/index.html">http://www.sample1.example.com/en/index.html</a>
<a href="http://www.sample1.example.com/en/error.html">http://www.sample1.example.com/en/error.html</a>	<a href="http://www.sample2.example.com/en/index.html">http://www.sample2.example.com/en/index.html</a>	<a href="http://www.sample1.example.com/en/error.html">http://www.sample1.example.com/en/error.html</a>

**Note**

- When configuring a redirect URL, the <http://example.com> URL is not the same as the <http://example.com/> URL, because the latter contains the complete path to the Webroot path, `/`.
- If a load balancing virtual server is configured with both a backup virtual server and a redirect URL, the backup virtual server takes precedence over the redirect URL. A redirect is used only when both the primary and backup virtual servers are DOWN.

**To configure a virtual server to redirect the client request to a URL by using the CLI**

1. Create a load balancing virtual server.

```
set lb vserver -redirect url
```

2. Verify that the redirect URL option is working as expected. Disable the virtual server.

```
disable vserver <vserver_name>
```

3. Access the website URL from a web browser to verify that the request is redirected as expected. You might have to clear the web browser cache and make a new connection before accessing the website.

4. Enable virtual server.

```
enable vserver <vserver_name>
```

**To configure a virtual server to redirect the client request to a URL by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, to add a new virtual server, click **Add**.
3. To edit an existing virtual server, select the virtual server from the list and click **Edit**.
4. On the **Advanced Settings** tab, click **Protection**. In the **Redirect URL** field, type the redirect URL (for example, <http://www.newdomain.com/mysite/maintenance>).
5. Click **OK**.

**Configure a backup load balancing virtual server**

June 7, 2023

You can configure the NetScaler appliance to direct requests to a backup virtual server when the primary load balancing virtual server is DOWN or unavailable. The backup virtual server is a proxy and is transparent to the client. The appliance can also send a notification message to the client regarding the site outage.

The backup load balancing virtual server ensures minimal disruption when the primary method is unavailable, increasing the availability and reliability of the load balanced environment.

**Note:**

The backup virtual server continues to handle the existing connections, even after the primary virtual server is deleted or disabled.

You can configure a backup load balancing virtual server when you create it, or you can change the optional parameters of an existing virtual server. You can also configure a backup virtual server for an existing backup virtual server, thus creating cascading backup virtual servers. The maximum depth of cascading backup virtual servers is 10.

If you have multiple virtual servers that connect to two servers, you have a choice for what happens if the primary virtual server goes DOWN and then comes back up. The default behavior is for the primary virtual server to resume its role as primary. However, you can configure the backup virtual server to remain in control when it takes over. For example, you can sync the updates on the backup virtual server to the primary virtual server and then manually force the original primary server to resume its role. In this case, you can designate the backup virtual server to remain in control when the primary virtual server goes DOWN and then comes back up.

You can configure a redirect URL on the primary load balancing virtual server as a fallback when both the primary and the backup virtual servers are DOWN or have reached their threshold for handling requests. When services bound to virtual servers are OUT OF SERVICE, the appliance uses the redirect URL.

**Backup LB Method** is displayed if the following load balancing methods are selected:

- Least connection
- Least response time
- Round robin
- Least bandwidth
- Least packets
- Custom load
- Least request
- Static proximity

**Note**

If a load balancing virtual server is configured with both a backup virtual server and a redirect URL, then the backup virtual server takes precedence over the redirect URL. A redirect is used only when the primary and backup virtual servers are down.

**To set a backup virtual server by using the CLI**

At the command prompt, type:

```
1 set lb vserver <vServerName> -backupVserver <BackupVServerName> [-
 disablePrimaryOnDown]
2 <!--NeedCopy-->
```

**Example:**

```
1 set lb vserver Vserver-LB-1 -backupVserver Vserver-LB-2 -
 disablePrimaryOnDown
2 <!--NeedCopy-->
```

**To set a backup virtual server by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
2. In Advanced Settings, click **Protection**, and select a backup virtual server.
3. If you want the backup virtual server to remain in control until you manually enable the primary virtual server even if the primary virtual server comes back up, select **Disable Primary When Down**.

**Note:** Starting from NetScaler version 12.1 build 51.xx, the GUI displays the effective state of that server indicating if the backup is active or not.

The effective state of the current server can be one of the following:

- **UP** –Indicates that the server is UP
- **DOWN** –Indicates that the server is DOWN
- **UP (Backup Active)** –Indicates that either the primary or the secondary virtual server is UP and traffic is directed to the backup virtual server.
- **DOWN (Backup Active)** –Indicates that both the primary and the backup virtual servers are down and traffic is routed to the backup virtual server.

When the **Disable Primary When Down** option is enabled on the primary virtual server and the primary server goes DOWN and is back UP again, the traffic is still served by the backup virtual

server until the primary virtual server is re-enabled explicitly. You can use the command `enable lb vserver <vserver_name>` command to re-enable the primary virtual server.

## Configure spillover

May 2, 2023

A spillover configuration on the appliance consists of a primary virtual server that is configured with a spillover method, a spillover threshold, and a backup virtual server. Backup virtual servers can also be configured for spillover, creating a chain of backup virtual servers.

The spillover method specifies the operational condition on which you want to base your spillover configuration (for example, the number of established connections, bandwidth, or combined health of the server farm). When a new connection arrives, the appliance verifies that the primary virtual server is up and compares the operational condition with the configured spillover threshold. If the threshold is reached, the spillover feature diverts new connections to the first available virtual server in the backup chain. The backup virtual server manages the connections it receives until the load on the primary falls below the threshold.

If you configure spillover persistence, the backup virtual server continues to process the connections it received, even after the load on the primary falls below the threshold. If you configure spillover persistence and a spillover persistence timeout, the backup virtual server processes connections for only the specified period after the load on the primary falls below the threshold.

**Note:** Usually, spillover is triggered if the value associated with the spillover method exceeds the threshold (for example, number of connections). However with the server-health spillover method, spillover is triggered if the health of the server farm falls below the threshold.

You can configure spillover in one of the following ways:

- Specify a predefined spillover method. Four predefined methods are available, and they fulfill common spillover requirements.
- Configure policy based spillover. In policy based spillover, you use a NetScaler rule to specify the conditions for spillover to occur. NetScaler rules give you the flexibility to configure spillover for various operational conditions.

Use policy based spillover if a predefined method does not satisfy your requirements. If you configure both for a primary virtual server, the policy based spillover configuration takes precedence over the predefined method.

First, you create the primary virtual server and the virtual servers that you need for the backup chain. You set up the backup chain by specifying one virtual server as the backup for the primary (that is, you

create a secondary virtual server), a virtual server as the backup for the secondary (that is, you create a tertiary virtual server), and so on. Then, you configure spillover by either specifying a predefined spillover method or creating and binding spillover policies.

For instructions for assigning a virtual server as the backup for another virtual server, see [Configuring a Backup Load Balancing Virtual Server](#).

## Configure a predefined spillover method

Predefined spillover methods fulfill some of the more common spillover requirements. To use one of the predefined spillover methods, you configure spillover parameters on the primary virtual server. To create a chain of backup virtual servers, you also configure spillover parameters on backup virtual servers.

If the backup virtual servers reach their own threshold values, and the service type is TCP, the NetScaler appliance sends clients a TCP reset. For service types HTTP, SSL, and RTSP, it diverts new requests to the redirect URL configured for the primary virtual server. A redirect URL can be specified for only HTTP, SSL, and RTSP virtual servers. If a redirect URL is not configured, the NetScaler appliance sends clients a TCP reset (if the virtual server is of type TCP) or an HTTP 503 response (if the virtual server is of type HTTP or SSL).

**Note:** With RTSP virtual servers, the NetScaler appliance uses only data connections for spillover. If the backup RTSP virtual server is not available, the requests are redirected to an RTSP URL and an RTSP redirect message is sent to the client.

### To configure a predefined spillover method for a virtual server by using the command line interface

At the command prompt, type:

```
1 set lb vserver <vServerName> -soMethod <spilloverType> -soThreshold <
 positiveInteger> -soPersistence ENABLED -soPersistenceTimeout <
 positiveInteger>
2 <!--NeedCopy-->
```

#### Example

```
1 set lb vserver Vserver-LB-1 -soMethod Connection -soThreshold 1000 -
 soPersistence enabled -soPersistenceTimeout 2
2 <!--NeedCopy-->
```

## To configure a predefined spillover method for a virtual server by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
2. In Advanced Settings, click **Protection**, and set the spillover parameters.

## Configure policy based spillover

Spillover policies, which are based on rules (expressions), enable you to configure the appliance for a wider range of spillover scenarios. For example, you can configure spillover based on the virtual server's response time, or based on the number of connections in the virtual server's surge queue.

To configure policy based spillover, first create a spillover action. You then select the expression that you want to use in the spillover policy, configure the policy, and associate the action with it. Finally, you bind the spillover policy to a load balancing, content switching, or global server load balancing virtual server. You can bind multiple spillover policies to a virtual server, with priority numbers. The appliance evaluates the spillover policies in ascending order of priority numbers and performs the action associated with the last policy to evaluate to TRUE.

A virtual server can also have a backup action. The backup action is performed if the virtual server does not have one or more backup virtual servers, or if all backup virtual servers are DOWN, disabled, or have reached their own spillover limits.

When a spillover policy results in an UNDEF condition (an exception thrown when the result of policy evaluation is undefined), an UNDEF action is performed. The UNDEF action is always ACCEPT. You cannot specify an UNDEF action of your choice.

## Configuring a Spillover Action

A spillover action is performed when the spillover policy with which it is associated evaluates to TRUE. Currently, SPILLOVER is the only supported spillover action.

**To configure policy based spillover by using the command line interface** At the command prompt, type the following commands to configure a spillover policy and verify the configuration:

```
1 add spillover action <name> -action SPILLOVER
2
3 show spillover action <name>
4 <!--NeedCopy-->
```

**Example**

```
1 add spillover action mySoAction -action SPILLOVER
2 Done
3 <!--NeedCopy-->
```

```
1 show spillover action mySoAction
2 1) Name: mySoAction Action: SPILLOVER
3 Done
4 <!--NeedCopy-->
```

**Selecting an Expression for the Spillover Policy**

In the policy expression, you can use any virtual-server based expression that returns a Boolean value. For example, you can use one of the following expressions:

```
1 SYS.VSERVER("vserver").RESPTIME.GT(<int>)
2 SYS.VSERVER("vserver").STATE.EQ(" <string> "), and
3 SYS.VSERVER("vserver").THROUGHPUT.LT (<int>)
4 <!--NeedCopy-->
```

In addition to the existing functions such as RESPTIME, STATE, and THROUGHPUT, you can use the following virtual server based functions that have been introduced with this feature:

**Averagesurgecount** Returns the average number of requests in the surge queues of active services. Returns 0 (zero) if there are no active services. Raises an UNDEF condition if used with a content switching or global server load balancing virtual server.

**Activeservices** Returns the number of active services. Raises an UNDEF condition if used with a content switching or global server load balancing virtual server.

**Activetransactions** Returns the value of the virtual-server-level counter for current active transactions.

**is\_dynamic\_limit\_reached** Returns a Boolean TRUE if the number of connections that the virtual server manages is equal to the dynamically calculated threshold. The dynamic threshold is the sum of the maximum client (Max Clients) settings of the bound services that are UP.

You can use a policy expression to implement any of the predefined spillover methods. The following table maps the predefined spillover methods to the expressions you can use to implement them:

Table 1. Converting predefined spillover methods to policy expressions

Predefined spillover method	Corresponding expression
CONNECTION	SYS.VSERVER("<vserver-name>").CONNECTIONS, used with the GT(int) arithmetic function.
BANDWIDTH	SYS.VSERVER("<vserver-name>").THROUGHPUT, used with the GT(int) arithmetic function.
HEALTH	SYS.VSERVER("<vserver-name>").HEALTH, used with the LT(int) arithmetic function.
DYNAMICCONNECTION	SYS.VSERVER("<vserver-name>").IS_DYNAMIC_LIMIT_REACHED <b>Note:</b> If you implement policy based spillover by using the IS_DYNAMIC_LIMIT_REACHED function, you must also configure the predefined DYNAMICCONNECTION method for the virtual server, so that the statistics required for spillover to work are collected.

### Configuring a Spillover Policy

A spillover policy uses a Boolean expression as a rule to specify the conditions that must be met for spillover to occur.

**To configure a spillover policy by using the command line interface** At the command prompt, type the following commands to configure a spillover policy and verify the configuration:

```

1 add spillover policy <name> -rule <expression> -action <string> [-
 comment <string>]
2
3 show spillover policy <name>
4 <!--NeedCopy-->
```

#### Example

```

1 > add spillover policy mySoPolicy -rule SYS.VSERVER("v1").RESPTIME.GT
 (50) -action mySoAction -comment "Triggers spillover when the
 vserver's response time is greater than 50 ms."
2 Done
3
4 > show spillover policy mySoPolicy
5
6 1) Name: mySoPolicy Rule: "SYS.VSERVER("v1").RESPTIME.GT(50)" Action:
 mySoAction Hits: 0 ActivePolicy: 0
```

```

7 Comment: "Triggers spillover when the vserver's response time is
 greater than 50 ms."
8 Done
9 >
10 <!--NeedCopy-->

```

## Binding a Spillover Policy to a Virtual Server

You can bind a spillover policy to load balancing, content switching, or global server load balancing virtual servers). You can bind multiple policies to a virtual server, with Goto expressions controlling the flow of evaluation.

**To bind a spillover policy to a virtual server by using the command line interface** At the command prompt, type the following commands to bind a spillover policy to a load balancing, content switching, or global server load balancing virtual server and verify the configuration:

```

1 bind (lb | cs | gslb) vserver <name> -policyName <string> -priority <
 positive_integer> [-gotoPriorityExpression <expression>]
2
3 show (lb | cs | gslb) vserver <name>
4 <!--NeedCopy-->

```

### Example

```

1 > bind lb vserver vserver1 -policyName mySoPolicy -priority 5
2 Done
3 > show lb vserver vserver1
4 vserver1 (2.2.2.12:80) - HTTP Type: ADDRESS
5 . . .
6
7 1) Spillover Policy Name: mySoPolicy Priority: 5
8 GotoPriority Expression: END
9 Flowtype: REQUEST
10 Done
11 >
12 <!--NeedCopy-->

```

## Configuring a Backup Action for a Spillover Event

A backup action specifies what to do when the spillover threshold is reached but one or more backup virtual servers are either not configured or are down, disabled, or have reached their own thresholds.

Note: For the predefined spillover methods that are configured directly on the virtual server (as values of the Spillover Method parameter), the backup action is not configurable. By default, the appliance sends clients a TCP reset (if the virtual server is of type TCP) or an HTTP 503 response (if the virtual server is of type HTTP or SSL).

The backup action is configured on the virtual server. You can configure the virtual server to accept requests (after the threshold specified by the policy is reached), redirect clients to a URL, or simply drop requests even before establishing TCP or SSL connections until the number of requests falls below the threshold. Therefore, lesser memory resources are utilized as the connections are reset even before allocating any data structures.

**To configure a backup action for spillover by using the CLI** At the command prompt, type the following commands to configure a backup action and verify the configuration:

```
1 set lb vserver <name> -soBackupAction <soBackupAction>
2
3 show lb vserver <name>
4 <!--NeedCopy-->
```

**Example:**

```
1 set lb vserver vs1 -soBackupAction REDIRECT -redirectURL `http://www.
 mysite.com/maintenance`
2 Done
3 > show lb vserver vs1
4 vs1 (10.102.29.76:80) - HTTP Type: ADDRESS
5 State: UP
6 . . .
7 Redirect URL: `http://www.mysite.com/maintenance`
8 . . .
9 Done
10 <!--NeedCopy-->
```

**To configure a backup action for spillover by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
2. In Advanced Settings, click **Protection**, and then specify a spillover backup action.

## Connection failover

May 2, 2023

Connection failover helps prevent disruption of access to applications deployed in a distributed environment. In a NetScaler High Availability (HA) setup, *connection failover* (or *connection mirroring-CM*) refers to keeping active an established TCP or UDP connection when a failover occurs. The new primary NetScaler appliance has information about the connections established before the failover and continues to serve those connections. After failover, the client remains connected to the same

physical server. The new primary appliance synchronizes the information with the new secondary appliance. If the L2Conn parameter is set, Layer 2 connection parameters are also synchronized with the secondary.

Note:

Consider a HA setup, where a client establishes a session with the primary node, which in turn establishes a session with the back end server. When a failover is triggered in this state, the packets received on a new primary from the existing client and server nodes are treated as stale packets, and the client and server connections are reset. Whereas if stateless connection failover is enabled (USIP is ON), after the failover, the connections are not reset when you receive packets from client or server nodes. Instead, the client and server connections are created dynamically.

You can set up connection failover in either stateless or stateful mode. In the stateless connection failover mode, the HA nodes do not exchange any information about the connections that are failed over. This method has no runtime overhead.

In the stateful connection failover mode, the primary appliance synchronizes the data of the failed-over connections with the new secondary appliance.

Connection failover is helpful if your deployment has long lasting connections. For example, if you are downloading a large file over FTP and a failover occurs during the download, the connection breaks and the download is aborted. However, if you configure the connection failover in stateful mode, the download continues even after the failover.

## How connection failover works on NetScaler appliances

In a stateless connection failover, the new primary appliance tries to re-create the packet flow according to the information contained in the packets it receives.

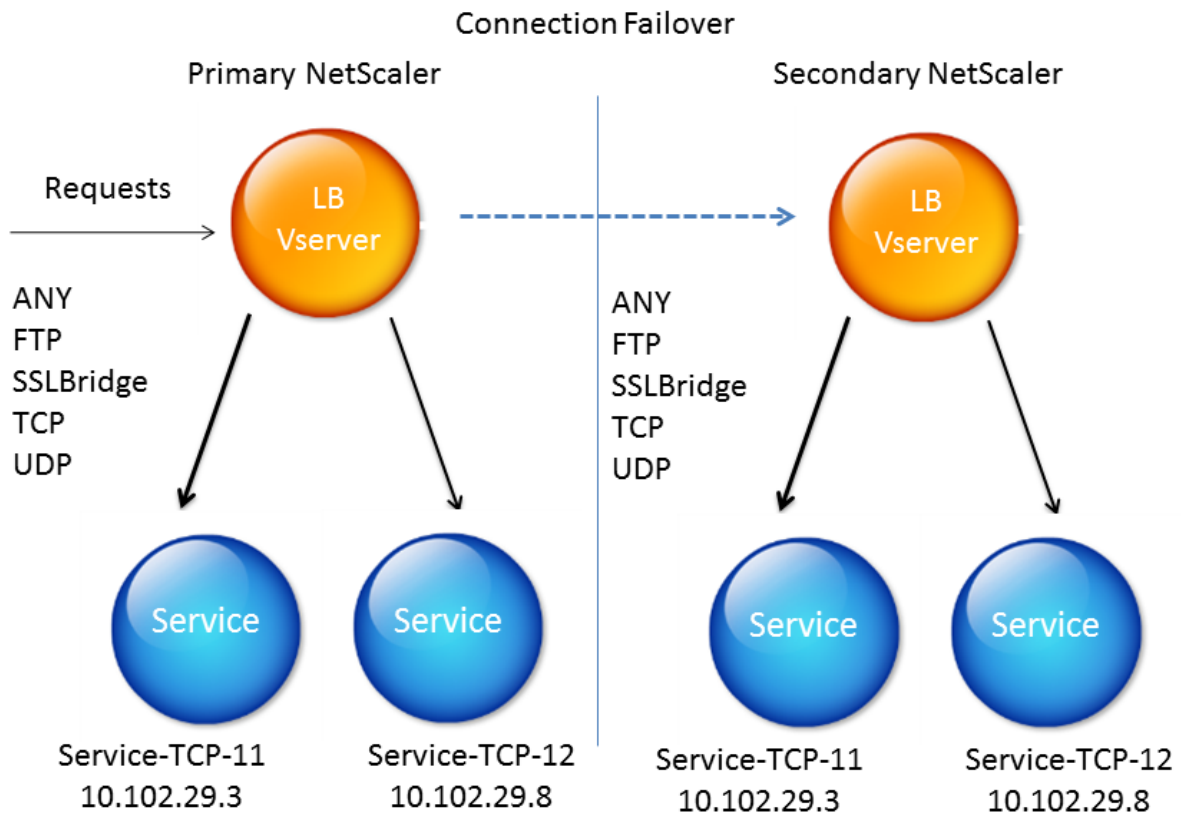

In stateful failover, to maintain current information about the mirrored connections, the primary appliance sends messages to the secondary appliance. The secondary appliance maintains the data related to the packets but uses it only in the event of a failover. If a failover occurs, the new primary (old secondary) appliance starts using the stored data about the mirrored connections and accepting traffic. During the transition period, the client and server might experience a brief disruption and retransmissions.

Note:

Verify that the primary appliance is able to authorize itself on the secondary appliance. To verify the correct configuration of the passwords, use the show `rpcnode` command from the command line or use the RPC option of the **Network** menu in the GUI.

A basic HA configuration with connection failover contains the entities shown in the following figure.

Figure 1. Connection Failover Entity Diagram

**Note**

Connection failover is not supported after either of the following events:

- 1 - An upgrade to a later release.
- 2 - An upgrade to a later build within the same release, **if** the **new** build uses a different HA version.

**Supported setup**

Connection failover can be configured only on load balancing virtual servers. It cannot be configured on content switching virtual servers. If you enable connection failover on load balancing virtual servers that are attached to a content switching virtual server, connection failover does not work because the load balancing virtual servers do not initially accept the traffic.

The following table describes the setup supported for connection failover.

Table 1. Connection Failover - Supported Setup

Setting	Stateless	Stateful
Service type	ANY.	ANY, UDP, TCP, FTP, SSL_BRIDGE.
Load balancing methods	All methods supported for the service type ANY. However, if Source IP persistence is not set, the SRCIPSRCPORHASH method must be used.	All methods applicable to the supported service types.
Persistence types	SOURCEIP persistence.	All types applicable to the supported service types are supported.
USIP	Must be ON.	No restriction. It can be ON or OFF.
Service bindings	Service can be bound to only one virtual server.	Service can be bound to one or more virtual servers.
Internet Protocol (IP) versions	IPv4 and IPv6	IPV4 and IPV6
Redundancy support	Clustering and high availability	High availability
INC mode	Not supported	Supported when virtual server service type is ANY, mode is DSR (MAC, IPTUNNEL, TOS), and USIP is enabled on the services bound to the virtual server.

**Note:**

Stateful connection failover is supported only for connection-based switching services, for example, TCP. Because HTTP uses request-based switching, it does not support connection failover. In SSL, the existing connections are reset after the failover.

**Features affected by connection failover**

The following table lists the features affected if connection failover is configured.

Table 2. How Connection Failover Affects NetScaler Features

---

Feature	Impact of Connection Failover
SYN protection	For any connection, if a failover occurs after the appliance issues SYN-ACK but before it receives the final ACK, the connection is not supported by the connection failover. The client must reissue the request to establish the connection.
Surge protection	If the failover occurs before a connection with the server is established, the new primary appliance tries to establish the connection with the server. It also retransmits all the packets held during surge protection.
Access down	If enabled, the access-down functionality takes precedence over the connection failover.
Application firewall	The Application firewall feature is not supported.
INC	Independent network configuration (INC) is supported in the high availability mode only when the virtual server service type is ANY, mode is DSR (MAC, IPTUNNEL, TOS), and USIP is enabled on the services bound to the virtual server. In all other scenarios, INC is not supported.
TCP buffering	TCP buffering is not compatible with connection mirroring.
Close on response	After failover, the NATPCBs might not be closed on response.

---

### To configure connection failover by using GUI

Navigate to **Traffic Management > Load Balancing > Virtual Servers**. Open the virtual server, and in **Advanced Settings**, click **Protection**, and select **Connection Failover** as **Stateful**.

### To configure connection failover by using CLI

At the command prompt:

```
1 set lb vserver <vServerName> -connFailover <Value>
2 show lb vserver <vServerName>
3 <!--NeedCopy-->
```

**Example:**

```
1 set lb vserver Vserver-LB-1 -connFailover stateful
2 Done
3 <!--NeedCopy-->
```

When connection failover is disabled on a virtual server, the resources allocated to the virtual server are freed.

**To disable connection failover by using CLI**

At the command prompt:

```
1 set lb vserver <vServerName> -connFailover <Value>
2 show lb vserver <vServerName>
3 <!--NeedCopy-->
```

**Example:**

```
1 set lb vserver Vserver-LB-1 -connFailover disable
2 Done
3 <!--NeedCopy-->
```

**To disable connection failover by using GUI**

Navigate to **Traffic Management> Load Balancing> Virtual Servers**. Open the virtual server, in **Protection**, select **Connection Failover** as Disabled.

## Flush the surge queue

May 2, 2023

When a physical server receives a surge of requests, it becomes slow to respond to the clients that are currently connected to it, which leaves users dissatisfied and disgruntled. Often, the overload also causes clients to receive error pages. The NetScaler appliance provides features such as surge protection, which controls the rate at which new connections to a service can be established and thus avoid overloads.

The appliance does connection multiplexing between clients and physical servers. When it receives a client request to access a service on a server, the appliance looks for an already established connection to the server that is free. If it finds a free connection, it uses that connection to establish a virtual link between the client and the server. If it does not find an existing free connection, the appliance establishes a new connection with the server, and establishes a virtual link between the client

and the server. However, if the appliance cannot establish a new connection with the server, it sends the client request to a surge queue. If all the physical servers bound to the load balancing or content switching virtual server reach the upper limit on client connections (max client value, surge protection threshold or maximum capacity of the service), the appliance cannot establish a connection with any server. The surge protection feature uses the surge queue to regulate the speed at which connections are opened with the physical servers. The appliance maintains a different surge queue for each service bound to the virtual server.

The length of a surge queue increases whenever a request comes for which the appliance cannot establish a connection. The length of a surge queue decreases in any of the following conditions:

- A request in the queue gets sent to the server.
- A request gets timed out and is removed from the queue.

If the surge queue for a service or service group becomes too long, you might want to flush it. You can flush the surge queue of a specific service or service group, or of all the services and service groups bound to a load balancing virtual server. Flushing a surge queue does not affect the existing connections. Only the requests present in the surge queue get deleted. For those requests, the client has to make a fresh request.

You can also flush the surge queue of a content switching virtual server. If a content switching virtual server forwards some requests to a particular load balancing virtual server, and the load balancing virtual server also receives some other requests, when you flush the surge queue of the content switching virtual server, only the requests received from this content switching virtual server are flushed. The other requests in the surge queue of the load balancing virtual server are not flushed.

Note: You cannot flush the surge queues of cache redirection, authentication, VPN, or GSLB virtual servers or GSLB services.

Note: Do not use the Surge Protection feature if Use Source IP (USIP) is enabled.

### **To flush a surge queue by using the CLI**

The flush ns surgeQ command works in the following manner:

- You can specify the name of a service, service group, or virtual server whose surge queue has to be flushed.
- If you specify a name while running the command, the surge queue of the specified entity is flushed. If more than one entity has the same name, the appliance flushes the surge queues of all those entities.
- If you specify the name of a service group, and a server name and port while running the command, the appliance flushes the surge queue of only the specified service group member.

- You cannot directly specify a service group member (<serverName> and <port>) without specifying the name of the service group (<name>) and you cannot specify <port> without a <serverName>. Specify the <serverName> and <port> if you want to flush the surge queue for a specific service group member.
- If you run the command without specifying any names, the appliance flushes the surge queues of all the entities present on the appliance.
- If a service group member is identified with a server name, you must specify the server name in this command; you cannot specify its IP address.

At the command prompt, type:

```
1 flush ns surgeQ [-name <name>] [-serverName <serverName> <port>]
2 <!--NeedCopy-->
```

### Examples

```
1 flush ns surgeQ - name SVC1ANZGB - serverName 10.10.10.1 80
2 <!--NeedCopy-->
```

The previous command flushes the surge queue of the service or virtual server that is named SVC1ANZGB and has IP address as 10.10.10

```
1 flush ns surgeQ
2 <!--NeedCopy-->
```

The previous command flushes all the surge queues on the appliance.

### To flush a surge queue by using the GUI

Navigate to **Traffic Management > Content Switching > Virtual Servers**, select a virtual server and, in the Action list, select **Flush Surge Queue**.

## Manage a load balancing setup

May 2, 2023

An existing Load Balancing setup does not require a great deal of work to maintain as long as it is unchanged, but most do not remain unchanged for long. Increasing load requires new load-balanced servers and eventually new NetScaler appliances, which must be configured and added to the existing setup. Old servers wear out and must be replaced, requiring removal of some servers and addition

of others. Upgrades to your networking equipment or changes to topology might also require modifications to your load balancing setup. Therefore, you need to perform operations on server objects, services, and virtual servers. The Visualizer can display your configuration graphically, and you can perform operations on the entities in the display. You can also take advantage of other features that facilitate management of the traffic through your load balancing setup.

## Manage server objects

May 2, 2023

During basic load balancing setup, when you create a service, a server object with the IP address of the service is created, if one does not exist. If you prefer for your service objects named with domain names rather than IP addresses, you might also have created one or more server objects manually. You can enable, disable, or remove any server object.

When you enable or disable a server object, you enable or disable all services associated with the server object. When you refresh the NetScaler appliance after disabling a server object, the state of its service appears as OUT OF SERVICE. If you specify a wait time when disabling a server object, the server object continues to handle established connections for the specified amount of time, but rejects new connections. If you remove a server object, the service to which it is bound is also deleted.

### To enable a server by using the CLI

At the command prompt, type:

```
1 enable server <name>
2 <!--NeedCopy-->
```

#### Example:

```
1 enable server 10.102.29.5
2 <!--NeedCopy-->
```

### To enable or disable a server object by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Servers**.
2. Select the server and, in the Action list, select **Enable** or **Disable**.

### To disable a server object by using the CLI

At the command prompt, type:

```
1 disable server <name> <delay>
2 <!--NeedCopy-->
```

**Example:**

```
1 disable server 10.102.29.5 30
2 <!--NeedCopy-->
```

**To remove a server object by using the CLI**

At the command prompt, type:

```
1 rm server <name>
2 <!--NeedCopy-->
```

**Example:**

```
1 rm server 10.102.29.5
2 <!--NeedCopy-->
```

**To remove a server object by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Servers**.
2. Select a server, and click **Remove**.

**Manage services**

May 2, 2023

Services are enabled by default when you create them. You can disable or enable each service individually. When disabling a service, you normally specify a wait time during which the service continues to handle established connections, but rejects new ones, before shutting down. If you do not specify a wait time, the service shuts down immediately. During the wait time, the service's state is OUT OF SERVICE.

You can remove a service when it is no longer used. When you remove a service, it is unbound from its virtual server and deleted from the NetScaler configuration.

**To enable or disable a service by using the CLI**

At the command prompt, type:

```

1 enable service <name>
2
3 disable service <name> <DelayInSeconds>
4 <!--NeedCopy-->

```

**Examples:**

```

1 enable service Service-HTTP-1
2 disable service Service-HTTP-1 30
3 <!--NeedCopy-->

```

**To enable or disable a service by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Open a service and, in the **Action** list, select **Enable** or **Disable**.

**Identify the cause for the service state marked DOWN by using the GUI**

Starting from NetScaler version 13.0 build 41.20, you can view the monitor probe information on the GUI for the services that are DOWN without navigating to the monitor binding interface. The value in the **Server State** column of the Services page is clickable. You can click **DOWN** to identify the root cause because of which the service is marked DOWN.

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Click **DOWN** in the **Server State** column corresponding to the service that is DOWN.

The Service to Load Balancing Monitor Binding page appears.

The **Last Response** column displays the reason because of which the service is marked DOWN.

## Manage a load balancing virtual server

May 2, 2023

Virtual servers are enabled by default when you create them. You can disable and enable virtual servers manually. If you disable a virtual server, the virtual service's state appears as OUT OF SERVICE. When this happens, the virtual server terminates all connections, either immediately or after allowing existing connections to complete, depending on the setting of the `downStateFlush` parameter. If `downStateFlush` is ENABLED (default), all the connections are flushed. If DISABLED, the virtual server continues to serve requests on existing connections.

You remove a virtual server only when you no longer require the virtual server. Before you remove it, you must unbind all services from it.

### To enable or disable a virtual server by using the CLI

At the command prompt, type:

```
1 enable lb vserver <name>
2 <!--NeedCopy-->
```

```
1 disable lb vserver <name>
2 <!--NeedCopy-->
```

#### Examples:

```
1 enable lb vserver Vserver-LB-1
2 disable lb vserver Vserver-LB-1
3 <!--NeedCopy-->
```

### To enable or disable a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Select a virtual server, and in the **Action** list, select **Enable** or **Disable**.

### To unbind a service from a virtual server by using the CLI

At the command prompt, type:

```
1 unbind lb vserver <name> <serviceName>
2 <!--NeedCopy-->
```

#### Example:

```
1 unbind lb vserver Vserver-LB-1 Service-HTTP-1
2 <!--NeedCopy-->
```

### To unbind a service from a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open a virtual server, and click in the **Services** section.
3. Select a service and click **Unbind**.

### Identify the cause for the virtual server state marked DOWN by using the GUI

Starting from NetScaler version 13.0 build 41.20, you can view the monitor probe information on the GUI for the virtual servers that are DOWN without navigating to the monitor binding interface. The value in the **% HEALTH** column of the Virtual Server page is clickable. You can click the value in the **% HEALTH** column to identify the root cause because of which the virtual server is marked DOWN.

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Click the value in the **% HEALTH** column corresponding to the virtual server that is down.

The Service and Service Group Monitor page appears. The services and service groups bound to this virtual server are displayed in the respective tabs.

### If you are using services bound to load balancing virtual, perform the following:

In the **Services** tab, click **DOWN** corresponding to the service that is down.

The **Last Response** column in the Service to Load Balancing Monitor Binding page displays the reason because of which the virtual server is marked down.

Service to Load Balancing Monitor Binding				
MONITOR NAME	CONFIGURED STATE	CURRENT STATE	LAST RESPONSE	WEIGHT
ping	ENABLED	# UNKNOWN	Probing ownership is with some other node in cluster.	1

Total Weight 1  
Monitoring Threshold 0

**If you are using service groups bound to load balancing virtual, perform the following:**

In the **Service Groups** tab, Click **DOWN** in the Services and Service Group Monitor page and then click **DOWN** in the Service Group Member page.

The **Last Response** column in the Service Groups Member Monitors page displays the reason because of which the virtual server is marked down.

### Services and Service Group Monitor

Services 1    **Service Groups** 1

SERVICE GROUP NAME	STATE	EFFECTIVE STATE	TRAFFIC DOMAIN
svg-10a	● ENABLED	● DOWN <span style="border: 1px solid #000; border-radius: 50%; padding: 2px;">1</span>	0

[Services and Service Group Monitor](#) / [Service Group Member](#)

### Service Group Member

4.4.4.4	4.4.4.4	99	1	None	--	ENABLED	● DOWN <span style="border: 1px solid #000; border-radius: 50%; padding: 2px;">2</span>

[Services and Service Group Monitor](#) / [Service Group Member](#) / [Service Groups Member Monitors](#)

### Service Groups Member Monitors

TOTAL PROBES	TOTAL FAILED PROBES	TOTAL CURRENT FAILED PROBES	LAST RESPONSE
12	12	12	● Failure - No SNIP available to send the monitor probe. <span style="border: 1px solid #000; border-radius: 50%; padding: 2px;">3</span>

## Load balancing visualizer

October 8, 2023

The Load Balancing Visualizer is a tool that you can use to view and modify the load balancing configuration in a graphical format. Following is an example of the Visualizer display.

You can use the visualizer to view the following:

- The services and service groups that are bound to a virtual server.
- The monitors that are bound to each service.
- The policies that are bound to the virtual server.
- The policy labels, if configured.
- Configuration details of any displayed element.

You can also use the Visualizer to add and bind new objects, modify existing ones, and enable or disable objects. Most configuration elements displayed in the Visualizer appear under the same names as in other parts of the configuration utility. However, unlike the rest of the configuration utility, the Visualizer groups services that have the same configuration details and monitor bindings into an entity called a service container.

A service container is set of similar services and service groups that are bound to a single load balancing virtual server. The services in the container have the same properties, except for the name, IP address, and port, and their monitor bindings must have the same weight and binding state. When you bind a new service to a virtual server, it is placed into an existing container if its configuration and monitor bindings match those of other services. Otherwise, it is placed in its own container.

The following procedures provide only the basic steps for using the Visualizer. Because the Visualizer duplicates functionality in other areas of the Load Balancing feature, other methods of viewing or configuring all the settings that can be configured in the Visualizer are provided throughout the Load Balancing documentation.

Note: The Visualizer requires a graphic interface, so it is available only through the configuration utility.

### **To view load balancing virtual server properties by using the Visualizer**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, select the virtual server that you want to view, and then click **Visualizer**.

### **To view configuration details for services, service groups, and monitors by using the Visualizer**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, select the virtual server that you want to view, and then click **Visualizer**.
3. In the Load Balancing Visualizer dialog box, double-click the entity to view the configuration details of the entity that is bound to this virtual server, you can do the following:

### **To view configuration details for policies and policy labels by using the Visualizer in the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, select the virtual server that you want to view, and then click Visualizer.
3. In the Load Balancing Visualizer dialog box, double-click the policies entity to view the policies that are bound to this virtual server.

### **To modify a resource in a load balancing configuration by using the Visualizer**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, select the virtual server that you want to configure, and then click Visualizer.
3. In the Load Balancing Visualizer dialog box, on the Visualizer image, double-click the resource that you want to modify.

### **To add a load balancing configuration by using the Visualizer**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, select the virtual server that you want to configure, and then click Visualizer.
3. In the Load Balancing Visualizer dialog box, click + to add the resource.

## **Manage client traffic**

May 2, 2023

Managing client connections properly helps to ensure that your applications remain available to users even when your NetScaler appliance is experiencing high loads. Various load balancing features and other features available on the appliance can be integrated into a load balancing setup to process load more efficiently, divert it when necessary, and prioritize the tasks that the appliance must perform:

- **Sessionless load balancing.** You can configure sessionless load balancing virtual servers and perform load balancing without creating sessions in configurations that use DSR or intrusion detection systems (IDS).
- **Integrated caching.** You can redirect HTTP requests to a cache.
- **Delayed cleanup.** You can configure delayed cleanup of virtual server connections to prevent the cleanup process from using CPU cycles during periods when the NetScaler appliance is experiencing high loads.

- **Rewrite.** You can use the Rewrite feature to modify port and protocol when performing HTTP redirection, or insert the virtual server IP address and port into a custom Request header.
- **RTSP NAT.**
- **Rate-based monitoring.** You can enable rate-based monitoring to divert excess traffic.
- **Layer 2 Parameters.** You can configure a virtual server to use the L2 parameters to identify a connection.
- **ICMP Response.** You can configure the appliance to send ICMP responses to PING requests according to your settings. On the IP address corresponding to the virtual server, set the ICMP RESPONSE to VSVR\_CNTRLD, and on the virtual server, set the `ICMP VSERVER RESPONSE`. The following settings can be made on a virtual server:
  - When you set `ICMP VSERVER RESPONSE` to PASSIVE on all virtual servers, the appliance always responds.
  - When you set `ICMP VSERVER RESPONSE` to ACTIVE on all virtual servers, the appliance responds even if one virtual server is UP.
  - When you set `ICMP VSERVER RESPONSE` to ACTIVE on some and PASSIVE on others, the appliance responds even if one virtual server set to ACTIVE is UP.

## Configure sessionless load balancing virtual servers

May 2, 2023

When the NetScaler appliance performs load balancing, it creates and maintains sessions between clients and servers. The maintenance of session information places a significant load on the appliance resources, and sessions might not be needed in scenarios such as a direct server return (DSR) setup and the load balancing of intrusion detection systems (IDS). To avoid creating sessions when they are not necessary, you can configure a virtual server on the appliance for sessionless load balancing. In sessionless load balancing, the appliance carries out load balancing on a per-packet basis.

Sessionless load balancing can operate in MAC-based forwarding mode or IP-based forwarding mode.

For MAC-based forwarding, the IP address of the sessionless virtual server must be specified on all the physical servers to which the traffic is forwarded.

For IP-based forwarding in sessionless load balancing, the IP address and port of the virtual server need not be specified on the physical servers, because this information is included in the forwarded packets. When forwarding a packet from the client to the physical server, the appliance leaves client details such as IP address and port unchanged and adds the IP address and port of the destination.

## Supported setup

NetScaler sessionless load balancing supports the following service types and load balancing methods:

### Service Types

- ANY for MAC-based redirection
- ANY, DNS, and UDP for IP-based redirection

### Load Balancing Methods

- Round Robin
- Least Bandwidth
- LRTM (Least response time method)
- Source IP Hash
- Destination IP Hash
- Source IP Destination IP Hash
- Source IP Source Port Hash
- Custom Load

### Limitations

Sessionless load balancing has the following limitations:

- The appliance must be deployed in two-arm mode.
- A service must be bound to only one virtual server.
- Sessionless load balancing is not supported for service groups.
- Sessionless load balancing is not supported for domain based services (DBS services).
- Sessionless load balancing in the IP mode is not supported for a virtual server that is configured as a backup to a primary virtual server.
- You cannot enable spillover mode.
- For all the services bound to a sessionless load balancing virtual server, the Use Source IP (USIP) option must be enabled.
- For a wildcard virtual server or service, the destination IP address is not changed.

#### Note:

- While configuring a virtual server for sessionless load balancing, explicitly specify a supported load balancing method. The default method, Least Connection, cannot be used for sessionless load balancing.

- To configure sessionless load balancing in MAC-based redirection mode on a virtual server, the MAC-based forwarding option must be enabled on the NetScaler appliance.

### To add a sessionless virtual server by using the CLI

At the command prompt, type the following commands to add a sessionless virtual server and verify the configuration:

```
1 add lb vserver <name>@ <serviceType> <IPAddress>@ <port> -m <
 redirectionMode> -sessionless <(ENABLED|DISABLED)> -lbMethod <
 load_balancing_method>
2
3 show lb vserver <name>
4 <!--NeedCopy-->
```

#### Example:

```
1 add lb vserver sesslessv1 any 11.11.12.123 54 -sessionless ENABLED -
 lbMethod roundrobin -m ip
2 Done
3 show lb vserver sesslessv1
4 sesslessv1 (11.11.12.123:54) - ANY Type: ADDRESS
5 State: DOWN
6 ...
7 Effective State: DOWN
8 Client Idle Timeout: 120 sec
9 Down state flush: ENABLED
10 ...
11 Persistence: NONE
12 Sessionless LB: ENABLED
13 Connection Failover: DISABLED
14 L2Conn: OFF
15 1) Policy : cmp_text Priority:8680 Inherited
16 2) Policy : cmp_nocmp_ie60 Priority:8690 Inherited
17 <!--NeedCopy-->
```

### To configure sessionless load balancing on an existing virtual server

At the command prompt, type:

```
1 set lb vserver <name>@ -m <redirectionMode> -sessionless <(ENABLED|
 DISABLED)> -lbMethod <load_balancing_method>
2 <!--NeedCopy-->
```

#### Example

```
1 set lb vserver sesslessv1 -m mac -sessionless ENABLED -lbmethod lrtm
2 Done
3 <!--NeedCopy-->
```

**Note**

For a service that is bound to a virtual server on which the `-m MAC` option is enabled, you must bind a non-user monitor.

**To configure a sessionless virtual server by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open the virtual server, and in Advanced Settings, click Traffic Settings, and then select Sessionless Load Balancing.

**Redirect HTTP requests to a cache**

May 2, 2023

The NetScaler cache redirection feature redirects HTTP requests to a cache. You can significantly reduce the impact of responding to HTTP requests and improve your website performance through proper implementation of the cache redirection feature.

A cache stores frequently requested HTTP content. When you configure cache redirection on a virtual server, the NetScaler appliance sends cacheable HTTP requests to the cache, and non-cacheable HTTP requests to the origin Web server.

**To configure cache redirection on a virtual server by using the CLI**

At the command prompt, type:

```
1 set lb vserver <name> -cacheable <Value>
2 <!--NeedCopy-->
```

**Example:**

```
1 set lb vserver Vserver-LB-1 -cacheable yes
2 <!--NeedCopy-->
```

**To configure cache redirection on a virtual server by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
2. In Advanced Settings, click Traffic Settings, and select Cacheable.

## Enable cleanup of virtual server connections

May 2, 2023

Under certain conditions, you can configure the `downStateFlush` setting to immediately terminate existing connections when a service or a virtual server is marked DOWN. Terminating existing connections frees resources, and in certain cases speeds recovery of overloaded load balancing setups.

The state of a virtual server depends on the states of the services bound to it. The state of each service depends on the responses of the load balanced servers to probes and health checks sent by the monitors that are bound to that service. Sometimes the load balanced servers do not respond. If a server is slow or busy, monitoring probes can time out. If repeated monitoring probes are not answered within the configured timeout period, the service is marked DOWN.

A virtual server is marked DOWN only when all services bound to it are marked DOWN. When a virtual server goes DOWN, it terminates all connections, either immediately or after allowing existing connections to complete.

Do not enable the `downStateFlush` setting on those application servers that must complete their transactions. You can enable this setting on Web servers whose connections can safely be terminated when they are marked DOWN.

The following table summarizes the effect of this setting on an example configuration consisting of a virtual server, `Vserver-LB-1`, with one service bound to it, `Service-TCP-1`. In the table, E and D denote the state of the `downStateFlush` setting: E means Enabled, and D means Disabled.

---

Vserver-LB-1	Service-TCP-1	State of connections
E	E	Both client and server connections are terminated.

Vserver-LB-1	Service-TCP-1	State of connections
E	D	For some service types, such as TCP, for which the NetScaler appliance does not support connection reuse, both client and server connections are terminated. For service types, such as HTTP, for which the appliance supports connection reuse, both client and server connections are terminated only if a transaction is active on those connections. If a transaction is not active, only client connections are terminated.
D	E	For some service types, such as TCP, for which the NetScaler appliance does not support connection reuse, both client and server connections are terminated. For service types, such as HTTP, for which the appliance supports connection reuse, both client and server connections are terminated only if a transaction is active on those connections. If a transaction is not active, only server connections are terminated.
D	D	Neither client nor server connections are terminated.

If you want to disable a service only when all the established connections are closed by the server or the client, you can use the graceful shutdown option. For information about the graceful shutdown of a service, see [Graceful Shutdown of Services](#).

## To configure the down state flush setting on a virtual server by using the CLI

At the command prompt, type:

```
1 set lb vserver <name> -downStateFlush <Value>
2 <!--NeedCopy-->
```

### Example:

```
1 set lb vserver Vserver-LB-1 -downStateFlush enabled
2 <!--NeedCopy-->
```

## To configure the down state flush setting on a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
2. In Advanced Settings, click Traffic Settings, and select Down State Flush.

## Rewrite ports and protocols for HTTP redirection

May 2, 2023

Virtual servers and the services that are bound to them might use different ports. When a service responds to an HTTP connection with a redirect, you might need to configure the NetScaler appliance to modify the port and the protocol to make sure that the redirection goes through successfully. You do this by enabling and configuring the `redirectPortRewrite` setting.

This setting affects only HTTP and HTTPS traffic. If this setting is enabled on a virtual server, the virtual server rewrites the port on redirects, replacing the port used by the service with the port used by the virtual server.

If the virtual server or service is of type SSL, you must enable SSL redirect on the virtual server or service. If both the virtual server and service are of type SSL, enable SSL redirect on the virtual server.

The `redirectPortRewrite` setting can be used in the following scenarios:

- The virtual server is of type HTTP and the services are of type SSL.
- The virtual server is of type SSL and the services are of type HTTP.
- The virtual server is of type HTTP and the services are of type HTTP.
- The virtual server is of type SSL and the services are of type SSL.

Scenario 1: The virtual server is of type HTTP and services are of type SSL. SSL redirect, and optionally port rewrite, is enabled on the service. If port rewrite is enabled, the port of HTTPS URLs is rewritten. HTTP URLs from the server are sent as is to the client.

*Only SSL redirect is enabled. The virtual server can be configured on any port. See the following table:*

Redirect URL from the Server	Redirect URL sent to the Client
<a href="http://domain.com/">http://domain.com/</a>	<a href="http://domain.com/">http://domain.com/</a>
<a href="http://domain.com:8080/">http://domain.com:8080/</a>	<a href="http://domain.com:8080/">http://domain.com:8080/</a>
<a href="https://domain.com/">https://domain.com/</a>	<a href="https://domain.com/">https://domain.com/</a>
<a href="https://domain.com:444/">https://domain.com:444/</a>	<a href="https://domain.com:444/">https://domain.com:444/</a>

*SSL redirect and port rewrite are enabled. The virtual server is configured on port 80. See the following table:*

Redirect URL from the Server	Redirect URL sent to the Client
<a href="http://domain.com/">http://domain.com/</a>	<a href="http://domain.com/">http://domain.com/</a>
<a href="http://domain.com:8080/">http://domain.com:8080/</a>	<a href="http://domain.com:8080/">http://domain.com:8080/</a>
<a href="https://domain.com/">https://domain.com/</a>	<a href="https://domain.com/">https://domain.com/</a>
<a href="https://domain.com:444/">https://domain.com:444/</a>	<a href="https://domain.com/">https://domain.com/</a>

*SSL redirect and port rewrite are enabled. Virtual server is configured on port 8080. See the following table:*

Redirect URL from the Server	Redirect URL sent to the Client
<a href="http://domain.com/">http://domain.com/</a>	<a href="http://domain.com/">http://domain.com/</a>
<a href="http://domain.com:8080/">http://domain.com:8080/</a>	<a href="http://domain.com:8080/">http://domain.com:8080/</a>
<a href="https://domain.com/">https://domain.com/</a>	<a href="http://domain.com:8080/">http://domain.com:8080/</a>
<a href="https://domain.com:444/">https://domain.com:444/</a>	<a href="http://domain.com:8080/">http://domain.com:8080/</a>

Scenario 2: The virtual server is of type SSL and services are of type HTTP. If port rewrite is enabled, only the port of HTTP URLs is rewritten. HTTPS URLs from the server are sent as is to the client.

*SSL redirect is enabled on the virtual server. The virtual server can be configured on any port. See the following table.*

Redirect URL from the Server	Redirect URL sent to the Client
<a href="http://domain.com/">http://domain.com/</a>	<a href="https://domain.com/">https://domain.com/</a>
<a href="http://domain.com:8080/">http://domain.com:8080/</a>	<a href="https://domain.com:8080/">https://domain.com:8080/</a>
<a href="https://domain.com/">https://domain.com/</a>	<a href="https://domain.com/">https://domain.com/</a>
<a href="https://domain.com:444/">https://domain.com:444/</a>	<a href="https://domain.com:444/">https://domain.com:444/</a>

SSL redirect and port rewrite are enabled on the virtual server. The virtual server is configured on port 443. See the following table:

Redirect URL from the Server	Redirect URL sent to the Client
<a href="http://domain.com/">http://domain.com/</a>	<a href="https://domain.com/">https://domain.com/</a>
<a href="http://domain.com:8080/">http://domain.com:8080/</a>	<a href="https://domain.com/">https://domain.com/</a>
<a href="https://domain.com/">https://domain.com/</a>	<a href="https://domain.com/">https://domain.com/</a>
<a href="https://domain.com:444/">https://domain.com:444/</a>	<a href="https://domain.com:444/">https://domain.com:444/</a>

SSL redirect and port rewrite are enabled. The virtual server is configured on port 444. See the following table:

Redirect URL from the Server	Redirect URL sent to the Client
<a href="http://domain.com/">http://domain.com/</a>	<a href="https://domain.com:444/">https://domain.com:444/</a>
<a href="http://domain.com:8080/">http://domain.com:8080/</a>	<a href="https://domain.com:444/">https://domain.com:444/</a>
<a href="https://domain.com/">https://domain.com/</a>	<a href="https://domain.com/">https://domain.com/</a>
<a href="https://domain.com:445/">https://domain.com:445/</a>	<a href="https://domain.com:445/">https://domain.com:445/</a>

Scenario 3: The virtual server and service are of type HTTP. Port rewrite must be enabled on the virtual server. Only the port of HTTP URLs is rewritten. HTTPS URLs from the server are sent as is to the client.

The virtual server is configured on port 80. See the following table:

Redirect URL from the Server	Redirect URL sent to the Client
<a href="http://domain.com/">http://domain.com/</a>	<a href="http://domain.com/">http://domain.com/</a>

Redirect URL from the Server	Redirect URL sent to the Client
<a href="http://domain.com:8080/">http://domain.com:8080/</a>	<a href="http://domain.com/">http://domain.com/</a>
<a href="https://domain.com/">https://domain.com/</a>	<a href="https://domain.com/">https://domain.com/</a>
<a href="https://domain.com:444/">https://domain.com:444/</a>	<a href="https://domain.com:444/">https://domain.com:444/</a>

The virtual server is configured on port 8080. See the following table:

Redirect URL from the Server	Redirect URL sent to the Client
<a href="http://domain.com/">http://domain.com/</a>	<a href="http://domain.com:8080/">http://domain.com:8080/</a>
<a href="http://domain.com:8080/">http://domain.com:8080/</a>	<a href="http://domain.com:8080/">http://domain.com:8080/</a>
<a href="https://domain.com/">https://domain.com/</a>	<a href="https://domain.com/">https://domain.com/</a>
<a href="https://domain.com:445/">https://domain.com:445/</a>	<a href="https://domain.com:445/">https://domain.com:445/</a>

Scenario 4: The virtual server and service are of type SSL. If port rewrite is enabled, only the port of HTTPS URLs is rewritten. HTTP URLs from the server are sent as is to the client.

SSL redirect is enabled on the virtual server. The virtual server can be configured on any port. See the following table:

Redirect URL from the Server	Redirect URL sent to the Client
<a href="http://domain.com/">http://domain.com/</a>	<a href="http://domain.com/">http://domain.com/</a>
<a href="http://domain.com:8080/">http://domain.com:8080/</a>	<a href="http://domain.com:8080/">http://domain.com:8080/</a>
<a href="https://domain.com/">https://domain.com/</a>	<a href="https://domain.com/">https://domain.com/</a>
<a href="https://domain.com:444/">https://domain.com:444/</a>	<a href="https://domain.com:444/">https://domain.com:444/</a>

SSL redirect and port rewrite are enabled on the virtual server. The virtual server is configured on port 443. See the following table:

Redirect URL from the Server	Redirect URL sent to the Client
<a href="http://domain.com/">http://domain.com/</a>	<a href="http://domain.com/">http://domain.com/</a>
<a href="http://domain.com:8080/">http://domain.com:8080/</a>	<a href="http://domain.com:8080/">http://domain.com:8080/</a>
<a href="https://domain.com/">https://domain.com/</a>	<a href="https://domain.com/">https://domain.com/</a>

Redirect URL from the Server	Redirect URL sent to the Client
<a href="https://domain.com:444/">https://domain.com:444/</a>	<a href="https://domain.com/">https://domain.com/</a>

SSL redirect and port rewrite are enabled on the virtual server. The virtual server is configured on port 444. See the following table:

Redirect URL from the Server	Redirect URL sent to the Client
<a href="http://domain.com/">http://domain.com/</a>	<a href="http://domain.com/">http://domain.com/</a>
<a href="http://domain.com:8080/">http://domain.com:8080/</a>	<a href="http://domain.com:8080/">http://domain.com:8080/</a>
<a href="https://domain.com/">https://domain.com/</a>	<a href="https://domain.com:444/">https://domain.com:444/</a>
<a href="https://domain.com:445/">https://domain.com:445/</a>	<a href="https://domain.com:444/">https://domain.com:444/</a>

### To configure HTTP redirection on a virtual server by using the CLI

At the command prompt, type:

```
1 set lb vserver <name> -redirectPortRewrite (ENABLED | DISABLED)
2 <!--NeedCopy-->
```

#### Example:

```
1 set lb vserver Vserver-LB-1 -redirectPortRewrite enabled
2 <!--NeedCopy-->
```

### To configure HTTP redirection on a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open the virtual server, and in the Advanced Settings pane, click Traffic Settings, and then select Rewrite.

### To configure SSL Redirect on an SSL virtual server or service by using the CLI

At the command prompt, type:

```
1 set ssl vserver <vServerName> - sslRedirect (ENABLED | DISABLED)
2
3 set ssl service <serviceName> - sslRedirect (ENABLED | DISABLED)
4 <!--NeedCopy-->
```

**Example:**

```
1 set ssl vserver Vserver-SSL-1 -sslRedirect enabled
2
3 set ssl service service-SSL-1 -sslRedirect enabled
4 <!--NeedCopy-->
```

**To configure SSL redirection and SSL port rewrite on an SSL virtual server or service by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
2. In Advanced Settings, click SSL Parameters, and select SSL Redirect.

**Insert IP address and port of a virtual server in the request header**

May 2, 2023

If you have multiple virtual servers that communicate with different applications on the same service, you must do the following:

Configure the NetScaler appliance to add the IP address and port number of the appropriate virtual server to the HTTP requests that are sent to that service. This setting allows applications running on the service to identify the virtual server that sent the request.

If the primary virtual server is down and the backup virtual server is up, the configuration settings of the backup virtual server are added to the client requests. If you want the same header tag to be added, regardless of whether the requests are from the primary virtual server or backup virtual server, then you must configure the required header tag on both virtual servers.

**Note:** This option is not supported for wild card virtual servers or dummy virtual servers.

**To insert the IP address and port of the virtual server in the client requests by using the CLI**

At the command prompt, type:

```
1 set lb vserver <name> -insertVserverIPPort <insertVserverIPPort> [<
 vipHeader>]
2 <!--NeedCopy-->
```

**Example:**

```
1 set lb vserver Vserver-LB-1 -insertVserverIPPort VipAddr
2 <!--NeedCopy-->
```

## To insert the IP address and port of the virtual server in the client requests by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open the virtual server, and in the Advanced Settings pane, click **Traffic Settings**, and then select Virtual Server IP Port Insertion and specify a virtual server IP port header.

## Use a specified source IP for back-end communication

May 2, 2023

For communication with the physical servers or other peer devices, the NetScaler appliance uses an IP address owned by it as the source IP address. The NetScaler appliance maintains a pool of its IP addresses, and dynamically selects an IP address while connecting with a server. Depending on the subnet in which the physical server is placed, the appliance decides which IP address to use. This address pool is used for sending traffic and monitor probes.

In many situations, you might want the appliance to use a specific IP address or any IP address from a specific set of IP addresses for back-end communications. The following are a few examples:

- A server can distinguish monitor probes from traffic if the source IP address used for monitor probes belongs to a specific set.
- To improve server security, a server might be configured to respond to requests from a specific set of IP addresses or, sometimes, from a single specific IP address. In such a case, the appliance can use only the IP addresses accepted by the server as the source IP address.
- The appliance can manage its internal connections efficiently if it can distribute its IP addresses into IP sets and use an address from a set only for connecting to a specific service.

To configure the appliance to use a specified source IP address, create net profiles (network profiles) and configure the appliance entities to use the profile. A net profile can be bound to load balancing or content switching virtual servers, NetScaler Gateway VPN virtual servers, services, service groups, or monitors. A net profile has NetScaler owned IP addresses (SNIPs and VIPs) that can be used as the source IP address. It can be a single IP address or a set of IP addresses, referred to as an IP set. If a net profile has an IP set, the appliance dynamically selects an IP address from the IP set at the time of connection. If a profile has a single IP address, the same IP address is used as the source IP.

If a net profile is bound to a load balancing or content switching virtual server, the profile is used for sending traffic to all the services bound to it. If a net profile is bound to a service group, the appliance uses the profile for all the members of the service group. If a net profile is bound to a monitor, the appliance uses the profile for all the probes sent from the monitor.

**Note:**

- When a NetScaler appliance uses a VIP address to communicate with a server, it uses session entries to identify whether the traffic destined to the VIP address is a response from a server or a request from a client.
- You can bind a net profile to NetScaler Gateway VPN virtual servers. However, you need to note some points when binding a net profile. For more information, see [Points to note when binding a net profile to VPN virtual server](#).
- The net profile IPs bound to a service or service group are not only used for sending traffic towards the corresponding back-end servers, but also for the DNS requests that are triggered by any unresolved back-end FQDN.

**Usage of a net profile for sending traffic**

If the Use Source IP Address (USIP) option is enabled, the appliance uses the IP address of the client and ignores all the net profiles. If the USIP option is not enabled, the appliance selects the source IP in the following manner:

- If there is no net profile on the virtual server or the service/service group, the appliance uses the default method.
- If there is a net profile only on the service/service group, the appliance uses that net profile.
- If there is a net profile only on the virtual server, the appliance uses the net profile.
- If there is a net profile both on the virtual server and service/service group, the appliance uses the net profile bound to the service/service group.

**Usage of a net profile for sending monitor probes:**

For monitor probes, the appliance selects the source IP in the following manner:

- If there is a net profile bound to the monitor, the appliance uses the net profile of the monitor. It ignores the net profiles bound to the virtual server or service/service group.
- If there is no net profile bound to the monitor,
  - If there is a net profile on the service/service group, the appliance uses the net profile of the service/service group.
  - If there is no net profile even on the service/service group, the appliance uses the default method of selecting a source IP.

Note: If there is no net profile bound to a service, the appliance looks for a net profile on the service group if the service is bound to a service group.

To use a specified source IP address for communication, go through the following steps:

1. Create IP sets from the pool of SNIPs and VIPs owned by the NetScaler appliance. An IP set can consist of both SNIP and VIP addresses. For instructions, see [Creating IP Sets](#).
2. Create net profiles. For instructions, see [Creating a Net Profile](#).
3. Bind the net profiles to the appliance entities. For instructions, see [Binding a Net Profile to a NetScaler Entity](#).

**Note:**

- A net profile can have only the IP addresses specified as SNIP and VIP on the NetScaler appliance.
- Source IP persistence is not honored for NetScaler initiated packets.

## Manage net profiles

A net profile (or network profile) contains an IP address or an IP set. During communication with physical servers or peers, the NetScaler appliance uses the addresses specified in the profile as the source IP address.

- For instructions on creating a network profile, see [Creating a Network Profile](#).
- For instructions on binding a network profile to a NetScaler entity, see [Binding a Net Profile to a NetScaler Entity](#).

## Create an IP set

An IP set is a set of IP addresses, which are configured on the NetScaler appliance as Subnet IP addresses (SNIPs) or Virtual IP addresses (VIPs). An IP set is identified with a meaningful name that helps in identifying the usage of the IP addresses contained in it. To create an IP set, add an IP set, and bind NetScaler owned IP addresses to it. SNIP addresses and VIP addresses can be present in the same IP set.

### To create an IP set by using the CLI

At the command prompt, type the following commands:

```
1 add ipset <name>
2
3 bind ipset <name> <IPAddress>
```

```
4 <!--NeedCopy-->
```

Or

```
1 bind ipset <name> <IPAddress>
2
3 show ipset [<name>]
4 <!--NeedCopy-->
```

The preceding command shows the names of all the IP sets on the appliance if you do not pass any name. It shows the IP addresses bound to the specified IP set if you pass a name.

### Examples

```
1 1.
2 > add ipset skpnwipset
3 Done
4 > bind ipset skpnwipset 21.21.20.1
5 Done
6
7 2.
8 > add ipset testnwipset
9 Done
10 > bind ipset testnwipset 21.21.21.[21-25]
11 IPAddress "21.21.21.21" bound
12 IPAddress "21.21.21.22" bound
13 IPAddress "21.21.21.23" bound
14 IPAddress "21.21.21.24" bound
15 IPAddress "21.21.21.25" bound
16 Done
17
18 3.
19 > bind ipset skipipset 11.11.11.101
20 ERROR: Invalid IP address
21 [This IP address could not be added because this is not an IP address
22 owned by the NetScaler appliance]
23 > add ns ip 11.11.11.101 255.255.255.0 -type SNIP
24 ip "11.11.11.101" added
25 Done
26 > bind ipset skipipset 11.11.11.101
27 IPAddress "11.11.11.101" bound
28 Done
29 4.
30 > sh ipset
31 1) Name: ipset-1
32 2) Name: ipset-2
33 3) Name: ipset-3
34 4) Name: skpnewipset
35 Done
36
37 5.
38 > sh ipset skpnewipset
39 IP:21.21.21.21
```

```
39 IP:21.21.21.22
40 IP:21.21.21.23
41 IP:21.21.21.24
42 IP:21.21.21.25
43 Done
44 <!--NeedCopy-->
```

### To create an IP set by using the GUI

Navigate to **System > Network > IP Sets**, and create an IP set.

### Create a net profile

A net profile (network profile) consists of one or more SNIP or VIP addresses of the NetScaler appliance.

### To create a net profile by using the CLI

At the command prompt, type:

```
1 add netprofile <name> [-srcIp <srcIpVal>]
2 <!--NeedCopy-->
```

If the srcIpVal is not provided in this command, it can be provided later by using the `set netprofile` command.

#### Examples

```
1 add netprofile skpnetprofile1 -srcIp 21.21.20.1
2 Done
3
4 add netprofile baksnp -srcIp bakipset
5 Done
6
7 set netprofile yahnp -srcIp 12.12.23.1
8 Done
9
10 set netprofile citkbnp -srcIp citkbipset
11 Done
12 <!--NeedCopy-->
```

### Bind a net profile to a NetScaler entity

A net profile can be bound to a load balancing virtual server, service, service group, or a monitor.

Note: You can bind a net profile at the time of creating a NetScaler entity or bind it to an existing entity.

### To bind a net profile to a server by using the command line interface

You can bind a net profile to load balancing virtual servers and content switching virtual servers. Specify the appropriate virtual server.

At the command prompt, type:

```
1 set lb vsrver <name> -netProfile <net_profile_name>
2 <!--NeedCopy-->
```

Or

```
1 set cs vsrver <name> -netProfile <net_profile_name>
2 <!--NeedCopy-->
```

#### Examples

```
1 set lb vsrver skpnwvs1 -netProfile gntnp
2 Done
3 set cs vsrver mmdcsv -netProfile mmdnp
4 Done
5 <!--NeedCopy-->
```

### To bind a net profile to a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open the virtual server.
2. In Advanced Settings, click **Profiles**, and set a net profile.

### To bind a net profile to a service by using the CLI

At the command prompt, type:

```
1 set service <name> -netProfile <net_profile_name>
2 <!--NeedCopy-->
```

#### Example

```
1 set service brnssvc1 -netProfile brnsnp
2 Done
3 <!--NeedCopy-->
```

**To bind a net profile to a service by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, click **Profiles**, and set a net profile.

**To bind a net profile to a service group by using the CLI**

At the command prompt, type:

```
1 set servicegroup <serviceGroupName> -netProfile <net_profile_name>
2 <!--NeedCopy-->
```

**Example**

```
1 set servicegroup ndhsvcgrp -netProfile ndhnp
2 Done
3 <!--NeedCopy-->
```

**To bind a net profile to a service group by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Service Groups**, and open a service group.
2. In Advanced Settings, click **Profiles**, and set a net profile.

**To bind a net profile to a monitor by using the CLI**

At the command prompt, type:

```
set monitor <monitor_name> -netProfile <net_profile_name>
```

**Example**

```
1 set monitor brnsecvmon1 -netProfile brnsmonnp
2 Done
3 <!--NeedCopy-->
```

**To bind a net profile to a monitor by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. Open a monitor, and set the net profile.

## Set a time-out value for idle client connections

May 2, 2023

You can configure a virtual server to terminate any idle client connections after a configured time-out period (in seconds) elapses. When you configure this setting, the NetScaler appliance waits for the time you specify and, if the client is idle after that time, it closes the client connection. By default, the client idle time-out value is set to 180 seconds.

### To set a time-out value for idle client connections by using the CLI

At the command prompt, type:

```
1 set lb vserver <name> -cltTimeout <Value>
2 <!--NeedCopy-->
```

#### Example:

```
1 set lb vserver Vserver-LB-1 -cltTimeout 100
2 <!--NeedCopy-->
```

### To set a time-out value for idle client connections by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In **Advanced Settings**, click **Traffic Settings**, and set the client idle time-out value in seconds.

## Manage RTSP connections

May 2, 2023

The NetScaler appliance can use either of two topologies—NAT-on mode or NAT-off mode—to load balance RTSP servers. In NAT-on mode, Network Address Translation (NAT) is enabled and configured on the appliance. RTSP requests and responses both pass through the appliance. You must therefore configure the appliance to perform network address translation (NAT) to identify the data connection.

For more information about enabling and configuring NAT, see [IP Addressing](#).

In NAT-off mode, NAT is not enabled and configured. The appliance receives RTSP requests from the client and routes them to the service that it selects using the configured load balancing method. The

load balanced RTSP servers send their responses directly to the client, bypassing the appliance. You must therefore configure the appliance to use Direct Server Return (DSR) mode, and assign publicly accessible FQDNs in DNS to your load balanced RTSP servers.

For more information about enabling and configuring DSR mode, see [Configuring Load Balancing in Direct Server Return Mode](#). For more information about configuring DNS, see [Domain Name System](#). In either case, when you configure RTSP load balancing, you must also configure `rtspNat` to match the topology of your load balancing setup.

### To configure RTSP NAT by using the CLI

At the command prompt, type:

```
1 set lb vserver <name> - RTSPNAT <ValueOfRTSPNAT>
2 <!--NeedCopy-->
```

#### Example:

```
1 set lb vserver vserver-LB-1 - RTSPNAT ON
2 <!--NeedCopy-->
```

### To configure RTSP NAT by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server of type RTSP.
2. In Advanced Settings, click **Traffic Settings**, and select **RTSP Natting**.

## Manage client traffic based on traffic rate

May 2, 2023

You can monitor the rate of traffic that flows through load balancing virtual servers and control the behavior of the NetScaler appliance based on the traffic rate. For example:

- Throttle the traffic flow if it is too high.
- Cache information based on the traffic rate.
- If the traffic rate is too high, redirect excess traffic to a different load balancing virtual server.
- Apply rate-based monitoring to HTTP and Domain Name System (DNS) requests.

For more information on rate-based policies, see [Rate Limiting](#).

## Identify a connection with layer 2 parameters

May 2, 2023

Generally, to identify a connection, the NetScaler appliance uses the 4-tuple of client IP address, client port, destination IP address, and destination port. When you enable the L2 Connection option, the Layer 2 parameters of the connection (channel number, MAC address, and VLAN ID) are used in addition to the normal 4-tuple.

Enabling the L2Conn parameter for a load balancing virtual server allows multiple TCP and non-TCP connections with the same 4-tuple (<source IP>:<source port>:<destination IP>:<destination port>) to co-exist on the NetScaler appliance. The appliance uses both the 4-tuple and the Layer 2 parameters to identify TCP and non-TCP connections.

You can enable the L2Conn option in the following scenarios:

- Multiple VLANs are configured on the NetScaler appliance, and a firewall is set up for each VLAN.
- You want the traffic originating from the servers in one VLAN and bound for a virtual server in another VLAN to pass through the firewalls configured for both VLANs.

Therefore, when an nCore NetScaler appliance on which the l2Conn parameter is set for one or more load balancing virtual servers is downgraded to a Classic build or to an nCore build that does not support the l2Conn parameter, the load balancing configurations that use the l2Conn parameter become ineffective.

### To configure the L2 connection option by using the CLI

At the command prompt, type:

```
1 add lb vserver <name> <serviceType> <IPAddress>@ <port> -l2Conn ON
2 <!--NeedCopy-->
```

#### Example

```
1 add lb vserver LB-VIP1 HTTP 10.1.1.254 80 -l2Conn ON
2 <!--NeedCopy-->
```

### To configure the L2 connection option by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In Advanced Settings, select Traffic Settings, and select Layer 2 Parameters.

## Configure the Prefer Direct Route option

May 2, 2023

On a wildcard load balancing virtual server if you explicitly configure a route to a destination, by default, the NetScaler appliance forwards traffic according to the configured route. If you want the appliance to not look up for the configured route, you can set the Prefer Direct Route option to NO.

If a device is directly connected to a NetScaler appliance, the appliance directly forwards traffic to the device. For example, if the destination of a packet is a firewall, the packet need not be routed through another firewall. However, sometimes, you might want the traffic to go through the firewall even if the device is directly connected to it. In such cases, you can set the Prefer Direct Route Option to NO.

Note: The preferDirectRoute setting is applicable to all the wildcard virtual servers on the NetScaler appliance.

### To set the Prefer Direct Route option by using the CLI

At the command prompt, type:

```
1 set lb parameter -preferDirectRoute (YES | NO)
2 <!--NeedCopy-->
```

#### Example:

```
1 set lb parameter -preferDirectRoute YES
2 <!--NeedCopy-->
```

### To set the Prefer Direct Route option by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Configure Load Balancing parameters**.
2. Select Prefer Direct Route.

## Use a source port from a specified port range for back-end communication

May 2, 2023

By default, for configurations with USIP option disabled or with USIP and use proxy port options enabled, the NetScaler appliance communicates to the servers from a random source port (greater than 1024).

The appliance supports using a source port from a specified port range for communicating to the servers. One of the use cases of this feature is for servers that are configured to identify received traffic belonging to a specific set based on the source port for logging and monitoring purposes. For example, identifying internal and external traffic for logging purpose.

Configuring the NetScaler appliance to use a source port from a port range for communicating to the servers consists of the following tasks:

- **Create a net profile and set the source port range parameter.** A source port range parameter specifies one or more port ranges. The appliance randomly selects one of the free ports from the specified port ranges and used it as the source port for each connection to servers.
- **Bind the net profile to load balancing virtual servers, services, or service groups:** A net profile with source port range setting can be bound to a virtual server, service, or a service group of a load balancing configuration. For a connection to a virtual server, the appliance randomly selects one of the free ports from the specified port ranges of a net profile and use this port as the source port for connecting to one of the bound servers.

### To specify a source port range or ranges by using the CLI

At the command prompt, type:

```
1 bind netProfile <name> (-srcPortRange <int[-int]> ...)
2
3 show netprofile <name>
4 <!--NeedCopy-->
```

### To specify a source port range or ranges by using the GUI

1. Navigate to **System > Network > Net Profiles**.
2. Set the **Source Port Range** parameter while adding or modifying NetProfiles.

### Sample Configuration

In the following sample configuration, net profile PARTIAL-NAT-1 has partial NAT settings and is bound to load balancing virtual server LBVS-1, which is of type ANY. For packets received on LBVS-1 from 192.0.0.0/8, the NetScaler appliance translates the last octet of the packet's source IP address to 100. For example, a packet with source IP address 192.0.2.30 received on LBVS-1, the NetScaler appliance translates the source IP address to 100.0.2.30 before sending it one of the bound servers.

```
1 `` `
2 > add netprofile CUSTOM-SRCPORT-NP-1
3 Done
4 > bind netprofile CUSTOM-SRCPRT-NP-1 - srcportrange 2000-3000
5
6 Done
7 > bind netprofile CUSTOM-SRCPRT-NP-1 - srcportrange 5000-6000
8
9 Done
10 > add lb vserver LBVS-1 ANY 203.0.113. 61 * -netprofile PARTIAL-NAT-1
11
12 Done
13 <!--NeedCopy--> `` `
```

## Configure source IP persistency for back-end communication

May 2, 2023

By default, for a load balancing configuration with the USIP option disabled and a net profile bound to a virtual server or services or service groups, the NetScaler appliance uses the round robin algorithm to select an IP address from the net profile for communicating with the servers. Because of this selection method, the IP address selected can be different for different sessions of a specific client.

Some situations require that the NetScaler appliance route all of a specific client's traffic from the same IP address when sending the traffic to servers. The servers can then, for example, identify traffic belonging to a specific set for logging and monitoring purposes.

The source IP persistency option of a net profile enables the NetScaler appliance to use the same address, specified in the net profile, to communicate with servers about all sessions initiated from a specific client to a virtual server.

### To enable source IP persistency in a net profile by using the CLI

To enable source IP persistency while adding a net profile, at the command prompt, type:

```
1 add netProfile <name> -srcippersistency (ENABLED | DISABLED)
2
3 show netprofile <name>
4 <!--NeedCopy-->
```

To enable source IP persistency in an existing net profile, at the command prompt, type:

```
1 set netProfile <name> -srcippersistency (ENABLED | DISABLED)
2
3 show netprofile <name>
```

```
4 <!--NeedCopy-->
```

## To enable source IP persistency in a net profile by using the GUI

1. Navigate to **System > Network > Net Profiles**.
2. Select **Source IP Persistency** while adding or modifying a net profile.

## Example

In the following sample configuration, net profile NETPROFILE-IPPRSTNCY-1 has the source IP persistency option enabled and is bound to load balancing virtual server LBVS-1.

The NetScaler appliance always uses the same IP address (in this example, 192.0.2.11) to communicate with servers bound to LBVS-1, for all sessions initiated from a specific client to the virtual server.

```
1 `` `
2 > add ipset IPSET-1
3
4 Done
5 > bind ipset IPSET-1 192.0.2.[11-15]
6 IPAddress "192.0.2.11" bound
7 IPAddress "192.0.2.12" bound
8 IPAddress "192.0.2.13" bound
9 IPAddress "192.0.2.14" bound
10 IPAddress "192.0.2.15" bound
11 Done
12 > add netprofile NETPROFILE-IPPRSTNCY-1 -srcIp IPSET-1 -
 srcippersistency ENABLED
13
14 Done
15 > set lb vserver LBVS-1 -netprofile NETPROFILE-IPPRSTNCY-1
16
17 Done
18 <!--NeedCopy--> `` `
```

## Use IPv6 link local addresses on the server side of a load balancing setup

May 2, 2023

IPv6 link local address is supported for services, service groups, and servers of a load balancing configuration. You can specify a link local IPv6 address along with the associated VLAN ID in services, service

groups, and servers configurations. The NetScaler appliance uses the link local SNIP6 address from the same VLAN as specified in the services, service groups, and servers configurations to communicate with them.

A link local IPv6 address and the associated VLAN ID are specified in the following format in services, service groups, and servers configurations: `<IPv6_Addrs>%<vlan_id>`

For example, `fe80:123:4567::a%2048:`, `fe80:123:4567::a` is the link local address AND 2048 is the VLAN ID.

```
1 > add service SERVICE-1 fe80:123:4567::a%2048 HTTP 80
2
3 Done
4 > bind servicegroup SERVICE-GROUP-1 fe80::1%24 80
5
6 Done
7 > add server SERVER-1 fe80:b:c:d::e:f:a/64%1028
8
9 Done
```

## Advanced load balancing settings

April 8, 2021

In addition to configuring virtual servers, you can configure advanced settings for services.

To configure advanced load balancing settings, see the following sections:

- [Gradually step up the load on a new service with virtual server–level slow start](#)
- [The no-monitor option for services](#)
- [Protect applications on protected servers against traffic surges](#)
- [Enable cleanup of virtual server and service connections](#)
- [Graceful shutdown of services](#)
- [Enable or disable persistence session on TROFS services](#)
- [Direct requests to a custom webpage](#)
- [Enable access to services when down](#)
- [Enable TCP buffering of responses](#)
- [Enable compression](#)
- [Maintain client connection for multiple client requests](#)
- [Insert IP address of the client in the request header](#)
- [Retrieve location details from user IP address using geolocation database](#)
- [Use the source IP address of the client when connecting to the server](#)
- [Configure the source port for server-side connections](#)

- [Set a limit on the number of client connections](#)
- [Set a limit on the number of requests per connection to the server](#)
- [Set a threshold value for the monitors bound to a service](#)
- [Set a timeout value for idle client connections](#)
- [Set a timeout value for idle server connections](#)
- [Set a limit on the bandwidth usage by clients](#)
- [Redirect client requests to a cache](#)
- [Retain the VLAN identifier for VLAN transparency](#)
- [Configure automatic state transition based on percentage health of bound services](#)

## **Gradually step up the load on a new service with virtual server–level slow start**

May 2, 2023

You can configure the NetScaler appliance to gradually increase the load on a service (the number of requests that the service receives per second) immediately after the service is either added to a load balancing configuration or has a state change from DOWN to UP (in this document, the term “new service” is used for both situations). You can either increase the load manually with load values and intervals of your choice (manual slow start) or configure the appliance to increase the load at a specified interval (automated slow start) until the service is receiving as many requests as the other services in the configuration. During the ramp-up period for the new service, the appliance uses the configured load balancing method.

This functionality is not available globally. It has to be configured for each virtual server. The functionality is available only for virtual servers that use one of the following load balancing methods:

- Round robin
- Least connection
- Least response time
- Least bandwidth
- Least packets
- LRTM (Least Response Time Method)
- Custom load

For this functionality, you need to set the following parameters:

- The new service request rate, which is the amount by which to increase the number or percentage of requests sent to a new service each time the rate is incremented. That is, you specify the size of the increment in terms of either the number of requests per second or the percentage

of the load being borne, at the time, by the existing services. If this value is set to 0 (zero), slow start is not performed on new services.

Note: In an automated slow start mode, the final increment is smaller than the specified value if the specified value would place a heavier load on the new service than on the other services.

- The increment interval, in seconds. If this value is set to 0 (zero), the load is not incremented automatically. You have to increment it manually.

With an automated slow start, a service is taken out of the slow start phase when one of the following conditions applies:

- The actual request rate is less than the new service request rate.
- The service does not receive traffic for three successive increment intervals.
- The request rate has been incremented 200 times.
- The percentage of traffic that the new service must receive is greater than or equal to 100.

With manual slow start, the service remains in the slow start phase until you take it out of that phase.

### Manual slow start

If you want to manually increase the load on a new service, do not specify an increment interval for the load balancing virtual server. Specify only the new service request rate and the units. With no interval specified, the appliance does not increment the load periodically. It maintains the load on the new service at the value specified by the combination of the new service request rate and units until you manually modify either parameter. For example, if you set the new service request rate and unit parameters to 25 and “per second,” respectively, the appliance maintains the load on the new service at 25 requests per second until you change either parameter. When you want the new service to exit the slow start mode and receive as many requests as the existing services, set the new service request rate parameter to 0.

As an example, assume that you are using a virtual server to load balance 2 services, Service1 and Service2, in round robin mode. Further assume that the virtual server is receiving 240 requests per second, and that it is distributing the load evenly across the services. When a new service, Service3, is added to the configuration, you might want to increase the load on it manually through values of 10, 20, and 40 requests per second before sending it its full share of the load. The following table shows the values to which you set the three parameters.

Table 1. Parameter Values

Parameter	Value
Interval in seconds	0

Parameter	Value
New service request rate	10, 20, 40, and 0, at intervals that you choose
Units for the new service request rate	Requests per second

When you set the new service request rate parameter to 0, Service3 is no longer considered a new service, and receives its full share of the load.

Assume that you add another service, Service4, during the ramp-up period for Service3. In this example, Service4 is added when the new service request rate parameter is set to 40. Therefore, Service4 begins receiving 40 requests per second.

The following table shows the load distribution on the services during the period described in this example.

Table 2. Load Distribution on Services when Manually Stepping Up the Load

	new service request rate = 10 req/sec (Service3added)	new service request rate = 20 req/sec	new service request rate = 40 req/sec (Service4added)	new service request rate = 0 req/sec (new services exit slow start mode)
<b>Service1</b>	115	110	80	60
<b>Service2</b>	115	110	80	60
<b>Service3</b>	10	20	40	60
<b>Service4</b>	-	-	40	60
<b>Total req/sec (load on the virtual server)</b>	240	240	240	240

### Automated slow start

If you want the appliance to increase the load on a new service automatically at specified intervals until the service can be considered capable of handling its full share of the load, set the new service request rate parameter, the units parameter, and the increment interval. When all the parameters are set to values other than 0, the appliance increments the load on a new service by the value of the new service request rate, at the specified interval, until the service is receiving its full share of the load.

As an example, assume that four services, Service1, Service2, Service3, and Service4, are bound to a load balancing virtual server, vserver1. Further assume that vserver1 receives 100 requests per second, and that it distributes the load evenly across the services (25 requests per second per service). When you add a fifth service, Service5, to the configuration, you might want the appliance to send the new service 4 requests per second for the first 10 seconds, 8 requests per second for the next 10 seconds, and so on, until it is receiving 20 requests per second. For this requirement, the following table shows the values to which you set the three parameters:

Table 3. Parameter Values

Parameter	Value
Interval in seconds	10
Increment value	4
Units for the new service request rate	Requests per second

With this configuration, the new service begins receiving as many requests as the existing services 50 seconds after it is added or its state has changed from DOWN to UP. During each interval in this period, the appliance distributes to the existing servers the excess of requests that would have been sent to the new service in the absence of stepwise increments. For example, in the absence of stepwise increments, each service, including Service5, would have received 20 requests each per second. With stepwise increments, during the first 10 seconds, when Service5 receives only 4 requests per second, the appliance distributes the excess of 16 requests per second to the existing services, resulting in the distribution pattern shown in the following table and figure over the 50-second period. After the 50-second period, Service5 is no longer considered a new service, and it receives its normal share of traffic.

Table 4. Load Distribution Pattern on All Services for the 50-second Period Immediately after Service5 is Added

	0 sec	10 sec	20 sec	30 sec	40 sec	50 sec
<b>Req/sec forService1</b>	25	24	23	22	21	20
<b>Req/sec forService2</b>	25	24	23	22	21	20

	0 sec	10 sec	20 sec	30 sec	40 sec	50 sec
<b>Req/sec forService3</b>	25	24	23	22	21	20
<b>Req/sec forService4</b>	25	24	23	22	21	20
<b>Req/sec forService5</b>	0	4	8	12	16	20
<b>Total req/sec (load on the virtual server)</b>	100	100	100	100	100	100

Figure 1. A Graph of the Load Distribution Pattern on All Services for the 50-second Period Immediately after Service5 is Added

An alternative requirement might be for the appliance to send Service5 25% of the load on the existing services in the first 5 seconds, 50% in the next 5 seconds, and so on, until it is receiving 20 requests per second. For this requirement, the following table shows the values to which you set the three parameters.

Table 5. Parameter Values

Parameter	Value
Interval in seconds	5
Increment value	25
Units for the new service request rate	Percent

With this configuration, the service begins receiving as many requests as the existing services 20 seconds after it is added or its state has changed from DOWN to UP. The traffic distribution during the ramp-up period for the new service is identical to the one described earlier, where the unit for the step increments was “requests per second.”

### Set the slow start parameters

You set the slow start parameters by using either the `set lb vserver` or the `add lb vserver` command. The following command is for setting slow start parameters when adding a virtual server.

### To configure stepwise load increments for a new service by using the command line interface

At the command prompt, type the following commands to configure stepwise increments in the load for a service and verify the configuration:

```

1 add lb vserver <name> <serviceType> <IPAddress> <port> [-
 newServiceRequest <positive_integer>] [<newServiceRequestUnit>] [-
 newServiceRequestIncrementInterval <positive_integer>]
2
3 show lb vserver <name>
4 <!--NeedCopy-->

```

#### Example

```

1 set lb vserver BR_LB -newServiceRequest 5 PER_SECOND -
 newServiceRequestIncrementInterval 10
2 Done
3
4 show lb vserver BR_LB
5 BR_LB (192.0.2.33:80) - HTTP Type: ADDRESS
6 State: UP
7 ...
8 ...
9 New Service Startup Request Rate: 5 PER_SECOND, Increment Interval: 10
10 ...
11 ...
12 Done

```

### To configure stepwise load increments for a new service by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In Advanced Settings, select Method, and set the following slow start parameters:
  - New Service Startup Request Rate.
  - New Service Request Unit.
  - Increment Interval.

### The no-monitor option for services

May 2, 2023

If you use an external system to perform health checks on the services and do not want the NetScaler appliance to monitor the health of a service, you can set the no-monitor option for the service. If you do so, the appliance does not send probes to check the health of the service but shows the service as UP. Even if the service goes DOWN, the appliance continues to send traffic from the client to the service as specified by the load balancing method.

The monitor can be in the ENABLED or DISABLED state when you set the no-monitor option, and when you remove the no-monitor option, the earlier state of the monitor is resumed.

You can set the no-monitor option for a service when creating the service. You can also set the no-monitor option on an existing service.

The following are the consequences of setting the no-monitor option:

- If a service for which you enabled the no-monitor option goes down, the appliance continues to show the service as UP and continues to forward traffic to the service. A persistent connection to the service can worsen the situation. In that case, or if many services shown as UP are actually DOWN, the system may fail. To avoid such a situation, when the external mechanism that monitors the services reports a service as DOWN, remove the service from the NetScaler configuration.
- If you configure the no-monitor option on a service, you cannot configure load balancing in the Direct Server Return (DSR) mode. For an existing service, if you set the no-monitor option, you cannot configure the DSR mode for the service.

## To set the no-monitor option for a new service by using the CLI

At the command prompt, type the following commands to create a service with the health monitor option, and verify the configuration:

```
1 add service <serviceName> <IP | serverName> <serviceType> <port> -
 healthMonitor (YES|NO)
2 <!--NeedCopy-->
```

### Example:

```
1 add service nomonsrvc 10.102.21.21 http 80 -healthMonitor no
2 Done
3
4 show service nomonsrvc
5 nomonsrvc (10.102.21.21:80) - HTTP
6 State: UP
7 Last state change was at Mon Nov 15 22:41:29 2010
8 Time since last state change: 0 days, 00:00:00.970
9 Server Name: 10.102.21.21
10 Server ID : 0 Monitor Threshold : 0
11 ...
12 Access Down Service: NO
13 ...
14 Down state flush: ENABLED
15 Health monitoring: OFF
16
17 1 bound monitor:
18 1) Monitor Name: tcp-default
19 State: UNKNOWN Weight: 1
20 Probes: 3 Failed [Total: 3 Current: 3]
21 Last response: Probe skipped - Health monitoring is turned off.
22 Response Time: N/A
23 Done
24 <!--NeedCopy-->
```

## To set the no-monitor option for an existing service by using the CLI

At the command prompt, type the following command to set the health monitor option:

```
1 set service <name> -healthMonitor (YES|NO)
2 <!--NeedCopy-->
```

### Example:

```
1 By default, the state of a service and the state of the corresponding
 monitor are UP.
2 >show service LB-SVC1
3 LB-SVC1 (10.102.29.5:80) - HTTP
4 State: UP
5
```

```
6
7 1) Monitor Name: http-ecv
8 State: UP Weight: 1
9 Probes: 99992 Failed [Total: 0 Current: 0]
10 Last response: Success - Pattern found in response.
11 Response Time: 3.76 millisec
12 Done
13
14 When the no-monitor option is set on a service, the state of the
 monitor changes to UNKNOWN.
15 set service LB-SVC1 -healthMonitor NO
16 Done
17
18 show service LB-SVC1
19 LB-SVC1 (10.102.29.5:80) - HTTP
20 State: UP
21 Last state change was at Fri Dec 10 10:17:37 2010.
22 Time since last state change: 5 days, 18:55:48.710
23 Health monitoring: OFF
24
25 1) Monitor Name: http-ecv
26 State: UNKNOWN Weight: 1
27 Probes: 100028 Failed [Total: 0 Current: 0]
28 Last response: Probe skipped - Health monitoring is turned off.
29 Response Time: 0.0 millisec
30 Done
31 When the no-monitor option is removed, the earlier state of the monitor
 is resumed.
32 > set service LB-SVC1 -healthMonitor YES
33 Done
34 >show service LB-SVC1
35 LB-SVC1 (10.102.29.5:80) - HTTP
36 State: UP
37 Last state change was at Fri Dec 10 10:17:37 2010
38 Time since last state change: 5 days, 18:57:47.880
39 1) Monitor Name: http-ecv
40 State: UP Weight: 1
41 Probes: 100029 Failed [Total: 0 Current: 0]
42 Last response: Success - Pattern found in response.
43 Response Time: 5.690 millisec
44 Done
45 <!--NeedCopy-->
```

## To set the no-monitor option for a service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open the service, and clear Health Monitoring.

## Protect applications on protected servers against traffic surges

May 2, 2023

The NetScaler appliance provides the surge protection option to maintain the capacity of a server or cache. The appliance regulates the flow of client requests to servers and controls the number of clients that can simultaneously access the servers. The appliance blocks any surges passed to the server, thus preventing overloading of the server.

For surge protection to function correctly, you must enable it globally. For more information about surge protection, see [Surge Protection](#).

### To set surge protection on the service by using the CLI

At the command prompt, type:

```
1 set service <name> -sp <Value>
2 <!--NeedCopy-->
```

#### Example:

```
1 set service Service-HTTP-1 -sp ON
2 <!--NeedCopy-->
```

### To set surge protection on the service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a source.
2. In Advanced Settings, select **Traffic Settings**, and select **Surge Protection**.

## Enable cleanup of virtual server and service connections

May 2, 2023

The state of a virtual server depends on the states of the services bound to it. The state of each service depends on the responses of the load balanced servers to probes or health checks sent by the monitors that are bound to that service. Sometimes the load balanced servers do not respond. If a server is slow or busy, monitoring probes can time out. If repeated monitoring probes are not answered within the configured timeout period, the service is marked DOWN. If a service or virtual server is marked DOWN, the server and client side connections must be flushed. Terminating existing connections frees resources, and in certain cases speeds recovery of overloaded load balancing setups.

Under certain conditions, you can configure the **downStateFlush** setting to immediately terminate existing connections when a service or a virtual server is marked DOWN. Do not enable the downStateFlush setting on those application servers that must complete their transactions. You can enable this setting on Web servers whose connections can safely be terminated when they marked DOWN.

The following table summarizes the effect of this setting on an example configuration consisting of a virtual server, Vserver-LB-1, with one service bound to it, Service-1. In the table, E and D denote the state of the downStateFlush setting: E means Enabled, and D means Disabled.

Vserver-LB-1	Service-1	State of Connections
E	E	Both client and server connections are terminated.
E	D	For some service types, such as TCP, for which the NetScaler appliance does not support connection reuse, both client and server connections are terminated. For service types, such as HTTP, for which the appliance supports connection reuse, both client and server connections are terminated only if a transaction is active on those connections. If a transaction is not active, only client connections are terminated.

Vserver-LB-1	Service-1	State of Connections
D	E	For some service types, such as TCP, for which the NetScaler appliance does not support connection reuse, both client and server connections are terminated. For service types, such as HTTP, for which the appliance supports connection reuse, both client and server connections are terminated only if a transaction is active on those connections. If a transaction is not active, only server connections are terminated.
D	D	Neither client nor server connections are terminated.

If you want to disable a service only when all the established connections are closed by the server or the client, you can use the graceful shutdown option. For information about the graceful shutdown of a service, see [Graceful Shutdown of Services](#).

### To set down state flush on the service by using the CLI

At the command prompt, type:

```
1 set service <name> -downStateFlush (ENABLED | DISABLED)
2 <!--NeedCopy-->
```

#### Example:

```
1 set service Service-HTTP-1 -downStateFlush enabled
2 <!--NeedCopy-->
```

### To set down state flush on the service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select **Traffic Settings**, and select **Down State Flush**.

## To set down state flush on the virtual server by using the CLI

At the command prompt, type:

```
1 set lb vserver <name> -downStateFlush (ENABLED | DISABLED)
2 <!--NeedCopy-->
```

### Example:

```
1 set lb vserver vsvr1 -downStateFlush enabled
2 <!--NeedCopy-->
```

## To set down state flush on the virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In Advanced Settings, select **Traffic Settings**, and select **Down State Flush**.

## Graceful shutdown of services

May 2, 2023

During scheduled network outages such as system upgrades or hardware maintenance, you may have to close or disable some services. You can later enable the service by using the “enable service <name>” command.

To avoid disrupting established sessions, you can place a service in the Transition Out of Service (TROFS) state by doing one of the following:

- Adding a TROFS code or string to the monitor—Configure the server to send a specific code or string in response to a monitor probe.
- Explicitly disable the service and:
  - Set a delay (in seconds).
  - Enable graceful shutdown.

### Adding a TROFS Code or String

If you bind only one monitor to a service, and the monitor is TROFS-enabled, it can place the service in the TROFS state on the basis of the server’s response to a monitor probe. This response is compared with the value in the trofsCode parameter for an HTTP monitor or the trofsString parameter for an

HTTP-ECV or TCP-ECV monitor. If the code matches, the service is placed in the TROFS state. In this state, it continues to honor the persistent connections.

If multiple monitors are bound to a service, the effective state of the service is calculated on the basis of the state of all the monitors that are bound to the service. Upon receiving a TROFS response, the state of the TROFS-enabled monitor is considered as UP for the purpose of this calculation. For more information about how a NetScaler appliance designates a service as UP, see [Setting a Threshold Value for the Monitors Bound to a Service](#).

**Important:**

- You can bind multiple monitors to a service, but must not TROFS-enable more than one of them.
- You can convert a TROFS-enabled monitor to a monitor that is not TROFS-enabled, but not vice versa.

**To configure a TROFS code or string in a monitor by using the command line interface**

At the command prompt, type one of the following commands:

```
1 add lb monitor <monitor-name> HTTP -trofsCode <respcode>
2
3 add lb monitor <monitor-name> HTTP-ECV -trofsString <resp string>
4
5 add lb monitor <monitor-name> TCP-ECV -trofsString <resp string>
6 <!--NeedCopy-->
```

**To modify the TROFS code or string by using the command line interface**

At the command prompt, type one of the following commands:

```
1 set lb monitor <trofs monitorname> HTTP -trofscode <newcode>
2
3 set lb monitor <trofs monitorname> HTTP-ECV -trofsstring <new string>
4
5 set lb monitor <trofs monitorname> TCP-ECV -trofsstring <new string>
6 <!--NeedCopy-->
```

**Note:** You can use the set command only if a TROFS-enabled monitor was added earlier. You cannot use this command to set the TROFS code or string for a monitor that is not TROFS-enabled.

**To configure a TROFS code or string in a monitor by using the configuration utility**

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. On the Monitors pane, click Add, and do one of the following:

- Select Type as HTTP, and specify a TROFS Code.
- Select Type as HTTP-ECV or TCP-ECV, and specify a TROFS String.

## Disabling a Service

Often, however, you cannot estimate the amount of time needed for all the connections to a service to complete the existing transactions. If a transaction is unfinished when the wait time expires, shutting down the service may result in data loss. In this case, you can specify graceful shutdown for the service, so that the service is disabled only when all the current active client connections are closed by either the server or the client. See the following table for behavior if you specify a wait time in addition to graceful shutdown.

Persistence is maintained according to the specified method even if you enable graceful shutdown. The system continues to serve all the persistent clients, including new connections from the clients, unless the service is marked DOWN during the graceful shutdown state as a result of the checks made by a monitor.

The following table describes the graceful shutdown options.

State	Results
Graceful shutdown is enabled and a wait time is specified.	Service is shut down after the last of the current active client connections is served, even if the wait time has not expired. The appliance checks the status of the connections once every second. If the wait time expires, any open sessions are closed.
Graceful shutdown is disabled and a wait time is specified.	Service is shut down only after the wait time expires, even if all established connections are served before expiration.
Graceful shutdown is enabled and no wait time is specified.	Service is shut down only after the last of the previously established connections is served, regardless of the time taken to serve the last connection.
Graceful shutdown is disabled and no wait time is specified.	No graceful shutdown. Service is shut down immediately after the disable option is chosen or the disable command is issued. (The default wait time is zero seconds.)

To terminate existing connections when a service or a virtual server is marked DOWN, you can use

the Down State Flush option. For more information, see [Enabling Cleanup of Virtual Server Connections](#).

### To configure graceful shutdown for a service by using the command line interface

At the command prompt, type the following commands to shut down a service gracefully and verify the configuration:

```
1 disable service <name> [<delay>] [-graceFul (YES|NO)]
2
3 show service <name>
4 <!--NeedCopy-->
```

#### Example:

```
1 > disable service svc1 6000 -graceFul YES
2 Done
3 >show service svc1
4 svc1 (10.102.80.41:80) - HTTP
5 State: GOING OUT OF SERVICE (Graceful, Out Of Service in 5998 seconds)
6 Last state change was at Mon Nov 15 22:44:15 2010
7 Time since last state change: 0 days, 00:00:01.160
8 ...
9 Down state flush: ENABLED
10
11 1 bound monitor:
12 1) Monitor Name: tcp-default
13 State: UP Weight: 1
14 Probes: 13898 Failed [Total: 0 Current: 0]
15 Last response: Probe skipped - live traffic to service.
16 Response Time: N/A
17 Done
18
19 >show service svc1
20 svc1 (10.102.80.41:80) - HTTP
21 State: OUT OF SERVICE
22 Last state change was at Mon Nov 15 22:44:19 2010
23 Time since last state change: 0 days, 00:00:03.250
24 Down state flush: ENABLED
25
26 1 bound monitor:
27 1) Monitor Name: tcp-default
28 State: UNKNOWN Weight: 1
29 Probes: 13898 Failed [Total: 0 Current: 0]
30 Last response: Probe skipped - service state OFS.
31 Response Time: N/A
32 Done
33 <!--NeedCopy-->
```

## To configure graceful shutdown for a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open the service, and from the Action list, click Disable. Enter a wait time, and select Graceful.

## Enable or disable persistence session on TROFS services

April 19, 2021

You can set the `trofsPersistence` flag to specify whether a service in the transition out of service (TROFS) state must maintain persistent sessions. When a monitor is TROFS enabled, it can place a service in the TROFS state on the basis of the server's response to a monitor probe. This response is compared with the value in the `trofsCode` parameter for an HTTP monitor or the `trofsString` parameter for an HTTP-ECV or TCP-ECV monitor. If the code matches, the service is placed in the TROFS state. In this state, it continues to honor the active client connections. In some cases, the honored active sessions might have to include persistent sessions. But in other cases, especially those involving long-lived persistence sessions or persistence methods such as custom server ID, honoring the persistent sessions can prevent the service from transitioning to the out-of-service state.

If you set the `trofsPersistence` flag to `ENABLED`, persistent sessions are honored. If you set it to `DISABLED`, they are not.

## To set the `trofsPersistence` flag by using the command line interface

At the command prompt, type one of the following commands to set the `trofsPersistence` flag for a new virtual server or an existing virtual server, or to return the setting to its default value:

```
1 add lb vserver <name> [-trofsPersistence (ENABLED | DISABLED)]
2
3 set lb vserver <name> [-trofsPersistence (ENABLED | DISABLED)]
4
5 unset lb vserver <name> [-trofsPersistence]
6 <!--NeedCopy-->
```

### Argument

**`trofsPersistence`.** Honor current active client connections and new requests on persistence sessions when the service is in TROFS state.

Possible values: `ENABLED`, `DISABLED`. Default: `ENABLED`.

### Examples:

```
1 add lb vserver v1 http 10.102.217.42 80 -persistencetype SOURCEIP -
 trofsPersistence ENABLED
2
3 set lb vserver v1 -trofsPersistence DISABLED
4
5 unset lb vserver v1 -trofsPersistence
6 <!--NeedCopy-->
```

## Direct requests to a custom webpage

May 2, 2023

### Warning

SureConnect (SC) is deprecated from NetScaler 12.0 build 56.20 onwards and as an alternative, Citrix recommends you to use the AppQoE feature. For more information, see [AppQoE](#).

For SureConnect to function correctly, you must set it globally. The NetScaler provides the SureConnect option to ensure the response from an application.

### To set SureConnect on the service by using the CLI

At the command prompt, type:

```
1 set service <name> -sc <Value>
2 <!--NeedCopy-->
```

### Example:

```
1 set service Service-HTTP-1 -sc ON
2 <!--NeedCopy-->
```

### To set SureConnect on the service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select Traffic Settings, and select **Sure Connect**.

## Enable access to services when down

May 2, 2023

You can enable access to a service when it is disabled or in a DOWN state by configuring the NetScaler appliance to use Layer 2 mode to bridge the packets sent to the service. Normally, when requests are forwarded to services that are DOWN, the request packets are dropped. When you enable the **Access Down** setting, however, these request packets are sent directly to the load balanced servers.

For more information about Layer 2 and Layer 3 modes, see [IP Addressing](#).

For the appliance to bridge packets sent to the DOWN services, enable Layer 2 mode with the `access-Down` parameter.

### To enable access down on a service by using the CLI

At the command prompt, type:

```
1 set service <name> -accessDown <Value>
2 <!--NeedCopy-->
```

#### Example:

```
1 set service Service-HTTP-1 -accessDown YES
2 <!--NeedCopy-->
```

### To enable access down on a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select **Traffic Settings**, and select **Access Down**.

## Enable TCP buffering of responses

May 2, 2023

The NetScaler appliance provides a TCP buffering option that buffers only responses from the load balanced server. This enables the appliance to deliver server responses to the client at the maximum speed that the client can accept them. The appliance allocates from 0 through 4095 MB (MB) of memory for TCP buffering, and from 4 through 20480 kilobytes (KB) of memory per connection.

Note: TCP buffering set at the service level takes precedence over the global setting.

For more information about configuring TCP buffering globally, see [TCP Buffering](#).

## To enable TCP Buffering on a service by using the CLI

At the command prompt, type:

```
1 set service <name> -TCPB <Value>
2 <!--NeedCopy-->
```

### Example:

```
1 set service Service-HTTP-1 -TCPB YES
2 <!--NeedCopy-->
```

## To enable TCP Buffering on a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select **Traffic Settings**, and select **TCP Buffering**.

## Enable compression

May 2, 2023

The NetScaler appliance provides a compression option to transparently compress HTML and text files by using a set of built-in compression policies. Compression reduces bandwidth requirements and can significantly improve server responsiveness in bandwidth-constrained setups. The compression policies are associated with services bound to the virtual server. The policies determine whether a response can be compressed and send compressible content to the appliance, which compresses it and sends it to the client.

Note: For compression to function correctly, you must enable it globally. For more information about configuring compression globally, see [Compression](#).

## To enable compression on a service by using the CLI

At the command prompt, type:

```
1 set service <name> -CMP <YES | NO>
2 <!--NeedCopy-->
```

### Example:

```
1 set service Service-HTTP-1 -CMP YES
2 <!--NeedCopy-->
```

## To enable compression on a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select **Traffic Settings**, and select **Compression**.

## Enable external health check for UDP and non-HTTP virtual servers

September 6, 2023

In public clouds, you can use the NetScaler appliance as a second-tier load balancer when the native load balancer is used as the first tier. The native load balancer can be an application load balancer (ALB) or a network load balancer (NLB). Most of the public clouds do not support UDP health probes in their native load balancers. Hence, if these servers are down their actual status might not be updated. As a result, traffic is sent unconditionally to NetScaler, even if the request cannot be serviced.

To monitor the health of such applications, NetScaler supports HTTP and TCP health checks.

An HTTP or TCP listener is created for a content switching virtual server when both the `probeProtocol` and `probePort` parameters are configured. The listener reflects the status of the virtual server. The `ProbeSuccessResponseCode` parameter applies only to HTTP and returns the configured string when the probe is successful.

## To enable external health check for UDP and non-HTTP TCP virtual servers by using CLI

At the command prompt, type:

```
1 add lb vserver <name> <serviceType> <IPAddress> <port> -ProbeProtocol <
 HTTP/TCP> -ProbePort <port-num> -ProbeSuccessResponseCode<http-code>
2 <!--NeedCopy-->
```

### Example:

```
1 add lb vserver Vserver-UDP-1 HTTP 10.102.29.60 80 -ProbeProtocol TCP -
 probeport 5000 -probesuccessResponseCode 200ok
2 <!--NeedCopy-->
```

## To enable external health check for UDP and non-HTTP TCP virtual servers by using GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and then create a virtual server.
2. Click **Add** to create a virtual server.

3. In the **Basic Settings** pane, update the following details:
  - a) Probe Protocol –Select the protocol (HTTP or TCP) of the probe for external health check of the virtual server.
  - b) Probe Success Response Code –Enter the response string for a successful probe. This parameter is applicable only for the HTTP protocol.
    - Default Value: 200ok
    - Maximum Length: 63
  - c) Probe Port –Enter the port number for HTTP or TCP monitoring.
4. Click **OK**.

## Maintain client connection for multiple client requests

May 2, 2023

You can set the client keep-alive parameter to configure an HTTP or SSL service to keep a client connection to a website open across multiple client requests. If client keep-alive is enabled, even when the load balanced Web server closes a connection, the NetScaler appliance keeps the connection between the client and itself open. This setting allows services to serve multiple client requests on a single client connection.

If you do not enable this setting, the client opens a new connection for every request that it sends to the website. The client keep-alive setting saves the packet round trip time required to establish and close connections. This setting also reduces the time to complete each transaction. Client keep-alive can be enabled only on HTTP or SSL service types.

Client keep-alive set at the service level takes precedence over the global client keep-alive setting. For more information about client keep-alive, see [Client Keep-Alive](#).

### To enable the client keep-alive on a service by using the CLI

At the command prompt, type:

```
1 set service <name> -CKA <Value>
2 <!--NeedCopy-->
```

#### Example:

```
1 set service Service-HTTP-1 -CKA YES
2 <!--NeedCopy-->
```

## To enable the client keep-alive on a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select **Traffic Settings**, and select **Client Keep-Alive**.

## Insert the IP address of the client in the request header

May 2, 2023

A NetScaler uses the subnet IP (SNIP) address to connect to the server. The server need not be aware of the client.

However, in some situations, the server needs to be aware of the client it has to serve. When you enable the client IP setting, the appliance inserts the client's IPv4 or IPv6 address while forwarding the requests to the server. The server inserts this client IP in the header of the responses. The server is thus aware of the client.

**Note:** To insert multiple headers, you need to perform one of the following:

- Add rewrite policies to check CLIENT.IS\_SSL and insert appropriate header.
- Bind the appropriate rewrite policy for each virtual server based on the type.

## To insert the client IP address in the client request by using the CLI

At the command prompt, type:

```
1 set service <name> -CIP <Value> <cipHeader>
2 <!--NeedCopy-->
```

### Example:

```
1 set service Service-HTTP-1 -CIP enabled X-Forwarded-For
2 <!--NeedCopy-->
```

## To insert the client IP address in the client request by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and edit a service.
2. In the **Service Settings** pane, click the **edit icon**.
3. In the **Load Balancing Service** pane, select the **Insert Client IP Address** check box.

## Retrieve location details from user IP address using geolocation database

May 2, 2023

**Note** This feature is available from NetScaler release 12.1 build 50.x and later.

The NetScaler appliance can get user location details like continent, county, and city. For any public IP address from a geo location database. It is performed using the advanced policy infrastructure. The retrieved location details are then used in a rewrite action or a responder action for performing the following use cases.

- Insert an HTTP header with user location details (such as country, city information) when sending the client request to the back-end server.
- Add country name in the HTML page response for an invalid user.

The appliance can also log the location details using the audit logging mechanism.

### Getting user location details using geolocation functions

The components interact as per the following:

1. User sends a client request from a particular geographic location.
2. The NetScaler appliance looks for the user IP address from the client request and retrieves the geo location details. The details include continent, country, region, city, ISP, organization, or custom details from a geolocation database.
3. Once the location details are retrieved, the appliance uses either a responder policy or a rewrite policy to evaluate the request.
4. In a rewrite policy, the appliance adds a header with the geo location details and sends it to the back-end server. For example, insert a custom HTTP header with country information.
5. In a responder policy, the appliance evaluates the HTTP request and based on policy evaluation, allows access to the users or redirects the user to an error page. It states the region from where they are accessing the application does not have access.

### Setting up geolocation database

As a pre-requisite, you must have a geolocation database to run on the NetScaler appliance. The geolocation database files are available with NetScaler firmware. To download the database files from a vendor, convert it into NetScaler format and import it into your appliance.

For more information about the geolocation database, see [Add a location file to create static proximity database](#) topic.

## Geolocation functions

The following table gives a list of geolocation functions that retrieves location details of any public IP address. These functions can be used in rewrite or responder policies.

---

Geolocation function	Example
CLIENT.IP.SRC.LOCATION	Asia.In.Karnataka.Bangalore
CLIENT.IP.SRC.LOCATION.GET (1).LOCATION_LONG	India
CLIENT.IP.SRC.LOCATION(3)	Asia.In.Karnataka
CLIENT.IP.SRC.LAT_LONG	12,77
CLIENT.IPV6.SRC.LOCATION	North America.US.California.Santa Clara.Verizon.Citrix
CLIENT.IPV6.SRC.LOCATION(3)	North America.US.California
CLIENT.IPV6.SRC.LOCATION.GET(1).LOCATION_LONG	United States
CLIENT.IPV6.SRC.LOCATION.GET(3)	California
CLIENT.IPV6.SRC.LAT_LONG	36, -119

---

## Configuring geolocation functions

To configure geolocation functions using advanced policy infrastructure, you must enable the load balancing, rewrite, and responder features and then complete the following use cases.

### Enable load balancing, responder, rewrite features

If you want the NetScaler appliance to authorize user access from a particular geo location, you must enable the load balancing, rewrite, and responder features.

```
1 enable ns feature loadbalancing rewrite responder
2 <!--NeedCopy-->
```

### Use case 1: Configuring geolocation function for redirecting invalid users outside geo location

When a user from India is requesting access to a webpage, block the request and respond with an HTML page with country name.

The following steps help you to complete the configuration of this use case.

- Add responder action
- Add responder policy
- Bind responder policy to load balancing server

For more information about the GUI procedures for rewrite action and rewrite policy configuration, see [Responder](#) topic

**Add responder action** Add a responder action to respond with HTML page with country name.

At the command prompt, type:

```
1 add responder action <name> <type> (<target> | <htmlpage>) [-comment <
 string>] [-responseStatusCode <positive_integer>][-reasonPhrase <
 string>]
2 <!--NeedCopy-->
```

**Example:**

```
1 add responder action responder_act respondwith "HTTP.REQ.VERSION + \"
 304 Requested Page not allowed in your country - \" + CLIENT.IP.SRC.
 LOCATION.GET (1).LOCATION_LONG + \"\r\n\""
2 <!--NeedCopy-->
```

**Add audit log message action** You can configure audit message actions to log messages at various log levels, either in syslog format only or in both syslog and `newslog` formats. Audit-message actions use expressions to specify the format of the audit messages.

To create an audit message action by using the command line interface

At the command prompt, type:

```
add audit messageaction <name> <logLevel> <stringBuilderExpr> [-
logtoNewslog (YES|NO)]
```

**Example:**

```
1 add audit messageaction msg1 DEBUG "\"Request Location: \"+CLIENT.IP.
 SRC.LOCATION"
2 <!--NeedCopy-->
```

**Add responder policy** Add a responder policy to identify requests coming from India and associate the responder action to this policy.

At the command prompt, type:

```
1 add responder policy <name> <rule> <action> [<undefAction>] [-comment <
 string>] [-logAction <string>] [-appflowAction <string>]
2 <!--NeedCopy-->
```

**Example:**

```
1 add responder policy responder_pol CLIENT.IP.SRC.MATCHES_LOCATION("Asia
 .India.*.*.*.*") responder_act -logaction msg1
2 <!--NeedCopy-->
```

**Bind responder policy to load balancing server** Bind the responder policy to a load balancing virtual server of type HTTP/SSL.

At the command prompt, type:

```
1 bind lb vserver <vserver name> -policyName < policy_name > -priority
 <> -type <L7InlineREQUEST | L4Inline-REQUEST>
2 <!--NeedCopy-->
```

**Example:**

```
1 bind lb vserver http_vserver -policyName responder_pol -priority 100 -
 type REQUEST
2 <!--NeedCopy-->
```

**Use case 2: Configuring geolocation function for inserting new HTTP header with location details for back-end to respond**

Consider a scenario, where a NetScaler appliance must insert the user location in the HTTP header of a request sent to the application server so that the server can use the information for some business logic.

The following steps help you to complete the configuration of this use case.

- Add rewrite action
- Add rewrite policy
- Bind rewrite policy to load balancing

For more information about the GUI procedures for rewrite action and rewrite policy configuration, see [Responder](#) topic.

**Add rewrite action** Add a rewrite action to insert a custom HTTP header with user geolocation details in the request and send it back-end servers.

At the command prompt, type:

```
1 add rewrite action <name> <type> <target> [<stringBuilderExpr>] [-
 search <expression>] [-refineSearch <string>] [-comment <string>]
2 <!--NeedCopy-->
```

**Example:**

```
1 add rewrite action rewrite_act insert_http_header "User_location"
 CLIENT.IP.SRC.LOCATION
2 <!--NeedCopy-->
```

**Add rewrite policy** Add a rewrite policy to evaluate if the rewrite action must be run. In this case, all requests going to the application server must have a custom HTTP header, so the rule can be “true.”  
At the command prompt, type:

```
1 add rewrite policy <name> <rule> <action> [<undefAction>] [-comment <
 string>] [-logAction <string>]
2 <!--NeedCopy-->
```

**Example:**

```
1 add rewrite policy rewrite_pol true rewrite_act -logaction log_act
2 <!--NeedCopy-->
```

**Bind rewrite policy to load balancing** Bind the rewrite policy to the required load balancing virtual server of type HTTP/SSL.

At the command prompt, type:

```
1 bind lb vserver <vserver name> -policyName < policy_name > -priority
 <> -type <L7InlineREQUEST | L4Inline-REQUEST>
2 <!--NeedCopy-->
```

**Example:**

```
1 bind lb vserver http_vserver -policyName rewrite_pol -priority 100 -
 type REQUEST
2 <!--NeedCopy-->
```

## Syslog support for logging geolocation details (optional)

If you prefer to log the user’s geolocation details, you must specify the SYSLOG action to be performed when a request matches the policy. The appliance stores the details as a log message in the ns.log file. For more information about SYSLOG and NSLOG auditing, see [Audit logging](#) topic.

### Output for user geolocation details

The following output is logged in the appliance using the SYSLOG or `newslog` action if you try to access an application from the Bangalore location and if the appliance uses the geolocation function, “CLIENT.IP.SRC.LOCATION”.

```
1 Asia.India.Karnataka.Banglore
2 <!--NeedCopy-->
```

**Sample output log:**

```
1 07/23/2018:19:03:54 GMT Debug 0-PPE-0 : default REWRITE Message 22 0 :
 "Request Location: asia.in.karnataka.bangalore.*.*"
2 07/23/2018:19:23:55 GMT Debug 0-PPE-0 : default RESPONDER Message 32 0
3 Done
4 <!--NeedCopy-->
```

## Use the source IP address of the client when connecting to the server

May 2, 2023

You can configure the NetScaler appliance to forward packets from the client to the server without changing the source IP address. This is useful when you cannot insert the client IP address into a header, such as when working with non-HTTP services.

For more information about configuring USIP globally, see [Enabling Use Source IP Mode](#).

### To enable USIP mode for a service by using the CLI

At the command prompt, type:

```
1 set service <name> -usip (YES | NO)
2 <!--NeedCopy-->
```

**Example:**

```
1 set service Service-HTTP-1 -usip YES
2 <!--NeedCopy-->
```

### To enable USIP mode for a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, in the Service Settings section, select **Use Source IP Address**.

## Use client source IP address for back end communication in a v4-v6 load balancing configuration

May 2, 2023

In a v4-to-v6 load balancing configuration, for services with USIP disabled, the NetScaler appliance communicates to the related servers from one of the configured IPv6 SNIP (SNIP6) addresses.

For services with USIP enabled, you must set the global USIP NAT prefix parameter for making the related servers aware of the client's IP address of the request packets. USIP NAT prefix is a global IPv6 prefix of length 32/40/48/56/64/96 bits configured on the NetScaler appliance.

For a load balancing service that has USIP enabled, the appliance translates the IPv4 request packet to an IPv6 packet and sets the source IP address of the translated IPv6 packet to a concatenation of:

- the USIP NAT prefix of length of 32/40/48/56/64/96 bits.
- zeros padded if the USIP NAT prefix length is less than 96 bits. Number of bits padded with zeros = 96-USIP NAT prefix length. For example, if the USIP NAT prefix length is 64, then the number of bits padded with zeros = 96-64 = 32.
- the IPv4 source address [32 bits] that was received in the request packet. In other words, the last 32 bits of the source IPv6 address is set to the IPv4 address of the client.

On receiving an IPv6 response packet from the server, the NetScaler appliance translates the IPv6 packet to an IPv4 packet and sets the destination IP address of the translated IPv4 packet to the last 32 bits of the destination IP address of the IPv6 packet.

**Note:** This feature is not supported for NetScaler Gateway configuration and, content switching and cache redirection load balancing configurations.

### Configuration Steps

Configuring USIP for a v4-to-v6 load balancing configuration consists of the following tasks:

- **Add global USIP NAT prefix.** It is a global IPv6 prefix of length 32/40/48/56/64/96 bits to be configured on the appliance.
- **Enable global USIP mode.** For more information, see [Enable Use Source IP Mode](#).
- **Enable USIP mode for load balancing services.** For more information, see [Use source IP address of the client when connecting to the server](#).

**To add a global USIP NAT prefix by using the CLI:**

- `set ipv6 -usipnatprefix <prefix/prefix_length>`
- `show ipv6`

**To add a global USIP NAT prefix by using the GUI:**

1. Navigate to **System > Network**, and click **Change IPv6 Settings**.
2. On the **Configure Configuration for IPV6** screen, set the **USIP NAT Prefix** parameter.

**Sample configuration**

```
1 > set ipv6 -usipnatprefix 2001:DB8:90::/64
2 Done
3
4 > enable ns mode USIP
5 Done
6
7 > add lb vserver LBVS-1 HTTP 203.0.113.90 80
8 Done
9
10 > add service SVC-1 2001:DB8:5001::30 HTTP 80 -usip yes
11 Done
12
13 > add service SVC-2 2001:DB8:5001::60 HTTP 80 -usip yes
14 Done
15
16 > bind lb vserver LBVS-1 SVC-1
17 Done
18
19 > bind lb vserver LBVS-1 SVC-2
20 Done
21
22 <!--NeedCopy-->
```

**Configure the source port for server-side connections**

May 2, 2023

When the NetScaler appliance connects to a physical server, it can use the source port from the client's request, or it can use a proxy port as the source port for the connection. You can set the Use Proxy Port parameter to YES to handle situations such as the following scenario:

- The NetScaler appliance is configured with two load balancing virtual servers, LBVS1 and LBVS2.
- Both the virtual servers are bound to the same service, S-ANY.
- Use (the client's) source IP address (USIP) is enabled on the service.
- Client C1 sends two requests, Req1 and Req2, for the same service.
- LBVS1 receives Req1 and LBVS2 receives Req2.
- LBVS1 and LBVS2 forward the request to S-ANY, and when S-ANY sends the response, LBVS1 and LBVS2 forward the response to the client.

- Consider two cases:
  - Use the client port. When the appliance uses the client port, both the virtual servers use the client’s IP address (because USIP is ON) and the client’s port when connecting to the server. Therefore, when the service sends the response, the appliance cannot determine which virtual server must receive the response.
  - Use proxy port. When the appliance uses a proxy port, the virtual servers use the client’s IP address (because USIP is ON), but different ports when connecting to the server. Therefore, when the service sends the response, the port number identifies the virtual server that must receive the response.

However, if you require a fully transparent configuration, such as a fully transparent cache redirection configuration, you must disable the Use Proxy port Setting so that the NetScaler appliance can use the source port from the client’s request.

The Use Proxy Port option becomes relevant if the use source IP (USIP) option is enabled. For TCP-based service types, such as TCP, HTTP, and SSL, the option is enabled by default. For UDP-based service types, such as UDP and DNS, including ANY, the option is disabled by default. For more information about the USIP option, see “[Enabling Use Source IP Mode.](#)”

You can configure the **Use Proxy Port** setting either globally or on a given service.

### Configure the use proxy port setting on a service

You configure the **Use ProxyPort** setting on the service if you want to override the global setting.

#### To configure the Use Proxy Port setting on a service by using the CLI

At the command prompt, type:

```
1 set service <name> -useProxyPort (YES | NO)
2 <!--NeedCopy-->
```

#### Example:

```
1 set service svc1 -useproxyport YES
2 Done
3
4 show service svc1
5 svc1 (10.102.29.30:80) - HTTP
6 State: UP
7 . . .
8 Use Source IP: YES Use Proxy Port: YES
9 . . .
10 Done
11 <!--NeedCopy-->
```

### To configure the Use Proxy Port setting on a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select Traffic Settings, and select **Use Proxy Port**.

### Configure the use proxy port setting globally

You configure the **Use Proxy Port** setting globally if you want to apply the setting to all the services on the NetScaler appliance. The service-specific **Use Proxy Port** settings overrides the global setting.

### To configure the Use Proxy Port setting globally by using the CLI

At the command prompt, type the following commands to configure the **Use Proxy Port** setting globally and verify the configuration:

```
1 set ns param -useproxyport (ENABLED | DISABLED)`
2 show ns param`
3 <!--NeedCopy-->
```

#### Example:

```
1 set ns param -useproxyport ENABLED
2
3 Done
4
5 show ns param
6 Global configuration settings:
7 . . .
8 Use Proxy Port: ENABLED
9 Done
10 <!--NeedCopy-->
```

### To configure the Use Proxy Port setting globally by using the GUI

Navigate to **System > Settings > Change global system** settings, and select or clear Use Proxy Port.

## Set a limit on the number of client connections

May 2, 2023

You can specify a maximum number of client connections that each load balanced server can handle. The NetScaler appliance then opens client connections to a server only until this limit is reached.

When the load balanced server reaches its limit, monitor probes are skipped, and the server is not used for load balancing until it has finished processing existing connections and frees up capacity.

For more information on the **Maximum Client** setting, see [Load Balancing Domain-Name Based Services](#).

Note: Connections that are in the process of closing are not considered for this limit.

### To set a limit to the number of client connections by using the CLI

At the command prompt, type:

```
1 set service <name> -maxclient <Value>
2 <!--NeedCopy-->
```

#### Example:

```
1 set service Service-HTTP-1 -maxClient 1000
2 <!--NeedCopy-->
```

### To set a limit to the number of client connections by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select **Thresholds & Timeouts**, and select **Maximum Clients**.

## Set a limit on the number of requests per connection to the server

May 2, 2023

The NetScaler appliance can be configured to reuse connections to improve performance. In some scenarios, however, load balanced Web servers might have issues when connections are reused for too many requests. For HTTP or SSL services, use the max request option to limit the number of requests sent through a single connection to a load balanced Web server.

Note: You can configure the max request option for HTTP or SSL services only.

### To limit the number of client requests per connection by using the CLI

At the command prompt, type:

```
1 set service <ServiceName> -maxReq <Value>
2 <!--NeedCopy-->
```

**Example:**

```
1 set service Service-HTTP-1 -maxReq 100
2 <!--NeedCopy-->
```

**To limit the number of client requests per connection by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select **Thresholds & Timeouts**, and select **Maximum Requests**.

**Set a threshold value for the monitors bound to a service**

May 2, 2023

The NetScaler appliance designates a service as UP only when the sum of the weights of all monitors bound to it and that are UP is equal to or greater than the threshold value configured on the service. The weight for a monitor specifies how much that monitor contributes to designating the service to which it is bound as UP.

By default, the monitor threshold is set to 0 and monitor weights are set to 1. All monitors have equal weightage then and a service can go DOWN when any one of the monitors goes DOWN.

For example, assume that three monitors, named Monitor-HTTP-1, Monitor-HTTP-2, and Monitor-HTTP-3 respectively, are bound to Service-HTTP-1, and that the threshold configured on the service is three. Suppose the following weights are assigned to each monitor:

- The weight of Monitor-HTTP-1 is 1.
- The weight of Monitor-HTTP-2 is 3.
- The weight of Monitor-HTTP-3 is 1.

The service is marked UP only when one of the following is true:

- Monitor-HTTP-2 is UP.
- Monitor-HTTP-2 and Monitor-HTTP-1 or Monitor-HTTP-3 are UP
- All three monitors are UP.

**To set the monitor threshold value on a service by using the CLI**

At the command prompt, type:

```
1 set service <name> -monThreshold <Value>
2 <!--NeedCopy-->
```

**Example:**

```
1 set service Service-HTTP-1 -monThreshold 100
2 <!--NeedCopy-->
```

**To set the monitor threshold value on a service by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select **Thresholds & Timeouts**, and select **Monitor Threshold**.

**Set a timeout value for idle client connections**

May 2, 2023

You can configure the service with a time-out value to terminate any idle client connections when the configured time elapses. If the client is idle during the configured time, the NetScaler appliance closes the client connection.

**To set a timeout value for idle client connections by using the CLI**

At the command prompt, type:

```
1 set service <name> -cltTimeout <Value>
2 <!--NeedCopy-->
```

**Example:**

```
1 set service Service-HTTP-1 -cltTimeout 100
2 <!--NeedCopy-->
```

**To set a timeout value for idle client connections by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select **Thresholds & Timeouts**, and select **Client Idle Time-out**.

**Set a timeout value for idle server connections**

May 2, 2023

You can configure a service with a timeout value to terminate any idle server connections when the configured time (in seconds) elapses. If the server is idle for the configured amount of time, the NetScaler appliance closes the server connection.

### To set a timeout value for idle server connections by using the CLI

At the command prompt, type:

```
1 set service <name> -svrTimeout <Value>
2 <!--NeedCopy-->
```

#### Example:

```
1 set service Service-HTTP-1 -svrTimeout 100
2 <!--NeedCopy-->
```

### To set a timeout value for idle server connections by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select **Thresholds & Timeouts**, and select **Server Idle Time-out**.

## Set a limit on the bandwidth usage by clients

May 2, 2023

Sometimes, servers might have limited bandwidth to handle client requests and might become overloaded. To prevent overloading a server, you can specify a maximum limit on the bandwidth, in Kbps, processed by the server. The NetScaler appliance forwards requests to a load balanced server only until this limit is reached.

### To set a maximum bandwidth limit on a service by using the CLI

At the command prompt, type:

```
1 set service <name> -maxBandwidth <Value>
2 <!--NeedCopy-->
```

#### Example:

```
1 set service Service-HTTP-1 -maxBandwidth 100
2 <!--NeedCopy-->
```

## To set a maximum bandwidth limit on a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service.
2. In Advanced Settings, select **Thresholds & Timeouts**, and select **Maximum Bandwidth**.

## Redirect client requests to a cache

April 19, 2021

You can configure a service to redirect client requests to a cache, and forward the non-cacheable requests to a service chosen by the configured load balancing method.

## To set cache redirection on a service by using the CLI

At the command prompt, type:

```
1 set service <name> -cacheable <Value>
2 <!--NeedCopy-->
```

### Example:

```
1 set service Service-HTTP-1 -cacheable YES
2 <!--NeedCopy-->
```

## To set cache redirection on a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Open a service, and set the Cache Type.

## Retain the VLAN identifier for VLAN transparency

April 19, 2021

You can configure a load balancing virtual server to retain the client's VLAN identifier in packets that are to be forwarded to servers. The virtual server must be a wildcard virtual server of type ANY, and must be functioning in MAC mode.

## To configure a load balancing virtual server to retain the client VLAN ID by using the CLI

At the command prompt, type the following command to configure a load balancing virtual server to retain the client VLAN ID and verify the configuration:

```
1 set lb vserver <name> -m MAC -macmodeRetainvlan ENABLED
2
3 show lb vserver <name>
4 <!--NeedCopy-->
```

### Note

For a service that is bound to a virtual server on which the `-m MAC` option is enabled, you must bind a non-user monitor.

## To configure a load balancing virtual server to retain the client VLAN ID by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In Advanced Settings, select **Traffic Settings**, and select **Retain VLAN ID**.

## Configure automatic state transition based on percentage health of bound services

May 2, 2023

You can configure a load balancing virtual server to automatically transition from the UP state to the DOWN state if the percentage of active services falls below a configured threshold. For example, if you bind 10 services to a load balancing virtual server and configure a threshold of 50% for that virtual server, it transitions from UP to DOWN if six or more services are DOWN. When the percentage health rises above the threshold value, the virtual server returns to the UP state.

You can also enable an SNMP alarm called ENTITY-STATE if you want the NetScaler appliance to notify you when the percentage health of bound services causes a virtual server to change state.

## To configure percentage based automatic state transition by using the CLI

At the command prompt, type the following commands to configure an automatic state transition for a virtual server and verify the configuration:

```
1 set lb vserver <name> -healthThreshold <positive_integer>
2
3 show lb vserver <name>
4 <!--NeedCopy-->
```

### To configure percentage based automatic state transition by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In Advanced Settings, select **Traffic Settings**, and set a **Health Threshold**.

### To enable the ENTITY-STATE alarm by using the CLI

At the command prompt, type the following commands to enable the ENTITY-STATE SNMP alarm and verify the configuration:

```
1 enable snmp alarm ENTITY-STATE
2
3 show snmp alarm
4 <!--NeedCopy-->
```

### To enable the ENTITY-STATE alarm by using the GUI

1. Navigate to **System > SNMP > Alarms**.
2. Select **ENTITY-STATE** and, in the Action list, select **Enable**.

## Static proximity based on NetScaler location

June 12, 2023

#### Note

The proximity from self parameter is available from release 13.1 build 48.x onwards.

When you configure the static proximity load balancing method, a server is chosen based on the client IP address instead of the NetScaler loopback IP address. As a result, the response time might be higher. The parameter proximity from self when enabled, ensures that the request is sent to a server that is closest to the NetScaler by using the NetScaler loopback IP address. Setting this parameter to YES accelerates the response time if the servers are located closer to the NetScaler as compared to the client.

## Prerequisite

Select static proximity as the load balancing method

### To configure the `proximityFromSelf` parameter by using the CLI

At the command prompt, type the following commands to configure `proximityFromSelf` parameter and verify the configuration

```
1 set lbparameter -proximityFromSelf <NO/YES>
2 show lbparameter
3
4 <!--NeedCopy-->
```

#### Example:

```
1 set lbparameter -proximityFromSelf Yes
2 <!--NeedCopy-->
```

### To configure the Proximity from Self parameter by using the GUI

1. Navigate to **Traffic Management > Load Balancing**.
2. In the Load Balancing page under the **Settings** section, click **Change Load Balancing Parameters**.
3. Select **Proximity from Self**.
4. Click **OK**.

## Built-in monitors

May 2, 2023

The NetScaler appliance contains various built-in monitors that you can use to monitor your services. These built-in monitors handle most of the common protocols. They provide options to modify some parameters, such as interval, response time-out to meet your requirements. However, you cannot modify the monitor name and protocol. For more information, see [Modifying Monitors](#). You can also bind a built-in monitor to a service and unbind it from the service.

#### Note

You can create a custom monitor based on a built-in monitor. To learn how to create custom monitors, see [Configuring Monitors in a Load Balancing Setup](#).

## TCP-based application monitoring

May 2, 2023

The NetScaler appliance has two built-in monitors that monitor TCP-based applications: `tcp-default` and `ping-default`. When you create a service, the appropriate default monitor is bound to it automatically, so that the service can be used immediately if it is UP. The `tcp-default` monitor is bound to all TCP services. The `ping-default` monitor is bound to all non-TCP services.

You can't delete or modify default monitors. When you bind any other monitor to a TCP service, the default monitor is unbound from the service. The following table lists the monitor types, and the parameters and monitoring processes associated with each type.

Monitor type	Specific parameters	Process
tcp	Not applicable	The NetScaler appliance establishes a 3-way handshake with the monitor destination, and then closes the connection. If the appliance observes TCP traffic to the destination, it does not send TCP monitoring requests. This occurs if LRTM is disabled. By default, LRTM is disabled on this monitor.
http	<code>httprequest ["HEAD /"]</code> - HTTP request that is sent to the service. <code>respcode [200]</code> - A set of HTTP response codes are expected from the service.	The NetScaler appliance establishes a 3-way handshake with the monitor destination. After the connection is established, the appliance sends HTTP requests, and then compares the response code with the configured set of response codes.

---

Monitor type	Specific parameters	Process
tcp-ecv	send [""'] - is the data that is sent to the service. The maximum permissible length of the string is 512 bytes. recv [""'] - expected response from the service. The maximum permissible length of the string is 128 bytes. The last character is NULL termination.	The NetScaler appliance establishes a 3-way handshake with the monitor destination. When the connection is established, the appliance uses the send parameter to send specific data to the service and expects a specific response through the receive parameter. Different servers send different sizes of segments. However, the pattern must be within 16 TCP segments.
http-ecv	send [""'] - HTTP data that is sent to the service; recv [""'] - the expected HTTP response data from the service	The NetScaler appliance establishes a 3-way handshake with the monitor destination. When the connection is established, the appliance uses the send parameter to send the HTTP data to the service and expects the HTTP response that the receive parameter specifies. (HTTP body part without including HTTP headers). Empty response data matches any response. Expected data might be anywhere in the first 24 K bytes of the HTTP body of the response.
ping	Not Applicable	The NetScaler appliance sends an ICMP echo request to the destination of the monitor and expects an ICMP echo response.

---

To configure built-in monitors for TCP-based applications, see [Configuring Monitors in a Load Balancing Setup](#).

## To configure TCP-based monitors by using CLI

Type the following command:

```
1 add lb monitor <monitorName> <type> -respCode <int[-int]> -httpRequest
 <string> -resptimeout <integer> [<units>] -retries <integer> -
 downTime <integer> [<units>] -action <action>
2 <!--NeedCopy-->
```

### Example for TCP monitor type:

```
1 add lb monitor Exch2010-RPC-AddressBook TCP -LRTM ENABLED -interval 10
 -resptimeout 5 -destPort 59601
2 <!--NeedCopy-->
```

### Example for HTTP monitor type:

```
1 add lb monitor Mon_S4B_FE_2 HTTP -respCode 200 -httpRequest "GET /
 Autodiscover/XFrame/XFrame.html" -LRTM ENABLED -retries 10 -secure
 YES
2 <!--NeedCopy-->
```

### Example for HTTP-ECV monitor type:

```
1 add lb monitor STM_EXC2016_SSLBridge_MON HTTP-ECV -send "GET /owa/
 healthcheck.htm" -recv "200 OK" -LRTM ENABLED -destPort 443 -secure
 YES
2 <!--NeedCopy-->
```

### Example for PING monitor type:

```
1 add lb monitor lbmon-localhost-ping PING -LRTM DISABLED -destIP
 127.0.0.1
2 <!--NeedCopy-->
```

## SSL service monitoring

October 10, 2023

The NetScaler appliance has built-in secure monitors, TCPS, and HTTPS. You can use the secure monitors to monitor HTTP and non-HTTP traffic. To configure a secure HTTP monitor, select the monitor type as HTTP, and set the secure flag. To configure a secure TCP monitor, select the monitor type as TCP, and set the secure flag. The secure monitors work as follows:

- **Secure TCP monitoring.** The NetScaler appliance establishes a TCP connection. After the connection is established, the appliance performs an SSL handshake with the server. After the handshake is over, the appliance closes the connection.

- **Secure HTTP monitoring.** The NetScaler appliance establishes a TCP connection. After the connection is established, the appliance performs an SSL handshake with the server. When the SSL connection is established, the appliance sends HTTP requests over the encrypted channel and checks the response codes.

The following table describes the available built-in monitors for monitoring SSL services.

Monitor type	Probe	Success criteria (Direct condition)
TCP	TCP connection; SSL handshake	Successful TCP connection established and successful SSL handshake.
HTTP	TCP connection; SSL handshake; Encrypted HTTP request	Successful TCP connection is established, successful SSL handshake is performed, and expected HTTP response code in server HTTP response is encrypted.
TCP-ECV	TCP connection. SSL handshake (Data sent to a server is encrypted.)	Successful TCP connection is established, successful SSL handshake is performed, and expected TCP data is received from the server.
HTTP-ECV	TCP connection; SSL handshake (Encrypted HTTP request)	Successful TCP connection is established, successful SSL handshake is performed, and expected HTTP data is received from the server.

### Sample configuration for HTTP-ECV health check monitor

HTTP services have predefined monitors capable of Extended Content Verification (ECV).

These monitors are used when a validation is required beyond a successful TCP connection. These monitors validate the service as UP, when all the following criteria are met:

- A successful TCP connection.
- A particular type of request must be generated.
- A specific message is expected in reply from the **Receive String**.

For these monitors, a request string is configured along with a reply string. If the reply string received by the NetScaler monitor matches the configured string, then the service is marked UP.

## Bind a monitor to a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, create a service, and specify the protocol as **SSL**. Click **OK**.
2. Click in the **Service to Load Balancing Monitor Binding** pane, and click **Add Binding**.
3. Choose the monitor type as **HTTP-ECV** and click **Edit**.
4. In the **Configure Monitor** pane under **Basic Parameters** tab, enter values for the following parameters:
  - **Send String** –The string that the monitor must send to the service.
  - **Receive String** –The string that the monitor must receive to mark the service as UP.
5. Click **OK** to complete the monitor configuration.
6. Click **Select**.
7. Click **Bind** to bind the **HTTP-ECV** monitor to the service.
8. Click **Close**.

## Create and bind a monitor to a service by using the CLI

At the command prompt, type:

```
1 add lb monitor <monitor-name> http-ecv
2 bind service <servicename> -monitorName <monitor-name>
3 <!--NeedCopy-->
```

### Example:

```
1 add lb monitor monitor-1 http-ecv
2 bind service services1 -monitorName monitor-1
3 <!--NeedCopy-->
```

## HTTP/2 service monitoring

May 2, 2023

NetScaler appliance supports HTTP/2 monitors for monitoring the health status of HTTP/2 services.

HTTP/2 monitor can be configured in two different ways. Depending on the traffic type, you can configure an HTTP/2 monitor.

- **HTTP/2 Direct.** You can configure HTTP/2 Direct for monitoring non-secure HTTP/2 services.
- **HTTP/2 SSL.** You can configure HTTP/2 SSL for monitoring secure traffic over SSL. Enable the secure flag parameter in the HTTP/2 to monitor the SSL traffic.

The `http2direct` and `http2ssl` are the two different built-in monitors that are supported for the HTTP/2 protocol.

The following table lists the configuration types, and monitoring processes associated with each type.

Configuration type	Probe	Success criteria
HTTP/2 Direct	TCP Connection; HTTP2 Connection preface & Settings Negotiation; HTTP2 Request	HTTP/2 response status code must match the configured response code.
HTTP/2 SSL	TCP Connection; SSL Handshake; HTTP2 Connection preface & Settings Negotiation; HTTP2 Request	The server must always select <a href="#">ALPN</a> with the HTTP/2 protocol and the HTTP/2 response status code must match the configured response code.

### Bind the HTTP/2 monitor to a service by using the CLI

At the command prompt, type:

- `bind service <servicename> -monitorName <name>`
- `bind service <servicename> -monitorName <name>`

#### Example:

- `bind service s1 -monitorName http2direct`
- `bind service s2 -monitorName http2ssl`

## Proxy protocol service monitoring

May 2, 2023

NetScaler appliance with a proxy protocol supports monitor check. The monitor check ensures that the back end server also supports the proxy protocol. The NetScaler appliance has four built-in monitor types for HTTP or TCP related services: HTTP, HTTPS, HTTP-ECV, and TCP-ECV.

The following table lists the monitor types, and the parameters and monitoring processes associated with each type.

Configuration type	Probe	Success criteria
HTTP	<code>httprequest ["HEAD /"]</code> - HTTP request that is sent to the service. <code>respcode [200]</code> - A set of HTTP response codes are expected from the service.	The NetScaler appliance establishes a 3-way handshake with the monitor destination. After the connection is established, the appliance sends HTTP requests, and then compares the response code with the configured set of response codes.
HTTPS	<code>httprequest ["HEAD /"]</code> - HTTPS request that is sent to the service. <code>respcode [200]</code> - A set of HTTPS response codes are expected from the service.	The NetScaler appliance establishes a 3-way handshake with the monitor destination. After the connection is established, the appliance sends HTTPS requests, and then compares the response code with the configured set of response codes.
HTTP-ECV	<code>send ["]</code> - HTTP data that is sent to the service. <code>Received ["]</code> - the expected HTTP response data from the service	The NetScaler appliance establishes a 3-way handshake with the monitor destination. When the connection is established, the appliance uses the <code>send</code> parameter to send the HTTP data to the service and expects the HTTP response that the <code>receive</code> parameter specifies. (HTTP body part without including HTTP headers). Empty response data matches any response. Expected data might be anywhere in the first 24 K bytes of the HTTP body of the response.

Configuration type	Probe	Success criteria
TCP-ECV	send [""'] - is the data that is sent to the service. The maximum permissible length of the string is 512 K bytes. received [""'] - the expected response from the service. The maximum permissible length of the string is 128 K bytes.	The NetScaler appliance establishes a 3-way handshake with the monitor destination. When the connection is established, the appliance uses the send parameter to send specific data to the service and expects a specific response through the receive parameter. Different servers send different sizes of segments. However, the pattern must be within 16 TCP segments.

You can configure the proxy protocol monitor using [netprofile](#).

### Configure proxy protocol monitor by using the CLI

At the command prompt, type:

1. Add net profile with proxy protocol enabled

```
add netprofile <name> -proxyProtocol (ENABLED | DISABLED)
```

Example:

```
1 add netprofile profile1 -proxyProtocol ENABLED
```

1. Bind the net profile to a service.

```
set service <name> -netprofile <netprofile-name>
```

Example:

```
1 set service S1 -netprofile profile1
```

#### Note

You can run the preceding command if you want net profile to bound to a service.

1. Bind the net profile to a monitor.

```
set lb monitor <monitor-name> <type> -netprofile <netprofile-name>
```

Example:

```
1 set lb monitor http1 HTTPS -netprofile profile1
```

**Note**

- You can run the preceding command if you want the net profile to bound to a monitor.
- You can select a monitor type of your choice. It can be HTTP, HTTPS, TCP-ECV, or HTTP-ECV.

**Important**

- In a general case, the net profile (proxy protocol enabled) bound to a service is considered.
- If the net profile is bound to both monitor and service, the net profile bound to monitor is considered. The net profile bound to service is ignored.

## FTP service monitoring

May 2, 2023

To monitor FTP services, the NetScaler appliance opens two connections to the FTP server. It first connects to the control port, which is used to transfer commands between a client and an FTP server. After it receives the expected response, it connects to the data port, which is used to transfer files between a client and an FTP server. Only when the FTP server responds as expected, on both the connections, it is marked UP.

Note: Monitor probes originate from the NSIP address.

The NetScaler appliance has two built-in monitors for FTP services: the FTP monitor and the FTP-EXTENDED monitor. The FTP-EXTENDED monitor is a scriptable monitor. It uses the nsftp.pl script. The FTP-EXTENDED monitor script is enhanced to send secure probes to FTP services. You can create a monitor of type FTP-EXTENDED. The nsftp.pl script is automatically taken from the default directory.

### To send secure FTP probes to FTP services by using the CLI

At the command prompt, type:

```
1 add lb monitor <monitorName> <type> -username <string> -password <
 string> -filename <filename>
2 <!--NeedCopy-->
```

Example

```
1 add monitor mon1 FTP-EXTENDED -username root -password freesbd -
 filename fsdf
2 <!--NeedCopy-->
```

### To send secure FTP probes to FTP services by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. Specify the monitor type as **FTP-EXTENDED**, and set the parameters.
3. In **Special Parameters**, specify a **File Name**, **User Name**, and **Password**.

To configure built-in monitors to check the state of FTP services, see [Configuring Monitors in a Load Balancing Setup](#).

### Secure monitoring of servers by using SFTP

May 2, 2023

A user script 'nssftp.pl' is added to support SSH File Transfer Protocol (SFTP) monitoring. It is available in the current list of in-built NetScaler user monitors and is located in the /netscaler/monitors directory. The SFTP monitor uses the specified user name and password to check if the file is present on the server.

### To configure secure monitoring using SFTP by using the CLI

At the command prompt, type:

```
1 add lb monitor <monitorName> <type> -scriptName <string> -scriptArgs <
 string> -secure (YES | NO)
2 <!--NeedCopy-->
```

#### Example:

```
1 add monitor SFTP_MON USER - scriptname nssftp.pl - scriptargs " file=
 example.txt;user=sam;password=sam_passwd "
2 <!--NeedCopy-->
```

### To configure secure monitoring using SFTP by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors** and in **Type** specify **USER**.

2. In **Special Parameters**, in **Script Name**, select nssftp.pl.
3. Specify the **Script Arguments**.

## Set SSL parameters on a secure monitor

April 19, 2021

### Important

This feature is supported only on the new Default profiles. For more information about these profiles, see [Enhanced SSL Profiles Infrastructure Overview](#).

A monitor inherits either the global settings or the settings of the service to which it is bound. If a monitor is bound to a non-SSL or non-SSL\_TCP service, such as SSL\_BRIDGE, you cannot configure it with SSL settings such as the protocol version or the ciphers to be used. Therefore, if your deployment requires SSL-based monitoring of the back-end servers, the monitoring is ineffective.

You can have more control over SSL-based monitoring of back-end servers, by binding an SSL profile to a monitor. An SSL profile contains SSL parameters, cipher bindings, and ECC bindings. For example, you can set server authentication, ciphers, and protocol version in an SSL profile and bind the profile to a monitor. To perform server authentication, you must also bind a CA certificate to a monitor. To perform client authentication, you must bind a client certificate to the monitor. New parameters for the “bind lb monitor” command enable you to do so.

### Note

The SSL settings take effect only if you add a secure monitor. Also, the SSL profile type must be **BackEnd**.

## Monitor Types that Support SSL Profiles

SSL profiles can be bound to the following monitor types:

- HTTP
- HTTP-ECV
- TCP
- TCP-ECV
- HTTP-INLINE

## To specify an SSL profile while adding a monitor by using the command line

At the command prompt, type:

```
1 add lb monitor <monitorName> <type> -secure YES -sslprofile <string>
2
3 set lb monitor <monitorName> <type> -secure YES -sslprofile <string>
4 <!--NeedCopy-->
```

### Example:

```
1 add ssl profile prof1 -sslProfileType BackEnd
2
3 add lb monitor mon1 HTTP -secure YES -sslprofile prof1
4 <!--NeedCopy-->
```

## To bind a certificate-key pair to a monitor by using the command line

At the command prompt, type:

```
1 bind monitor <monitor name> -certkeyName <string> [(-CA [-crlCheck (
 Mandatory | Optional) | -ocspCheck (Mandatory | Optional)]
2 <!--NeedCopy-->
```

## SIP service monitoring

May 2, 2023

A NetScaler has two built-in monitors that you can use to monitor SIP services: the **SIP-UDP** and **SIP-TCP** monitors. A SIP monitor periodically checks the SIP service to which the SIP monitor is bound, by sending SIP request methods to the SIP service. If the SIP service replies with a response code, the monitor marks the service as UP. If the SIP service does not respond, or responds incorrectly, it is marked as DOWN.

Parameter	Specifies
sipURI	SIP addressing schema of the SIP server.
sipmethod	Type of SIP request used to probe the SIP service. Specify one of the following methods: INVITE, OPTION (the default), REGISTER
respcode	SIP response code with which the SIP service responds the probe request. Default: 200.

## RADIUS service monitoring

May 2, 2023

The NetScaler appliance RADIUS monitor periodically checks the state of the RADIUS service to which it is bound by sending an authentication request to the service. The RADIUS server authenticates the RADIUS monitor and sends a response. By default, the monitor expects to receive a response code of 2, the default Access-Accept response, from the RADIUS server. As long as the monitor receives the appropriate response, it marks the service UP.

Note: RADIUS monitor supports only PAP type authentication.

- If the client authenticated successfully, the RADIUS server sends an Access-Accept response. The default access-accept response code is 2, and this is the code that the appliance uses.
- If the client fails to authenticate successfully (such as when there is a mismatch in the user name, password, or secret key), the RADIUS server sends an Access-Reject response. The default access-reject response code is 3, and this is the code that the appliance uses.

---

Parameter	Specifies
<code>userName</code>	User name on the RADIUS/NNTP/FTP/FTP-EXTENDED/MYSQL/POP3 server. This user name is used in the probe.
<code>password</code>	Password used in monitoring RADIUS/NNTP/FTP/FTP-EXTENDED/MYSQL/POP3/LDAP servers.
<code>radKey</code>	Shared secret key value that the RADIUS server uses during client authentication.
<code>radNASid</code>	NAS-ID that is encapsulated in the payload when an access request is made.
<code>radNASip</code>	The IP address that is encapsulated in the payload when an access-request is made. When <code>radNASip</code> is not configured, the NetScaler appliance sends the mapped IP address (MIP) to the RADIUS server as the NAS IP address.

---

To monitor a RADIUS service, you must configure the RADIUS server to which it is bound as follows:

1. Add the user name and password of the client that the monitor uses for authentication to the RADIUS authentication database.

2. Add the IP address and secret key of the client to the appropriate RADIUS database.
3. Add the IP addresses that the appliance uses to send RADIUS packets to the RADIUS database. If the NetScaler appliance has more than one mapped IP address, or if a subnet IP address (SNIP) is used, you must add the same secret key for all the IP addresses.

**Caution:** If the IP address used by the appliance is not added to the RADIUS database, the RADIUS server discards all packets.

To configure built-in monitors to check the state of the RADIUS server, see [Configuring Monitors in a Load Balancing Setup](#).

## Monitor accounting information delivery from a RADIUS server

May 2, 2023

You can configure a monitor called a *RADIUS accounting* monitor to determine whether the RADIUS server used for Authentication, Authorization, and Accounting (NetScaler AAA) is delivering accounting information as expected. The monitor is of type `RADIUS_ACCOUNTING`. The probe is generated by a Perl script called `nsbmradius.pl`, which is located in the `/nsconfig/monitors/` directory. The script sends successive accounting request probes to the RADIUS server. The probe is considered successful only if the RADIUS accounting server responds with a packet whose Code field is set to 5, which, according to RFC 2866, indicates an Accounting-Response packet.

When configuring a RADIUS accounting monitor, you must specify a secret key. You can specify optional parameters, each of which represents a RADIUS attribute, such as `Acct-Status-Type` and `Framed-IP-Address`. For information about these attributes, see RFC 2865, “Remote Authentication Dial In User Service (RADIUS),” and RFC 2866, “RADIUS Accounting.”

### To configure a RADIUS accounting monitor by using the command line interface

At the command prompt, type the following commands to configure a RADIUS accounting monitor and verify the configuration:

```
1 add lb monitor <monitorName> RADIUS_ACCOUNTING [-userName <string>] {
2 -password }
3 {
4 -radKey }
5 [-radNASip <ip_addr>] [-radAccountType <positive_integer>] [-
 radFramedIP <ip_addr>] [-radAPN <string>] [-radMSISDN <string>] [-
 radAccountSession <string>]
6
7 show lb monitor <monitorName>
8 <!--NeedCopy-->
```

### Example

```
1 add lb monitor radAccntMon RADIUS_ACCOUNTING -radKey "8d#>9jr4rV)L7%a2-
 zW13sM"
2 <!--NeedCopy-->
```

## DNS and DNS-TCP service monitoring

May 2, 2023

The NetScaler appliance has two built-in monitors that can be used to monitor DNS services: DNS and DNS-TCP. When bound to a service, either monitor periodically checks the state of that DNS service by sending a DNS query to it. The query resolves to an IPv4 or IPv6 address. That IP address is then checked against the list of test IP addresses that you configure. The list can contain up to five IP addresses. If the resolved IP address matches at least one IP address on the list, the DNS service is marked as up. If the resolved IP does not match any IP addresses on the list, the DNS service is marked as down.

Parameter	Description
query	<p>The DNS query (domain name) sent to the DNS service that is being monitored. Default value: “</p> <p>query</p> <p>The DNS query (domain name) sent to the DNS service that is being monitored. Default value: “\007”If the DNS query succeeds, the service is marked as UP. Otherwise, it is marked as DOWN. For a reverse monitor, if the DNS query succeeds, the service is marked as UP. Otherwise, it is marked as DOWN. For a reverse monitor, if the DNS query succeeds, the service is marked as DOWN. Otherwise, it is marked as UP. If no response is received, the service is marked as DOWN.</p>
queryType	<p>The type of DNS query that is sent. Possible values: Address, Zone.</p>
<a href="#">IPAddress</a>	<p>List of IP addresses that are checked against the response to the DNS monitoring probe.</p>

---

Parameter	Description
IPv6	Select this check box if the IP address uses the IPv6 format.

---

To configure the built-in DNS or DNS-TCP monitors, see [Configuring Monitors in a Load Balancing Setup](#).

## LDAP service monitoring

May 2, 2023

The NetScaler appliance has one built-in monitor that can be used to monitor LDAP services: the LDAP monitor. It periodically checks the LDAP service to which it is bound by authenticating and sending a search query to it. If the search is successful, the service is marked UP. If the LDAP server does not locate the entry, a failure message is sent to the LDAP monitor, and the service is marked DOWN.

Configure the LDAP monitor to define the search that it must perform when sending a query. You can use the Base DN parameter to specify a location in the directory hierarchy where the LDAP server must start the test query. You can use the Attribute parameter to specify an attribute of the target entity.

Note: Monitor probes originate from the NSIP address.

---

Parameter	Specifies
baseDN	Base name for the LDAP monitor from where the LDAP search must start. If the LDAP server is running locally, the default value of base is <code>dc=netScaler,dc=com</code> .
bindDN	BDN name for the LDAP monitor.
filter	Filter for the LDAP monitor. Use the filter parameter in a query to limit the number of results. If you do not specify this parameter in the query, the filter applies for the entire object class, which might be a costly operation, such as a high CPU usage.
password	Password used in monitoring LDAP servers.

---

Parameter	Specifies
attribute	Attribute for the LDAP monitor.

To configure the built-in LDAP monitor, see [Configuring Monitors in a Load Balancing Setup](#).

## MySQL service monitoring

May 2, 2023

The NetScaler appliance has one built-in monitor that can be used to monitor MySQL services: the MySQL monitor. It periodically checks the MySQL service to which it is bound by sending a search query to it. If the search is successful, the service is marked UP. If the MySQL server does not respond or the search fails, a failure message is sent to the MySQL monitor, and the service is marked DOWN.

Note: Monitor probes originate from the NSIP address.

Parameter	Specifies
database	Database that is used for the MySQL monitor.
sqlQuery	SQL query that is used for the MySQL monitor.

To configure a built-in MySQL monitor, see [Configuring Monitors in a Load Balancing Setup](#).

### To configure MySQL monitors by using CLI

Type the following command:

```
1 add lb monitor <monitorName> <type> -scriptName <string> -scriptArgs <
 string>
2 <!--NeedCopy-->
```

#### Example:

```
1 add lb monitor mysql1 USER -scriptName nsmysql.pl -scriptArgs "database
 =cloud;user=cloud;password=password;query=show tables from cloud"
2 <!--NeedCopy-->
```

## SNMP service monitoring

May 2, 2023

The NetScaler appliance has one built-in monitor that can be used to monitor SMNP services: the SNMP monitor. It periodically checks the SNMP agent on the service to which it is bound by sending a query for the enterprise identification ID (OID) that you configure for monitoring. If the query is successful, the service is marked UP. If the SNMP service finds the OID that you specified, the query succeeds and the SNMP monitor marks the service UP. If it does not find the OID, the query fails and the SNMP monitor marks service DOWN.

Note: Monitor probes originate from the NSIP address.

---

Parameter	Specifies
SNMPOID	OID that is used for the SNMP monitor.
snmpCommunity	Community that is used for the SNMP monitor.
snmpThreshold	Threshold that is used for the SNMP monitor.
snmpVersion	SNMP version that is used for load monitoring. Possible Values: V1, V2.

---

To configure the built-in SNMP monitor, see [Configuring Monitors in a Load Balancing Setup](#).

## NNTP service monitoring

May 2, 2023

The NetScaler appliance has one built-in monitor that can be used to monitor NNTP services: the NNTP monitor. It periodically checks the NNTP service to which it is bound by connecting to the service and checking for the existence of the newsgroup that you specify. If the newsgroup exists, the search is successful and the service is marked UP. If the NNTP service does not respond or the search fails, the service is marked DOWN.

Note: Monitor probes originate from the NSIP address.

The NNTP monitor can optionally be configured to post a test message to the newsgroup as well.

---

Parameter	Specifies
<code>userName</code>	User name on the RADIUS/NNTP/FTP/FTP-EXTENDED/MYSQL/POP3 server. This user name is used in the probe.
<code>password</code>	Password used in monitoring RADIUS/NNTP/FTP/FTP-EXTENDED/MYSQL/POP3/LDAP servers.
<code>group</code>	Group name to be queried for NNTP monitor.

---

To configure the built-in NNTP monitor, see [Configuring Monitors in a Load Balancing Setup](#).

## POP3 service monitoring

May 2, 2023

The NetScaler appliance has one built-in monitor that can be used to monitor POP3 services: the POP3 monitor. It periodically checks the POP3 service to which it is bound by opening a connection with a POP3 server. If the POP3 server responds with the correct response codes within the configured time period, it marks the service UP. If the POP3 service does not respond, or responds incorrectly, it marks the service DOWN.

Note: Monitor probes originate from the NSIP address.

---

Parameter	Specifies
<code>userName</code>	User name POP3 server. This user name is used in the probe.
<code>password</code>	Password used in monitoring POP3 servers.
<code>scriptName</code>	The path and name of the script to execute.
<code>dispatcherIP</code>	The IP address of the dispatcher to which the probe is sent.
<code>dispatcherPort</code>	The port of the dispatcher to which the probe is sent.

---

To configure the built-in POP3 monitor, see [Configuring Monitors in a Load Balancing Setup](#).

## To configure POP3 monitors by using CLI

Type the following command:

```
1 add lb monitor <monitorName> <type> -scriptName <string> -scriptArgs <
 string>
2 <!--NeedCopy-->
```

### Example:

```
1 add lb monitor pop31 USER -scriptName nspop3.pl -scriptArgs "user=
 test@lbmon1.net;password=Freebsd123"
2
3 <!--NeedCopy-->
```

## SMTP service monitoring

May 2, 2023

The NetScaler appliance has a built-in monitor that can be used to monitor SMTP services: the SMTP monitor. The monitor checks the SMTP service to which it is bound by opening a connection with it and conducting a series of handshakes to ensure that the server is operating correctly. If the SMTP service completes the handshakes properly, the monitor marks the service UP. Else, if the SMTP service does not respond, or responds incorrectly, it marks the service DOWN.

Note: Monitor probes originate from the NSIP address.

---

Parameter	Specifies
scriptName	The path and name of the script to run.
dispatcherIP	The IP Address of the dispatcher to which the probe is sent.
dispatcherPort	The port of the dispatcher to which the probe is sent.

---

To configure the built-in SMTP monitor, see [Configuring Monitors in a Load Balancing Setup](#).

## RTSP service monitoring

May 2, 2023

The NetScaler appliance has one built-in monitor that can be used to monitor RTSP services: the RTSP monitor. It periodically checks the RTSP service to which it is bound by opening a connection with the load balanced RTSP server. The type of connection that it opens, and the response that it expects, differs depending upon the network configuration. If the RTSP service responds as expected within the configured time period, it marks the service UP. If the service does not respond, or responds incorrectly, it marks the service DOWN.

The NetScaler appliance can be configured to load balance RTSP servers using two topologies: NAT-off and NAT-on. RTSP servers send their responses directly to the client, bypassing the appliance. The appliance must be configured to monitor RTSP services differently depending upon which topology your network uses. The appliance can be deployed either in inline or non-inline mode in both NAT-off and NAT-on mode.

In NAT-off mode, the appliance operates as a router: it receives RTSP requests from the client and routes them to the service that it selects using the configured load balancing method. If your load balanced RTSP servers are assigned publicly accessible FQDNs in DNS, the load balanced servers send their responses directly to the client, bypassing the appliance. The following figure demonstrates this configuration.

Figure 1. RTSP in NAT-off Mode

The flow of requests and responses in this scenario is as follows:

1. The client sends a DESCRIBE request to the appliance. The appliance uses the configured load balancing method to choose a service, and routes the request to Media Server-1.
2. The client sends a SETUP request to the appliance. If the RTSP session ID is exchanged in the DESCRIBE request, the appliance, using RTSPSID persistence, routes the request to Media Server-1. If the RTSP session ID is exchanged in the SETUP request, the appliance does one of the following:
  - If the RTSP request comes on the same TCP connection, it routes the request to Media Server-1, maintaining persistence.
  - If the request arrives on a different TCP connection, it uses the configured load balancing method to choose a service, and sends the request to that service, not maintaining persistence. This means that the request might be sent to a different service.
3. Media Server-1 receives the SETUP request from the appliance, allocates resources to process the RTSP request, and sends the appropriate session ID to the client.

Note: The appliance does not perform NAT to identify the RTSP connection, because the RTSP connections bypass it.
4. For subsequent requests, the client then uses the session ID to identify the session and send control messages to the media server. Media Server-1 performs the requested actions, such as play, forward, or rewind.

In NAT-on mode, the appliance receives RTSP requests from the client and routes those requests to the appropriate media server using the configured load balancing method. The media server then sends its responses to the client through the appliance, as illustrated in the following diagram.

Figure 2. RTSP in NAT-on Mode

The flow of requests and responses in this scenario is as follows:

1. The client sends a DESCRIBE request to the appliance. The appliance uses the configured load balancing method to choose a service, and routes the request to Media Server-1.
2. The client sends a SETUP request to the appliance. If the RTSP session ID is exchanged in the DESCRIBE request, the appliance, using the RTSPSID persistence, routes the request to Media Server-1. If the RTSP session ID is exchanged in the SETUP request, the appliance does one of the following:
  - If the RTSP request comes on the same TCP connection, it routes the request to Media Server-1, maintaining persistence.
  - If the request arrives on a different TCP connection, it uses the configured load balancing method to choose a service, and sends the request to that service, not maintaining persistence. This means that the request might be sent to a different service.
3. Media Server-1 receives the SETUP request from the appliance, allocates resources to process the RTSP request, and sends the appropriate session ID to the client.
4. The appliance performs NAT to identify the client for RTSP data connections, and the RTSP connections pass through the appliance and are routed to the correct client.
5. For subsequent requests, the client then uses the session ID to identify the session and send control messages to the appliance. The appliance uses RTSPSID persistence to identify the appropriate service, and routes the request to Media Server-1. Media Server-1 performs the requested action, such as play, forward, or rewind.

The RTSP monitor uses the RTSP protocol to evaluate the state of the RTSP services. The RTSP monitor connects to the RTSP server and conducts a sequence of handshakes to ensure that the server is operating correctly.

Parameter	Specifies
rtspRequest	The RTSP request string that is sent to the RTSP server (for example, OPTIONS *). The default value is 07. The length of the request must not exceed 163 characters.
respCode	Set of response codes that are expected from the service.

For instructions on configuring an RTSP monitor, see [Configuring Monitors in a Load Balancing Setup](#).

## ARP request monitoring

May 2, 2023

The NetScaler appliance has one built-in monitor that can be used to monitor ARP requests: the ARP monitor. This monitor periodically sends an ARP request to the service to which it is bound, and listens for the expected response. If it receives the expected response, it marks the service UP. If it receives no response or the wrong response, it marks the service DOWN.

ARP locates a hardware address for a load balanced server when only the network layer address is known. ARP is compatible with IPv4 to translate IP addresses to Ethernet MAC addresses. ARP monitoring is not relevant to IPv6 networks, and is therefore not supported on those networks.

There are no special parameters for the ARP monitor.

For instructions on configuring an ARP monitor, see [Configuring Monitors in a Load Balancing Setup](#).

## Citrix Virtual Desktops Delivery Controller service monitoring

May 2, 2023

In desktop virtualization, the NetScaler appliance can be used to load balance the Citrix Virtual Desktops Delivery Controller servers deployed by the Citrix Virtual Desktops environment. The NetScaler appliance provides a built-in monitor, `CITRIX-XD-DDC` monitor, which monitors the Citrix Virtual Desktops Delivery Controller servers. In addition to the health check, you can also verify whether the probe is sent by a valid user of the Citrix Virtual Desktops Delivery Controller server.

The monitor sends a probe to the Citrix Virtual Desktops Delivery Controller server in the form of an XML message. If the server responds to the probe with the identity of the server farm, the probe is considered to be successful and the server's status is marked as UP. If the HTTP response does not have a success code or the identity of the server farm is not present in the response, the probe is considered to be a failure and the server's status is marked as DOWN.

The Validate Credentials option determines the probe to be sent by the monitor to the Citrix Virtual Desktops Delivery Controller server, that is, whether to request only the server name or to also validate the login credentials.

Note: Regardless of whether the user credentials (user name, password, and domain) are specified on the

`CITRIX-XD-DDC` monitor, the Citrix Virtual Desktops Delivery Controller server validates the user credentials only if the option to validate credentials is enabled on the monitor.

If you use the wizard for configuring the load balancing of the Citrix Virtual Desktops servers, the `CITRIX-XD-DDC` monitor is automatically created and bound to the Citrix Virtual Desktops Delivery Controller services.

### To add an XD-DDC monitor with the validate credentials option by using the command line interface

At the command prompt, type the following commands to add an XD-DDC monitor and verify the configuration:

```

1 add lb monitor <monitorName> <monitorType> -userName <userName> -
 password <password> -domain <domain_name> -validateCred YES
2
3 show lb monitor <monitorName>
4 <!--NeedCopy-->

```

#### Example:

```

1 > add lb monitor xdddcmon Citrix-xd-ddc -userName Administrator -
 password E12Dc35450a1 -domain dhop -validateCred YES
2 Done
3 > show lb monitor xdddcmon
4 1) Name.....:xdddcmon Type.....:CITRIX-XD-DDC State.....: ENABLED
5
6 Standard parameters:
7 Interval.....:5 sec...Retries.....:3
8 Response timeout.....:2 sec...Down time.....:30 sec
9 Reverse.....:NO...Transparent.....:NO
10 Secure.....:NO...LRTM.....:ENABLED
11 Action.....:Not applicable...Deviation.....:0 sec
12 Destination IP.....:Bound service
13 Destination port.....:Bound service
14 Iptunnel.....:NO
15 TOS.....:NO...TOS ID.....:0
16 SNMP Alert Retries.....:0...Success Retries.....:1
17 Failure Retries.....:0
18
19 Special parameters:
20 User Name.....:"Administrator"
21 Password.....:*****
22 DDC Domain.....: "dhop"
23 Done
24 <!--NeedCopy-->

```

### To specify the validate credentials option on an XD-DDC monitor by using the command line interface

At the command prompt, type:

```
1 set lb monitor <monitorName> <monitorType> -userName -password -domain
 <domain_name> -validateCred YES
2 <!--NeedCopy-->
```

**Example:**

```
1 set lb monitor XD_DDC_21.21.21.22_443_mn CITRIX-xd-ddc -userName
 Administrator -password D123S1R2A123 -domain dhop -validateCred YES
2 Done
3 <!--NeedCopy-->
```

**To configure an XD-DDC monitor with the validate credentials option by using the configuration utility**

Navigate to **Traffic Management > Load Balancing > Monitors**, and create a monitor of type **Citrix -XD-DDC**.

**Citrix StoreFront stores monitoring**

August 8, 2023

You can configure a user monitor for a Citrix StoreFront store. The monitor determines the state of the StoreFront store by successively probing the account service, discovery service, and authentication endpoint (if the Citrix StoreFront Store is an authenticated store). If any of those services do not respond to the probe, the monitor probe fails, and the StoreFront store is marked as DOWN. The monitor sends probes to the IP address and port of the bound service. For more information, see [Citrix StoreFront Store Services API](#).

Note: Monitor probes originate from the NSIP address. However, if the subnet of a StoreFront server is different from that of the appliance, then the subnet IP (SNIP) address is used.

You can also bind a StoreFront monitor to a service group. A monitor is bound to each member of the service group and probes are sent to the IP address and port of the bound member (service). Also, because each member of a service group is now monitored by using the member's IP address, you can now use the StoreFront monitor to monitor StoreFront cluster nodes that are added as members of the service group.

In earlier releases, the StoreFront monitor tried to authenticate anonymous stores. As a result, a service can be marked as DOWN and you cannot launch Citrix Virtual Apps and Citrix Virtual Desktops by using the URL of the load balancing virtual server.

The probe order has changed. The monitor now determines the state of the StoreFront store by successively probing the account service, the discovery document, and then the authentication service, and skips authentication for anonymous stores.

The host name parameter for StoreFront monitors is deprecated. The secure parameter is now used to determine whether to use HTTP (the default) or HTTPS to send monitor probes.

To use HTTPS, set the secure option to Yes.

## Create a StoreFront monitor by using the CLI

At the command prompt, type the following commands to configure a StoreFront monitor and verify the configuration:

```
1 add lb monitor <monitorName> STOREFRONT <string> -storeName <string> [-
 storefrontacctservice (YES | NO)] -secure (YES | NO)
2
3 show lb monitor <monitorName>
4 <!--NeedCopy-->
```

### Example

```
1 add lb monitor storefront_ssl STOREFRONT -storename myStore -
 storefrontacctservice YES -secure YES
2 <!--NeedCopy-->
```

## Create a StoreFront monitor by using the GUI

Navigate to **Traffic Management > Load Balancing > Monitors**, and create a monitor of type **STOREFRONT**.

### Basic parameter settings:

- Interval: The time interval between two successive probes. The default time interval is 5 seconds.
- Response Time-out: The duration for which NetScaler waits before it marks a probe as FAILED. The default duration is 2 seconds.
- Store Name: The StoreFront store that must be monitored. By default, the user monitor uses the /Citrix/StoreWeb store for monitoring.
- StoreFront Account Service: Enable or disable probing for the StoreFront account service.
- Check Backend Services: This option enables the monitoring of services running on the StoreFront server.
- Secure: Enable this option if you are using HTTPS.

## ← Create Monitor

▶ **Advanced Parameters**

### Note

For more information about the StoreFront monitors, see [StoreFront documentation](#).

### Extended StoreFront monitor

NetScaler introduces an extended StoreFront monitor that can simulate the authentication and app enumeration on the Citrix StoreFront store on behalf of a test user account. You must pre-configure and enable the test user account on StoreFront for monitoring. Provide the test user credentials, store name, and the **nssf\_extend.pl** script to use the functionalities of this monitor.

If the StoreFront monitor is bound to a service group, it uses the user credentials to monitor all the members of the service group. Therefore, we recommend that you provide the test user credentials in the Active Directory of all the service group members. Ensure that the test user credentials do not expire if the monitor is active and that at least one app is authorized for the test user.

### Configure the extended StoreFront monitor by using the GUI

- Navigate to **Traffic Management > Load Balancing > Monitors** and click **Add**.
- Select the type as **USER**.
- In the **Basic Parameters** section, provide the following details:
  - **Secure Arguments:** Provide the username, password, and the store name in this field. The details must be in the format `user=<DomainName\username>;password=<password>;store=/Citrix/StoreWeb`. If the store name is not provided, the default store `/Citrix/StoreWeb` is used for monitoring.
  - **Script name:** Select the `nssf_extend.pl` script.
  - **Interval** and **Response Time-Out:** Set the time interval and response to greater values, preferably in minutes. This ensures the completion of the monitor probe as the StoreFront monitor makes multiple HTTP/HTTPS calls.

### Configure the extended StoreFront monitor by using the CLI

Use the following command to configure the extended StoreFront monitor on the CLI:

```
add lb monitor <monitorName> USER -scriptName nssf_extend.pl -secureArgs
"user=<DomainName\username>;password=<password>;store=/Citrix/StoreWeb
;" -interval 2 Min -resptimeout 1 Min
```

#### Note:

For authentication, use the Secure Arguments parameter instead of the Script Arguments parameter. The Secure Arguments parameter saves the user credentials in an encrypted format.

### Error messages

The following table describes the error messages that are displayed when the monitor probing fails. Refer to the **Description** column for details about the error.

Error	Description
Insufficient number of arguments	The admin must provide the user name and password in the Secure Arguments parameter.
Invalid argument format	The admin must provide the secure arguments in the correct format - “ <code>user=&lt;DomainName&gt;&lt;username&gt;;password=&lt;password&gt;;store=/Citrix/Storeweb or user=&lt;DomainName&gt;&lt;username&gt;;password=&lt;password&gt;</code> ”
ASP.NET_SessionId or CsrfToken are not generated	The <code>CSRF</code> token or <code>ASP.NET_SessionId</code> cookies were not found in the response from StoreFront.
Unable to get client configuration	The monitor is unable to fetch the client configuration settings from StoreFront.
CtxsDeviceId cookie is missing	The <code>CtxsDeviceId</code> cookie was not found in the response from StoreFront.
Unable to fetch API endpoint for authentication methods	The StoreFront monitor is unable to fetch the API endpoint to get the list of the configured authentication methods.
Login with username/password is not supported	The username and password method is disabled on StoreFront. It must be enabled on StoreFront.
Unable to fetch Authentication endpoint	The endpoint for authentication is not reachable from the monitor.
Incorrect username or password	The test user credentials configured for the StoreFront monitor are invalid.
Incorrect Domain name Configured	The domain name configured for the StoreFront monitor is incorrect.
Authentication unsuccessful	Authentication has failed on StoreFront.
Authorization cookie is not generated	The authorization cookie was not found in response from StoreFront.
Enumeration doesn't have all the required fields	No apps were enumerated or the app enumeration was incomplete.
App Enumeration Failure	The enumeration of apps from StoreFront has failed.
Logout Unsuccessful	The logoff of the session is unsuccessful. It might result in a build-up of unexpired sessions on StoreFront.

In the outputs of the `show service <name>` and `show servicegroup <name>` commands, you can view the status of the monitor probing on the `Last response` field.

**Example 1:**

```
1 show service svc
2 State: UP
3 Last state change was at Wed Aug 2 08:53:37 2023
4 Time since last state change: 0 days, 00:00:21.900
5
6 ...
7
8 Monitor Name: extended_monitor
9 State: DOWN Weight: 1 Passive: 0
10 Probes: 3 Failed [Total: 3 Current: 3]
11 Last response: Failure - Authorization cookie is not generated
12 Response Time: 5000.000 millisec
13 <!--NeedCopy-->
```

**Example 2:**

```
1 show servicegroup sg_ext_monitor
2 sg_ext_monitor - HTTP
3 State: ENABLED Effective State: PARTIAL-UP Monitor Threshold : 0
4 Max Conn: 0 Max Req: 0 Max Bandwidth: 0 kbits
5
6 ...
7
8 1) Monitor Name: extended_monitor State: ENABLED Weight: 1 Passive: 0
9 1) 10.106.44.33:80 State: UP Server Name: 10.106.44.33 Server ID:
 None Weight: 1 Order: Default
10
11 ...
12
13 Monitor Name: extended_monitor State: UP Passive: 0
14 Probes: 4 Failed [Total: 0 Current: 0]
15 Last response: Success - Probe succeeded.
16 Response Time: 1.039 millisec
17 2) 10.106.44.34:80 State: DOWN Server Name: 10.106.44.34 Server ID:
 None Weight: 1 Order: Default
18
19 ...
20
21 Monitor Name: extended_monitor State: DOWN Passive: 0
22 Probes: 4 Failed [Total: 4 Current: 4]
23 Last response: Failure - Authorization cookie is not generated
24 <!--NeedCopy-->
```

## Oracle ECV service monitoring

June 12, 2023

The Extended Content Verification (ECV) monitor on a NetScaler can be used to monitor Oracle databases. To track the state of each load balanced database server in real time, you need to bind a Oracle ECV monitor to each service. The monitor tests the service by sending periodic probes to the service in the form of an SQL Query, sometimes referred to as performing a health check. If the Oracle ECV monitor receives a timely response to its probes and the configured expression evaluates to true , it marks the service as UP. If it does not receive a timely response to the designated number of probes or the configured expression evaluates to false, it marks the service as DOWN.

The Netscaler Oracle ECV monitoring supports all Oracle versions up to 21c and all password based authentication protocols.

### Unsupported security features

The NetScaler Oracle ECV monitor supports only password-based authentication. It doesn't support all security related features and capabilities.

The following security features are not supported:

- Data encryption (SQLNET.ENCRYPTION\_SERVER=required)
- Data integrity (SQLNET.CRYPTO\_CHECKSUM\_SERVER=required)
- Long identifiers (O8L\_LI)
- TLS authentication/Encryption
- External authentication services, such as Kerberos and Radius
- Compression
- Oracle wallet

### Custom monitors

May 2, 2023

In addition to built-in monitors, you can use custom monitors to check the state of your services. The NetScaler appliance provides several types of custom monitors based on scripts that are included with the NetScaler operating system. The scripts can be used to determine the state of services based on the load on the service or network traffic sent to the service. Custom monitors are the inline monitors, user monitors, and load monitors.

With these types of monitors, you can use the supplied functionality, or you can create your own scripts and use those scripts to determine the state of the service to which the monitor is bound.

## Configure HTTP-inline monitors

May 2, 2023

Inline monitors analyze and probe the responses from the services to which they are bound only when those services receive client requests. The inline monitor is of type HTTP-INLINE and can only be configured with HTTP and HTTPS services. An inline monitor determines that the service to which it is bound is UP by checking its responses to the requests that are sent to it. When no client requests are sent to the service, the inline monitor probes the service by using the configured URL.

Note: Inline monitors cannot be bound to HTTP or HTTPS Global Server Load Balancing (GSLB) remote or local services because these services represent virtual servers rather than actual load balanced Web servers.

Inline monitors have a time-out value and a retry count when probes fail. You can select any of the following action types for the NetScaler appliance to take when a failure occurs:

- **NONE.** No explicit action is taken. You can view the service and monitor, and the monitor indicates the number of current contiguous error responses and cumulative responses checked.
- **LOG.** Logs the event in ns/syslog and displays the counters.
- **DOWN.** Marks the service down and does not direct any traffic to the service. This setting breaks any persistent connections to the service. This action also logs the event and displays counters.

After the service is down, the service remains DOWN for the configured downtime. After the downtime elapses, the inline monitor uses the configured URL to probe the service to see if it is available again. If the probe succeeds, the state of the service is changed to UP. Traffic is directed to the service, and monitoring resumes as before.

To configure inline monitors, see [Configuring Monitors in a Load Balancing Setup](#).

### To configure HTTP-inline monitors by using CLI

Type the following command:

```
1 add lb monitor <monitorName> <type> -respCode <int[-int]> -httpRequest
 <string> -resptimeout <integer> [<units>] -retries <integer> -
 downTime <integer> [<units>] -action <action>
2 <!--NeedCopy-->
```

#### Example:

```

1 add lb monitor http_inline HTTP-INLINE -respCode 200 304 -httpRequest "
 HEAD /var/static/empty.htm" -resptimeout 4 -retries 1 -downTime 2 -
 action NONE
2 <!--NeedCopy-->

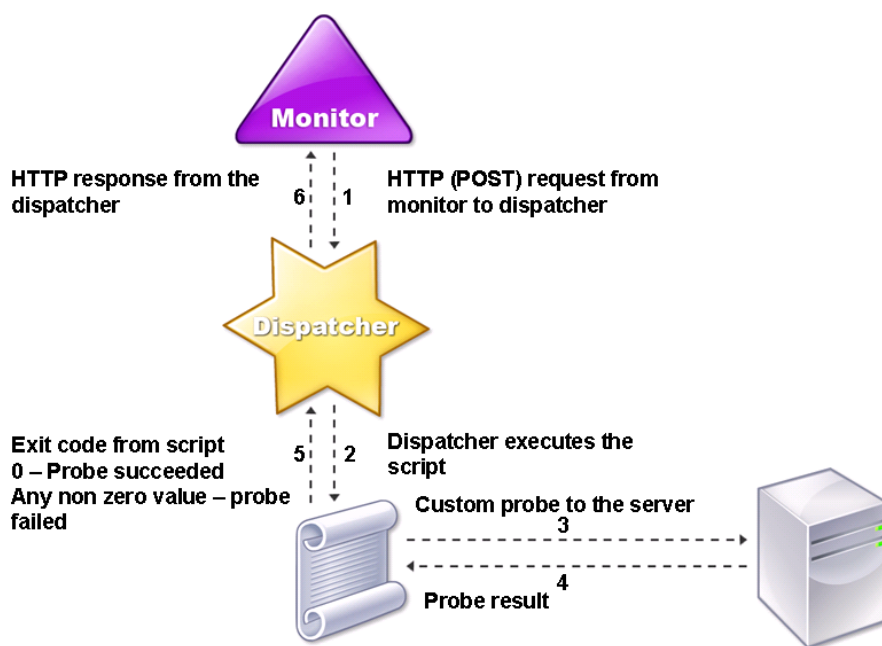

```

## Understand user monitors

August 11, 2023

User monitors extend the scope of custom monitors. You can create user monitors to track the health of customized applications and protocols that the NetScaler appliance does not support. The following diagram illustrates how a user monitor works.

Figure 1. User Monitors

A user monitor requires the following components.

**Dispatcher.** A process, on the appliance, that listens to monitoring requests. A dispatcher can be on the loopback IP address (127.0.0.1) and port 3013. Dispatchers are also known as internal dispatchers. A dispatcher can also be a web server that supports the Common Gateway Interface (CGI). Such

dispatchers are also known as external dispatchers. They are used for custom scripts that do not run on the FreeBSD environment, such as .NET scripts.

**Note:**

You can configure the monitor and the dispatcher to use HTTPS instead of HTTP by enabling the “secure” option on the monitor, and configure it as an external dispatcher. However, an internal dispatcher understands only HTTP, and cannot use HTTPS.

In a HA setup, the dispatcher runs on both the primary and secondary NetScaler appliances. The dispatcher remains inactive on the secondary appliance.

**Script.** The script is a program that sends custom probes to the load balanced server and returns the response code to the dispatcher. The script can return any value to the dispatcher, but if a probe succeeds, the script must return a value of zero (0). The dispatcher considers any other value as probe failure.

The NetScaler appliance is bundled with sample scripts for commonly used protocols. The scripts exist in the `/nsconfig/monitors` directory. If you want to add a script, add it there. To customize an existing script, create a copy with a new name and modify it.

**Important:**

- Starting with NetScaler release 13.0 build 41.20, you can use the `nsntlm-lwp.pl` script to create a monitor for monitoring a secure NTLM server.
- Starting with release 10.1 build 122.17, the script files for user monitors are in a new location.

If you upgrade an MPX or VPX virtual appliance to release 10.1 build 122.17 or later, the changes are as follows:

- A new directory named `conflicts` is created in `/nsconfig/monitors/` and all the built-in scripts of the previous builds are moved to this directory.
- All new built-in scripts are available in the `/netscaler/monitors/` directory. All custom scripts are available in the `/nsconfig/monitors/` directory.
- Save a new custom script in the `/nsconfig/monitors/` directory.
- After the upgrade is completed, if a custom script is created and saved in the `/nsconfig/monitors/` directory, with the same name as the built-in script, the script in the `/netscaler/monitors/` directory takes priority. The custom script does not run.

If you provision a virtual appliance with release 10.1 build 122.17 or later, the changes are as follows:

- All built-in scripts are available in the `/netscaler/monitors/` directory.
- The `/nsconfig/monitors/` directory is empty.
- If you create a custom script, you must save it in the `/nsconfig/monitors/` directory.

For the scripts to function correctly:

- The maximum number of characters in the name of the script must not exceed 63.
- The maximum number of script arguments that can be provided to a script must not exceed 512.
- The maximum number of characters that can be provided in the parameter script arguments must not exceed 639.

To debug the script, you must run it by using the `nsumon-debug.pl` script from the CLI. You use the script name (with its arguments), IP address, and the port as the arguments of the `nsumon-debug.pl` script. Users must use the script name, IP address, port, time-out, and the script arguments for the `nsumon-debug.pl` script.

At the CLI, type:

```
1 nsumon-debug.pl <scriptname> <IP> <port> <timeout> <partitionID> [
 scriptarguments] [is_secure]
2 <!--NeedCopy-->
```

**Important:** Starting with release 10.5 build 57.x, the 11.0 script files for user monitors support IPv6 addresses and include the following changes:

- For the following protocols, new `pm files` have been included for IPv6 support.
  - RADIUS
  - NNTP
  - POP3
  - SMTP
- The following sample scripts in `/netscaler/monitors/` has been updated for IPv6 support:
  - `nsbmradius.pl`
  - `nsldap.pl`
  - `nsnntp.pl`
  - `nspop3 nssf.pl`
  - `nssnmp.pl`
  - `nswi.pl`
  - `nstftp.pl`
  - `nssmtp.pl`
  - `nsrdp.pl`
  - `nsntlm-lwp.pl`
  - `nsftp.pl`

- nsappc.pl

After upgrading to release 10.5 build 57.x, or 11.0, if you want to use your existing custom scripts with IPv6 services, make sure that you update the existing custom scripts with the changes provided in the updated sample scripts in `/netscaler/monitors/`.

**Note:**

The sample script `nsmysql.pl` does not support the IPv6 address. If an IPv6 service is bound to a user monitor that uses `nsmysql.pl`, the probe fails.

- The following LB monitor types have been updated to support IPv6 addresses:

- USER
- SMTP
- NNTP
- LDAP
- SNMP
- POP3
- FTP\_EXTENDED
- StoreFront
- APPC
- CITRIX\_WI\_EXTENDED

If you are creating a custom script that uses one of these LB monitors types, ensure to include IPv6 support in the custom script. Refer to the associated sample script in `/netscaler/monitors/` for the changes that you have to make in the custom script for IPv6 support.

To track the status of the server, the monitor sends an HTTP POST request to the configured dispatcher. This POST request contains the IP address and port of the server, and the script that must be run. The dispatcher runs the script as a child process, with user-defined parameters (if any). Then, the script sends a probe to the server. The script sends the status of the probe (response code) to the dispatcher. The dispatcher converts the response code to an HTTP response and sends it to the monitor. Based on the HTTP response, the monitor marks the service as up or down.

The NetScaler appliance logs the error messages to the `/var/nslog/nsumond.log` file when user monitor probes fail. These detailed error messages are displayed in the GUI, and in the CLI for the `show service/service group` commands.

The following table lists the user monitors and the possible reasons for failure.

---

User monitor type	Probe failure reasons
SMTP	Monitor fails to establish a connection to the server.
NNTP	Monitor fails to establish a connection to the server. Missing or invalid script arguments, which can include an invalid number of arguments or argument format. Monitor fails to find the NNTP group.
LDAP	Monitor fails to establish a connection to the server. Missing or invalid script arguments, which can include an invalid number of arguments or argument format. Monitor fails to bind to the LDAP server. Monitor fails to locate an entry for the target entity in the LDAP server.
FTP	The connection to the server times out. Missing or invalid script arguments, which can include an invalid number of arguments or argument format. Logon fails. Monitor fails to find the file on the server.
POP3	Monitor fails to establish a connection to the database. Missing or invalid script arguments, which can include an invalid number of arguments or argument format. Logon fails. Preparation of the SQL query fails. Execution of the SQL query fails.
SNMP	Monitor fails to establish a connection to the database. Missing or invalid script arguments, which can include an invalid number of arguments or argument format.

User monitor type	Probe failure reasons
RDP (Windows Terminal Server)	<p>Logon fails.</p> <p>Monitor fails to create the SNMP session.</p> <p>Monitor fails to find the object identifier.</p> <p>The monitor threshold value setting is greater than or equal to the actual threshold of the monitor.</p> <p>Missing or invalid script arguments, which can include an invalid number of arguments or argument format.</p> <p>Monitor fails to create a socket.</p> <p>Mismatch in versions.</p> <p>Monitor fails to confirm connection.</p>

You can view the log file from the CLI by using the following commands:

```

1 > shell
2 root@ns# cat /var/nslog/nsumond.log
3 root@ns# exit
4 >
5 <!--NeedCopy-->

```

The command opens a BSD shell, displays the log file on the screen, closes the BSD shell, and returns you to the CLI.

Before NetScaler release 13.0 build 52.X, the `show service/service group` command displayed a generic error message saying “probe failed” as the cause for the user monitor probe failure.

**Example:**

```

1 show service ftp
2
3 Monitor Name: mon2
4 State: UNKNOWN Weight: 1 Passive: 0
5 Probes: 3 Failed [Total: 0 Current: 0]
6 Last response: Failure - Probe failed.
7 Response Time: 1071.838 millisec
8 <!--NeedCopy-->

```

From NetScaler release 13.0 build 52.X onwards, the `show service/service group` command displays the actual cause for the user monitor probe failure.

**Example:**

```
1 show service ftp
2
3 Monitor Name: mon2
4 State: DOWN Weight: 1 Passive: 0
5 Probes: 729 Failed [Total: 726 Current: 726]
6 Last response: Failure - Login failed.
7 Response Time: 8000.0 millisec
8 <!--NeedCopy-->
```

User monitors also have a time-out value and a retry count for probe failures. You can use user monitors with non-user monitors. During high CPU utilization, a non-user monitor enables faster detection of a server failure.

If the user monitor probe times out during high CPU usage, the state of the service remains unchanged.

**Example1:**

```
1 add lb monitor <name> USER - scriptname <script-name> -resptimeout 5
 seconds
2 <!--NeedCopy-->
```

**Note**

For scriptable monitors, the response timeout must be configured to a value equal to the expected timeout + 1 second. For example, if you expect the timeout to be 4 seconds, configure the response timeout as 5 seconds.

**Example2:**

```
1 add lb monitor <name> USER - scriptname <script-name> -scriptargs <
 Arguments> -secureargs <Arguments>
2 <!--NeedCopy-->
```

**Note:**

We recommend that you use the `secureargs` parameter instead of the `scriptargs` parameter for any sensitive data that is related to the scripts.

## How to use a user monitor to check websites

August 29, 2023

You can configure a user monitor to check for specific website problems that are reported by HTTP servers using specific HTTP codes. The following table lists the HTTP response codes that this user monitor expects.

---

HTTP response code	Meaning
200 - success	Probe success.
503 - service unavailable	Probe failure.
404 - not found	Script not found or cannot run.
500 - Internal server error	Internal error/resource constraints in dispatcher (out of memory, too many connections, unexpected system error, or too many processes). The service is not marked DOWN.
400 - bad request	Error parsing HTTP request.
502 - bad gateway	Error decoding script's response.

---

Configure the user monitor for HTTP by using the following parameters.

---

Parameter	Specifies
scriptName	The path and name of the script to run.
scriptArgs	The strings that are added in the POST data. A backslash (\) character in the scriptArgs parameter must be escaped with an additional backslash character for the parameter to work as intended. For example, use \\n instead of \n.
dispatcherIP	The IP address of the dispatcher to which the probe is sent.
dispatcherPort	The port of the dispatcher to which the probe is sent.
localfileName	The name of a monitor script file on the local system.
destPath	A particular location on the NetScaler appliance where the uploaded local file is stored.

---

To create a user monitor to monitor HTTP, see [Configuring Monitors in a Load Balancing Setup](#).

## Understand the internal dispatcher

May 2, 2023

You can use a custom user monitor with the internal dispatcher. Consider a case where you need to track the health of a server based on the presence of a file on the server. The following diagram illustrates this scenario.

Figure 1. Using a user monitor with the internal dispatcher

A possible solution is to use a Perl script that initiates an FTP session with the server and checks for the presence of the file. You can then create a user monitor that uses the Perl script. The NetScaler appliance includes such a Perl script (nsftp.pl), in the /nsconfig/monitors/ directory.

You can use a user monitor with an external dispatcher. Consider a case where you must track the health of a server based on the state of an SMTP service on another server. This scenario is illustrated in the following diagram.

Figure 2. Using a user monitor with an external dispatcher

A possible solution would be to create a Perl script that checks the state of the SMTP service on the server. You can then create a user monitor that uses the Perl script.

## Configure user monitor

May 2, 2023

User monitors track the health of custom applications and protocols that a NetScaler appliance does not support. This is an extended scope of custom monitors. To configure a user monitor, you must perform the following steps:

- Write a script that can monitor the services bound to it.
- Upload the script to the `/nsconfig/monitors` directory on the NetScaler appliance.
- Provide executable permission to the script.

If the monitor type is a protocol that the appliance does not support, only then you must use a monitor of type **USER**. User monitors support only Perl and Bash type scripts. They do not support Python scripts.

**Note**

Monitor probes originate from the NSIP address. The `scriptargs` configured for the monitor type **USER** is displayed in the running configuration and `ns.conf` files.

For more information about monitors, see [Configure monitors](#).

**To configure a user monitor by using the CLI**

At the command prompt, type:

```
1 add lb monitor <monitorName> USER -scriptname <NameOfScript> -
 scriptargs <Arguments> -secureargs <Arguments>
2 <!--NeedCopy-->
```

**Example1:**

```
1 add monitor Monitor-User-1 USER -scriptname nsftp.pl -scriptargs "file
 =/home/user/
2 sample.txt;user=root;password=passwd"
3 <!--NeedCopy-->
```

**Example2:**

```
1 add monitor Monitor-User-1 USER -scriptname nsftp.pl -scriptargs "file
 =/home/user/
2 sample.txt -secureargs "user=root;password=passwd"
3 <!--NeedCopy-->
```

**Note**

The `secureargs` parameter stores the script arguments in an encrypted format instead of the plain text format. Citrix recommends you use the `secureargs` parameter instead of the `scriptargs` parameter for any sensitive data that is related to the scripts, for example, user name and password. If you choose to use both the parameters together, the script specified in `-scriptname` must accept the arguments in the order: `<scriptargs> <secureargs>`. Specify the first few arguments in the `<scriptargs>` parameter; and the rest of the arguments in the `<secureargs>` parameter. That is, maintain the order defined for the arguments. Secure arguments are applicable only for the internal dispatcher. If you want to use an external dispatcher, Citrix recommends securing the vulnerable data in your scripts.

**Example 3:**

Let's say you have already configured the `scriptargs` parameter with the arguments: "a=b;c=d;e=f".

```
1 add monitor mon1 USER -scriptargs "a=b;c=d;e=f"
2 <!--NeedCopy-->
```

If you want to use the `secureargs` parameter instead of `scriptargs` parameter, do the following:

- Nullify the `scriptargs` parameter.
- Provide all the arguments under `secureargs` parameter.

```
1 set monitor mon1 USER -scriptargs "" -secureargs "a=b;c=d;e=f"
2 <!--NeedCopy-->
```

## To configure a user monitor by using the GUI

1. Navigate to **Traffic Management> Load Balancing> Monitors**, click **Add**.
2. In the **Create monitor** page, do the following:
  - Select the monitor type as **USER**.
  - Choose the script from the drop-down menu or upload your own script.
  - Enter appropriate values for the **Script Arguments** and **Secure Arguments** fields.
  - Click **Create**.

A user monitor is created.

## Understand load monitors

May 2, 2023

Load monitors use SNMP polled OIDs to calculate load. The load monitor uses the IP address of the service to which it is bound (the destination IP address) for polling. It sends an SNMP query to the service, specifying the OID for a metric. The metrics can be CPU, memory, or number of server connections. The server responds to the query with a metric value. The metric value in the response is compared with the threshold value. The NetScaler appliance considers the service for load balancing only if the metric is less than the threshold value. The service with the lowest load value is considered first.

The following diagram illustrates a load monitor configured for the services described in the basic load balancing setup discussed in [Setting Up Basic Load Balancing](#).

Figure 1. Operation of Load Monitors

Note: The load monitor does not determine the state of the service. It only enables the appliance to consider the service for load balancing.

After you configure the load monitor, you must then configure the metrics that the monitor will use. For load assessment, the load monitor considers server parameters known as metrics, which are defined within the metric tables in the appliance configuration. Metric tables can be of two types:

- **Local.** By default, this table exists in the appliance. It consists of four metrics: connections, packets, response time, and bandwidth. The appliance specifies these metrics for a service, and SNMP queries are not originated for these services. These metrics cannot be changed.
- **Custom.** A user-defined table. Each metric is associated with an OID.

By default, the appliance generates the following tables:

- NetScaler
- RADWARE
- CISCO-CSS
- LOCAL
- FOUNDRY
- ALTEON

You can either add the appliance-generated metric tables, or you can add tables of your own choosing, as shown in the following table. The values in the metric table are provided only as examples. In an actual scenario, consider the real values for the metrics.

Metric name	OIDs	Weight	Threshold
CPU	1.2.3.4	2	70
Memory	4.5.6.7	3	80
Connections	5.6.7.8	4	90

To calculate the load for one or more metrics, you assign a weight to each metric. The default weight is 1. The weight represents the priority given to each metric. If the weight is high, the priority is high. The appliance chooses a service based on the SOURCEIPDESTIP hash algorithm.

You can also set the threshold value for each metric. The threshold value enables the appliance to select a service for load balancing if the metric value for the service is less than the threshold value. The threshold value also determines the load on each service.

## Configure load monitors

February 27, 2023

To configure a load monitor, first create the load monitor. For instructions on creating a monitor, see [Creating Monitors](#). Next, select, or create the metric table to define a set of metrics that determine the state of the server, and (if you create a metric table) bind each metric to the metric table.

### To create a metric table by using the command line interface

At the command prompt, type the following commands:

```
1 add lb metricTable <metricTableName>
2
3 bind lb metricTable <metricTableName> <metric> <SNMPOID>
4 <!--NeedCopy-->
```

#### Example:

```
1 add lb metricTable Table-Custom-1
2
3 bind lb metricTable Table-Custom-1 1.3.6.1.4.1.5951.4.1.1.41.1.5 11
4 <!--NeedCopy-->
```

## To create a metric table and bind metrics to it by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Metric Tables** and create a metric table.
2. To bind metrics, click **Bind** and specify a metric and an SNMP OID.

## Unbind metrics from a metrics table

September 21, 2020

You can unbind metrics from a metrics table if the metrics need to be changed, or if you want to remove the metrics table entirely.

### To unbind metrics from a metric table by using the command line interface

At the command prompt, type:

```
1 unbind lb metricTable <metricTable> <metric>
2 <!--NeedCopy-->
```

#### Example:

```
1 unbind metricTable Table-Custom-1 1.3.6.1.4.1.5951.4.1.1.41.1.5
2 <!--NeedCopy-->
```

### To unbind metrics from a metric table by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Metric Tables**.
2. Open a metric table, select a metric, and click **Delete**.

You can view the detail of all configured metric tables, such as name and type, to determine whether the metric table is internal or created and configured.

## Configure reverse monitoring for a service

May 2, 2023

A reverse monitor marks a service as DOWN if the probe criteria are satisfied and UP if they are not satisfied. For example, if you want a backup service to receive traffic only when the primary service is

DOWN, you can bind a reverse monitor to the secondary service but configure it to probe the primary service.

The NetScaler appliance supports the following reverse monitors:

- HTTP
- ICMP
- TCP (from release 11.1 build 49.x)

## Configuring HTTP Reverse Monitoring for a Service

The following table describes the conditions of HTTP direct and reverse monitoring for a service:

Condition	Direct	Reverse
Connection not established.	Fail	Fail
HTTP response code matches the probe's specifications.	Success	Fail
HTTP response code does not match the probe's specifications.	Fail	Success
Probe timed out.	Fail	Fail

### To configure HTTP reverse monitoring for a service by using the CLI

At the command prompt, type:

```
1 add lb monitor <Monitor_Name> HTTP -respCode 200 -httpRequest "HEAD /"
 -destIP <Primary_Service_IP_Address> -destPort 80 -reverse YES
2
3 bind service <Secondary_Service_Name> -monitorname <Monitor_Name>
4 <!--NeedCopy-->
```

## Configuring ICMP Reverse Monitoring for a Service

The following table describes the conditions of ICMP direct and reverse monitoring for a service:

Condition	Direct	Reverse
ICMP echo reply is received.	Success	Fail

Condition	Direct	Reverse
Probe timed out.	Fail	Success

### To configure ICMP reverse monitoring for a service by using the CLI

At the command prompt, type:

```

1 add lb monitor <Monitor_Name> PING -destIP <Primary_Service_IP_Address>
 -reverse YES
2
3 bind service <Secondary_Service_Name> -monitorname <Monitor_Name>
4 <!--NeedCopy-->

```

### Configuring TCP Reverse Monitoring for a Service

If a direct TCP monitor receives a RESET in response to a monitor probe, the service is marked DOWN. However, if a reverse TCP monitor receives a RESET response, the probe is considered successful, and the service is marked UP.

The following table describes the conditions of TCP reverse monitoring for a service:

Condition	Direct	Reverse
TCP connection is established.	Success	Fail
Probe timed out.	Fail	Fail
Response to probe is RESET.	Fail	Success

### To configure TCP reverse monitoring for a service by using the CLI

At the command prompt, type:

```

1 add lb monitor <Monitor_Name> TCP -destip <Primary_Service_IP_Address>
 -destport <primary_service_port> -reverse YES
2
3 bind service <Secondary_Service_Name> -monitorname <Monitor_Name>
4 <!--NeedCopy-->

```

### To configure reverse monitoring by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors.**

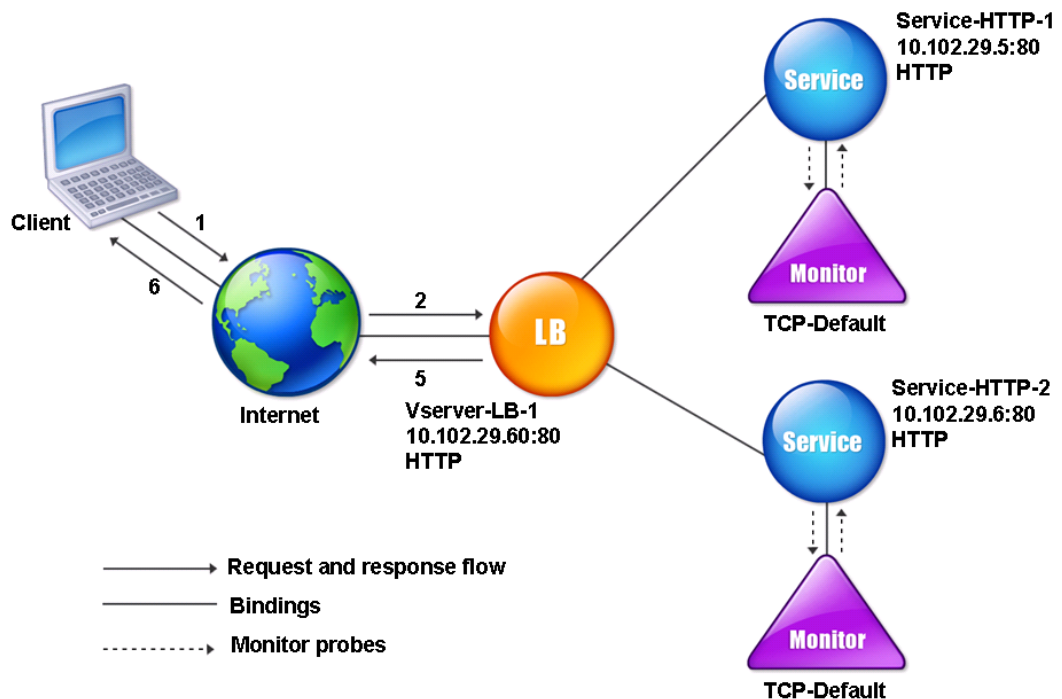

2. Create an HTTP, ICMP, or TCP monitor and select **Reverse**.

## Configure monitors in a load balancing setup

April 8, 2021

To configure monitors on a website, you first decide whether to use a built-in monitor or create your own monitor. If you create a monitor, you can choose between creating a monitor based on a built-in monitor, or creating a custom monitor that uses a script that you write to monitor the service. For more information about creating custom monitors, see [Custom Monitors](#). Once you have chosen or created a monitor, you then bind it to the appropriate service. The monitor names can be up to 255 characters in length. The following conceptual diagram illustrates a basic load balancing setup with monitors.

Figure 1. How monitors operate

As shown, each service has a monitor bound to it. The monitor probes the load balanced server via its service. As long as the load balanced server responds to the probes, the monitor marks it UP. If the

load balanced server fails to respond to the designated number of probes within the designated time period, the monitor marks it DOWN.

This section includes the following details:

- [Creating Monitors](#)
- [Configuring Monitoring Parameters to Determine the Service Health](#)
- [Binding Monitors to Services](#)
- [Modifying Monitors](#)
- [Enabling and Disabling Monitors](#)
- [Unbinding Monitors](#)
- [Removing Monitors](#)
- [Viewing Monitors](#)
- [Closing Monitor Connections](#)
- [Ignoring the Upper Limit on Client Connections for Monitor Probes](#)

## Create monitors

May 2, 2023

The NetScaler appliance provides a set of built-in monitors. It also allows you to create custom monitors, either based on the built-in monitors or from scratch.

### To create a monitor by using the CLI

At the command prompt, type:

```
1 add lb monitor <monitorName> <monitorType> [<interval>]
2
3 add lb mon monitor-HTTP-1 HTTP
4
5 add lb mon monitor-HTTP-2 TCP 2
6 <!--NeedCopy-->
```

### To create a monitor by using the GUI

1. Navigate to **Traffic Management> Load Balancing> Monitors**.
2. Click **Add** and create a monitor type that meets your requirement.

The Create Monitor screen contains two sections, **Basic Parameters** and **Advanced Parameters**.

Depending on the monitor type, the **Basic Parameters** section contains the parameters that must be set for each monitor. The **Advanced Parameters** section contains the parameters that can be used in advanced use cases.

The following figure is a sample of a Create Monitor page of the ARP monitor type.

← Create Monitor

Name\*  
 ⓘ

Type\*  
 > ⓘ

**Basic Parameters**

 Reverse  
 Transparent  
 LRTM (Least Response Time using Monitoring)  
 IP Tunnel

▲ Advanced Parameters

#### Note

Prior to NetScaler release 12.0 build 56.20, Basic Parameters and Advanced Parameters are named Standard Parameters and Special Parameters respectively.

## Configure monitor parameters to determine the service health

May 2, 2023

You can configure the following monitoring parameters to mark a service as DOWN based on the monitoring probes.

### Retries

Maximum number of probes to send to establish the state of a service for which a monitoring probe fails.

### failureRetries

Number of retries that must fail, out of the number specified for the Retries parameter, for a service to be marked as DOWN. For example, if the Retries parameter is set to 10 and the Failure Retries parameter is set to 6, out of the 10 probes sent, at least six probes must fail if the service is to be marked as DOWN.

### alertRetries

Number of consecutive probe failures after which the appliance generates an SNMP trap called monProbeFailed.

### Setting alertRetries to a value higher than the Retries value

The alertRetries parameter, which specifies the maximum number of consecutive monitoring-probe failures after which the NetScaler appliance generates an SNMP trap called monProbeFailed, can now be set to a value higher than the Retries value (which specifies the maximum number of probes to send to establish the state of a service for which a monitoring probe failed). If the alertRetries value is higher than the Retries value, the SNMP trap is not sent until after the service is DOWN.

For example, if you set Retries to 3, alertRetries to 12, and the time interval to 5 seconds, the service is marked DOWN after 15 seconds (35), *but no alert is generated*. If the monitor probes are still failing after 60 seconds (125), the NetScaler appliance generates a monProbeFailed trap. If a probe succeeds at some time between 15 and 60 seconds, the service is marked UP and no alert is generated.

Setting the alertRetries value to a value higher than the Retries value helps in generating only genuine alerts and avoid false positives during scheduled restarts.

**To set the alertRetries parameter value to a higher value than the Retries value by using the command line interface** At the command prompt, type:

```
1 add lb monitor <monitorName> [-retries <integer>] [-alertRetries <integer>]
2 <!--NeedCopy-->
```

**Example:**

**add lb monitor** monitor-HTTP-1 HTTP -retries 3 -alertRetries 12

**To set the alertRetries parameter value to a higher value than the Retries value by using the GUI**

1. Navigate to **Configuration > Traffic Management > Load Balancing > Monitors**.
2. Click **Add** to add a new monitor or select an existing monitor and click **Edit**.
3. In the **Retries** box, type the value for the Retries parameter.
4. In the **SNMP Alert Retries** box, type the value for the `alertRetries` parameter.

## Bind monitors to services

May 2, 2023

After creating a monitor, you bind it to a service. You can bind one or multiple monitors to a service. If you bind one monitor to a service, that monitor determines whether the service is marked UP or DOWN.

If you bind multiple monitors to a service, the NetScaler appliance checks the state of all the monitors and then decides the state of the service. You can configure different weights to a monitor. The weight of a monitor specifies how much that monitor contributes to designating the service as UP or DOWN. A monitor with a greater weight has a higher preference in marking the service UP or DOWN. Default weight is 1. Therefore, even if one of the monitors fails, the service is marked as DOWN. For more information, see [Set a threshold value for the monitors bound to a service](#).

**Note:** The destination IP address of a monitor probe can be different than the server IP address and port.

### To bind a monitor to a service by using the CLI

At the command prompt, type:

```
1 bind service <name> (-monitorName <string>)
2 <!--NeedCopy-->
```

#### Example:

```
1 bind service s1 -monitorName tcp
2 <!--NeedCopy-->
```

### To bind a monitor to a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Open the service, and add a monitor.

## Modify monitors

April 19, 2021

You can modify the settings for any monitor that you created.

Note: Two sets of parameters apply to monitors: those that apply to all monitors, regardless of type, and those that are specific to a monitor type. For information on parameters for a specific monitor type, see the description for that type of monitor.

### To modify an existing monitor by using the CLI

At the command prompt, type:

```
1 set lb monitor <monitorName> <type> -interval <interval> -resptimeout <
 resptimeout>
2 <!--NeedCopy-->
```

#### Example:

```
1 set mon monitor-HTTP-1 HTTP -interval 50 milli
2 -resptimeout 20 milli
3 <!--NeedCopy-->
```

## To modify an existing monitor by using the GUI

Navigate to **Traffic Management > Load Balancing > Monitors**, and open a monitor to modify.

## Enable and disable monitors

April 19, 2021

By default, monitors bound to services and service groups are enabled. When you enable a monitor, the monitor begins probing the services to which it is bound. If you disable a monitor bound to a service, the state the service is determined using the other monitors bound to the service. If the service is bound to only one monitor, and if you disable the monitor, the state of the service is determined using the default monitor.

### To enable a monitor by using the CLI

At the command prompt, type:

```
1 enable lb monitor <monitorName>
2 <!--NeedCopy-->
```

#### Example:

```
1 enable lb mon monitor-HTTP-1
2 <!--NeedCopy-->
```

### To enable a monitor by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. Select a monitor, and from the Action list, select Enable or Disable.

### To disable a monitor by using the CLI

At the command prompt, type:

```
1 disable lb monitor <monitorName>
2 <!--NeedCopy-->
```

#### Example:

```
1 disable lb mon monitor-HTTP-1
2 <!--NeedCopy-->
```

## Unbind monitors

April 19, 2021

You can unbind monitors from a service and service group. When you unbind a monitor from the service group, the monitors are unbound from the individual services that constitute the service group. When you unbind a monitor from a service or a service group, the monitor does not probe the service or the service group.

Note: When you unbind all user-configured monitors from a service or a service group, the default monitor is bound to the service and the service group. The default monitors then probes the service or the service groups.

### To unbind a monitor from a service by using the CLI

At the command prompt, type:

```
1 unbind lb monitor <monitorName>
2 <!--NeedCopy-->
```

#### Example:

```
1 unbind mon monitor-HTTP-1 Service-HTTP-1
2 <!--NeedCopy-->
```

### To unbind a monitor from a service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**, and open a service to modify.
2. Click in the Monitors section, select a monitor, and click **Unbind**.

## Remove monitors

May 2, 2023

After you unbind a monitor that you created from its service, you can remove that monitor from the NetScaler configuration. (If a monitor is bound to a service, it cannot be removed.)

Note: When you remove monitors bound to a service, the default monitor is bound to the service. You cannot remove default monitors.

## To remove a monitor by using the CLI

At the command prompt, type:

```
1 rm lb monitor <monitorName> <type>
2 <!--NeedCopy-->
```

### Example:

```
1 rm lb monitor monitor-HTTP-1 HTTP
2 <!--NeedCopy-->
```

## To remove a monitor by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. Select a monitor, and click **Delete**.

## View monitors

May 2, 2023

You can view the services and service groups that are bound to a monitor. You can verify the settings of a monitor to troubleshoot your NetScaler configuration. The following procedure describes the steps to view the bindings of a monitor to the services and service groups.

## To view monitor bindings by using the CLI

At the command prompt, type:

```
1 show lb monbindings <MonitorName>
2 <!--NeedCopy-->
```

### Example:

```
1 show lb monbindings monitor-HTTP-1
2 <!--NeedCopy-->
```

## To view monitor bindings by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. Select a monitor, and in the Action list, click **Show Bindings**.

## To view monitors by using the CLI

At the command prompt, type:

```
1 show lb monitor <monitorName>
2 <!--NeedCopy-->
```

### Example:

```
1 show lb mon monitor-HTTP-1
2 <!--NeedCopy-->
```

## To view monitors by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors**. The details of the available monitors appear in the Monitors pane.

## Close monitor connections

May 2, 2023

The NetScaler appliance sends probes to the services through the monitors bound to the services. By default, the monitor on the appliance and the physical server follow the complete handshake procedure even for monitor probes. However, this procedure adds overhead to the monitoring process and might not be always necessary.

For the TCP type monitor, you can configure the appliance to close a monitor-probe connection after receiving SYN-ACK from the service. To do so, set the value of the monitorConnectionClose parameter to RESET. If you want the monitor-probe connection to go through the complete procedure, set the value to FIN.

**Note:** The monitorConnectionClose setting is applicable only for type TCP and TCP-Default monitors.

### To configure monitor-connection closure by using the command line interface:

At the command prompt, type:

```
1 set lb parameter -monitorConnectionClose <monitor_conn_close_option>
2 <!--NeedCopy-->
```

### Example

```
1 set lb parameter -monitorConnectionClose RESET
2 <!--NeedCopy-->
```

**To configure monitor-connection closure by using the configuration utility:**

1. Navigate to **Traffic Management > Load Balancing > Configure Load Balancing Parameters**.
2. Select **FIN** or **Reset**.

**Closing Monitor Connections at the Service or Service Group Level**

You can also configure the appliance to close a monitor-probe connection at the service and service group level by setting the `monConnectionClose` parameter. If this parameter is not set, the monitor connection is closed by using the value set in the global load balancing parameters. If this parameter is set at the service or service group level, the monitor connection is closed by sending a connection termination message, with the FIN or RESET bit set, to the service or service group.

**To configure monitor-connection closure at the service level by using the CLI**

At the command prompt, type:

```
1 set service <service_name> -monConnectionClose (RESET | FIN)
2 <!--NeedCopy-->
```

**To configure monitor-connection closure at the service group level by using the CLI**

At the command prompt, type:

```
1 set serviceGroup <service_name> -monConnectionClose (RESET | FIN)
2 <!--NeedCopy-->
```

**To configure monitor-connection closure at the service level by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Add or edit a service, and in **Basic Settings**, set the **Monitoring Connection Close Bit**.

**To configure monitor-connection closure at the service group level by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. Add or edit a service group, and in **Basic Settings**, set the **Monitoring Connection Close Bit**.

**Note:** For closing a monitor-probe connection using global load balancing parameters, you can configure `monitorConnectionClose` to FIN or RESET. When you configure the `monitorConnectionClose` parameter to;

- FIN: The appliance performs a complete TCP handshake.
- RESET: The appliance closes the connection after receiving the SYN-ACK from the service.

In the lighter version of NetScaler CPX, the `monitorConnectionClose` parameter value is set to RESET by default and cannot be changed to FIN at the global level. However, you can change the `monitorConnectionClose` parameter to FIN at the service level.

## Ignore the upper limit on client connections for monitor probes

May 2, 2023

Depending on considerations such as the capacity of a physical server, you can specify a limit on the maximum number of client connections made to any service. If you have set such a limit on a service, the NetScaler appliance stops sending requests to the service when the threshold is reached and resumes sending connections to the service after the number of existing connections falls to within the limits. You can configure the appliance to skip this check when it sends monitor-probe connections to a service.

Note: You cannot skip the maximum-client-connections check for an individual service. If you specify this option, it applies to all the monitors bound to all the services configured on the NetScaler appliance.

### To set the Skip MaxClients for Monitor Connections option by using the CLI

At the command prompt, type:

```
1 set lb parameter -monitorSkipMaxClient (ENABLED|DISABLED)
2 <!--NeedCopy-->
```

#### Example:

```
1 set lb parameter -monitorSkipMaxClient enabled
2 <!--NeedCopy-->
```

### To set the Skip MaxClients for Monitor Connections option by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Configure Load Balancing Parameters**.
2. Select **Skip MaxClients for Monitoring Connections**.

## Manage a large scale deployment

May 2, 2023

The NetScaler appliance contains several features that are helpful when you are configuring a large load balancing deployment. Instead of configuring virtual servers and services individually, you can create groups of virtual servers and services. You can also create a range of virtual servers and services, and you can translate or mask virtual server and service IP addresses.

You can set persistence for a group of virtual servers. You can bind monitors to a group of services. Creating a range of virtual servers and services of identical type allows you to set up and configure those servers in a single procedure. This significantly shortens the time required to configure those virtual servers and services.

By translating or masking IP addresses, you can take down virtual servers and services. You can then make changes to your infrastructure, without extensive reconfiguration of your service and virtual server definitions.

## Ranges of virtual servers and services

April 19, 2021

When you configure load balancing, you can create ranges of virtual servers and services, eliminating the need to configure virtual servers and services individually. For example, you can use a single procedure to create three virtual servers with three corresponding IP addresses. When more than one argument uses a range, the ranges must be of the same size.

The following are the types of ranges you can specify when adding services and virtual servers to your configuration:

- **Numeric ranges.** Instead of typing a single number, you can specify a range of consecutive numbers.

For example, you can create a range of virtual servers by specifying a starting IP address, such as 10.102.29.30, and then typing a value for the last byte that indicates the range, such as 34. In this example, five virtual servers are created with IP addresses that range between 10.102.29.30 and 10.102.29.34.

Note: The IP addresses of the virtual servers and services must be consecutive.

- **Alphabetic ranges.** Instead of typing a literal letter, you can substitute a range for any single letter, for example, [C-G]. This results in all letters in the range being included, in this case C, D, E, F, and G.

For example, if you have three virtual servers named `Vserver-x`, `Vserver-y`, and `Vserver-z`, instead of configuring them separately, you can type `vserver [x-z]` to configure them all.

## Creating a range of virtual servers

### To create range of virtual servers by using the CLI

At the command prompt, type one of the following commands:

```
1 add lb vserver <name>@ <protocol> -range <rangeValue> <IPAddress> [<
 port>]
2
3 add lb vserver <name>@[<rangeValue>] <protocol> <IPAddress[<rangeValue
 >]> [<port>]
4 <!--NeedCopy-->
```

#### Example:

```
1 add lb vserver Vserver-LB-2 http -range 6 10.102.29.30 80
2 <!--NeedCopy-->
```

OR

```
1 add lb vserver vserver[P-R] http 10.102.29.[26-28] 80
2
3 vserver "vserverP" added
4
5 vserver "vserverQ" added
6
7 vserver "vserverR" added
8
9 Done
10 <!--NeedCopy-->
```

### To create range of virtual servers by using the CLI

At the command prompt, type one of the following commands:

```
1 add lb vserver <name>@ <protocol> -range <rangeValue> <IPAddress> [<
 port>]
2
3 add lb vserver <name>@**[**<rangeValue>**]** <protocol> <IPAddress[<
 rangeValue>]> [<port>]
4 <!--NeedCopy-->
```

#### Example:

```
1 add lb vserver Vserver-LB-2 http -range 6 10.102.29.30 80
2 <!--NeedCopy-->
```

OR

```
1 add lb vserver vserver[P-R] http 10.102.29.[26-28] 80
2 vserver "vserverP" added
3 vserver "vserverQ" added
4 vserver "vserverR" added
5 Done
6 <!--NeedCopy-->
```

### To create range of virtual servers by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Add a virtual server, and specify a range.

### Creating a range of services

If you specify a range for the service name, specify a range for the IP address too.

### To create range of services by using the CLI

At the command prompt, type the command:

```
1 add service <name>@ <IP>@ <protocol> <port>
2 <!--NeedCopy-->
```

#### Example:

```
1 > add service serv[1-3] 10.102.29.[102-104] http 80
2 service "serv1" added
3 service "serv2" added
4 service "serv3" added
5 Done
6 <!--NeedCopy-->
```

### Configure service groups

May 2, 2023

Configuring a service group enables you to manage a group of services as easily as a single service. For example, if you enable or disable any option, such as compression, health monitoring, or graceful shutdown, for a service group, the option gets enabled for all the members of the service group.

After creating a service group, you can bind it to a virtual server, and you can add services to the group. You can also bind monitors to service groups.

**Note**

You cannot bind a service and service group having the same IP address and port to the same virtual server.

The members of a service group are identified by IP address or server name.

Using domain-name based service (DBS) group members is advantageous because you need not re-configure the member on the NetScaler appliance if the IP address of the member changes. The appliance automatically senses such changes through the configured name server. This feature is useful in cloud scenarios, where the service provider can change a physical server or change the IP address for a service. If you specify a DBS group member, the appliance learns the IP address dynamically.

You can bind both IP-based and DBS members to the same service group.

Note: If you use DBS service group members, make sure that either a name server is specified or a DNS server is configured on the NetScaler appliance. A domain name is resolved into an IP address only if the corresponding address record is present on the appliance or the name server.

## Create service groups

You can configure up to 8192 service groups on the NetScaler appliance.

### To create a service group by using the command line

At the command prompt, type:

```
1 add servicegroup <ServiceGroupName> <Protocol>
2 <!--NeedCopy-->
```

#### Example:

```
1 add servicegroup Service-Group-1 HTTP
2 <!--NeedCopy-->
```

### To create a service group by using the configuration utility

Navigate to **Traffic Management > Load Balancing > Service Groups**, and add a service group.

## Bind a service group to a virtual server

When you bind a service group to a virtual server, the member services are bound to the virtual server.

### To bind a service group to a virtual server by using the command line interface

At the command prompt, type:

```
1 bind lb vserver <name>@ <serviceName>
2 <!--NeedCopy-->
```

#### Example:

```
1 bind lb vserver Vserver-LB-1 Service-Group-1
2 <!--NeedCopy-->
```

### To bind a service group to a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In Advanced Settings, select **Service Groups**.

## Bind a member to a service group

Adding services to a service group enables the service group to manage the servers. You can add the servers to a service group by specifying the IP addresses or the names of the servers.

In the GUI, if you want to add a domain-name based service group member, select **Server Based**.

With this option, you can add any server that has been assigned a name, regardless of whether the name is an IP address or a user-assigned name.

### To add members to a service group by using the command line interface

To configure a service group, at the command prompt, type:

```
1 bind servicegroup <serviceName> (<IP>@ | <serverName>) <port>
2 <!--NeedCopy-->
```

#### Examples:

```
1 bind servicegroup Service-Group-1 10.102.29.30 80
2
```

```
3 bind servicegroup Service-Group-2 1000:0000:0000:0000:0005:0600:700a
 :888b 80
4
5 bind servicegroup CitrixEdu s1.citrite.net
6 <!--NeedCopy-->
```

### To add members to a service group by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Service Groups** and open a service group.
2. Click in the Service Group section, and do one of the following:
  - To add an IP based service group member, select IP Based.
  - To add a server-name based service group member, select Server Based.

If you want to add a domain-name based service group member, select **Server Based**. With this option, you can add any server that has been assigned a name, regardless of whether the name is an IP address or a user-assigned name.

3. If adding a new IP based member, in the IP Address text box, type the IP address. If the IP address uses IPv6 format, select the IPv6 check box and then enter the address in the IP Address text box

Note: You can add a range of IP addresses. The IP addresses in the range must be consecutive. Specify the range by entering the starting IP address in the IP Address text box (for example, 10.102.29.30). Specify the end byte of the IP address range in the text box under Range (for example, 35). In the Port text box type the port (for example, 80), and then click Add.

4. Click Create.

### Bind a monitor to a service group

When you create a service group, the default monitor of the type appropriate for the group is automatically bound to it. Monitors periodically probe the servers in the service group to which they are bound and update the state of the service groups.

You can bind a different monitor of your own choice to the service group.

### To bind a monitor to a service group by using the command line interface

At the command prompt, type:

```
1 bind serviceGroup <serviceGroupName> -monitorName <string> -monState (
 ENABLED | DISABLED)
2 <!--NeedCopy-->
```

**Example:**

```
1 bind serviceGroup Service-Group-1 -monitorName monitor-HTTP-1
2 <!--NeedCopy-->
```

**To a bind monitor to a service group by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. Open a service group and, in Advanced Settings, click **Monitors**.

**Retain the original state of a service group member after disabling and enabling a virtual server**

From build 64.x, a new global option, `-retainDisableServer`, enables you to retain a service-group member's state when a server is disabled and reenabled.

Previously, a member's state would change from DISABLED to ENABLED under the following set of conditions:

- Two applications are deployed on the same port on a virtual server.
- Two service groups with a common member are bound to this virtual server, and the common member is enabled in one group and disabled in the other.
- The server is disabled and then reenabled.

Under these conditions, disabling the server disables all the service group members, and reenabling the server enables all the members, by default, regardless of their earlier states. To bring the members back to the original states, you must manually disable those members in the service group. This is a cumbersome task and prone to errors.

**Manage service groups**

May 2, 2023

You can change the settings of the services in a service group, and you can perform tasks such as enabling, disabling, and removing service groups. You can also unbind members from a service group. For more information about service groups, see [Configure service groups](#).

## Modify a service group

You can modify the attributes of service group members. You can set several attributes of the service group, such as maximum client, and compression. The attributes are set on the individual servers in the service group. You cannot set parameters on the service group such as transport information (IP address and port), weight, and server ID.

Note: A parameter you set for a service group is applied to the member servers in the group, not to individual services.

### To modify a service group by using the command line interface

At the command prompt, type the following command with one or more of the optional parameters:

```
1 set servicegroup <serviceName> [-type <type>] [-maxClient <maxClient>] [-maxReq <maxReq>] [-cacheable (YES|NO)] [-cip (ENABLED|DISABLED)] [-cipHeader <cipHeader>] [-usip (YES|NO)] [-sc (ON|OFF)] [-sp (ON|OFF)] [-cltTimeout <cltTimeout>] [-svrTimeout <svrTimeout>] [-cka (YES|NO)] [-TCPB (YES|NO)] [-CMP (**YES**|**NO**)] [-maxBandwidth <maxBandwidth>] [-maxThreshold <maxThreshold>] [-state (ENABLED|DISABLED)] [-downStateFlush (ENABLED|DISABLED)]
2 <!--NeedCopy-->
```

### Example:

```
1 set servicegroup Service-Group-1 -type TRANSPARENT
2
3 set servicegroup Service-Group-1 -maxClient 4096
4
5 set servicegroup Service-Group-1 -maxReq 16384
6
7 set servicegroup Service-Group-1 -cacheable YES
8 <!--NeedCopy-->
```

### To modify a service group by using the configuration utility

Navigate to **Traffic Management > Load Balancing > Service Groups**, and open the service group to modify.

## Remove a service group

When you remove a service group, the servers bound to the group retain their individual settings and continue to exist on the NetScaler appliance.

### To remove a service group by using the command line interface

At the command prompt, type:

```
1 rm servicegroup <ServiceGroupName>
2 <!--NeedCopy-->
```

#### Example:

```
1 rm servicegroup Service-Group-1
2 <!--NeedCopy-->
```

### To remove a service group by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. Select a service group, and click **Delete**.

### Unbind a member from a service group

When you unbind a member from the service group, the attributes set on the service group no longer apply to the member that you unbound. The member services retain its individual settings, however, and continue to exist on the NetScaler appliance.

### To unbind members from a service group by using the command line interface

At the command prompt, type:

```
1 unbind servicegroup <serviceGroupName> <IP>@ [<port>]
2 <!--NeedCopy-->
```

#### Example:

```
1 unbind servicegroup Service-Group-1 10.102.29.30 80
2 <!--NeedCopy-->
```

### To unbind members from a service group by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. Open a service group, and click in the Service Group Members section.
3. Select a service group member, and click **Unbind**.

## Unbind a service group from a virtual server

When you unbind a service group from a virtual server, the member services are unbound from the virtual server and continue to exist on the NetScaler appliance.

### To unbind a service group from a virtual server by using the command line interface

At the command prompt, type:

```
1 unbind lb vserver <name>@ <ServiceGroupName>
2 <!--NeedCopy-->
```

#### Example:

```
1 unbind lb vserver Vserver-LB-1 Service-Group-1
2 <!--NeedCopy-->
```

### To unbind a service group from a virtual server by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open the virtual server, and click in the Service Group section.
3. Select the service group, and click **Unbind**.

## Unbind monitors from service groups

When you unbind a monitor from a service group, the monitor that you unbound no longer monitors the individual services that constitute the group.

### To unbind a monitor from a service group using the command line interface

At the command prompt, type:

```
1 unbind serviceGroup <serviceGroupName> -monitorName <string>
2 <!--NeedCopy-->
```

#### Example:

```
1 unbind serviceGroup Service-Group-1 -monitorName monitor-HTTP-1
2 <!--NeedCopy-->
```

**To unbind a monitor from a service group by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. Open a service group, and click in the Monitors section.
3. Select a monitor, and click **Unbind**.

**Enable or Disable a service group**

When you enable a service group and the servers, the services belonging to the service group are enabled. Similarly, when a service belonging to a service group is enabled, the service group and the service are enabled. By default, service groups are enabled.

After disabling an enabled service, you can view the service using the configuration utility or the command line to see the amount of time that remains before the service goes DOWN.

**To disable a service group by using the command line interface**

At the command prompt, type:

```
1 disable servicegroup <ServiceGroupName>
2 <!--NeedCopy-->
```

**Example:**

```
1 disable servicegroup Service-Group-1
2 <!--NeedCopy-->
```

**To disable a service group by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. Select a service group, and in the Action list, click **Disable**.

**To enable a service group by using the command line interface**

At the command prompt, type:

```
1 enable servicegroup <ServiceGroupName>
2 <!--NeedCopy-->
```

**Example:**

```
1 enable servicegroup Service-Group-1
2 <!--NeedCopy-->
```

## To enable a service group by using the configuration utility

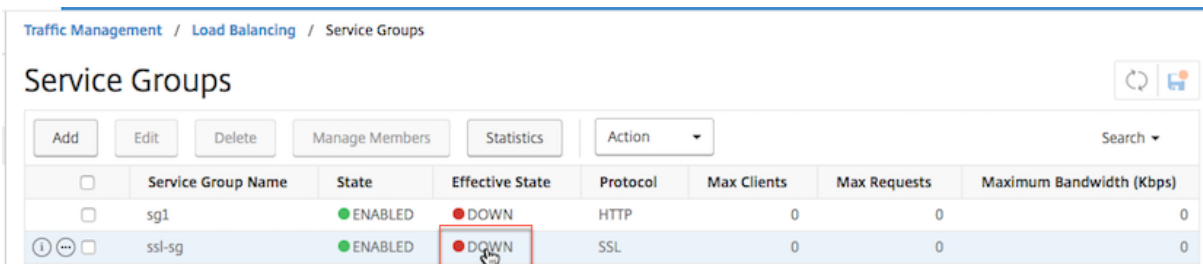

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. Select a service group, and in the Action list, click **Enable**.

## View the status of service groups members

Navigate to **Traffic Management > Load Balancing > Service Groups**.

In the Service Groups page, the **Effective State** column displays the status of the service groups. Status UP/DOWN in the **Effective State** column is clickable. You can click the status and get the list of members along with their status in the same view. Select a member and click the **Monitor Details** button to view the reason for the status being DOWN.

**Note:** Before NetScaler release 12.0 build 56.20, the status in the **Effective State** column was not clickable.

	Service Group Name	State	Effective State	Protocol	Max Clients	Max Requests	Maximum Bandwidth (Kbps)
<input type="checkbox"/>	sg1	ENABLED	DOWN	HTTP	0	0	0
<input checked="" type="checkbox"/>	ssl-sg	ENABLED	DOWN	SSL	0	0	0

## Viewing the properties of a service group

You can view the following settings of the configured service groups:

- Name
- IP address
- State
- Protocol
- Maximum client connections
- Maximum requests per connection
- Maximum bandwidth
- Monitor threshold

Viewing the details of the configuration can be helpful for troubleshooting your configuration.

**To view the properties of a service group by using the command line interface**

At the command prompt, type one of the following commands to display the group properties or the properties and the group members:

```
1 show servicegroup <ServiceGroupName>
2
3 show servicegroup <ServiceGroupName> -includemembers
4 <!--NeedCopy-->
```

**Example:**

```
1 show servicegroup Service-Group-1
2 <!--NeedCopy-->
```

**To view the properties of a service group by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. Click the arrow next to the service group.

**Viewing service group statistics**

You can view service-group statistical data, such as rate of requests, responses, request bytes, and response bytes. The NetScaler appliance uses the statistics of a service group to balance the load on the services.

**To view the statistics of a service group by using the command line interface**

At the command prompt, type:

```
1 stat servicegroup <ServiceGroupName>
2 <!--NeedCopy-->
```

**Example:**

```
1 stat servicegroup Service-Group-1
2 <!--NeedCopy-->
```

**To view the statistics of a service group by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. Select a service group, and click **Statistics**.

## Load balancing virtual servers bound to a service group

In large-scale deployments, the same service group can be bound to multiple load balancing virtual servers. In such a case, instead of viewing each virtual server to see the service group it is bound to, you can view a list of all the load balancing virtual servers bound to a service group. You can view the following details of each virtual server:

- Name
- State
- IP address
- Port

### To display the virtual servers bound to a service group by using the command line interface

At the command prompt, type the following command to display the virtual servers bound to a service group:

```
1 show servicegroupbindings <serviceName>
2 <!--NeedCopy-->
```

#### Example:

```
1 > show servicegroupbindings SVCGRPDTLS
2 SVCGRPDTLS - State :ENABLED
3 1) Test-pers (10.10.10.3:80) - State : DOWN
4 2) BRVSERV (10.10.1.1:80) - State : DOWN
5 3) OneMore (10.102.29.136:80) - State : DOWN
6 4) LBVIP1 (10.102.29.66:80) - State : UP
7 Done
8 >
9 <!--NeedCopy-->
```

### To display the virtual servers bound to a service group by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. Select a service group, and in the Action list, click **Show Bindings**.

## Configure a desired set of service group members for a service group in one NITRO API call

October 8, 2023

Support is added to configure a desired set of service group members for a service group in one NITRO API call. A new API, Desired State API, is added to support this configuration. Using Desired State API, you can:

- Provide a list of service group members in a single PUT request on “servicegroup\_servicegroupmemberlist\_b resource.
- Provide their weight and state (optional) in that PUT request.
- Effectively synchronize the appliance configuration with deployment changes around application servers.

The NetScaler appliance compares the requested desired member set with the configured member set. Then, it automatically binds the new members and unbinds the members that are not present in the request.

**Note:**

- This feature is supported only for service groups of type [API](#) .
- You can only bind IP address based services using Desired State API, domain name based services are not allowed.
- Previously, only one service group member can be bound in a NITRO call.

**Important**

Desired State API for ServiceGroup membership is supported in NetScaler cluster deployment.

**Use case: Synchronize deployment changes to NetScaler appliance in large scale deployments, such as Kubernetes**

In large scale and highly dynamic deployments (for example Kubernetes), the challenge is to keep the appliance configuration up-to-date with the rate of change of deployments to accurately serve the application traffic. In such deployments, controllers (Ingress or E-W Controller) are responsible for updating ADC configuration. Whenever there are changes to deployment, `kube-api server` sends the effective set of endpoints through ‘Endpoints event’ to the controller. The controller uses the Read-Delta-Modify approach where it performs the following:

- Fetches the currently configured endpoint set (service group member set of a service group) for the service from ADC appliance.
- Compares the configured endpoint set with the set in the received event.
- Binds the new endpoints (service group members) or unbinds the deleted endpoints.

Because the rate of change and the size of services is high in this environment, this configuration method is not efficient and might delay configuration updates.

Desired State API solves the problem by accepting the intended member set for a service group in a single API, and effectively updates the configuration.

## Create a service group of type API by using the CLI

At the command prompt, type;

```
1 add serviceGroup <serviceName>@ <serviceType> [-autoScale <
 autoScale>]
```

### Example:

```
1 add serviceGroup svg1 HTTP -autoScale API
```

You can configure the `autoDisablegraceful` and `autoDisabledelay` and `autoScale` parameters by using `add serviceGroup` or `set serviceGroup` command.

```
1 add serviceGroup <serviceName>@ <serviceType> \[-autoScale <
 autoScale>] \[-autoDisablegraceful \{ YES | NO\}] \[-autoDisabledelay
 <secs>]
2
3 add serviceGroup <serviceName>@ <serviceType> \[-autoScale \{API |
 CLOUD | DISABLED| DNS | POLICY\})]
4
5 set serviceGroup <serviceName> \[-autoDisablegraceful \{ YES | NO\}]
 \[-autoDisabledelay <secs>]
6
7 set serviceGroup <serviceName> \[-autoScale \{API |CLOUD | DISABLED
 | DNS | POLICY\})]
```

### Example:

```
1 add serviceGroup svg1 HTTP autoDisablegraceful YES -autoDisabledelay
 100
2
3 add serviceGroup svg1 HTTP -autoScale API
4
5 set serviceGroup svg1 -autoDisablegraceful YES -autoDisabledelay 100
6
7 set serviceGroup svg1 -autoScale API
```

## Arguments

**autoDisablegraceful** Indicates graceful shutdown of the service. If this option is enabled, the appliance waits for all outstanding connections to this service to be closed before deleting the service. For clients that already have a persistent session on the system, new connections or requests continue to be sent to this service. The service member is deleted only if there are no outstanding connections. Default value: NO

**autoDisabledelay** Indicates the time allowed (in seconds) for a graceful shutdown. During this period new connections or requests continue to be sent to this service for clients that already have a

persistent session on the system. Connections or requests from new clients that do not have persistence sessions on the system are not sent to the service. Instead, they are load balanced among other available services. After the delay time expires, the service member is deleted.

**Autoscale API** The Autoscale API argument enables using the Desired State API for binding the member set to an intended service group. You can set the service group from non-autoscale to Autoscale type of Desired State API, if all provided conditions match.

The desired state API checks if the IP address of the service group member is associated with any existing server. If the IP address matches with an existing server, the API reuses the existing server's IP address and name. If the IP address does not match with any existing server, the API creates a server and assigns the IP address itself as the server name.

Example:

Consider a server with IP address 2.2.2.2 and name as myserver that exists in a NetScaler appliance. Using the desired state API, you bind a set of service group members whose IP address ranges from 2.2.2.1 to 2.2.2.3.

As the IP address 2.2.2.2 is associated with an existing server, the API reuses the IP address and name (2.2.2.2 and myserver). As there are no existing servers with IP addresses, 2.2.2.1, 2.2.2.3, the API creates servers with these IP addresses. The API assigns the IP address itself as the server's name.

If the IP address provided in the desired state command conflicts with other NetScaler entities such as CS virtual server, then a conflict occurs. An error message gets displayed that contains the reason for failure. The IP address of the first service group member among the list of failed members is displayed in the error message.

Example:

Consider a server with IP address 2.2.2.8 which is used as an LB server. Using the desired state API, you try to bind a set of service group members whose IP address ranges from 2.2.2.2 - 2.2.2.11.

As 2.2.2.8 is already in use for LB service, a conflict occurs. The following error message is displayed that contains the reason for failure and the failed member bindings:

```
1 {
2 "errorcode": 304, "message": "Address already in use", "severity": "
3 ERROR", "servicegroup_servicegroupmemberlist_binding": {
4 "servicegroupname": "sg1", "failedmembers": [{
5 "ip": "2.2.2.8", "port": 80 }
6 , {
7 "ip": "2.2.2.9", "port": 80 }
8] }
9 }
10 <!--NeedCopy-->
```

The error code 304 displays the first service group member among the list of failed members, which is 2.2.2.8.

The `set serviceGroup Autoscale` command might fail if the existing member bindings meet any of these conditions:

- If the server bound to the service group is either a name server or a domain-based server.
- If the loopback server name is anything other than 127.0.0.1 or 0000:0000:0000:0000:0000:0000:0000:0001.
- If you choose different types of Autoscale (Cloud, API, DNS, and Policy) in a `set serviceGroup` command and `add serviceGroup` command.

**Important:**

- The `autoDisablegraceful` and `autoDisabledelay` parameters are applicable only for the service groups of Autoscale type “API” and “CLOUD.”
- If the `autoDisablegraceful` or the `autoDisabledelay` parameters are not configured, then service members are deleted immediately.

### **Unbind a service group member gracefully**

If any of the service group members is not in the desired state list, those members are gracefully unbound based on the `autoDisablegraceful` or `autoDisabledelay` parameter configuration.

- If one of these parameters is set, then the service group member is unbound gracefully.
- If none of these parameters are set, then the service group member is unbound immediately.

**Note:**

- Service group members identified for graceful unbind are displayed only when the `show service group` command is run.
- You cannot perform any operation (such as `set`, `unset`) on the service group member identified for graceful unbind.

The following figure displays a sample `show service group` command.

```
sh servicegroup sg1
 sg1 - HTTP
 State: ENABLED Effective State: OUT OF SERVICE Monitor Threshold : 0
 Max Conn: 0 Max Req: 0 Max Bandwidth: 0 kbits
 Use Source IP: NO
 Client Keepalive(CKA): NO
 TCP Buffering(TCPB): NO
 HTTP Compression(CMP): NO
 Idle timeout: Client: 180 sec Server: 360 sec
 Client IP: DISABLED
 Cacheable: NO
 SC: OFF
 SP: OFF
 Down state flush: ENABLED
 Monitor Connection Close : NONE
 AppFlow logging: ENABLED
 Autoscale mode: API
 ContentInspection profile name: ???
 Process Local: DISABLED
 Traffic Domain: 0
 Unbind Graceful: NO
 Unbind Delay: 1000
```

## Create a service group of type API by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Service Groups**, and click **Add**.
2. In **AutoScale Mode**, select **API**.

## Configure graceful shutdown or a time delay for an API type service group by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. In **AutoScale Mode**, select **API**.
3. In **Auto Disable Graceful**, select **YES**.
4. In **Auto Disable Delay**, enter the wait time for a graceful shutdown.

**Note:** The **Auto Disable Graceful** or **Auto Display Delay** fields are enabled only if you select **API** or **CLOUD** in **AutoScale Mode**.

## Configure automatic domain based service group scaling

May 2, 2023

A domain based service group consists of members whose IP addresses are obtained by resolving the domain names of servers that are bound to the service group. The domain names are resolved by a name server whose details you configure on the appliance. A domain based service group can also include IP-address based members.

The process of name resolution for a domain based server might return more than one IP address. The number of IP addresses in the DNS response is determined by the number of address (A) records configured for the domain name, on the name server. Even if the name resolution process returns multiple IP addresses, only one IP address is bound to the service group. To scale up or scale down a service group, you need to manually bind and unbind other domain based servers to and from the service group, respectively.

However, you can configure a domain based service group to scale automatically based on the complete set of IP addresses returned by a DNS name server for a domain based server. To configure automatic scaling, when binding a domain based server to a service group, enable the automatic scaling option. Following are the steps for configuring a domain based service group that scales automatically:

- Add a name server for resolving domain names. For more information about configuring a name server on the appliance, see [Adding a Name Server](#).
- Add a domain-based server. For information about adding a domain-based server, see [Configuring a server object](#).
- Add a service group and associate the domain based server to the service group, with the Autoscale option set to DNS. For information about adding a service group, see [Configuring Service Groups](#).

When a domain based server is bound to a service group and the automatic scaling option is set on the binding, a UDP monitor and a TCP monitor are automatically created and bound to the domain based server. The two monitors function as resolvers. The TCP monitor is disabled by default, and the appliance uses the UDP monitor to send DNS queries to the name server to resolve the domain name. If the DNS response is truncated (has the TC flag set to 1), the appliance falls back to TCP and uses the TCP monitor to send the DNS queries over TCP. Thereafter, the appliance continues to use only the TCP monitor.

The DNS response from the name server might contain multiple IP addresses for the domain name. With the automatic scaling option set, the appliance polls each of the IP addresses by using the default monitor, and then includes in the service group only those IP addresses that are up and available. After the IP address records expire, as defined by their time-to-live (TTL) values, the UDP monitor (or the TCP monitor, if the appliance has fallen back to using the TCP monitor) queries the name server for domain resolution and includes any new IP addresses in the service group. If an IP address that is part of the service group is not present in the DNS response, the appliance removes that address from the service group after gracefully closing existing connections to the group member, a process during which it does not allow any new connections to be established with the member. If a domain name

that resolved successfully in the past results in an NXDOMAIN response, all the service group members associated with that domain are removed.

Static (IP-address based) members and dynamically scaling domain based members can coexist in a service group. You can also bind members with different domain names to a service group with the automatic scaling option set. However, each domain name associated with a service group must be unique within the service group. You must enable the automatic scaling option for each domain based server that you want to use for automatic service group scaling. If an IP address is common to one or more domains, the IP address is added to the service group only once.

### Important

- DNS Autoscale is supported in a cluster deployment.
- Path monitoring for Autoscale service groups is not supported in cluster deployment.

## To configure a service group to scale automatically by using the command line interface

At the command prompt, type the following commands to configure the service group and verify the configuration:

```
1 add servicegroup <serviceName> <serviceType> -autoscale DNS
2 <!--NeedCopy-->
```

### Example

In the following example, server1 is a domain based server. The DNS response contains multiple IP addresses. Five addresses are available and are added to the service group.

```
1 > add serviceGroup servGroup -autoScale YES
2 Done
3 > sh servicegroup servGroup
4 servGroup - HTTP
5 State: ENABLED Monitor Threshold : 0
6 . . .
7 . . .
8 1) 192.0.2.31:80 State: UP Server Name: server1 (Auto
 scale) Server ID: None Weight: 1
9
10 Monitor Name: tcp-default State: UP
11 Probes: 2 Failed [Total: 0 Current: 0]
12 Last response: Success - TCP syn+ack received.
13
14 2) 192.0.2.32:80 State: UP Server Name: server1 (Auto
 scale) Server ID: None Weight: 1
15
```

```

16 Monitor Name: tcp-default State: UP
17 Probes: 2 Failed [Total: 0 Current: 0]
18 Last response: Success - TCP syn+ack received.
19
20 3) 192.0.2.36:80 State: UP Server Name: server1 (Auto
 scale) Server ID: None Weight: 1
21
22 Monitor Name: tcp-default State: UP
23 Probes: 2 Failed [Total: 0 Current: 0]
24 Last response: Success - TCP syn+ack received.
25
26 4) 192.0.2.55:80 State: UP Server Name: server1 (Auto
 scale) Server ID: None Weight: 1
27
28 Monitor Name: tcp-default State: UP
29 Probes: 2 Failed [Total: 0 Current: 0]
30 Last response: Success - TCP syn+ack received.
31
32 5) 192.0.2.80:80 State: UP Server Name: server1 (Auto
 scale) Server ID: None Weight: 1
33
34 Monitor Name: tcp-default State: UP
35 Probes: 2 Failed [Total: 0 Current: 0]
36 Last response: Success - TCP syn+ack received.
37 Done
38 <!--NeedCopy-->

```

## To configure a service group to scale automatically by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. Create a service group, and set the Autoscale mode to DNS.

## Overwriting TTL values

### Note:

This option is supported from NetScaler 12.1 build 51.xx and later.

NetScaler appliance is configured to periodically query the DNS server for any update in the SRV record associated with the application during application startup. By default, the periodicity for this query depends on the TTL published in the SRV record. In microservice or cloud world application, deployments change more dynamically. As a result, proxies have to be quicker in absorbing any changes to application deployment. Therefore, users are recommended to set the domain based service TTL parameter explicitly to a value that is lower than the SRV record TTL and is optimal for your deployment. You can overwrite the TTL value by two methods:

- While binding a member to the service group

- Setting the TTL value globally by using the set lb parameter command.

In case the TTL value is configured both while binding the service group member and also globally, then the TTL value specified while binding the service group member takes precedence.

If the TTL value is not specified either while binding a service group member or at the global level, the DBS monitor interval is derived from the TTL value in the DNS response.

### Overwriting the TTL values using the CLI

- To overwrite the TTL value while binding, at the command prompt, type:

```
1 bind serviceGroup <serviceGroupName> (<serverName> [-dbsTTL <secs>])
2 <!--NeedCopy-->
```

#### Example:

```
1 bind servicegroup svc_grp_1 web_serv -dbsTTL 10
2 <!--NeedCopy-->
```

- To overwrite the TTL value globally, at the command prompt, type:

```
1 set lb parameter [-dbsTTL <secs>]
2 <!--NeedCopy-->
```

#### Example:

```
1 set lb parameter -dbsTTL 15
2 <!--NeedCopy-->
```

### Overwriting the TTL values using the GUI

#### To overwrite the TTL value while binding:

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. In **Service Groups** page, select the service group that you have created and click **Edit**.
3. In **Load Balancing Service Groups** page, click **Service Group Members**.
4. In **Service Group Members Binding** page, select the server that you have created and click **Edit**.
5. In **Domain Based Service TTL**, enter the TTL value.

#### To overwrite the TTL value at the global level:

1. Navigate to **Traffic Management > Load Balancing > Change Load Balancing Parameters**.
2. In **Domain Based Service TTL**, enter the TTL value.

**Note:**

If the domain based server TTL value is set to 0, then the TTL value from the data packet is used.

**Specifying different name servers for service group and domain name bindings****Note:**

This option is supported from NetScaler 12.1 build 51.xx and later.

You can configure different name servers for different domain names in a specific group. Setting the nameServer parameter is optional while binding a DBS server to the service group. When a name-server is not specified while binding a member to the service group, the globally configured name-server is considered.

**Specifying name servers while binding a server to service groups using the CLI At the command prompt, type:**

```
1 bind serviceGroup <serviceGroupName> (<serverName> [-nameServer <
 ip_addr>] [-dbsTTL <secs>])
2 <!--NeedCopy-->
```

**Example:**

```
1 bind servicegroup svc_grp_1 web_serv -ns.nameserver.com 10.102.27.155
 -dbsTTL 10
2 <!--NeedCopy-->
```

**Specifying name servers while binding a server to service groups using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. In **Service Groups** page, select the service group that you have created and click **Edit**.
3. In **Load Balancing Service Groups** page, click **Service Group Members**.
4. In **Service Group Members Binding** page, select the server that you have created and click **Edit**.
5. In **Name Server**, specify the nameserver name to which the query for the bound domain must be sent.

**Auto delayed TROFS**

You can configure graceful movement of members in a service group to the TROFS state when IP addresses are removed from the DNS response. When the auto delayed TROFS option is enabled,

NetScaler waits for the highest response timeout across all monitors attached to the service group before moving the members to TROFS state.

This option is useful when a new set of IP addresses replaces the existing ones completely and the connectivity must be verified before adding the new IP addresses.

**Note:**

The `-autoDelayedTrofs` option is supported from NetScaler 13.1 build 37.xx and later.

### Configure auto delayed TROFS using the CLI

At the command prompt, type the following command:

```
1 add serviceGroup <serviceName>@ <serviceType> [-autoScale <
 autoScale>] [-autoDelayedTrofs (YES | NO)]
2 <!--NeedCopy-->
```

#### Example

```
1 > add serviceGroup sg1 HTTP -autoScale DNS -autoDelayedTrofs YES
2 <!--NeedCopy-->
```

### Configure auto delayed TROFS using the GUI

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. In **AutoScale Mode**, select **DNS**.
3. In **Auto Delayed Trofs**, select **YES**.

**Note:**

The Auto Delayed Trofs option is enabled only if you select DNS in AutoScale Mode.

### Service discovery using DNS SRV records

October 8, 2023

An SRV record (service record) is a specification of data in the Domain Name System that defines the location, that is the host name and the port number of servers for specified services. The record also defines the weight and priority of each server.

**Example of an SRV record:**

\_http.\_tcp.example.com. 100 IN SRV 10 60 5060 a.example.com.

The following table describes each item in an SRV record:

Service	Protocol	Name	TTL	Class	SRV	Priority	Weight	Port	Target
HTTP	TCP	example.com	100	IN	SRV	10	60	5060	a.example.com

You can use the DNS SRV records to discover the service endpoints. NetScaler appliance is configured to periodically query the DNS servers with the SRV record associated with a service. On receiving the SRV record, each of the target host published in the SRV record is bound to a service group associated with the service. Each of the bindings inherits the port, priority, and weight from the SRV record. For each service deployment the user has to configure the NetScaler appliance once while bringing it up, thus making it a single touch deployment for applications.

**Important:** The weight of dynamically learned service group members cannot be modified using the CLI or the GUI.

**Use case: Load balancing microservices**

Applications are moving toward microservice architecture from monolithic architectures. Movement to microservice architecture along with back-end server autoscale solution, is making application deployment more dynamic. To support such a dynamic deployment, the proxies or ADC must be able to dynamically detect the back-end application or service instances and absorb them into the proxy configuration.

The service discovery using DNS SRV records feature aids configuration of the NetScaler appliance in such a dynamic deployment scenario. Application developers can use some of the orchestration platforms to deploy the application. Orchestration platforms while instantiating containers during application deployment, might not assign the protocol specific standard port for each of these containers. In such scenarios, discovering the port information becomes the key to configuring the NetScaler appliance. SRV records are helpful in such a scenario. SRV record parameters such as the priority and weight can be used for better load balancing of applications.

- Priority parameter can be used to dictate the priority of the server pool.
- Weight parameter can be used to dictate the capacity of the back-end service instances and hence can be used for weighted load balancing.
- Whenever there is a change in the back-end server pool, for example a back-end instance is removed from the pool, the instance is removed gracefully only after all the existing client connections are honored.

**Note:**

- An A/AAAA records based service discovery, all resolved IP addresses have the same weight because you assign the weight to the domain being resolved.
- If the weight in SRV response is greater than 100, then services are not created.

**Priority based load balancing using SRV records**

You can use SRV records to perform priority-based load balancing. The priority based server pool can be an alternative for the backup virtual servers. The ns.conf file requires minimal configuration compared to the backup virtual servers.

In priority based load balancing using SRV records, a priority number is assigned to each of the server pool. The least number has the highest priority. One of the servers in the highest priority pool is selected for load balancing based on the server's health and availability. If all the servers in the highest priority server pool are down, then the servers that have the next highest priority are selected for load balancing. However, if the servers in the highest priority server pool are up again, then the servers are selected from the highest priority pool again.

Switching from one priority server pool to another server pool occurs gracefully by bleeding the existing client transactions. Therefore, the current clients do not see any break in the application access.

**To enable querying for SRV records using the CLI**

Perform the following tasks to enable querying for SRV records:

1. Create a server by specifying the query type parameter as SRV.

At the command prompt, type:

```
1 add server <name> <domain> [-queryType <queryType>])
2 <!--NeedCopy-->
```

**Example:**

```
1 add server web_serv example.com -queryType SRV
2 <!--NeedCopy-->
```

**Note:**

- By default, IPv4 queries are sent. To send IPv6 queries, you must enable the IPv6 domain.
  - The SRV target domain name must not exceed 127 characters.
2. Create a service group with the autoscale mode as DNS.

At the command prompt, type:

```
1 add serviceGroup <serviceName> <serviceType> [-autoScale <
 autoScale>]
2 <!--NeedCopy-->
```

**Example:**

```
1 add servicegroup svc_grp_1 http -autoscale dns
2 <!--NeedCopy-->
```

3. Bind the server created in step 1 to the service group as a member.

At the command prompt, type:

```
1 bind serviceGroup <serviceName> <serverName>
2 <!--NeedCopy-->
```

**Example:**

```
1 bind servicegroup svc_grp_1 web_serv
2 <!--NeedCopy-->
```

**Note:**

- When binding servers to service group members, you do not have to enter the port number for SRV server types. In case you specify a port number for SRV server type, an error message appears.
- You can optionally specify a name server and a TTL value while binding a server to the service group.

**To enable querying for SRV records using the GUI****Create a server**

1. Navigate to **Traffic Management > Load Balancing > Servers** and click **Add**.
2. In **Create Server** page, select domain name.
3. Enter the details of all the required parameters.
4. In **Query Type**, select **SRV**.
5. Click **Create**.

**Create a service group with autoscale mode as DNS**

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. In **Load Balancing Service Group** page, enter details of all the required parameters.

3. In **AutoScale Mode**, select **DNS**.
4. Click **OK**.

### **Bind server to the service group member**

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. In **Service Groups** page, select the service group that you have created and click **Edit**.
3. In **Load Balancing Service Groups** page, click **Service Group Members**.
4. In **Service Group Members Binding** page, select the server that you have created and click **Close**.

#### **Note:**

- While binding, you do not have to enter the port number for SRV server types. In case you enter a port number for SRV server type, an error message appears.
- You can optionally specify a name server and a TTL value while binding a server to the service group.

### **Overwriting TTL values**

NetScaler appliance is configured to periodically query the DNS server for any update in the SRV record associated with the application during application startup. By default, the periodicity for this query depends on the TTL published in the SRV record. In microservice or cloud world application, deployments change more dynamically. As a result, proxies have to be quicker in absorbing any changes to application deployment. Therefore, users are recommended to set the domain based service TTL parameter explicitly to a value that is lower than the SRV record TTL and is optimal for your deployment. You can overwrite the TTL value by two methods:

- While binding a member to the service group
- Setting the TTL value globally by using the set lb parameter command.

In case the TTL value is configured both while binding the service group member and also globally, then the TTL value specified while binding the service group member takes precedence.

If the TTL value is not specified either while binding a service group member or at the global level, the DBS monitor interval is derived from the TTL value in the DNS response.

### **Overwriting the TTL values using the CLI**

- To overwrite the TTL value while binding, at the command prompt, type:

```
1 bind serviceGroup <serviceName> (<serverName> [-dbsTTL <secs>])
2 <!--NeedCopy-->
```

**Example:**

```
1 bind servicegroup svc_grp_1 web_serv -dbsTTL 10
2 <!--NeedCopy-->
```

- To overwrite the TTL value globally, at the command prompt, type:

```
1 set lb parameter [-dbsTTL <secs>]
2 <!--NeedCopy-->
```

**Example:**

```
1 set lb parameter -dbsTTL 15
2 <!--NeedCopy-->
```

## Overwriting the TTL values using the GUI

### To overwrite the TTL value while binding:

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. In **Service Groups** page, select the service group that you have created and click **Edit**.
3. In **Load Balancing Service Groups** page, click **Service Group Members**.
4. In **Service Group Members Binding** page, select the server that you have created and click **Edit**.
5. In **Domain Based Service TTL**, enter the TTL value.

### To overwrite the TTL value at the global level:

1. Navigate to **Traffic Management > Load Balancing > Change Load Balancing Parameters**.
2. In **Domain Based Service TTL**, enter the TTL value.

**Note:** If the domain based server TTL value is set to 0, then the TTL value from the data packet is used.

## Specifying different name servers for service group and domain name bindings

You can configure different name servers for different domain names in a specific group. Setting the nameServer parameter is optional while binding a DBS server to the service group. When a name-server is not specified while binding a member to the service group, the globally configured name-server is considered.

## Specifying name servers while binding a server to service groups using the CLI

At the command prompt, type:

```
1 bind serviceGroup <serviceGroupName> (<serverName> [-nameServer <
 ip_addr>] [-dbstTTL <secs>])
2 <!--NeedCopy-->
```

**Example:**

```
1 bind servicegroup svc_grp_1 web_serv -ns.nameserver.com 10.102.27.155
 -dbstTTL 10
2 <!--NeedCopy-->
```

## Specifying name servers while binding a server to service groups using the GUI

1. Navigate to **Traffic Management > Load Balancing > Service Groups**.
2. In **Service Groups** page, select the service group that you have created and click **Edit**.
3. In **Load Balancing Service Groups** page, click **Service Group Members**.
4. In **Service Group Members Binding** page, select the server that you have created and click **Edit**.
5. In **Name Server**, specify the nameserver name to which the query for the bound domain must be sent.

## Translate the IP address of a domain-based server

May 2, 2023

To simplify maintenance on the NetScaler appliance and on the domain-based servers that are connected to it, you can configure IP address masks and translation IP addresses. These functions work together to parse incoming DNS packets and substitute a new IP address for a DNS-resolved IP address.

When configured for a domain-based server, IP address translation enables the appliance to locate an alternate server IP address when you take the server down for maintenance or if you make any other infrastructure changes that affect the server.

When configuring the mask, you must use standard IP mask values (a power of two, minus one) and zeros, for example, 255.255.0.0. Non-zero values are only permitted in the starting octets.

When you configure a translation IP for a server, you create a 1:1 correspondence between a server IP address and an alternate server that shares leading or trailing octets in its IP address. The mask blocks

particular octets in the original server's IP address. The DNS-resolved IP address is transformed to a new IP address by applying the translation IP address and the translation mask.

For example, you can configure a translation IP address of 10.20.0.0 and a translation mask of 255.255.0.0. If a DNS-resolved IP address for a server is 40.50.27.3, this address is transformed to 10.20.27.3. In this case, the translation IP address supplies the first two octets of the new address, and the mask passes through the last two octets from the original IP address. The reference to the original IP address, as resolved by DNS, is lost. Monitors for all services to which the server is bound also report on the transformed IP address.

When configuring a translation IP address for a domain-based server, you specify a mask and an IP address to which the DNS-resolved IP address is to be translated.

Note: Translation of the IP address is only possible for domain-based servers. You cannot use this feature for IP-based servers. The address pattern can be based on IPv4 addresses only.

### To configure a translation IP address for a server by using the command line interface

At the command prompt, type:

```
1 add server <name>@ <serverDomainName> -translationIp <
 translationIPAddress> -translationMask <netMask> -state <ENABLED|
 DISABLED>
2 <!--NeedCopy-->
```

#### Example:

```
1 add server myMaskedServer www.example.com -translationIp 10.10.10.10 -
 translationMask
2 255.255.0.0 -state ENABLED
3 <!--NeedCopy-->
```

### To configure a translation IP address for a server by using the configuration utility

Navigate to **Traffic Management > Load Balancing > Servers**, create a domain-based server, and specify a translation IP address.

## Mask a virtual server IP address

May 2, 2023

You can configure a mask and a pattern instead of a fixed IP address for a virtual server. This enables traffic that is directed to any of the IP addresses that match the mask and pattern to be rerouted to a

particular virtual server. For example, you can configure a mask that allows the first three octets of an IP address to be variable, so that traffic to 111.11.11.198, 22.22.22.198, and 33.33.33.198 is all sent to the same virtual server.

By configuring a mask for a virtual server IP address, you can avoid reconfiguration of your virtual servers due to a change in routing or another infrastructure change. The mask allows the traffic to continue to flow without extensive reconfiguration of your virtual servers.

The mask for a virtual server IP address works differently from an IP pattern definition for a server described in [Translating the IP Address of a Domain-Based Server](#). For a virtual server IP address mask, a non-zero mask is interpreted as an octet that is considered. For a service, the non-zero value is blocked.

Also, for a virtual server IP address mask, either leading or trailing values can be considered. If the virtual server IP address mask considers values from the left of the IP address, this is known as a forward mask. If the mask considers the values to the right side of the address, this is known as a reverse mask.

Note: The NetScaler appliance evaluates all forward mask virtual servers before evaluating reverse mask virtual servers.

When masking a virtual server IP address, you also need to create an IP address pattern for matching incoming traffic with the correct virtual server. When the appliance receives an incoming IP packet, it matches the destination IP address in the packet with the bits that are considered in the IP address pattern, and after it finds a match, it applies the IP address mask to construct the final destination IP address.

Consider the following example:

- Destination IP address in the incoming packet: 10.102.27.189
- IP address pattern: 10.102.0.0
- IP mask: 255.255.0.0
- Constructed (final) destination IP address: 10.102.27.189.

In this case, the first 16 bits in the original destination IP address match the IP address pattern for this virtual server, so this incoming packet is routed to this virtual server.

If a destination IP address matches the IP patterns for more than one virtual server, the longest match takes precedence. Consider the following example:

- Virtual Server 1: IP pattern 10.10.0.0, IP mask 255.255.0.0
- Virtual Server 2: IP pattern 10.10.10.0, IP mask 255.255.255.0
- Destination IP address in the packet: 10.10.10.45.
- Selected virtual server: Virtual Server 2.

The pattern associated with Virtual Server 2 matches more bits than that associated with Virtual Server 1, so IPs that match it is sent to Virtual Server 2.

Note: Ports are also considered if a tie-breaker is required.

## To configure a virtual server IP address mask by using the command line interface

At the command prompt, type:

```
1 add lb vserver <name>@ http -ipPattern <ipAddressPattern> -ipMask <
 ipMask> <listenPort>
2 <!--NeedCopy-->
```

### Example:

Pattern matching based on prefix octets:

```
1 add lb vserver myLBVserver http -ippattern 10.102.0.0 -ipmask
 255.255.0.0 80
2 <!--NeedCopy-->
```

Pattern matching based on trailing octets:

```
1 add lb vserver myLBVserver1 http -ippattern 0.0.22.74 -ipmask
 0.0.255.255 80
2 <!--NeedCopy-->
```

Modify a pattern-based virtual server:

```
1 set lb vserver myLBVserver1 -ippattern 0.0.22.74 -ipmask 0.0.255.255
2 <!--NeedCopy-->
```

If you configure the Virtual Server 1 as follows:

```
1 add lb vserver vs1 HTTP -ippattern 100.1.1.0 -ipmask 255.255.255.0 80
2 <!--NeedCopy-->
```

The NetScaler appliance will not respond to an ARP request on all the IP addresses. However, it responds to the virtual server traffic routed to all the IP addresses in that pattern.

## To configure a virtual server IP address mask by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the Address Type list, select IP Pattern, and specify an IP pattern and IP mask.

## Configure load balancing for commonly used protocols

May 2, 2023

In addition to websites and web-based applications, other types of network-deployed applications that use other common protocols often receive large amounts of traffic and therefore benefit from load balancing. Several of these protocols require specific configurations for load balancing to work properly. Among them are FTP, DNS, SIP, and RTSP.

If you configure your NetScaler appliance to use domain names for your servers rather than IPs, you might also need to set up IP translation and masking for those servers.

## **Load balance a group of FTP servers**

May 2, 2023

The NetScaler appliance can be used to load balance FTP servers. FTP requires that the user initiate two connections on two different ports to the same server: the control connection, through which the client sends commands to the server, and the data connection, through which the server sends data to the client. When the client initiates an FTP session by opening a control connection to the FTP server, the appliance uses the configured load balancing method to select an FTP service, and forwards the control connection to it. The load balanced FTP server then opens a data connection to the client for information exchange.

The following diagram describes the topology of a load balancing configuration for a group of FTP servers.

Figure 1. Basic Load Balancing Topology for FTP Servers

In the diagram, the services Service-FTP-1, Service-FTP-2, and Service-FTP-3 are bound to the virtual server Vserver-LB-1. Vserver-LB-1 forwards the client’s connection request to one of the services using the least connection load balancing method. Subsequent requests are forwarded to the service that the appliance initially selected for load balancing.

The following table lists the names and values of the basic entities configured on the appliance.

Entity type	Name	IP address	Port	Protocol
Vserver	Vserver-LB-1	10.102.29.25	21	FTP
Services	Service-FTP-1	10.102.29.21	21	FTP
	Service-FTP-2	10.102.29.22	21	FTP
	Service-FTP-3	10.102.29.23	21	FTP
Monitors	FTP	None	None	None

The following diagram shows the load balancing entities, and the values of the parameters that need to be configured on the appliance.

Figure 2. Load Balancing FTP Servers Entity Model

The appliance can also provide a passive FTP option to access FTP servers from outside of a firewall. When a client uses the passive FTP option and initiates a control connection to the FTP server, the FTP server also initiates a control connection to the client. It then initiates a data connection to transfer a file through the firewall.

To create services and virtual servers of type FTP, see [Setting Up Basic Load Balancing](#). Name the entities and set the parameters to the values described in the columns of the previous table. When you configure a basic load balancing setup, a default monitor is bound to the services.

Next, bind the FTP monitor to the services by following the procedure described in the section [Binding Monitors to Services](#).

### To create FTP monitors by using the CLI

At the command prompt, type:

```
1 add lb monitor <MonitorName> FTP -interval <Interval> -userName <
 UserName> -password <Password>
2 <!--NeedCopy-->
```

#### Example:

```
1 add lb monitor monitor-FTP-1 FTP -interval 360 -userName User -password
 User
2 <!--NeedCopy-->
```

## To create FTP monitors by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. Create a monitor of type FTP, and in Special Parameters, specify a user name and password.

## Load balance DNS servers

May 2, 2023

When you request DNS resolution of a domain name, the NetScaler appliance uses the configured load balancing method to select a DNS service. The DNS server to which the service is bound then resolves the domain name and returns the IP address as the response. The appliance can also cache DNS responses and use the cached information to respond to future requests for resolution of the same domain name. Load balancing DNS servers improve DNS response times.

The following diagram describes the topology of a load balancing configuration that load balances a group of DNS services.

Figure 1. Basic Load Balancing Topology for DNS Servers

In the diagram, the services Service-DNS-1, Service-DNS-2, and Service-DNS-3 are bound to the virtual server Vserver-LB-1. The virtual server Vserver-LB-1 forwards client requests to a service using the least connection load balancing method. The following table lists the names and values of the basic entities configured on the appliance.

Entity type	Name	IP address	Port	Protocol
Virtual Server	Vserver-LB-1	10.102.29.13	53	DNS
Services	Service-DNS-1	10.102.29.14	53	DNS
	Service-DNS-2	10.102.29.15	53	DNS
	Service-DNS-3	10.102.29.16	53	DNS
Monitors	monitor-DNS-1	None	None	None

The following diagram shows the load balancing entities and the values of the parameters that need to be configured on the appliance.

Figure 2. Load Balancing DNS Servers Entity Model

To configure a basic DNS load balancing setup, see [Setting Up Basic Load Balancing](#). Follow the procedures to create services and virtual servers of type DNS, naming the entities and setting the parameters using the values described in the previous table. When you configure a basic load balancing setup, the default ping monitor is bound to the services. For instructions on binding a DNS monitor to DNS services, you can also see [Binding Monitors to Services](#).

The following procedure describes the steps to create a monitor that maps a domain name to the IP address based on a query.

### To configure DNS monitors by using the CLI

At the command prompt, type:

```
1 add lb monitor <monitorName> DNS -query <domainName> -queryType <
 Address|ZONE> -IPAddress <ipAddress>
2 <!--NeedCopy-->
```

Example:

```
1 add lb monitor monitor-DNS-1 DNS -query www.citrix.com -queryType
 Address -IPAddress 10.102.29.66
2
3 add lb monitor monitor-DNS-2 DNS -query www.citrix2.com -queryType
 Address -IPAddress
4 1000:0000:0000:0000:0005:0600:700a::888b-888d
5 <!--NeedCopy-->
```

### To configure DNS monitors by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. Create a monitor of type DNS, and in Special Parameters, specify a query and query type.

## Load balance domain-name based services

May 2, 2023

When you create a service for load balancing, you can provide an IP address. Alternatively, you can create a server using a domain name. The server name (domain name) can be resolved using an IPv4 or IPv6 name server, or by adding an authoritative DNS record (A record for IPv4 or AAAA record for IPv6) to the NetScaler configuration.

When you configure services with domain names instead of IP addresses, and if the name server resolves the domain name to a new IP address, the monitor bound to the service runs a health check

on the new IP address, and updates the service IP address only when the IP address is found to be healthy. The monitor can be the default monitor bound to the service or you can bind any other supported monitor. It probes the service at regular intervals defined in the monitor parameters. If the domain name resolves to a new IP address, the monitor sends a fresh probe to check the health of the service. All subsequent probes are at the predefined interval.

**Note:** When you change the IP address of a server, the corresponding service is marked down for the first client request. The name server resolves the service IP address to the changed IP address for the next request, and the service is marked UP.

Domain-name based services have the following restrictions:

- The maximum domain name length is 255 characters.
- The Maximum Client parameter is used to configure a service that represents the domain name-based server. For example, a maxClient of 1000 is set for the services bound to a virtual server. When the connection count at the virtual server reaches 2000, the DNS resolver changes the IP address of the services. However, because the connection counter on the service is not reset, the virtual server cannot take any new connections until all the old connections are closed.
- When the IP address of the service changes, persistence is difficult to maintain.
- If the domain name resolution fails due to a timeout, the appliance uses the old information (IP address).
- When monitoring detects that a service is down, the appliance performs a DNS resolution on the service (representing the domain name-based server) to obtain a new IP address.
- Statistics are collected on a service and are not reset when the IP address changes.
- If a DNS resolution returns a code of “name error”(3), the appliance marks the service down and changes the IP address to zero.

When the appliance receives a request for a service, it selects the target service. This way, the appliance balances the load on your services. The following diagram describes the topology of a load balancing configuration that load balances a group of domain-name based servers (DBS).

Figure 1. Basic Load Balancing Topology for DBS Servers

The services Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 are bound to the virtual server Vserver-LB-1. The virtual server Vserver-LB-1 uses the least connection load balancing method to choose the service. The IP address of the service is resolved using the name server Vserver-LB-2.

The following table lists the names and values of the basic entities configured on the appliance.

Entity type	Name	IP address	Port	Protocol
Virtual Server	Vserver-LB-1	10.102.29.17	80	HTTP
	Vserver-LB-2	10.102.29.20	53	DNS
Servers	server-1	10.102.29.18	80	HTTP
	server-2	www.citrix.com	80	HTTP
Services	Service-HTTP-1	server-1	80	HTTP
	Service-HTTP-2	server-2	80	HTTP
	Service-HTTP-2	10.102.29.19	80	HTTP
Monitors	Default	None	None	None
Name Server	None	10.102.29.19	None	None

The following diagram shows the load balancing entities and the values of the parameters that need to be configured on the appliance.

Figure 2. Load Balancing DBS Servers Entity Model

To configure a basic load balancing setup, see [Setting Up Basic Load Balancing](#). Create the services and virtual servers of type HTTP, and name the entities and set the parameters using the values described in the previous table.

You can add, remove, enable, and disable external name servers. You can create a name server by specifying its IP address, or you can configure an existing virtual server as the name server.

### To add a name server by using the command line interface

At the command prompt, type:

```
1 add dns nameServer <dnsVserverName>
2 <!--NeedCopy-->
```

#### Example:

```
1 add dns nameServer Vserver-LB-2
```

2 <!--NeedCopy-->

## To add a name server by using the configuration utility

1. Navigate to **Traffic Management > DNS > Name Servers**.
2. Create a DNS name server of type DNS Virtual Server, and select a server from the DNS Virtual Server list.

You can also add an authoritative name server that resolves the domain name to an IP address.

### Note

You can add a name server of type TCP, UDP, or UDP\_TCP to resolver DBS probes. However, if TCP and UDP name servers coexists, and a UDP name server receives a response with the truncated bit, this response is not retried over the TCP name server.

## Load balance a group of SIP servers

May 2, 2023

The Session Initiation Protocol (SIP) is designed to initiate, manage, and terminate multimedia communications sessions. It has emerged as the standard for Internet telephony (VoIP). SIP messages can be transmitted over TCP or UDP. SIP messages are of two types: request messages and response messages.

The traffic in a SIP based communication system is routed through dedicated devices and applications (entities). In a multimedia communication session, these entities exchange messages. The following figure shows a basic SIP based communication system:

Figure 1. SIP Based Communication System

A NetScaler enables you to load balance SIP messages over UDP or over TCP (including TLS). You can configure the NetScaler to load balance SIP requests to a group of SIP proxy servers. To do so, you create a load balancing virtual server with the load balancing method and the type of persistence set to one of the following combinations:

- Call-ID hash load balancing method with no persistence setting
- Call-ID based persistence with least connection or round robin load balancing method
- Rule based persistence with least connection or round robin load balancing method

Also, by default, the NetScaler appends RPORT via the header of the SIP request, so that the server sends the response back to the source IP address and port from which the request originated.

Note: For load balancing to work, you must configure the SIP proxies so that they do not add private IP addresses or private domains to the SIP header/payload. SIP proxies must add to the SIP header a domain name that resolves to the IP address of the SIP virtual server. Also, the SIP proxies must communicate with a common database to share registration information.

### Server Initiated Traffic

For SIP-server initiated outbound traffic, configure RNAT on the NetScaler so that the private IP addresses used by the clients are translated into public IP addresses.

If you have configured SIP parameters that include the RNAT source or destination port, the appliance compares the values of the source and destination ports of the request packets with the RNAT source

port and RNAT destination port. If one of the values matches, the appliance updates the VIA header with RPORT. The SIP response from the client then traverses the same path as the request.

For server-initiated SSL traffic, the NetScaler uses a built-in certificate-key pair. If you want to use a custom certificate-key pair, bind the custom certificate-key pair to the NetScaler internal service named **nsrnatsip-127.0.0.1-5061**.

## Support for Policies and Expressions

The NetScaler default expressions language contains several expressions that operate on Session Initiation Protocol (SIP) connections. These expressions can be bound only to SIP based (sip\_udp, sip\_tcp or sip\_ssl) virtual servers, and to global bind points. You can use these expressions in content switching, rate limiting, responder, and rewrite policies.

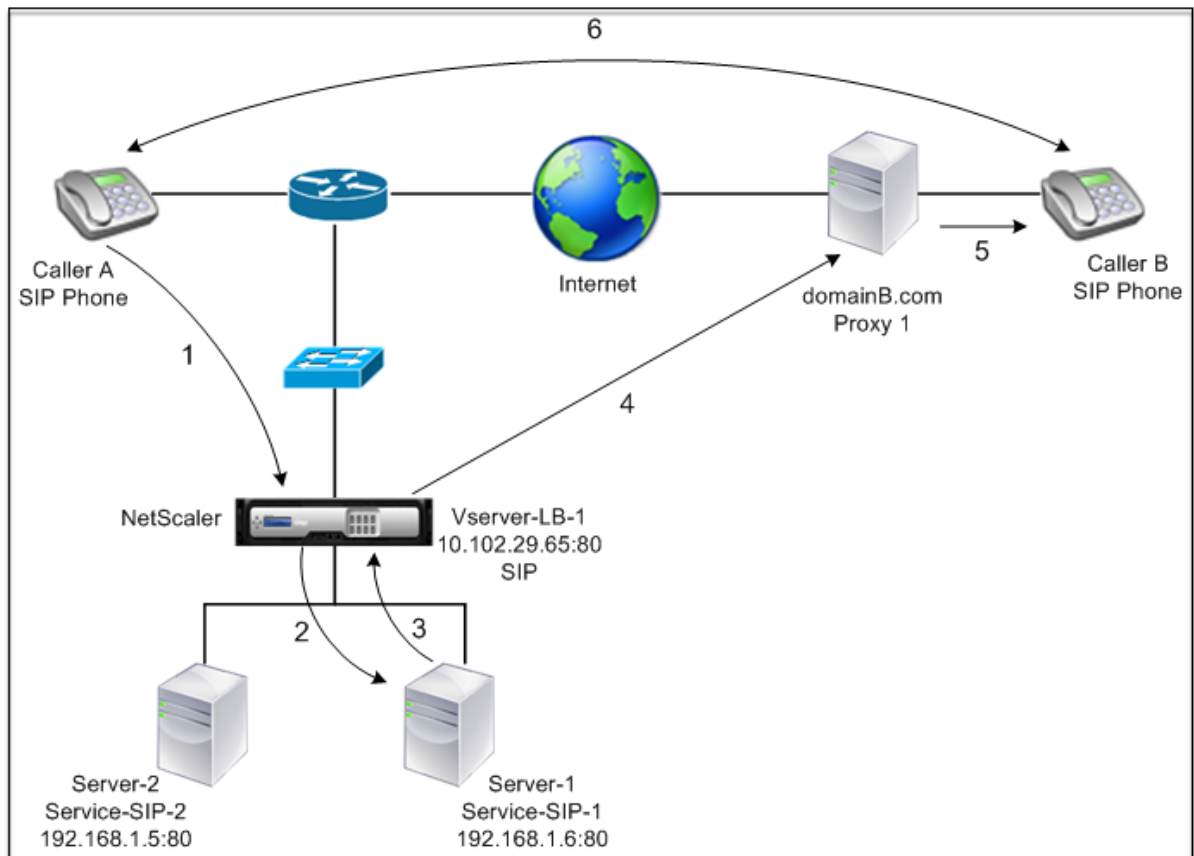

## Configuring Load Balancing for SIP Signaling Traffic over TCP or UDP

The NetScaler can load balance SIP servers that send requests over UDP or TCP, including TCP traffic secured by TLS. The ADC provides the following service types to load balance the SIP servers:

- SIP\_UDP –Used when SIP servers send SIP messages over UDP.
- SIP\_TCP –Used when SIP servers send SIP messages over TCP.
- SIP\_SSL –Used to secure SIP signaling traffic over TCP by using SSL or TLS. The NetScaler supports the following modes:
  - End-to-end TLS connection between the client, the ADC, and the SIP server.
  - TLS connection between the client and the ADC, and TCP connection between the ADC and the SIP server.
  - TCP connection between the client and the ADC, and TLS connection between the ADC and the SIP server.

The following figure shows the topology of a setup configured to load balance a group of SIP servers sending SIP messages over TCP or UDP.

Figure 2. SIP Load Balancing Topology

Entity type	Name	IP address	Port	Service type / Protocol
Virtual Server	Vserver-LB-1	10.102.29.65	80	SIP_UDP / SIP_TCP / SIP_SSL
Services	Service-SIP-1	192.168.1.6	80	SIP_UDP / SIP_TCP / SIP_SSL
	Service-SIP-2	192.168.1.5	80	SIP_UDP / SIP_TCP / SIP_SSL
Monitors	Default	None	80	SIP_UDP / SIP_TCP / SIP_SSL

Following is an overview of configuring basic load balancing for SIP traffic:

1. Configure services, and configure a virtual server for each type of SIP traffic that you want to load balance:

- **SIP\_UDP** –If you are load balancing the SIP traffic over UDP.
- **SIP\_TCP** –If you are load balancing the SIP traffic over TCP.
- **SIP\_SSL** –If you are load balancing and securing the SIP traffic over TCP.

Note: If you use SIP\_SSL, be sure to create an SSL certificate-key pair. For more information, see Adding a Certificate Key Pair.

2. Bind the services to the virtual servers.
3. If you want to monitor the states of the services with a monitor other than the default (**tcp-default**), create a custom monitor and bind it to the services. The NetScaler provides two custom monitor types, **SIP\_UDP** and **SIP\_TCP**, for monitoring SIP services.
4. If using a SIP\_SSL virtual server, bind an SSL certificate-key pair to the virtual server.
5. If you are using the NetScaler as the gateway for the SIP servers in your deployment, configure RNAT.
6. If you want to append RPORT to the SIP messages that are initiated from the SIP server, configure the SIP parameters.

## To configure a basic load balancing setup for SIP traffic by using the command line interface

Create one or more services. At the command prompt, type:

```
1 add service <name> <serverName> (SIP_UDP | SIP_TCP | SIP_SSL) <port>
2 <!--NeedCopy-->
```

### Example:

```
1 add service Service-SIP-UDP-1 192.0.2.5 SIP_UDP 80
2 <!--NeedCopy-->
```

Create as many virtual servers as necessary to handle the services that you created. The virtual server type must match the type of services that you bind to it. At the command prompt, type:

```
1 add lb vserver <name> <serverName> (SIP_UDP | SIP_TCP | SIP_SSL) <port>
2 <!--NeedCopy-->
```

### Example:

```
1 add lb vserver Vserver-LB-1 SIP_UDP 10.102.29.60 80
2 <!--NeedCopy-->
```

Bind each service to a virtual server. At the command prompt, type:

```
1 bind lb vserver <name> <serverName>
2 <!--NeedCopy-->
```

**Example:**

```
1 bind lb vserver Vserver-LB-1 Service-SIP-UDP-1
2 <!--NeedCopy-->
```

(Optional) Create a custom monitor of type SIP-UDP or SIP-TCP, and bind the monitor to the service. At the command prompt, type:

```
1 add lb monitor <monitorName> <monitorType> [<interval>]
2
3 bind lb monitor <monitorName> <ServiceName>
4 <!--NeedCopy-->
```

**Example:**

```
1 add lb monitor mon1 sip-UDP -sipMethod REGISTER -sipURI sip:mon@test.
 com -sipregURI sip:mon@test.com -respcode 200
2
3 bind monitor mon1 Service-SIP-UDP-1
4 <!--NeedCopy-->
```

If you created a SIP\_SSL virtual server, bind an SSL certificate key pair to the virtual server. At the command prompt, type: At the command prompt, type:

```
1 bind ssl vserver <vServerName> -certkeyName <certificate-KeyPairName> -
 CA - skipCAName
2 <!--NeedCopy-->
```

**Example:**

```
1 bind ssl vserver Vserver-LB-1 -certkeyName CertKey-SSL-1
2 <!--NeedCopy-->
```

Configure RNAT as required by your network topology. At the command prompt, type one of the following commands to create, respectively, an RNAT entry that uses a network address as the condition and SNIP as the NAT IP address, an RNAT entry that uses a network address as the condition and a unique IP address as the NAT IP address, an RNAT entry that uses an ACL as the condition and a SNIP as the NAT IP address, or an RNAT entry that uses an ACL as a condition and a unique IP address as the NAT IP address:

```
1 add rnat <name> (<network> | (<aclname> [-redirectPort <port>]))
2
3 bind rnat <name> <natIP>@ ...
4
5 show rnat
6 <!--NeedCopy-->
```

**Example:**

```
1 add rnat RNAT-1 192.168.1.0 255.255.255.0
2
```

```

3 bind rnat RNAT-1 -natip 10.102.29.50
4 <!--NeedCopy-->

```

If you want to use a custom certificate-key pair, bind the custom certificate-key pair to the NetScaler internal service named nsrnatsip-127.0.0.1-5061.

```

1 add ssl certKey <certkeyName> -cert <string> [-key <string>]
2
3 bind ssl service <serviceName> -certkeyName <string>
4 <!--NeedCopy-->

```

### Example:

```

1 add ssl certKey c1 -cert cert.epm -key key.ky
2
3 bind ssl service nsrnatsip-127.0.0.1-5061 -certkeyName c1
4 <!--NeedCopy-->

```

If you want to append RPORT to the SIP messages that the SIP server initiates, type the following command at the command prompt:

```

1 set lb sipParameters -rnatSrcPort <rnatSrcPort> -rnatDstPort<
 rnatDstPort> -retryDur <integer> -addRportVip <addRportVip> -
 sip503RateThreshold <sip503_rate_threshold_value>
2 <!--NeedCopy-->

```

### Sample Configuration for load balancing the SIP traffic over UDP

```

1 add service service-UDP-1 10.102.29.5 SIP_UDP 80
2
3 Done
4
5 add lb vserver vserver-LB-1 SIP_UDP 10.102.29.60 80
6
7 Done
8
9 bind lb vserver vserver-LB-1 service-UDP-1
10
11 Done
12
13 add lb mon mon1 sip-udp -sipMethod REGISTER -sipuRI sip:mon@test.com -
 sipregURI sip:mon@test.com -respcode 200
14
15 Done
16
17 bind mon mon1 service-UDP-1
18
19 Done
20
21 add rnat RNAT-1 192.168.1.0 255.255.255.0

```

```
22
23 Done
24
25 set lb sipParameters -rnatSrcPort 5060 -rnatDstPort 5060 -retryDur 1000
 -addRportVip ENABLED -sip503RateThreshold 1000
26
27 Done
28 <!--NeedCopy-->
```

### Sample Configuration for load balancing the SIP traffic over TCP

```
1 add service service-TCP-1 10.102.29.5 SIP_TCP 80
2
3 Done
4
5 add lb vserver vserver-LB-1 SIP_TCP 10.102.29.60 80
6
7 Done
8
9 bind lb vserver vserver-LB-1 service-TCP-1
10
11 Done
12
13 add lb mon mon1 sip-tcp -sipMethod REGISTER -sipURI sip:mon@test.com -
 sipregURI sip:mon@test.com -respcode 200
14
15 Done
16
17 bind mon mon1 service-TCP-1
18
19 Done
20
21 add rnat RNAT-1 192.168.1.0 255.255.255.0
22
23 Done
24
25 set lb sipParameters -rnatSrcPort 5060 -rnatDstPort 5060 -retryDur 1000
 -addRportVip ENABLED -sip503RateThreshold 1000
26
27 Done
28 <!--NeedCopy-->
```

### Sample Configuration for load balancing and securing SIP traffic over TCP

```
1 add service service-SIP-SSL-1 10.102.29.5 SIP_SSL 80
2
3 Done
4
5 add lb vserver vserver-LB-1 SIP_SSL 10.102.29.60 80
```

```
6
7 Done
8
9 bind lb vserver vserver-LB-1 service-SIP-SSL
10
11 Done
12
13 add lb mon mon1 sip-tCP -sipMethod REGISTER -sipURI sip:mon@test.com -
 sipregURI sip:mon@test.com -respcode 200
14
15 Done
16
17 bind mon mon1 service-SIP-SSL
18
19 Done
20
21 bind ssl vserver Vserver-LB-1 -certkeyName CertKey-SSL-1
22
23 Done
24
25 add rnat RNAT-1 192.168.1.0 255.255.255.0
26
27 Done
28
29 set lb sipParameters -rnatSrcPort 5060 -rnatDstPort 5060 -retryDur 1000
 -addRportVip ENABLED -sip503RateThreshold 1000
30
31 Done
32 <!--NeedCopy-->
```

## To configure a basic load balancing setup for SIP traffic by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and add a virtual server of type SIP\_UDP, SIP\_TCP, or SIP\_SSL.
2. Click the **Service** section, and add a service of type SIP\_UDP, SIP\_TCP, or SIP\_SSL.
3. (Optional) Click the **Monitor** section, and add a monitor of the type: SIP-UDP or SIP-TCP.
4. Bind the monitor to the service, and bind the service to the virtual server.
5. If you created a SIP\_SSL virtual server, bind an SSL certificate key pair to the virtual server. Click the Certificates section, and bind a certificate key pair to the virtual server.
6. Configure RNAT as required by your network topology. To configure RNAT:
  - a) Navigate to **System > Network > Routes**.
  - b) On the Routes page, click the **RNAT** tab.
  - c) In the details pane, click **Configure RNAT**.
  - d) In the Configure RNAT dialog box, do one of the following:

- If you want to use the network address as a condition for creating an RNAT entry, click **Network** and set the following parameters:
    - Network
    - Netmask
  - If you want to use an extended ACL as a condition for creating an RNAT entry, click **ACL** and set the following parameters:
    - ACL Name
    - Redirect Port
- e) To set a SNIP address as a NAT IP address, skip to step 7.
- f) To set a unique IP address as a NAT IP, in the Available NAT IP (s) list, select the IP address that you want to set as the NAT IP, and then click Add. The NAT IP you selected appears in the Configured NAT IPs' list.
- g) Click Create, and then click Close.

If you want to use a custom certificate-key pair, bind the custom certificate-key pair to the NetScaler internal service named **nsrnatsip-127.0.0.1-5061**. To bind the pair:

- a) Navigate to **Traffic Management > Load Balancing > Services** and click the Internal Services tab.
  - b) Select nsrnatsip-127.0.0.1-5061 and click **Edit**.
  - c) Click the **Certificates** section and bind a certificate key pair to the internal service.
7. If you want to append RPORT to the SIP messages that the SIP server initiates, configure the SIP parameters. Navigate to **Traffic Management > Load Balancing** and click Change SIP settings, set the various SIP parameters.

### SIP Expression and Policy Example: Compression Enabled in Client Requests

A NetScaler cannot process compressed client SIP requests, so the client SIP request fails.

You can configure a responder policy that intercepts the SIP NEGOTIATE message from the client and looks for the compression header. If the message includes a compression header, the policy responds with “400 Bad Request,” so that the client resends the request without compressing it.

At the command prompt, type the following commands to create the responder policy:

```
1 add responder action sipaction1 respondwith q{
2 "SIP/2.0 400 Bad Request\r\n\r\n" }
3
4
5 Done
6
7 add responder policy sippol1
8
```

```

9 add responder policy sippol1 "SIP.REQ.METHOD.EQ("NEGOTIATE")&&SIP.REQ.
 HEADER("Compression").EXISTS" sipaction1
10 <!--NeedCopy-->

```

## Load balance RTSP servers

May 2, 2023

The NetScaler appliance can balance the load on RTSP servers to improve the performance of audio and video streams over networks. The following diagram describes the topology of a load balancing setup configured to load balance a group of RTSP servers.

Figure 1. Load Balancing Topology for RTSP

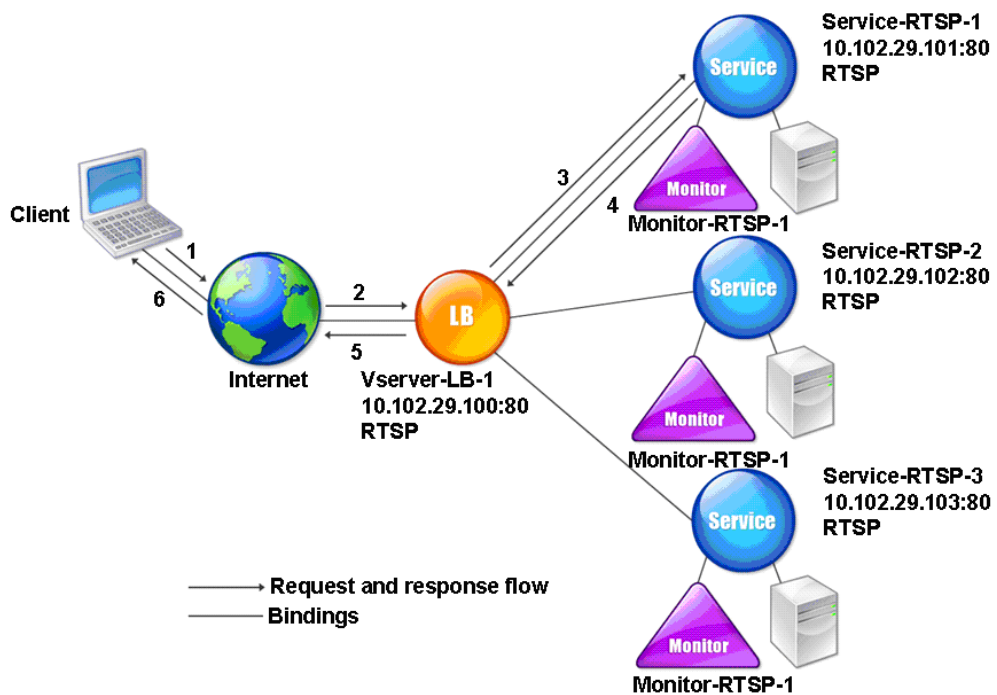

In the example, the services Service-RTSP-1, Service-RTSP-2, and Service-RTSP-3 are bound to the virtual server Vserver-LB-1. The following table lists the names and values of the example entities.

Entity type	Name	IP address	Port	Protocol
Virtual Server	Vserver-LB-1	10.102.29.100	554	RTSP
Services	Service-RTSP-1	10.102.29.101	554	RTSP
	Service-RTSP-2	10.102.29.102	554	RTSP
	Service-RTSP-3	10.102.29.103	554	RTSP
Monitors	Monitor-RTSP-1	None	554	RTSP

The following diagram shows the load balancing entities used in the RTSP configuration.

Figure 2. Load Balancing RTSP Servers Entity Model

To configure a basic load balancing setup for RTSP servers, see [Setting Up Basic Load Balancing](#). Create services and virtual servers of type RTSP. When you configure a basic load balancing setup, the default TCP-default monitor is bound to the services. To bind an RTSP monitor to these services, see [Binding Monitors to Services](#). The following procedure describes how create a monitor that checks RTSP servers.

## To configure RTSP monitors by using the CLI

At the command prompt, type:

```
1 add lb monitor <monitorName> <type>
2 <!--NeedCopy-->
```

### Example:

```
1 add lb monitor Monitor-RTSP-1 RTSP
2 <!--NeedCopy-->
```

## To configure RTSP monitors by using the GUI

Navigate to Traffic Management > Load Balancing > Monitors, and create a monitor of type RTSP.

## Load balance remote desktop protocol servers

May 2, 2023

Remote Desktop Protocol (RDP) is a multichannel-capable protocol that allows for separate virtual channels for carrying presentation data, serial device communication, licensing information, highly encrypted data (keyboard and mouse activity), and so on.

RDP is used for providing a GUI to another computer on the network. RDP is used with Windows terminal servers for providing fast access with almost real-time transmission of mouse movements and key presses even over low-bandwidth connections.

When multiple terminal servers are deployed to provide remote desktop services, the NetScaler appliance provides load balancing of the terminal servers (Windows 2003 and 2008 Server Enterprise Editions). Sometimes, a user who is accessing an application remotely may want to leave the application running on the remote machine but shut down the local machine. The user therefore closes the local application without logging out of the remote application. After reconnecting to the remote machine, the user must be able to continue with the remote application. To provide this functionality, the NetScaler RDP implementation honors the routing token (cookie) set by the Terminal Services Session Directory or Broker so that the client can reconnect to the same terminal server to which it was connected previously. The Session Directory, implemented on Windows 2003 Terminal Server, is referred to as Broker on Windows 2008 Terminal Server.

When a TCP connection is established between the client and the load balancing virtual server, the NetScaler applies the specified load balancing method and forwards the request to one of the termi-

nal servers. The terminal server checks the session directory to determine whether the client has a session running on any other terminal server in the domain.

If there is no active session on any other terminal server, the terminal server responds by serving the client request, and the NetScaler appliance forwards the response to the client.

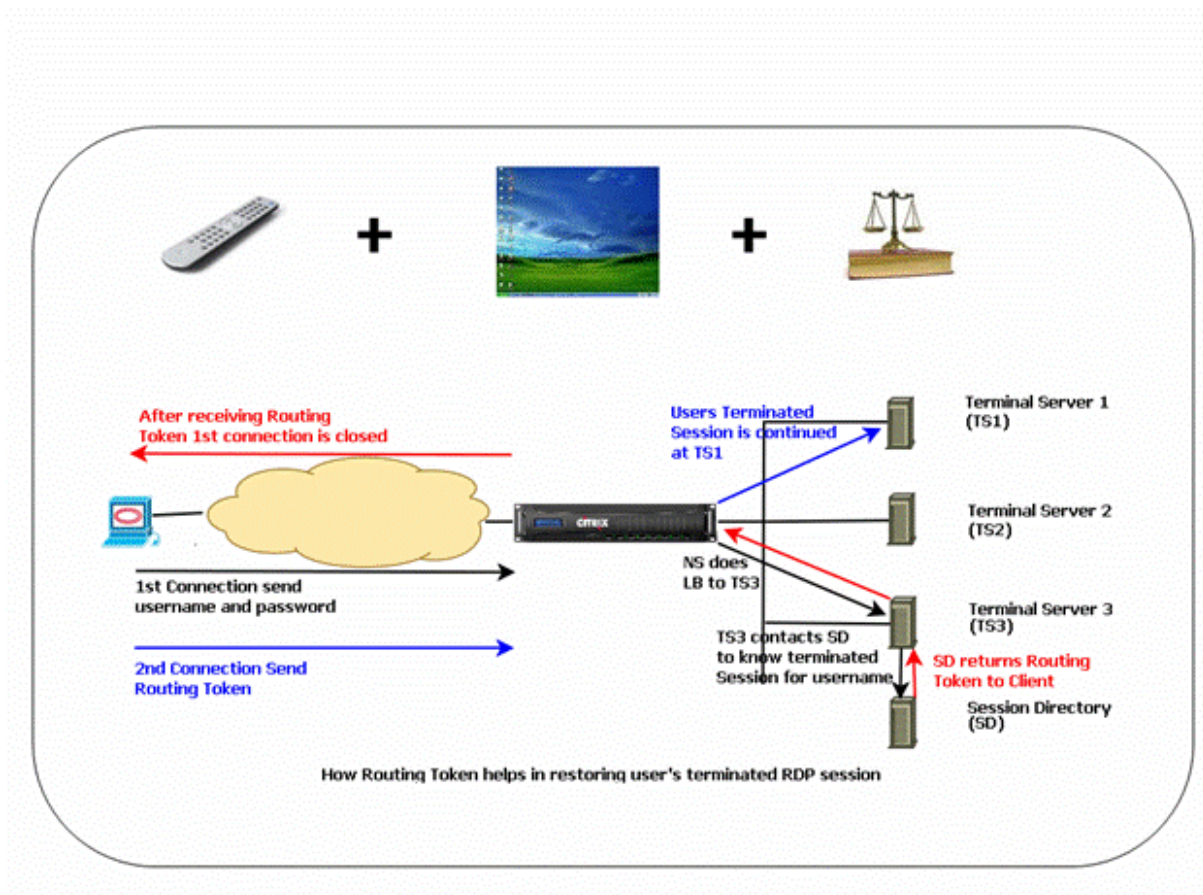

If there is an active session on any other terminal server, the terminal server that receives the request inserts a cookie (referred to as the routing token) with the details of the active session and returns the packets to the NetScaler appliance, which returns the packet to the client. The server closes the connection with the client. When the client retries to connect, the NetScaler reads the cookie information and forwards the packet to the terminal server on which the client has an active session.

The user on the client machine experiences a continuation of the service and does not have to take any specific action.

Note: The Windows Session Directory feature requires the Remote Desktop client that was first released with Windows XP. If a session with a Windows 2000 or Windows NT 4.0 Terminal Server client is disconnected and the client reconnects, the server with which the connection is established is selected by the load balancing algorithm.

The following diagram describes RDP load balancing.

Figure 1. Load Balancing Topology for RDP

### Note

- When an RDP service is configured, persistence is automatically maintained by using a routing token. You need not enable persistence explicitly.
- The NetScaler appliance supports only IP-based cookies.
- The nsrdp.pl script is not supported on any current version of Windows servers.

Ensure that the disconnected RDP sessions are cleared on the terminal servers at the back end to avoid flapping between two terminal servers when an RDP session is disconnected without logging out. For more information, see [https://docs.microsoft.com/en-us/previous-versions/windows/it-pro/windows-server-2003/cc758177\(v=ws.10\)#BKMK\\_2](https://docs.microsoft.com/en-us/previous-versions/windows/it-pro/windows-server-2003/cc758177(v=ws.10)#BKMK_2)

When you add an RDP service, by default, NetScaler adds a monitor of the type TCP and binds it to the service. The default monitor is a simple TCP monitor that checks whether a listening process exists at the 3389 port on the server specified for the RDP service. If there is a listening process at 3389, NetScaler marks this service as UP and if there is no listening process, it marks the service as DOWN.

For more efficient monitoring of an RDP service, in addition to the default monitor, you can configure a script monitor that is meant for the RDP protocol. When you configure the scripting monitor, the

NetScaler opens a TCP connection to the specified server and sends an RDP packet. The monitor marks the service as UP only if it receives a confirmation of the connection from the physical server. Therefore, from the scripting monitor, the NetScaler can know whether the RDP service is ready to service a request.

The monitor is a user-type monitor and the script is located on the NetScaler at `/nsconfig/monitors/n-srdp.pl`. When you configure the user monitor, the NetScaler runs the script automatically. To configure the scripting monitor, add the monitor and bind it to the RDP service.

To configure RDP load balancing, create services of type RDP and bind them to an RDP virtual server.

### To configure RDP load balancing services by using the command line interface

At the command prompt, type the following commands to configure an RDP load balancing setup and verify the configuration:

```
1 add service <name>@ <serverName> <serviceType> <port>
2 <!--NeedCopy-->
```

Note: Repeat the preceding command to add more services.

#### Example

```
1 > add service ser1 10.102.27.182 RDP 3389
2 Done
3 > add service ser2 10.102.27.183 RDP 3389
4 Done
5 >show service ser1
6 ser1 (10.102. 27.182:3389) - RDP
7 State: UP
8 ...
9 Server Name: 10.102.27.182
10 Server ID : 0 Monitor Threshold : 0
11 Down state flush: ENABLED
12 ...
13 1) Monitor Name: tcp-default
14 State: UP Weight: 1
15 ...
16 Response Time: 4.152 millisec
17 Done
18 <!--NeedCopy-->
```

### To configure RDP load balancing services by using the configuration utility

Navigate to **Traffic Management > Load Balancing > Services**, and create services of type RDP.

## To configure an RDP load balancing virtual server by using the command line interface

At the command prompt, type the following commands to configure an RDP load balancing virtual server and verify the configuration:

```
1 add lb vserver <name>@ <serviceType> <ipAddress> <port>
2
3 bind lb vserver <name>@ <serviceName>
4
5 Bind all the RDP services to be load balanced to the virtual server.
6 <!--NeedCopy-->
```

### Example:

This example has two RDP services bound to the RDP virtual server.

```
1 add lb vs v1 rDP 10.102.27.186 3389
2 Done
3
4 bind lb vs v1 ser1
5 service "ser1" bound
6
7 bind lb vs v1 ser2
8 service "ser2" bound
9 Done
10
11 sh lb vs v1
12 v1 (10.102.27.186:3389) - RDP Type: ADDRESS
13 State: UP
14 ...
15 No. of Bound Services : 2 (Total) 2 (Active)
16 Configured Method: LEASTCONNECTION
17 Current Method: Round Robin, Reason: A new service is bound
18 Mode: IP
19 Persistence: NONE
20 L2Conn: OFF
21
22 1) ser1 (10.102.27.182: 3389) - RDPState: UP Weight: 1
23 2) ser2 (10.102.27.183: 3389) - RDPState: UP Weight: 1
24 Done
25 <!--NeedCopy-->
```

## To configure an RDP load balancing virtual server by using the configuration utility

Navigate to **Traffic Management > Load Balancing > Virtual Servers**, create a virtual server of type RDP, and bind RDP services to this virtual server.

## To configure a scripting monitor for RDP services by using the command line interface

At the command prompt, type the following commands:

```
1 add lb monitor <monitorName> USER -scriptName nsrdp.pl
2
3 bind lb monitor <monitorName> <rdpServiceName>
4 <!--NeedCopy-->
```

### Example:

```
1 add service ser1 10.102.27.182 RDP 3389
2
3 add lb monitor RDP_MON USER -scriptName nsrdp.pl
4
5 bind lb monitor RDP_MON ser1
6
7 <!--NeedCopy-->
```

## To configure a scripting monitor for RDP services by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Monitors**, and create a monitor of type USER.
2. In Special Parameters, in the Script Name list, select nsrdp.pl, and then bind this monitor to an RDP service.

## Priority order for load balancing services

October 8, 2023

The priority order for services feature enables you to prioritize the order for services or service groups based on the load balancing selection preferences. You can configure the priority order when you do the following:

- Bind a service to a load balancing virtual server.
- Bind a service group to a load balancing virtual server.
- Bind a service group member to the load balancing service group.

Currently, you can configure the priority order for services using the following approaches. However, these approaches have the following limitations:

- Configuring a backup virtual server chain: The number of configuration lines is high, and you must run the `show` command several times to know the state of all the LB services for each virtual server.
- Configuring the preferred location: You must create location entries for all your application endpoints.

The priority order for services feature addresses the preceding limitations with fewer configuration commands, and helps you to accomplish the preferred location configuration without the need of location representation of all load balancing services' IP addresses.

### Configure priority order for load balancing services

To configure the priority order for load balancing services, the `-order <number>` parameter is added to the bind commands.

**Note:**

The lowest order number has the highest priority.

**Command:**

```
bind lb vserver <vservname> <servicename/servicegroupname> -order <number>
```

For example, consider a set of services that are bound to a load balancing virtual server (vs1). Using the

- `order <number>` parameter, you can prioritize the order of selection of services as follows:

- Set 1 (s1, s2) bound to vs1 -order 1
- Set 2 (s3, s4) bound to vs1 -order 2
- Set 3 (s5, s6) bound to vs1 -order 3

After you bind the services to vs1, and when vs1 receives the client traffic, the order of selection of services is as follows:

- The virtual server (vs1) first selects the services in set 1 (s1 and s2) with order number 1, because this set is assigned the lowest order number. By default, the lowest order number has the highest priority.
- If all the services in set 1 are DOWN, vs1 selects set 2 (s3 and s4) with order number 2.
- If all the services in set 1 and set 2 are down, vs1 selects set 3 (s5 and s6) with order number 3.

## Configure priority order for load balancing services using the CLI

To configure the priority order for the load balancing services, type the following commands at the command prompt:

1. Add an LB virtual server.

```
add lb vserver vs1 HTTP 1.1.1.1 80
```

2. Add LB services.

```
add service s[1-6] 2.2.2.[1-6] HTTP 80
```

3. Set the order number and bind the services to the LB virtual server.

```
bind lb vserver vs1 s1 -order 1
```

```
bind lb vserver vs1 s2 -order 1
```

```
bind lb vserver vs1 s3 -order 2
```

```
bind lb vserver vs1 s4 -order 2
```

```
bind lb vserver vs1 s5 -order 3
```

```
bind lb vserver vs1 s6 -order 3
```

## Configure priority order for load balancing services using the GUI

### Prerequisites:

- You have created a load balancing virtual server.
- You have created services.

To configure the priority order for load balancing services and bind them to the virtual server, do the following:

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and double-click the load balancing virtual server.
2. In **Load Balancing Virtual Server**, under the **Services and Service Groups** section, click **Load Balancing Virtual Server Service Binding**.
3. In the **Load Balancing Virtual Server Service Binding** dialog box, click **Add Binding**.
4. In the **Service Binding** dialog box, select a service.
5. Type a number in the **Order** field to set the priority order for the service.
6. Click **Bind**.
7. Repeat steps 1–6 to configure different priority order number for different services.

## Configure priority order for load balancing services using LB policy commands

By default, the lowest order number has the highest priority. However, you can defer this default behavior using the new LB action and policy commands. You can configure the service selection order based on the incoming client traffic or client data.

For example, consider a set of services that are bound to a virtual server (vs1). Using the `- order <number>` parameter, you have configured the priority order for services as follows:

- Set 1 (s1, s2) bound to vs1 –order 1
- Set 2 (s3, s4) bound to vs1 –order 2
- Set 3 (s5, s6) bound to vs1 –order 3

By default, the lowest order number has the highest priority. Therefore, the default priority order of preference is 1, 2, and 3 for services in set 1, set2, and set3, respectively. However, for a specific client traffic, you want to change the priority order to 3, 1, and 2. To achieve this, you can add an LB policy and bind it to vs1.

An LB policy command consists of two elements: a rule, and an action. The rule is associated with an action, which is performed if a request matches the rule.

**Note:**

The LB policy commands are common for both LB and GSLB configuration and are applicable for the requests handled by the NetScaler appliance.

### LB action

**Expression:**

```
add lb action <name> <type> <string>
```

**Example:**

```
add lb action act1 -type SELECTIONORDER -value 3 2 1
```

**Parameters:**

- `name`: Name of the action.
- `type`: Type of action.
- `string`: Value for the specified action.

## LB policy

### Expression:

```
add lb policy <name> <rule> <action> <undefaction>
```

### Example:

```
add lb policy pol1 -rule CLIENT.IP.SRC.EQ(8.8.8.8)-action act1
```

### Parameters:

- **name:** Name of the policy.
- **rule:** A rule consists of one or more expressions. The rule is associated with an action, which is performed if the request matches the rule.
- **action:** DROP, NOLBACTION, and RESET are supported.
- **undefaction:** The NetScaler appliance generates an undefined event (UNDEF event) when a request does not match a policy. You can use the `set lb param -undefAction <action>` command to set the undefined action. You can assign these actions to an undefined event: DROP, NOLBACTION, and RESET.

Let's consider an example where you add an LB action, LB policy, and bind the policy to a load balancing virtual server (vs1) as follows:

```
add lb action act1 -type SELECTIONORDER -value 3 1 2
add lb policy pol1 -rule CLIENT.IP.SRC.EQ(8.8.8.8)-action act1
bind lb vserver vs1 -policyName pol1 -priority 10
```

The rule selects the client traffic that matches the IP address, 8.8.8.8, and sends that traffic to vs1. The LB action type (`SELECTIONORDER`) defines the service selection order. After you bind the LB policy to vs1, and when vs1 receives the client traffic from the IP address 8.8.8.8, the services are selected in the following order:

1. The virtual server (vs1) selects services in set 3 (s5 and s6) with priority order 3.
2. If all the services in set 3 are DOWN, vs1 selects set 1 (s1 and s2) with priority order 2.
3. If all the services in set 3 and set 2 are down, the vs1 selects set 1 (s1 and s2) with order 1.

## Configure priority order for load balancing services with LB policy commands using the CLI

To configure priority order for load balancing services using LB policy commands, type the following commands at the command prompt:

1. Add an LB action.

```
add lb action act1 -type SELECTIONORDER -value 3 1 2
```

2. Add an LB policy.

```
add lb policy pol1 -rule CLIENT.IP.SRC.EQ(8.8.8.8)-action act1
```

3. Add an LB virtual server.

```
add lb vserver vs1 HTTP 1.1.1.1 80
```

4. Bind the LB policy to the LB virtual server.

```
bind lb vs vs1 -policyName pol1 -priority 10
```

5. Add LB services.

```
add service s[1-6] 2.2.2.[1-6] HTTP 80
```

6. Set the order and bind the services to the LB virtual server.

```
bind lb vserver vs1 s1 -order 1
```

```
bind lb vserver vs1 s2 -order 1
```

```
bind lb vserver vs1 s3 -order 2
```

```
bind lb vserver vs1 s4 -order 2
```

```
bind lb vserver vs1 s5 -order 3
```

```
bind lb vserver vs1 s6 -order 3
```

## Configure priority order for load balancing services with the LB policy commands using the GUI

### Prerequisites:

- You have created a load balancing virtual server.
- You have created services.

### Step 1 - Create an LB Action:

1. Navigate to **AppExpert > LB > Actions**.
2. In **LB Actions**, click **Add**.
3. In the **Create LB Actions** dialog box, specify values for the following parameters:
  - **Action Name**
  - **Type**
  - **Value**

**Note:**

The numbers in the **Value** field are separated by a space.

4. Click **Create**.

**Step 2 - Create an LB Policy:**

1. Navigate to **AppExpert > LB > Policies**.
2. In **LB Policies**, click **Add**.
3. In the **Create LB Policies** dialog box, specify values for the following parameters:
  - **Name:** pol1
  - **Action:** act1
  - **Undefined-Result Action:** NOLBACTION
  - **Expression:** CLIENT.IP.SRC.EQ(8.8.8.8)

4. Click **Create**.

**Step 3 - Bind the LB policy to the LB virtual server:**

1. Navigate to **Traffic Management > LB > Virtual Servers** and double-click the virtual server.
2. In **Advanced Settings**, click **Policies**.
3. In the **Policies** section, click the plus (+) icon.
4. In the **Choose Type** dialog box, specify values for the following parameters:
  - **Choose Policy:** LB
  - **Choose Type:** Request
5. Click **Add Binding**.
6. In the **Policy Binding** dialog box, specify values for the following parameters:
  - **Select Policy**

- **Priority**
- **Goto Expression**
- **Invoke LabelType**

7. Click **Bind**.

#### **Step 4 - Configure priority order for load balancing services:**

To configure priority order for load balancing services, see the **Configure priority order for load balancing services using the GUI** procedure.

### **Persistence settings for services**

If persistence is configured for a service, then preference is always given to persistence, by default.

For example, consider a service with persistence configured and priority order 1. If a service with priority order 0 is UP, then preference is always given to the service with priority order 1.

However, you can override this default behavior with the following CLI command:

```
set lb param -overridePersistencyforOrder <YES/NO>
```

Let's consider the following example:

A set of services is bound to a virtual server (vs1) with the following priority order:

- Set 1 (s1, s2) bound to vs1 – order 1
- Set 2 (s3, s4) bound to vs1 – order 2

Type the following command at the command prompt to override persistency:

```
set lb parameter -overridePersistencyforOrder YES
```

If set 1 (services with persistence is configured) is DOWN, then set 2 services handle all the requests until set 1 services are UP. A persistence entry for priority 2 is created.

Let's assume that after some time, the set 1 services are UP. Now, both set 1 and set 2 services are UP to handle the requests. In this scenario, new load balancing decisions are made as higher order services are UP. The persistence entry is overridden with a new load balancing entry.

### **Priority toggle**

With the priority toggle feature, you can toggle all the traffic to a low-priority service during version upgrade for a service with a higher priority order. You can use the following commands to toggle priority:

- `set lb vserver -toggleorder<Ascending/Descending>`

- `set lb vserver v1 -orderthreshold 80`

For example, let's consider that there are two services with the following priorities:

- Service 1- order 0
- Service 2 – order 1

By default, service 1 handles all the traffic. If service 1 needs to be upgraded, then the traffic needs to be rerouted to service 2.

At the command prompt, type the following commands to toggle priority:

```
set lb vserver -toggleorder Descending
```

By default, 0 has higher priority. However, after priority toggling, 1 is considered as a higher priority. If persistence entry is present for the service, the persistence preference behavior is as explained in the **Persistence settings for services** section.

## Use case 1: SMPP load balancing

May 2, 2023

Millions of short messages are exchanged daily between individuals and value-added service providers, such as banks, advertisers, and directory services, by using the short message peer to peer (SMPP) protocol. Often, message delivery is delayed because servers are overloaded and traffic is not optimally distributed among the servers. The NetScaler supports SMPP load balancing and provides optimal distribution of messages across your servers, preventing poor performance and outages.

The NetScaler performs load balancing on the server side when messages are received from clients and on the client side when messages are received from servers.

Load balancing of SMPP messages by the NetScaler provides the following benefits:

- Better load distribution on servers, which translates to faster response time to end users
- Server health monitoring and better failover capabilities
- Quick and easy addition of new servers (message centers) without changing the client configuration
- High availability

### Introduction to SMPP

SMPP is an application layer protocol for the transfer of short messages between External Short Message Entities (ESME), Routing Entities (RE) and Message Centers (MC) over long-lived TCP connections.

It is used for sending short message service (SMS) messages between friends, contacts, and third parties such as banks (mobile banking), advertisers (mobile commerce), and directory services. Messages from an ESME (non-mobile entity) arrive at the MC, which distributes them to short message entities (SMEs) such as mobile phones. SMPP is also used by SMEs to send short messages to third parties (for example, for purchase of products, bill payment, and funds transfer). These messages arrive at the MC and are forwarded to the destination MC or ESME.

The following diagram shows the different SMPP entities: ESMEs, REs, and MCs, in a mobile network.

### Architecture Overview of the Different SMPP Entities in a Mobile Network

Note: The terms client and ESME are used interchangeably throughout the document.

An ESME (client) opens a connection to the MC in one of the three modes: as a transmitter, a receiver, or a transceiver. As a transmitter, it can only submit messages for delivery. As a receiver, it can only receive messages. As a transceiver, the ESME can both submit and receives messages. The ESME sends the MC one of the three messages (also known as PDUs): `bind_transmitter`, `bind_receiver`, or `bind_transceiver`. The MC responds with a `bind_transmitter_resp`, `bind_receiver_resp`, or

bind\_transceiver\_resp, as appropriate for the request.

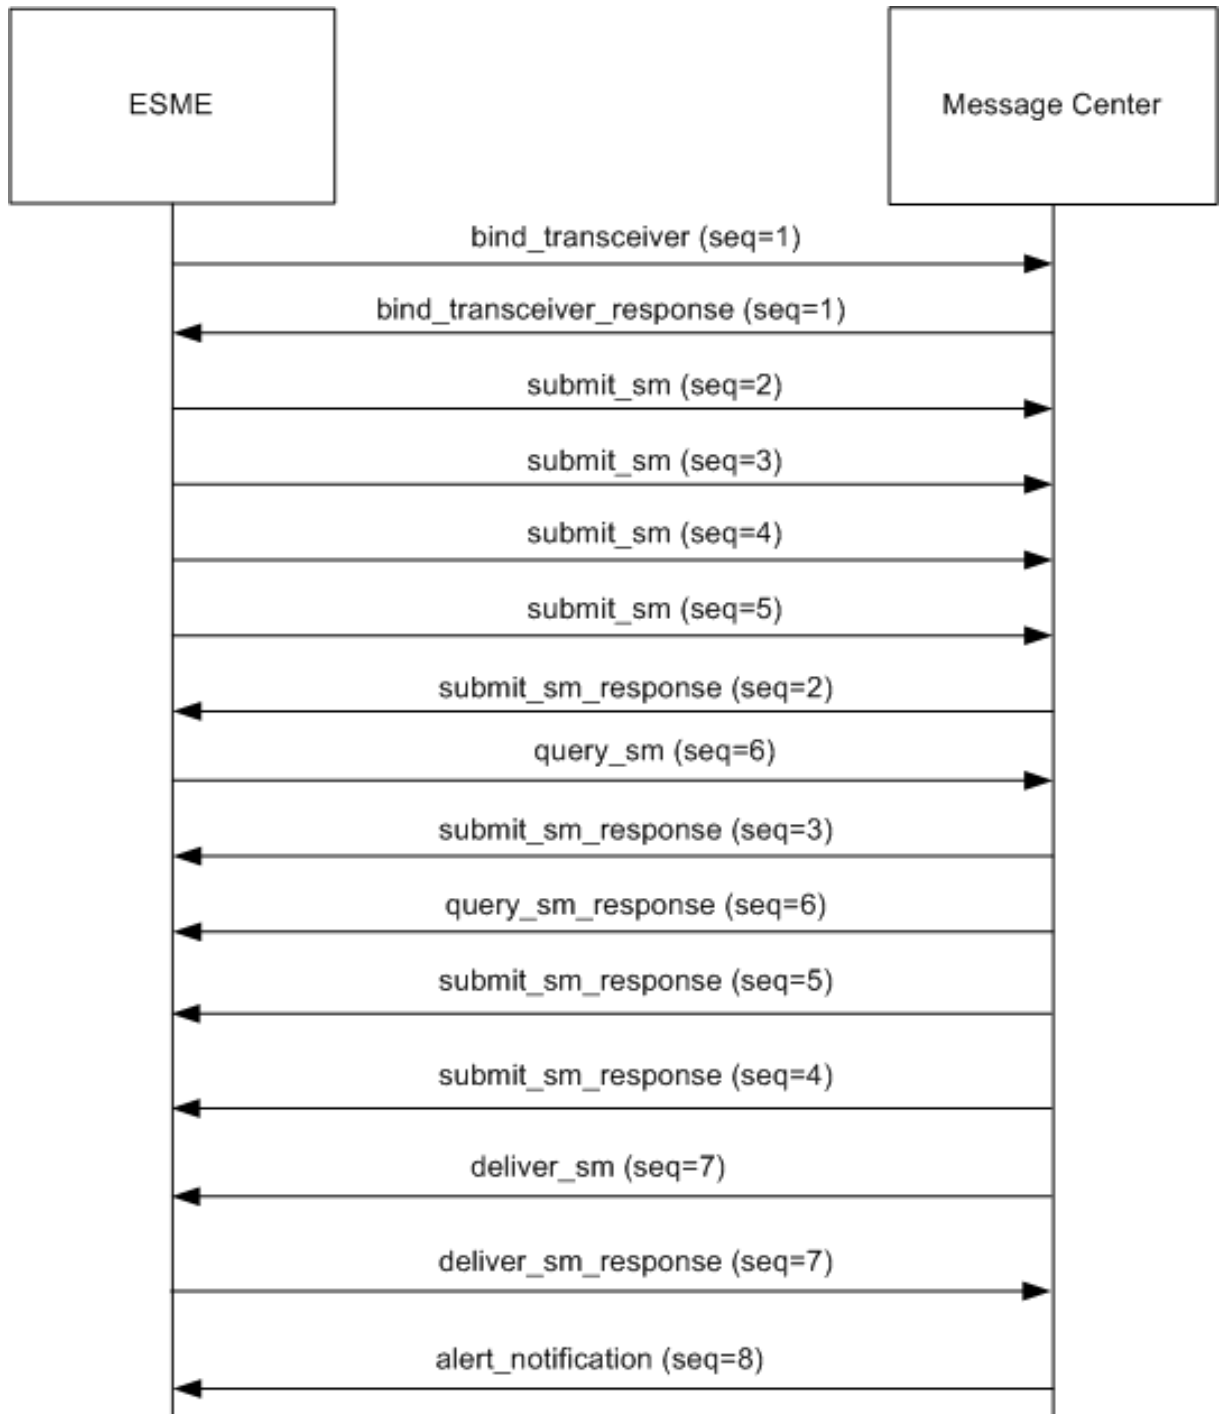

After the connection is established, the ESME can, depending on the mode in which it is bound to the MC, send a submit\_sm or data\_sm message, receive a deliver\_sm or data\_sm message, or send and receive any of these types of messages. The ESME can also send ancillary messages, such as query\_sm, replace\_sm, and cancel\_sm, to query the status of an earlier message delivery, replace an earlier message with a new message, or cancel an undelivered message.

If a message is not delivered because an ESME is not available or a mobile subscriber is not online, the message is queued. Later, when the MC detects that the mobile subscriber is now reachable, it sends an alert\_notification PDU to the ESME over a receiver or transceiver session, requesting delivery of any queued messages.

Each request PDU has a unique sequence number. The response PDU has the same sequence number as the original request. Because message exchange over SMPP can be in asynchronous mode, an ESME or an MC can send multiple requests at a time. The sequence number plays a crucial role in returning the response in the same SMPP session. In other words, the sequence number makes request and response matching possible.

The following diagram shows how the traffic flow uses the various PDUs when the ESME binds as a transceiver.

**Limitation:**

The NetScaler appliance does not support out bound operations. That is, a message center cannot initiate an SMPP session with an ESME through the NetScaler appliance.

## **How SMPP Load Balancing Works on the NetScaler**

An ESME (client) sends a bind message to open a connection to the NetScaler. The ADC authenticates each ESME and, if successful, responds with an appropriate message. The NetScaler establishes a connection with each message center and load balances all the messages among these message centers. When the ADC receives a message from a client, it reuses an open connection to the message center or sends a bind request to a message center if an open connection is not available.

The ADC can load balance messages originating from the clients and from the servers. It can monitor the health of the message centers and handle concatenated messages. It also provides content switching support for the message centers.

### **Messages Originating from the ESMEs**

Each ESME must be added as a user on the NetScaler for authentication. The client establishes a TCP connection with an SMPP virtual server configured on the ADC by sending a bind request. The ADC authenticates the client and, if successful, parses the bind message. The ADC then sends the request to the message center selected by the configured load balancing method. If a connection to the message center is not available for reuse, the ADC opens a TCP connection with the message center by sending a new bind request to the message center.

Before forwarding the response (submit\_sm\_resp or data\_sm\_resp) from the message center to the client, the ADC adds a custom server ID to the message ID to identify the message center for ancillary operations, such as query, replace, or cancel requests for a message, by the client. Requests from other clients are load balanced in the same way.

In the original bind request, a client specifies the address range that it can serve. This range is used for forwarding deliver\_sm or data\_sm messages from the message centers to the clients.

### **Messages Originating from a Message Center**

ESMEs that can handle a specific address range are grouped into a cluster. All the nodes in a cluster provide the same credentials. Within a cluster, only the round robin method is used for load balancing. To deliver mobile originated (MO) messages, the message center sends a deliver\_sm message to the NetScaler. If a cluster that can serve the destination address range (for example, numbers starting with 998) is bound to the ADC, it selects that cluster, and then load balances the message among the ESME nodes in that cluster.

If an ESME that can serve deliver\_sm messages for the address range is not bound to the ADC, and message queuing is enabled, the message is queued until such a client binds to the ADC in a receiver or transceiver mode. You can specify the size of the queue.

The following diagram illustrates the internal flow of PDUs between ESMEs, NetScaler, and the message centers. For simplicity, only two ESMEs and two message centers are shown.

Flow of messages (PDUs):

1. ESME1 sends bind request to NetScaler
2. NetScaler sends bind request to MC1
3. MC1 sends bind response to NetScaler
4. NetScaler sends bind response to ESME1
5. ESME1 sends submit\_sm(1) to NetScaler
6. ESME1 sends submit\_sm(2) to NetScaler
7. NetScaler forwards submit\_sm(1) to MC1
8. NetScaler sends bind request to MC2
9. MC2 sends bind response to NetScaler
10. NetScaler forwards submit\_sm(2) to MC2
11. MC1 sends submit\_sm\_resp(1) to NetScaler
12. MC2 sends submit\_sm\_resp(2) to NetScaler
13. NetScaler forwards submit\_sm\_resp(1) to ESME1
14. NetScaler forwards submit\_sm\_resp(2) to ESME1
15. ESME2 sends bind request to NetScaler

16. NetScaler sends bind response to ESME2
17. ESME2 sends submit\_sm(3) to NetScaler
18. NetScaler forwards submit\_sm(3) to MC1
19. MC2 sends deliver\_sm to NetScaler (ESME2 serves the address range specified in the message)
20. MC1 sends submit\_sm\_resp(3) to NetScaler
21. NetScaler forwards submit\_sm\_resp(3) to ESME2
22. NetScaler forwards deliver\_sm to ESME2
23. ESME2 sends deliver\_sm\_resp to NetScaler
24. MC1 sends alert\_notification to NetScaler (ESME1 serves the address range specified in the message)
25. NetScaler forwards deliver\_sm\_resp to MC2
26. NetScaler forwards the alert\_notification to ESME1

## Health Monitoring of Message Centers

By default, a TCP\_default monitor is bound to an SMPP service, but you can bind a custom monitor of type SMPP. The custom monitor opens a TCP connection to the message center and sends an enquire\_link packet. Depending on the success or failure of the probe, the service is marked UP or DOWN.

## Content Switching on Message Centers

Message centers can accept multiple connections (or bind requests) from ESMEs. You can configure the NetScaler to content switch these requests based on the SMPP bind parameters. Following are some common expressions for configuring methods to select a message center:

- Based on the address range: In the following sample expression, the ADC selects a specific message center if the address range starts at 988.

### Example:

```
SMPP.BINDINFO.ADDRESS_RANGE.CONTAINS("^988")
```

- Based the ESME ID: In the following sample expression, the ADC selects a specific message center if the ESME ID equals ESME1.

### Example:

```
SMPP.BINDINFO.SYSTEM_ID.EQ("ESME1")
```

- Based on the ESME type: In the following sample expression, the ADC selects a specific message center if the ESME type is VMS. VMS stands for voice mail system.

**Example:**

SMPP.BINDINFO.SYSTEM\_TYPE.EQ("VMS")

- Based on the type of number (TON) of the ESME: In the following sample expression, the ADC selects a specific message center if TON equals 1 (1 stands for an international number.)

**Example:**

SMPP.BINDINFO.ADDR\_TON.EQ(1)

- Based on the number plan indicator (NPI) of the ESME: In the following sample expression, the ADC selects a specific message center if NPI equals 0 (0 stands for an unknown connection.)

**Example:**

SMPP.BINDINFO.ADDR\_NPI.EQ(0)

- Based on the bind type: In the following sample expression, the ADC selects a specific message center if the bind type is TRANSCEIVER. (A transceiver can send and receive messages.)

**Example:**

SMPP.BINDINFO.TYPE.EQ(TRANSCEIVER)

## Concatenated Message Handling

An SMS can hold a maximum of 140 bytes. Longer messages must be broken down into smaller parts. If the destination mobile is capable, the messages are combined and delivered as one long SMS. The NetScaler forwards the fragments of a message to the same message center. Each message contains a reference number, a sequence number, and the total number of fragments. The reference number is the same for each fragment of a long message. The sequence number specifies that position of the particular fragment in the complete message. After all the fragments are received, the ESME combines the fragments into one long message and delivers the message to the mobile subscriber.

If a client disconnects from an active connection, the connection to the message center is not closed. It is reused for requests from other clients.

## Limitation

Message IDs, from the message center, longer than 59 bytes are not supported. If the message ID length returned by the message center is more than 59 bytes, ancillary operations fail and the NetScaler responds with an error message.

## Configuring SMPP Load Balancing on the NetScaler

Perform the following tasks to configure SMPP load balancing on the ADC:

1. Add an SMPP user. The ADC authenticates the user before it accepts a bind request from the user. The user is typically an ESME.
2. Add a load balancing virtual server, specifying the protocol as SMPP.
3. Add a service, specifying the protocol as SMPP, and a custom server ID that is unique for each server. Bind the service to the load balancing virtual server created earlier.
4. Optionally, create a service group and add services to the service group.
5. Optionally, add a monitor of type SMPP-ECV and bind it to the service. A TCP-default monitor is bound by default.
6. Set the SMPP parameters, such as client mode and message queue.

### To configure SMPP load balancing by using the command line

At the command prompt, type:

```
1 add smpp user <username> -password <password>
2 add service <name> <IP> SMPP <port> - customserverID <customserverID>
3 add lb vserver <name> <IP> SMPP <port>
4 bind lb vserver <name> <service name>
5 set smpp param
6 <!--NeedCopy-->
```

#### Example

```
1 add smpp user smppclient1 -password c03ebb540695b6110eb31172f32245a1 -
 encrypted -encryptmethod ENCMTHD_2
2 add smpp user smppclient2 -password c03ebb540695b6110eb31172f32245a1 -

7 bind lb vserver smppvs smmpsvc
8 set smpp param -addrange "d*"
9 <!--NeedCopy-->
```

### To configure SMPP load balancing by using the configuration utility

1. Navigate to **System > User Administration > SMPP Users**, and add an SMPP user.

2. Navigate to **Traffic Management > Load Balancing > Configure SMPP Parameters**, and set the parameters as required by your deployment.
3. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and add a virtual server of type SMPP.
4. Click in the Service section, add a service of type SMPP, and specify a Server ID.

## Use case 2: Configure rule based persistence based on a name-value pair in a TCP byte stream

May 2, 2023

Some protocols transmit name-value pairs in a TCP byte stream. The protocol in the TCP byte stream in this example is the Financial Information eXchange (FIX) protocol. In non-XML implementation, the FIX protocol enables two hosts communicating over a network to exchange business or trade-related information as a list of name-value pairs (called “FIX fields”). The field format is `<tag>=<value><delimiter>`. This traditional tag-value format makes the FIX protocol ideal for the use case.

The tag in a FIX field is a numeric identifier that indicates the meaning of the field. In the example;

- The tag 35 indicates the message type.
- The value after the equal sign holds a specific meaning for the given tag and is associated with a data type. A value of A for the tag 35 indicates that the message is a logon message.
- The delimiter is the nonprinting “Start of Header”(SOH) ASCII character (0x01), which is the caret symbol (^).
- Each field is also assigned a name. The field with tag 35 is the msgType field.

Following is an example of a logon message.

```
8=FIX.4.1 9=61 35=A 49=INVMGR 56=BRKR 34=1 52=20000426-12:05:06 98=0 108=30 10=157
```

Your choice of persistence type for a tag-value list such as the one shown above is determined by the options that are available to you for extracting a particular string from the list. Token-based persistence methods require you to specify the offset and length of the token that you want to extract from the payload. The FIX protocol does not allow you to do that, because the offset of a given field and the length of its value can vary from one message to another. This variation depends on the message type, the preceding fields, and the lengths of the preceding values. It also varies based on the implementation from one to another, depending on whether custom fields have been defined. Such variations make it impossible to predict the exact offset of a given field or to specify the length of the value that is to be extracted as the token. In this case, therefore, rule based persistence is the preferred persistence type.

Assume that a virtual server fixlb1 is load balancing TCP connections to a farm of servers hosting instances of a FIX-enabled application. You want to configure persistence for connections on the basis of the value of the SenderCompID field, which identifies the firm sending the message. The tag for this FIX field is 49 (shown in the earlier logon message example).

To configure rule based persistence for the load balancing virtual server, set the persistence type for the load balancing virtual server to RULE and configure the rule parameter with an expression. The expression must be one that extracts the portion of the TCP payload in which you expect to find the SenderCompID field, typecasts the resulting string to a name-value list based on the delimiters, and then extracts the value of the SenderCompID field (tag 49), as follows:

```
set lb vserver fixlb1 -persistenceType RULE -rule "CLIENT.TCP.PAYLOAD(300).TYPECAST_NVLIST_T('=', '^').VALUE("\49\"")"
```

Note: Backslash characters have been used in the expression because this is a CLI command. If you are using the configuration utility, do not enter the backslash characters.

If the client sends a FIX message that contains the name-value list in the earlier logon message example, the expression extracts the value INVMGR, and the NetScaler appliance creates a persistence session based on this value.

The argument to the PAYLOAD() function can be as large as you deem is necessary to include the SenderCompID field in the string extracted by the function. Optionally, you can use the SET\_TEXT\_MODE(IGNORECASE) function if you want the appliance to ignore the case when extracting the value of the field, and the HASH function to create a persistence session based on a hash of the extracted value. The following expression uses the SET\_TEXT\_MODE(IGNORECASE) and HASH functions:

```
CLIENT.TCP.PAYLOAD(500).TYPECAST_NVLIST_T('=', '^').SET_TEXT_MODE(IGNORECASE).VALUE("49").HASH
```

Following are more examples of rules that you can use to configure persistence for FIX connections (replace <tag> with the tag of the field whose value you want to extract):

- To extract the value of any FIX field in the first 300 bytes of the TCP payload, you can use the expression CLIENT.TCP.PAYLOAD(300).BEFORE\_STR("^").AFTER\_STR("<tag>=").
- To extract a string that is 20 bytes long at offset 80, cast the string to a name-value list, and then extract the value of the field that you want, use the expression CLIENT.TCP.PAYLOAD(100).SUBSTR(80,20).TYPECAST\_NVLIST\_T('=', '^').VALUE("<tag>").
- To extract the first 100 bytes of the TCP payload, cast the string to a name-value list, and extract the value of the third occurrence of the field that you want, use the expression CLIENT.TCP.PAYLOAD(100).TYPECAST\_NVLIST\_T('=', '^').VALUE("<tag>;2").

Note: If the second argument that is passed to the VALUE() function is n, the appliance extracts the value of the

(n+1)  
<sup>th</sup> instance of the field because the count starts from zero (0).

Following are more examples of rules that you can use to configure persistence. Only the payload-based expressions can evaluate data being transmitted through the FIX protocol. The other expressions are more general expressions for configuring persistence based on lower networking protocols.

- CLIENT.TCP.PAYLOAD(100)
- CLIENT.TCP.PAYLOAD(100).HASH
- CLIENT.TCP.PAYLOAD(100).SUBSTR(5,10)
- CLIENT.TCP.SRCPORT
- CLIENT.TCP.DSTPORT
- CLIENT.IP.SRC
- CLIENT.IP.DST
- CLIENT.IP.SRC.GET4
- CLIENT.IP.DST.GET4
- CLIENT.ETHER.SRCMAC.GET6
- CLIENT.ETHER.DSTMAC.GET5
- CLIENT.VLAN.ID

### **Use case 3: Configure load balancing in direct server return mode**

May 2, 2023

Load balancing in direct server return (DSR) mode allows the server to respond to clients directly by using a return path that does not flow through the NetScaler appliance. In DSR mode, however, the appliance can continue to perform health checks on services. In a high-data volume environment, sending server traffic directly to the client in DSR mode increases the overall packet handling capacity of the appliance because the packets do not flow through the appliance.

DSR mode has the following features and limitations:

- It supports one-arm mode and inline mode.
- The appliance ages out sessions based on idle timeout.
- Because the appliance does not proxy TCP connections (that is it does not send SYN-ACK to the client), it does not shut out SYN attacks. By using the SYN packet rate filter, you can control the rate of SYNs to the server. To control the rate of SYNs, set a threshold for the rate of SYNs. To get protection from SYN attacks, you must configure the appliance to proxy TCP connections. However, that requires the reverse traffic to flow through the appliance.

- In a DSR configuration, the NetScaler appliance does not replace the load balancing virtual server’s IP address with the destination server’s IP address. Instead, it forwards packets to a service by using the server’s MAC address. The VIP must be configured on the server and ARP must be disabled for the VIP which is configured on the server. Doing so prevents the client request from bypassing the appliance when it is configured in one-arm mode. For example, a user must configure VIP in the loopback interface and disable the ARP for the same VIP.
- The appliance obtains the server’s MAC address from the monitor bound to the service. However, custom user monitors (monitors of type USER), which use scripts stored on the NetScaler appliance, do not learn a server’s MAC address. If you use only custom monitors in a DSR configuration, for each request the virtual server receives, the appliance attempts to resolve the destination IP address to a MAC address (by sending ARP requests). Because the destination IP address is a virtual IP address owned by the NetScaler appliance, the ARP requests always resolve to the MAC address of the NetScaler interface. Therefore, all traffic received by the virtual server is looped back to the appliance. If you use user monitors in a DSR configuration, you must also configure another monitor of a different type (for example, a PING monitor) for the services, ideally with a longer interval between probes, so that the MAC address of the servers can be learned.
- The NetScaler appliance learns the server L2 parameters from the monitor that is bound to the service. For UDP-ECV monitors, configure a receive string to enable the appliance to learn the L2 parameters of the server. If the receive string is not configured and the server does not respond, then the appliance does not learn the L2 parameters but the service is set to UP. The traffic for this service is blackholed.

In the example scenario, the services Service-ANY-1, Service-ANY-2, and Service-ANY-3 are created and bound to the virtual server Vserver-LB-1. The virtual server load balances the client request to a service, and the service responds to clients directly, bypassing the NetScaler appliance. The following table lists the names and values of the entities configured on the NetScaler appliance in DSR mode.

Entity type	Name	IP address	Protocol
Virtual server	Vserver-LB-1	10.102.29.94	ANY
Services	Service-ANY-1	10.102.29.91	ANY
	Service-ANY-2	10.102.29.92	ANY
	Service-ANY-3	10.102.29.93	ANY
Monitors	TCP	None	None

The following diagram shows the load balancing entities and values of the parameters to be configured on the appliance.

Figure 1. Entity Model for Load Balancing in DSR Model

For the appliance to function correctly in DSR mode, the destination IP in the client request must be unchanged. Instead, the appliance changes the destination MAC to that of the selected server. This setting enables the server to determine the client MAC address for forwarding requests to the client while bypassing the server.

Next, you configure a basic load balancing setup as described in [Setting Up Basic Load Balancing](#), naming the entities and setting the parameters using the values described in the previous table.

After you configure the basic load balancing setup, you must customize it for DSR mode. To do this, you configure a supported load balancing method, such as the Source IP Hash method with a sessionless virtual server. You also need to set the redirection mode to allow the server to determine the client MAC address for forwarding responses and bypass the appliance.

After you configure the load balancing method and redirection mode, you need to enable the USIP mode on each service. The service then uses the source IP address when forwarding responses.

**To configure the load balancing method and redirection mode for a sessionless virtual server by using the command line interface**

At the command prompt, type:

```
1 set lb vserver <vServerName> -lbMethod <LBMethodOption> -m <
 RedirectionMode> -sessionless <Value>
2 <!--NeedCopy-->
```

### Example

```
1 set lb vserver Vserver-LB-1 -lbMethod SourceIPHash -m MAC -sessionless
 enabled
2 <!--NeedCopy-->
```

#### Note

For a service that is bound to a virtual server on which -m MAC option is enabled, you must bind a non-user monitor.

### To configure the load balancing method and redirection mode for a sessionless virtual server by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open a virtual server, select Redirection Mode as MAC Based, and method as SOURCEIPHASH.
3. In Traffic Settings, select Sessionless Load Balancing.

### To configure a service to use source IP address by using the command line interface

At the command prompt, type:

```
1 set service <ServiceName> -usip <Value>
2 <!--NeedCopy-->
```

#### Example:

```
1 set service Service-ANY-1 -usip yes
2 <!--NeedCopy-->
```

### To configure a service to use source IP address by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Open a service, and in Traffic Settings, select **Use Source IP Address**.

Some additional steps are required in certain situations, which are described in the succeeding sections.

## Use case 4: Configure LINUX servers in DSR mode

May 2, 2023

The LINUX operating system requires that you set up a loopback interface with the NetScaler appliance virtual IP address (VIP) on each load balanced server in the DSR cluster.

### To configure LINUX server in DSR mode

To create a loop back interface with the NetScaler appliance's VIP on each load balanced server, at the Linux OS prompt type the following commands:

```
1 ifconfig dummy0 up
2
3 ifconfig dummy0:0 inet <netscaler vip> netmask 255.255.255.255 up
4
5 echo 1 > /proc/sys/net/ipv4/conf/dummy0/arp_ignore
6
7 echo 2 > /proc/sys/net/ipv4/conf/dummy0/arp_announce
8 <!--NeedCopy-->
```

Then, run the software that remaps the TOS id to VIP.

**Note:** Add the correct mappings to the software before running it. In the preceding commands, the LINUX server uses dummy0 to connect to the network. When you use this command, type the name of the interface that your LINUX server uses to connect to the network.

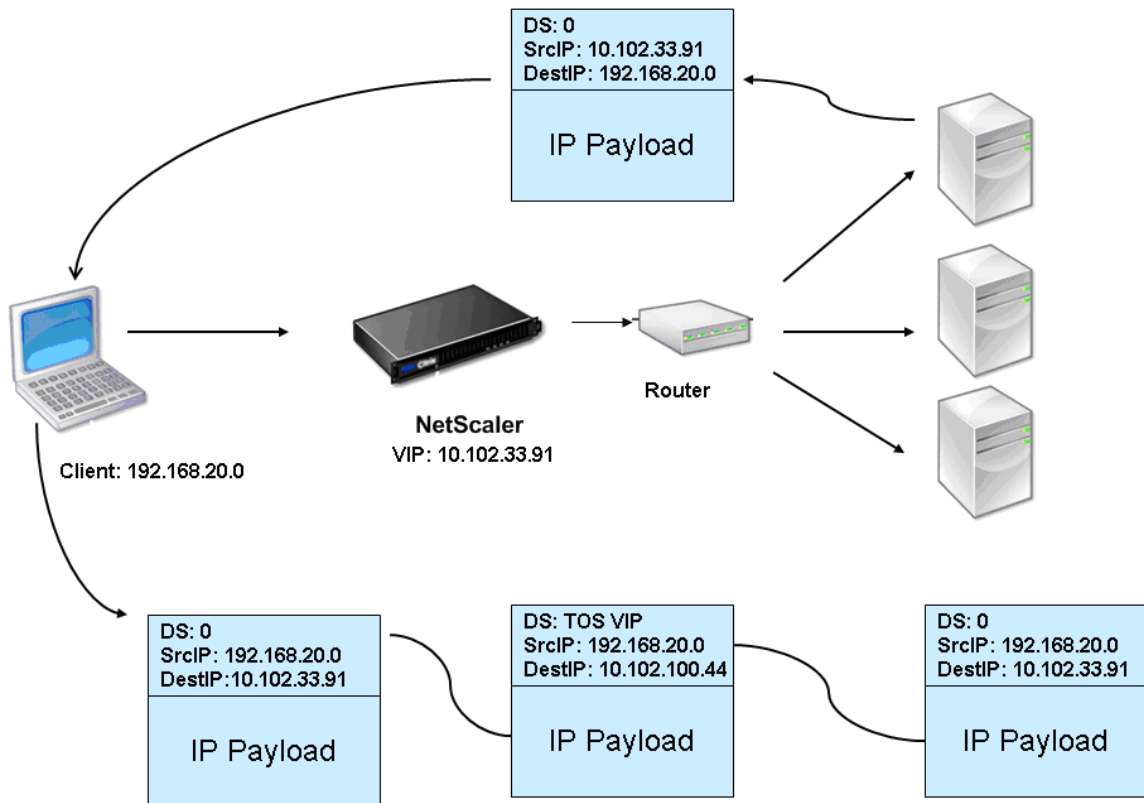

## Use case 5: Configure DSR mode when using TOS

May 2, 2023

Differentiated services (DS), also known as TOS (Type of Service), is a field that is part of the IPv4 packet header. The equivalent field in the IPv6 header is Traffic Class. TOS is used by upper layer protocols for optimizing the path for a packet. The TOS information encodes the NetScaler appliance virtual IP address (VIP), and the load balanced servers extract the VIP from it.

In the following scenario, the appliance adds the VIP to the **TOS** field in the packet and then forwards the packet to the load balanced server. The load balanced server then responds directly to the client, bypassing the appliance, as illustrated in the following diagram.

Figure 1. The NetScaler appliance in DSR mode with TOS

The TOS feature is customized for a controlled environment as follows:

- The environment must not have any stateful devices, such as stateful firewall and TCP gateways, in the path between the appliance and the load balanced servers.
- Routers at all the entry points to the network must remove the TOS field from all incoming packets to make sure that the load balanced server does not confuse another TOS field with that added by the appliance.
- Each server can have only 63 VIPs.
- The intermediate router must not send out ICMP error messages regarding fragmentation. The client does not understand the message, as the source IP address is the IP address of the load balanced server and not the NetScaler VIP.
- TOS is valid only for IP-based services. You cannot use domain name based services with TOS.

In the example, Service-ANY-1 is created and bound to the virtual server Vserver-LB-1. The virtual server load balances the client request to the service, and the service responds to clients directly, bypassing the appliance. The following table lists the names and values of the entities configured on the appliance in DSR mode.

Entity Type	Name	IP Address	Protocol
Virtual server	Vserver-LB-1	10.102.33.91	ANY
Services	Service-ANY-1	10.102.100.44	ANY
Monitors	PING	None	None

DSR with TOS requires that load balancing is set up on layer 3. To configure a basic load balancing setup for Layer 3, see [Setting Up Basic Load Balancing](#). Name the entities and set the parameters using the values described in the previous table.

After you configure the load balancing setup, you must customize the load balancing setup for DSR mode by configuring the redirection mode to allow the server to decapsulate the data packet and then respond directly to the client and bypass the appliance.

After specifying the redirection mode, you can optionally enable the appliance to transparently monitor the server. This enables the appliance to transparently monitor the load balanced servers.

### To configure the redirection mode for the virtual server by using the command line interface

At the command prompt, type:

```
1 set lb vserver <vServerName> -m <Value> -tosId <Value>
2 <!--NeedCopy-->
```

#### Example:

```
1 set lb vserver Vserver-LB-1 -m TOS -tosId 3
2 <!--NeedCopy-->
```

### To configure the redirection mode for the virtual server by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open a virtual server, and in Redirect Mode, select TOS ID.

### To configure the transparent monitor for TOS by using the command line interface

At the command prompt, type:

```
1 add monitor <MonitorName> <Type> -destip <DestinationIP> -tos <Value> -
 tosId <Value>
2 <!--NeedCopy-->
```

**Example:**

```
1 add monitor mon1 PING -destip 10.102.33.91 -tos Yes -tosId 3
2 <!--NeedCopy-->
```

**To create the transparent monitor for TOS by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. Create a monitor, select TOS, and type the TOS ID that you specified for the virtual server.

**Wildcard TOS Monitors**

In a load balancing configuration in DSR mode using TOS field, monitoring its services requires a TOS monitor to be created and bound to these services. A separate TOS monitor is required for each load balancing configuration in DSR mode using the TOS field, because a TOS monitor requires the VIP address and the TOS ID to create an encoded value of the VIP address. The monitor creates probe packets in which the **TOS** field is set to the encoded value of the VIP address. It then sends the probe packets to the servers represented by the services of a load balancing configuration.

With many load balancing configurations, creating a separate custom TOS monitor for each configuration is a significant, cumbersome task. Managing these TOS monitors is also a significant task. Now, you can create wildcard TOS monitors. Create only one wildcard TOS monitor for all load balancing configurations that use the same protocol (for example, TCP or UDP).

A wildcard TOS monitor has the following mandatory settings:

- Type = <protocol>
- TOS = Yes

The following parameters can be set to a value or can be left blank:

- Destination IP
- Destination Port
- TOS ID

A wildcard TOS monitor (with destination IP, Destination port, and TOS ID not set) bound to a DSR service automatically learns the TOS ID and the VIP address of the load balancing virtual server. The monitor creates probe packets with the TOS field set to the encoded VIP address and then sends the probe packets to the server represented by the DSR service.

**To create a wildcard TOS monitor by using the CLI**

At the command prompt, type:

```
1 add lb monitor <monitorName> <Type> -tos YES
2
3 show lb monitor <monitorName>
4 <!--NeedCopy-->
```

**To bind a wildcard TOS monitor to a service by using the CLI**

At the command prompt, type:

```
1 bind lb monitor <monitorName> <serviceName>
2
3 show lb monitor <monitorName>
4 <!--NeedCopy-->
```

**To create a wildcard TOS monitor by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. Add a monitor with the following parameter settings:
  - Type = <protocol>
  - TOS = YES

**To bind a wildcard TOS monitor to a service by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Open a service and bind a wildcard TOS monitor to it.

In the following sample configuration, V1, V2, and V3 are load balancing virtual servers of type ANY and has TOS ID set to 1, 2, and 3 respectively. S1, S2, S3, S4, and S5 are services of type ANY. S1 and S2 are bound to both V1 and V2. S3, S4, and S5 and bound to both V1 and V3. WLCD-TOS-MON is a wildcard TOS monitor with type TCP and is bound to S1, S2, S3, S4, and S5.

WLCD-TOS-MON automatically learns the TOD ID and VIP address of virtual servers bound to S1, S2, S3, S4, and S5.

Because S1 is bound to V1 and V2, WLCD-TOS-MON creates two types of probe packets for S1, one with the **TOS** field set to the encoded VIP address (203.0.113.1) of V1 and the other with the VIP address (203.0.113.2) of V2. The NetScaler then sends these probe packets to the server represented by S1. Similarly, WLCD-TOS-MON creates probe packets for S2, S3, S4, and S5.

```
1 add lb monitor WLCD-TOS-MON TCP -tos YES
2
3 Done
4
5 add lb vserver V1 ANY 203.0.113.1 * -m TOS - tosID 1
6
7 Done
8
9 add lb vserver V2 ANY 203.0.113.2 * -m TOS - tosID 2
10
11 Done
12
13 add lb vserver V3 ANY 203.0.113.3 * -m TOS - tosID 3
14
15 Done
16
17 add service S1 198.51.100.1 ANY *
18
19 Done
20
21 add service S2 198.51.100.2 ANY *
22
23 Done
24
25 add service S3 198.51.100.3 ANY *
26
27 Done
28
29 add service S4 198.51.100.4 ANY *
30
31 Done
32
33 add service S5 198.51.100.5 ANY *
34
35 Done
36
37 bind lb monitor WLCD-TOS-MON S1
38
39 Done
40
41 bind lb monitor WLCD-TOS-MON S2
42
43 Done
44
45 bind lb monitor WLCD-TOS-MON S3
46
47 Done
48
49 bind lb monitor WLCD-TOS-MON S4
50
51 Done
52
53 bind lb monitor WLCD-TOS-MON S5
```

```
54
55 Done
56
57 bind lb vserver V1 S1, S2, S3, S4, S5
58
59 Done
60
61 bind lb vserver V2, S1, S2
62
63 Done
64
65 bind lb vserver V3 S3, S4, S5
66
67 Done
68 <!--NeedCopy-->
```

## Use case 6: Configure load balancing in DSR mode for IPv6 networks by using the TOS field

May 2, 2023

You can configure load balancing in Direct Server Return (DSR) mode for IPv6 networks by using the Type of Service (TOS) field when the NetScaler appliance and the servers are in different networks.

**Note:** The TOS field is also called the Traffic Class field.

In DSR mode, when a client sends a request to a VIP6 address on a NetScaler appliance, the appliance forwards this request to the server by changing the destination IPv6 address of the packet to the IPv6 address of the server and sets an encoded value of the VIP6 address in the TOS (also called traffic class) field of the IPv6 header. You can configure the server to use the information in the TOS field to derive the VIP6 address from the encoded value, which is then used as source IP address in response packets. Response traffic directly goes to the client, bypassing the appliance.

Consider an example where a load balancing virtual server LBVS1, configured on a NetScaler appliance NS1, is used to load balance traffic across servers S1, S2, and S3. The NetScaler appliance NS1 and the servers S1, S2, and S3 are in different networks so router R1 is deployed between NS1 and the servers.

The following table lists the settings used in this example.

Entities	Name
IPv6 address of client C1	C1_IP (for reference purposes only)
Load balancing virtual server on NS1	LBVS1
IPv6 address of LBVS1	LBVS1_VIP6 (for references purpose only)
TOS value	TOS_LBVS1_VIP6 (for references purpose only)
Service for server S1 on NS1	SVC_S1
IPv6 address for server S1	S1_IP (for references purpose only)
Service for server S2 on NS1	SVC_S2
IPv6 address for server S1	S2_IP (for references purpose only)
Service for server S3 on NS1	SVC_S3
IPv6 address for server S1	S3_IP (for references purpose only)

Following is the traffic flow in the example scenario:

1. Client C1 sends a request to virtual server LBVS1.
2. LBVS1’s load balancing algorithm selects server S1 and the appliance opens a connection to S1. NS1 sends the request to S1 with:
  - TOS field set to TOS\_LBVS1\_VIP6.
  - Source IP address as C1\_IP.

3. The server S1, on receiving the request, uses the information in the TOS field to derive the LBVS1\_VIP6 address, which is the IP address of the virtual server LBVS1 on NS1. The server directly sends the response to C1, bypassing the appliance, with:

- Source IP address set to the derivedLBVS1\_VIP6 address so that the client communicates to the virtual server LBVS1 on NS1 and not to server S1.

### **To configure load balancing in DSR Mode using TOS, perform the following steps on the appliance**

1. Enable USIP mode globally.
2. Add the servers as services.
3. Configure a load balancing virtual server with a TOS value.
4. Bind the services to the virtual server.

### **To configure load balancing in DSR Mode using TOS by using the command line interface**

At the command prompt, type:

```
1 enable ns mode USIP
2
3 add service <serviceName> <IP> <serviceType> <port>
4 <!--NeedCopy-->
```

Repeat the earlier command as many times as necessary to add each server as a service on the NetScaler appliance.

```
1 add lb vserver <name> <serviceType> <ip> <port> -m <redirectionMode> -
 tosId <positive_integer>
2
3 bind lb vserver <vserverName> <serviceName>
4 <!--NeedCopy-->
```

### **To enable USIP mode by using the configuration utility**

Navigate to **System > Settings > Configure Modes**, and select **Use Source IP Address**.

### **To create services by using the configuration utility**

Navigate to **Traffic Management > Load Balancing > Services**, and create a service.

## To create a load balancing virtual server and bind services by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and create a virtual server.
2. Click in the Service section to bind a service to this virtual server.

## Use case 7: Configure load balancing in DSR mode by using IP Over IP

May 2, 2023

You can configure a NetScaler appliance to use direct server return (DSR) mode across Layer 3 networks by using IP tunneling, also called *IP over IP* configuration. As with standard load balancing configurations for DSR mode, this allows servers to respond to clients directly instead of using a return path through the NetScaler appliance. This improves response time and throughput. As with standard DSR mode, the NetScaler appliance monitors the servers and performs health checks on the application ports.

With IP over IP configuration, the NetScaler appliance and the servers do not need to be on the same Layer 2 subnet. Instead, the NetScaler appliance encapsulates the packets before sending them to the destination server. After the destination server receives the packets, it decapsulates the packets, and then sends its responses directly to the client. This is often referred to as L3DSR.

To configure L3-DSR mode on your NetScaler appliance:

- [Create a load balancing virtual server](#). Set the mode to IPTUNNEL and enable sessionless tracking.
- [Create services](#). Create a service for each back-end application and bind the services to the virtual server.
- [Configure for decapsulation](#). Configure either a NetScaler appliance or a back-end server to act as a decapsulator.

Note:

When you use a NetScaler appliance, the decapsulation setup is an IP tunnel between the ADC appliances with the back end doing L2DSR to the real servers.

## Configure a load balancing virtual server

Configure a virtual server to handle requests to your applications. Assign the service type that matches the service, or use a type of ANY for multiple services.

Set the forwarding method to IPTUNNEL and enable the virtual server to operate in sessionless mode. Configure any load balancing method that you want to use.

### To create and configure a load balancing virtual server for IP over IP DSR by using the command line interface

At the command prompt type the following command to configure a load balancing virtual server for IP over IP DSR and verify the configuration:

```
1 add lb vserver <name> serviceType <serviceType> IPAddress <ip> Port <
 port> -lbMethod <method> -m <ipTunnelTag> -sessionless [ENABLED |
 DISABLED]
2
3 show lb vserver <name>
4 <!--NeedCopy-->
```

#### Example:

In the following example, we have selected the load balancing method as sourceIPHash and configured sessionless load balancing.

```
1 add lb vserver Vserver-LB-1 ANY 1.1.1.80 * -lbMethod SourceIPHash -m
 IPTUNNEL -sessionless ENABLED
2 <!--NeedCopy-->
```

### To create and configure a load balancing virtual server for IP over IP DSR by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Create a virtual server, and specify Redirection Mode as **IP Tunnel Based**.

### Configure services for IP over IP DSR

After creating your load-balanced server, configure one service for each of your applications. The service handles traffic from the NetScaler appliance to those applications, and allows the NetScaler appliance to monitor the health of each application.

Assign the services to use USIP mode and bind a monitor of type IPTUNNEL to the service for tunnel-based monitoring.

### To create and configure a service for IP over IP DSR by using the command line interface

At the command prompt, type the following commands to create a service and optionally, create a monitor and bind it to the service:

```

1 add service <serviceName> <serverName> <serviceType> <port> -usip <usip
 >
2
3 add monitor <monitorName> <monitorType> -destip <ip> -iptunnel <
 iptunnel>
4
5 bind service <serviceName> -monitorName <monitorName>
6 <!--NeedCopy-->

```

**Example:**

In the following example, a monitor of type IPTUNNEL is created.

```

1 add monitor mon_DSR PING -destip 1.1.1.80 -iptunnel yes
2 add service svc_DSR01 2.2.2.100 ANY * -usip yes
3 bind service svc_DSR01 -monitorName mon_DSR
4 <!--NeedCopy-->

```

An alternative approach to simplify the routing at both the server and the ADC appliance is to setup both the ADC and server to use an IP from the same subnet. Doing so ensures that any traffic with a destination of a tunnel endpoint is sent over the tunnel. In the example, 10.0.1.0/30 is used.

**Note:**

The purpose of the monitor is to ensure that the tunnel is active by reaching the loopback of each server through the IP tunnel. If the service is not up, verify whether the outer IP routing between ADC and server is good. Also verify whether the inner IP addresses are reachable through the IP tunnel. Routes might be required on the server, or PBR is added to ADC depending on the chosen implementation.

**Example:**

```

1 add ns ip 10.0.1.2 255.255.255.252 -vServer DISABLED
2 add netProfile netProfile_DSR -srcIP 10.0.1.2
3 add lb monitor mon_DSR PING -LRTM DISABLED -destIP 1.1.1.80 -ipTunnel
 YES -netProfile netProfile_DSR
4 <!--NeedCopy-->

```

**To configure a monitor by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Monitors**.
2. Create a monitor, and select **IP Tunnel**.

**To create and configure a service for IP over IP DSR by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Create a service and, in **Settings** tab, select **Use Source IP Address**.

### To bind a service to a load balancing virtual server by using the command line interface

At the command prompt type the following command:

```
1 bind lb vserver <name> <serviceName>
2 <!--NeedCopy-->
```

#### Example:

```
1 bind lb vserver Vserver-LB-1 Service-DSR-1
2 <!--NeedCopy-->
```

### To bind a service to a load balancing virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open a virtual server, and click in the **Services** section to bind a service to the virtual server.

### Using the client IP address in the Outer header of tunnel packets

The NetScaler supports using the client-source IP address as the source IP address in the outer header of tunnel packets related to direct server return mode using IP tunneling. This feature is supported for DSR with IPv4 and DSR with IPv6 tunneling modes. For enabling this feature, enable the **use client source IP address** parameter for IPv4 or IPv6. This setting is applied globally to all the DSR configurations that use IP tunneling.

### To use a client-source IP address as the source IP address by using the CLI

At the command prompt, type:

- `set iptunnelparam -useclientsourceip [YES | NO]`
- `show iptunnelparam`

### To use client source IP address as the source IP address by using the GUI

1. Navigate to **System > Network**.
2. In **Settings** tab, click **IPv4 Tunnel Global Settings**.
3. In the **Configure IPv4 Tunnel Global Parameters** page, select **Use Client Source IP** check box.
4. Click **OK**.

### To use client source IP address as the source IP address by using the CLI

At the command prompt, type:

- `set ip6tunnelparam -useclientsourceip [YES | NO]`
- `show ip6tunnelparam`

### To use client source IP address as the source IP address by using the GUI

1. Navigate to **System > Network**.
2. In **Settings** tab, click **IPv6 Tunnel Global Settings**.
3. In the **Configure IPv6 Tunnel Global Parameters** page, select **Use Client Source IP** check box.
4. Click **OK**.

## Decapsulation configuration

You can configure either a NetScaler appliance or a back-end server as a decapsulation.

### NetScaler decapsulation

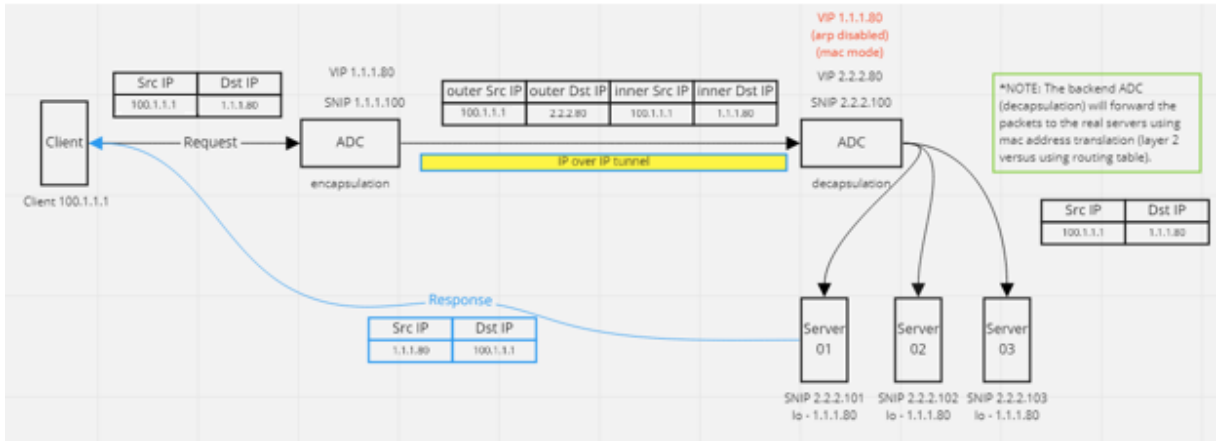

When a NetScaler appliance is used as a decapsulation, an IP tunnel must be created in the NetScaler appliance. For more details, see [Configuring IP Tunnels](#).

The NetScaler decapsulation setup consists of the following two virtual servers:

- The first virtual server receives the encapsulated packet and removes the outer IP encapsulation.
- The second virtual server has the IP of the original service on the front-end ADC and uses MAC translation to forward the packet towards the back end by using the MAC address of the bound services. This setup is typically known as L2DSR. Ensure to disable ARP on this virtual server.

### Example setup:

The following illustration shows a decapsulation setup using the ADC appliances.

The complete configuration required for the setup is as follows.

**Front-end ADC configuration:**

```

1 add service svc_DSR01 2.2.2.80 ANY * -usip YES -useproxyport NO
2 add lb vserver vip_DSR_ENCAP ANY 1.1.1.80 * -lbMethod SOURCEIPHASH -m
 IPTUNNEL -sessionless ENABLED
3 bind lb vserver vip_DSR_ENCAP svc_DSR01
4 <!--NeedCopy-->

```

**Back-end ADC configuration:**

```

1 add ipTunnel DSR-IPIP 1.1.1.100 255.255.255.255 *
2
3 add service svc_DSR01_01 2.2.2.101 ANY * -usip YES -useproxyport NO
4 add service svc_DSR01_02 2.2.2.102 ANY * -usip YES -useproxyport NO
5 add service svc_DSR01_03 2.2.2.103 ANY * -usip YES -useproxyport NO
6
7 add lb vserver vs_DSR_DECAP ANY 2.2.2.80 * -lbMethod SOURCEIPHASH -m
 IPTUNNEL -sessionless ENABLED -netProfile netProf_DSR_MBF_noIP
8
9 add ns ip 1.1.1.80 255.255.255.255 -type VIP -arp DISABLED -snmp
 DISABLED
10 add lb vserver vs_DSR_Relay ANY 1.1.1.80 * -lbMethod SOURCEIPHASH -m
 MAC -sessionless ENABLED
11
12 bind lb vserver vs_DSR_DECAP svc_DSR01_01
13 bind lb vserver vs_DSR_DECAP svc_DSR01_02
14 bind lb vserver vs_DSR_DECAP svc_DSR01_03
15
16 bind lb vserver vip_DSR_Relay svc_DSR01_01
17 bind lb vserver vip_DSR_Relay svc_DSR01_02
18 bind lb vserver vip_DSR_Relay svc_DSR01_03
19
20 add netProfile netProf_DSR_MBF_noIP -MBF ENABLED
21 add lb monitor mon_DSR_MAC PING -netProfile netProf_DSR_MBF_noIP
22 bind service svc_DSR01_01 -monitorName mon_DSR_MAC
23 bind service svc_DSR01_02 -monitorName mon_DSR_MAC
24 bind service svc_DSR01_03 -monitorName mon_DSR_MAC

```

```
25 <!--NeedCopy-->
```

The following example shows a testing setup using Ubuntu and Red Hat servers running apache2. These commands are set up on each back-end server.

```
1 sudo ip addr add 1.1.1.80 255.255.255.255 dev lo
2 sudo sysctl net.ipv4.conf.all.arp_ignore=1
3 sudo sysctl net.ipv4.conf.all.arp_announce=2
4 sudo sysctl net.ipv4.conf.eth4.rp_filter=2 (The interface has the
 external IP with route towards the ADC)
5 sudo sysctl net.ipv4.conf.all.forwarding=1
6 sudo ip link set dev lo arp on
7 <!--NeedCopy-->
```

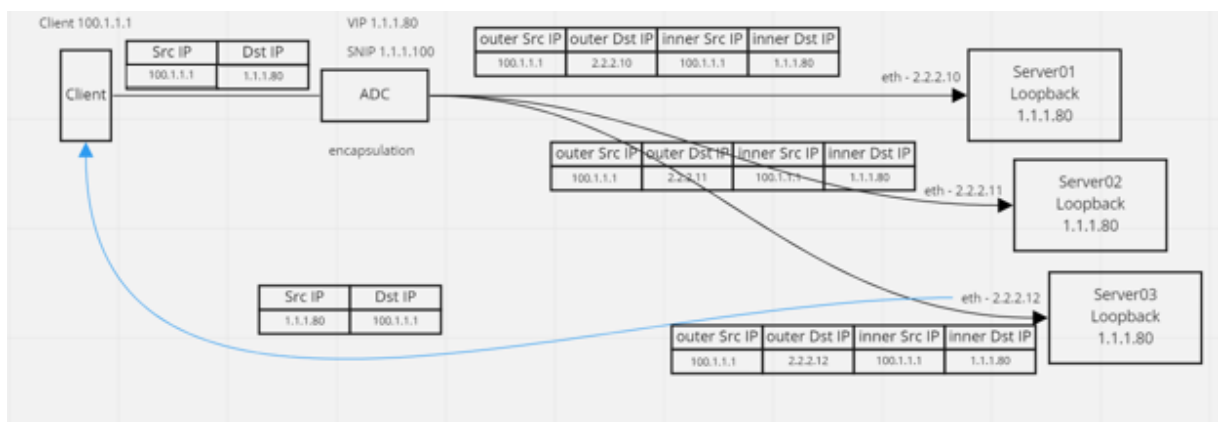

### Back-end server decapsulation

When you use the back-end servers as a decapsulation, the back-end configuration varies depending upon the server OS type. You can configure a back-end server as a decapsulation by following these steps:

1. Configure a loop back interface with IP for service IP.
2. Create a tunnel interface.
3. Add a route through tunnel interface.
4. Configure interface settings as required for traffic.

Note:  
Windows OS servers cannot do IP tunneling natively, so the commands are provided as examples for Linux based systems. Third-party plug-ins are available for Windows OS servers, however, that is outside the scope of this example.

The following illustration shows a decapsulation setup using the back-end servers.

### Example configuration:

In this example, 1.1.1.80 is the NetScaler virtual IP (VIP) address and 2.2.2.10-2.2.2.12 are the back-end server IP addresses. The VIP address is configured in the loopback interface, and a route is added through the tunnel interface. The monitors use the server IP, and tunnel the monitor packets over the IP tunnel using the tunnel endpoints.

The complete configuration required for the setup is as follows.

#### Front-end ADC configuration:

The following configuration creates a monitor that uses the tunnel endpoint as source. Then, send pings over tunnel to service IP address.

```
1 add ns ip 10.0.1.2 255.255.255.252 -vServer DISABLED
2 add netProfile netProfile_DSR -srcIP 10.0.1.2
3 add lb monitor mon_DSR PING -LRTM DISABLED -destIP 1.1.1.80 -ipTunnel
 YES -netProfile netProfile_DSR
4 <!--NeedCopy-->
```

The following configuration creates a VIP for service that uses the original source IP address. Then, forwards traffic over IP tunnel to back-end servers.

```
1 add service svc_DSR01 2.2.2.10 ANY * -usip YES -useproxyport NO
2 bind service svc_DSR01 -monitorName mon_DSR
3
4 add service svc_DSR02 2.2.2.11 ANY * -usip YES -useproxyport NO
5 bind service svc_DSR02 -monitorName mon_DSR
6
7 add service svc_DSR03 2.2.2.12 ANY * -usip YES -useproxyport NO
8 bind service svc_DSR03 -monitorName mon_DSR
9
10 add lb vserver vip_DSR_ENCAP ANY 1.1.1.80 * -lbMethod SOURCEIPHASH -m
 IPTUNNEL -sessionless ENABLED
11 bind lb vserver vip_DSR_ENCAP svc_DSR01
12 bind lb vserver vip_DSR_ENCAP svc_DSR02
13 bind lb vserver vip_DSR_ENCAP svc_DSR03
14 <!--NeedCopy-->
```

#### Back-end server configuration of each server:

The following commands are required for the back-end server to receive the IP packet, remove the outer encapsulation, then respond from the loopback to the original client IP. Doing so ensures the IP addresses in the packet received by the client match the IP addresses in the original request.

```
1 modprobe ipip
2 sudo ip addr add 1.1.1.80 255.255.255.255 dev lo
3 nmcli connection add type ip-tunnel ip-tunnel.mode ipip con-name tun0
4 ifname tun0 remote 198.51.100.5 local 203.0.113.10
5 nmcli connection modify tun0 ipv4.addresses '10.0.1.1/30'
6 nmcli connection up tun0
7 sudo sysctl net.ipv4.conf.all.arp_ignore=1
8 sudo sysctl net.ipv4.conf.all.arp_announce=2
9 sudo sysctl net.ipv4.conf.tun0.rp_filter=2
```

```

10 sudo sysctl net.ipv4.conf.all.forwarding=1
11 sudo ip link set dev lo arp off
12 <!--NeedCopy-->

```

## Use case 8: Configure load balancing in one-arm mode

May 2, 2023

In a one-arm setup, you connect the NetScaler appliance to the network through a single VLAN. The appliance receives the request from the client on a single VLAN and it sends the request to the server on the same VLAN. This is one of the simplest deployment scenarios, where the router, the servers and the appliance are all connected to the same switch. Client requests at the switch are forwarded to the appliance, and the appliance uses the configured load balancing method to select the service.

Figure 1. Load balancing in one-arm mode

In the example scenario, the services Service-ANY-1, Service-ANY-2, and Service-ANY-3 are created and bound to the virtual server Vserver-LB-1. The virtual server load balances the client request to a ser-

vice. The following table lists the names and values of the entities configured on the appliance in one-arm mode.

---

Entity type	Name	IP address	Protocol
Virtual server	Vserver-LB-1	10.102.29.94	ANY
Services	Service-ANY-1	10.102.29.91	ANY
	Service-ANY-2	10.102.29.92	ANY
	Service-ANY-3	10.102.29.93	ANY
Monitors	TCP	None	None

---

To configure a load balancing setup in one-arm mode, see [Setting Up Basic Load Balancing](#).

## Use case 9: Configure load balancing in the inline mode

May 2, 2023

In an inline mode (also called two-arm mode) setup, you connect the NetScaler appliance to the network through multiple VLANs. The appliance receives the request from the client on one VLAN and it sends the request to the server on another VLAN. In the two-arm setup, the appliance is connected between the servers and the client. Client requests at the switch are forwarded to the appliance, and the appliance uses the configured load balancing method to select the service.

The configuration and the entity diagram for inline mode are the same as described in [Configuring Load Balancing in One-arm Mode](#).

## Use case 10: Load balancing of intrusion detection system servers

May 2, 2023

To enable the NetScaler appliance to support load balancing of intrusion detection system (IDS) servers, the IDS servers and clients must be connected through a switch that has port mirroring enabled. The client sends a request to the server. Because port mirroring is enabled on the switch, the request packets are copied or sent to the NetScaler appliance virtual server port. The appliance then uses the configured load balancing method to select an IDS server, as shown in the following diagram.

Figure 1. Topology of Load Balanced IDS Servers

Note: Currently, the appliance supports load balancing of passive IDS devices only.

As illustrated in the preceding diagram, the IDS load balancing setup functions as follows:

1. The client request is sent to the IDS server, and a switch with a mirroring port enabled forwards these packets to the IDS server. The source IP address is the IP address of the client, and the destination IP address is the IP address of the server. The source MAC address is the MAC address of the router, and the destination MAC address is the MAC address of the server.
2. The traffic that flows through the switch is mirrored to the appliance. The appliance uses the layer 3 information (source IP address and destination IP address) to forward the packet to the selected IDS server without changing the source IP address or destination IP address. It modifies the source MAC address and the destination MAC address to the MAC address of the selected IDS server.

Note: When load balancing IDS servers, you can configure the SRCIPHASH, DESTIPHASH, or SRCIPDESTIPHASH load balancing methods. The SRCIPDESTIPHASH method is recommended because packets flowing from the client to a service on the appliance must be sent to a single IDS server.

Suppose Service-ANY-1, Service-ANY-2, and Service-ANY-3 are created and bound to Vserver-LB-1. The virtual server balances the load on the services. The following table lists the names and values of the entities configured on the appliance.

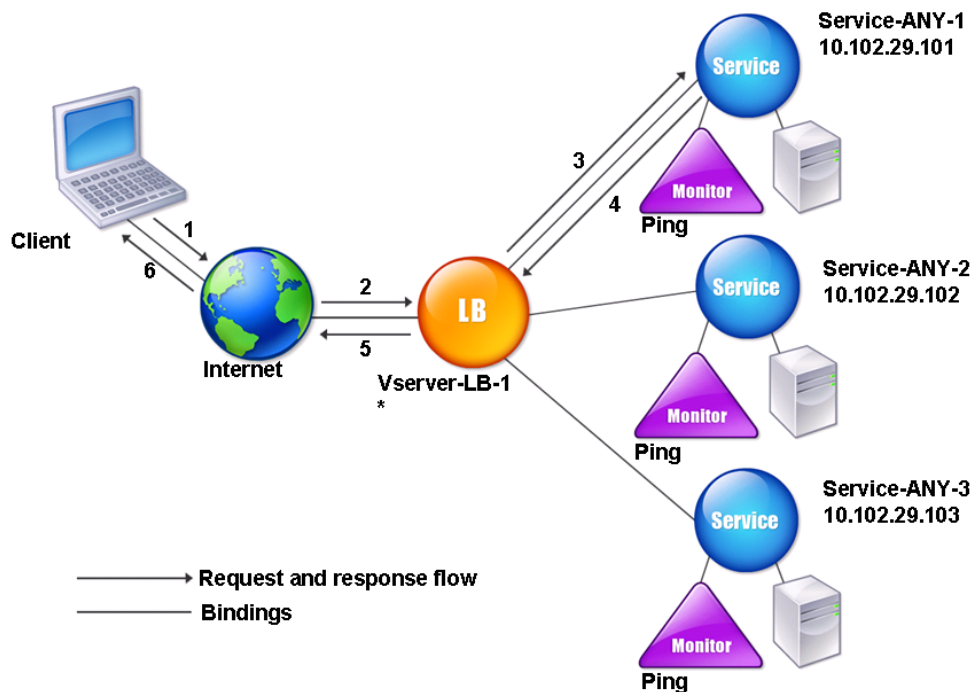

Entity type	Name	IP address	Port	Protocol
Virtual server	Vserver-LB-1	*	*	ANY
Services	Service-ANY-1	10.102.29.101	*	ANY

Entity type	Name	IP address	Port	Protocol
	Service-ANY-2	10.102.29.102	*	ANY
	Service-ANY-3	10.102.29.103	*	ANY
Monitors	Ping	None	None	None

Note: You can use inline mode or one-arm mode for an IDS load balancing setup.

The following diagram shows the load balancing entities and values of the parameters to be configured on the appliance.

Figure 2. Entity Model for Load Balancing IDS Servers

To configure an IDS load balancing setup, you must first enable MAC-based forwarding. Also disable layer 2 and layer 3 modes on the appliance.

### To enable MAC-based forwarding by using the command line interface

At the command prompt, type:

```
1 enable ns mode <ConfigureMode>
2 <!--NeedCopy-->
```

**Example:**

```
1 enable ns mode MAC
2 <!--NeedCopy-->
```

**To enable MAC-based forwarding by using the configuration utility**

Navigate to **System > Settings > Configure Modes**, and select **MAC Based Forwarding**.

Next, see “[Setting Up Basic Load Balancing](#)”, to configure a basic load balancing setup.

After you configure the basic load balancing setup, you must customize it for IDS by configuring a supported load balancing method (such as the SRCIPDESTIP Hash method on a sessionless virtual server) and enabling MAC mode. The appliance does not maintain the state of the connection and only forwards the packets to the IDS servers without processing them. The destination IP address and port remains unchanged because the virtual server is in the MAC mode.

**To configure a load balancing method and redirection mode for a sessionless virtual server by using the command line interface**

At the command prompt, type:

```
1 set lb vsrver <vServerName> -lbMethod <LBMethodOption> -m <
 RedirectionMode> -sessionless <Value>
2 <!--NeedCopy-->
```

**Example:**

```
1 set lb vsrver Vserver-LB-1 -lbMethod SourceIPDestIPHash -m MAC -
 sessionless enabled
2 <!--NeedCopy-->
```

**Note**

For a service that is bound to a virtual server on which the -m MAC option is enabled, you must bind a non-user monitor.

**To configure a load balancing method and redirection mode for a sessionless virtual server by using the configuration utility**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.

2. Open a virtual server and, in Redirection Mode, select MAC Based.
3. In Advanced Settings, click Methods, and select SRCIPDESTIPHASH. Click Traffic Settings, and select Sessionless Load Balancing.

### To set a service to use the source IP address by using the command line interface

At the command prompt, type:

```
1 set service <ServiceName> -usip <Value>
2 <!--NeedCopy-->
```

#### Example:

```
1 set service Service-ANY-1 -usip yes
2 <!--NeedCopy-->
```

### To set a service to use the source IP address by using the configuration utility

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Open a service, and in Settings select **Use Source IP Address**.

For USIP to function correctly, you must set it globally. For more information about configuring USIP globally, see [IP Addressing](#).

## Use case 11: Isolating network traffic using listen policies

May 2, 2023

#### Note

The traffic isolation solution using shadow virtual servers to simulate multitenant isolation is no more recommended. Alternatively, Citrix recommends you to use the NetScaler Admin Partitioning feature for such deployments. For more information, see [Admin Partitioning](#).

A common security requirement in a data center is to maintain network path isolation between the traffic of various applications or tenants. One application or tenant's traffic must be isolated from the traffic of other applications or tenants. For example, a financial services company would want to keep the traffic of its insurance department's applications separate from that of its financial services applications. In the past, this was easily achieved through physical separation of network service devices such as firewalls, load balancers, and IdP, and network monitoring and logical separation in the switching fabric.

As data center architectures evolve toward multitenant virtualized data centers, networking services in the aggregation layer of a data center are getting consolidated. This development has made network path isolation a critical component for network service devices and is driving the requirement for ADCs to be able to isolate traffic at the L4 to L7 levels. Furthermore, all the traffic of a particular tenant must go through a firewall before reaching the service layer.

To address the requirement of isolating the network paths, a NetScaler appliance identifies the network domains and controls the traffic across the domains. The NetScaler solution has two main components: listen policies and shadow virtual servers.

Each network path to be isolated is assigned a virtual server on which a listen policy is defined so that the virtual server listens to traffic only from a specified network domain.

To isolate the traffic, listen policies can be based on several client parameters or their combinations, and the policies can be assigned priorities. The following table lists the parameters that can be used in listen policies for identifying the traffic.

Category	Parameters
Ethernet protocol	Source MAC address, destination MAC address
Network interface	Network ID, receiving throughput, sending throughput, transmission throughput
IP protocol	Source IP address, destination IP address
IPv6 protocol	Source IPv6 address, destination IPv6 address
TCP protocol	Source port, destination port, maximum segment size, payload, and other options
UDP protocol	Source port, destination port
VLAN	ID

Table 1. Client Parameters Used to Define Listen Policies

On the NetScaler appliance, a virtual server is configured for each domain, with a listen policy specifying that the virtual server is to listen only to traffic for that domain. Also configured for each domain is a shadow load balancing virtual server, which listens to traffic destined for any domain. Each of the shadow load balancing virtual servers has a wildcard (\*) IP address and port, and its service type is set to ANY.

In each domain, a firewall for the domain is bound as a service to the shadow load balancing virtual server, which forwards all traffic through the firewall. Local traffic is forwarded to its destination, and traffic destined for another domain is forwarded to the firewall for that domain. The shadow load balancing virtual servers are configured for MAC mode redirection.

## How network paths are isolated

The following figure shows a typical traffic flow across domains. Consider the traffic flow within Network Domain 1, and between Network Domain 1 and Network Domain 2.

Figure 1. Isolating Network Path

### **Traffic within network domain 1**

Network Domain 1 has three VLANs: VLAN 11, VLAN110, and VLAN120. The following steps describe the traffic flow.

- A client from VLAN 11 sends a request for a service available from the service pool in VLAN 120.
- The load balancing virtual server LB-VIP1, which is configured to listen to traffic from VLAN 11, receives the request and forwards the request to VLAN 110. The virtual server in VLAN 110 forwards the request to shadow load balancing virtual server FW-VIP-1.
- FW-VIP-1, which is configured to listen to traffic from VLAN 110, receives the request and forwards it to VLAN 120.
- The load balancing virtual server in VLAN 120 load balances the request to one of the physical servers, App11, App12, or App13.
- The response sent by the physical server returns by the same path to the client in VLAN 11.

This configuration ensures that traffic is always segregated inside the NetScaler for all the traffic that originates from a client.

### **Traffic between network domain 1 and network domain 2**

Network Domain 1 has three VLANs: VLAN 11, VLAN 110, and VLAN 120. Network Domain 2 also has three VLANs: VLAN 22, VLAN 210, and VLAN 220. The following steps describe the traffic flow from VLAN 11 to VLAN 22.

- A client from VLAN 11, which belongs to Network Domain 1, sends a request for a service available from the service pool in VLAN 220, which belongs to the Network Domain 2.
- In Network Domain 1, the load balancing virtual server LB-VIP1, which is configured to listen to traffic from VLAN 11, receives the request and forwards the request to VLAN 110.
- Shadow load balancing virtual server FW-VIP-1, which is configured to listen to VLAN 110 traffic destined to any other domain, receives the request and forwards it to firewall virtual server FW-VIP-2 because the request is destined to a physical server in Network Domain 2.
- In Network Domain 2, FW-VIP-2 forwards the request to VLAN 220.
- The load balancing virtual server in VLAN 220 load balances the request to one of the physical servers, App21, App22, or App23.
- The response sent by the physical server returns by the same path through the firewall in Network Domain 2 and then to Network Domain 1 to reach the client in VLAN 11.

### **Configuration Steps**

To configure network path isolation by using listen policies, do the following:

- Add listen policy expressions. Each expression specifies a domain to which traffic is destined. You can use the VLAN ID or other parameters to identify the traffic.
- For each network domain, configure two virtual servers as follows:
  - Create a load balancing virtual server for which you specify a listen policy that identifies the traffic destined for this domain. You can specify the name of an expression created earlier, or you can create an expression while creating the virtual server.
  - Create another load balancing virtual server, referred to as shadow virtual server, for which you specify a listen policy expression that applies to traffic destined for any domain. On this virtual server, set the service type to ANY and the IP address and port to an asterisk (\*). Enable MAC-based forwarding on this virtual server.
  - Enable the L2 Connection option on both the virtual servers.  
Generally, to identify a connection, the NetScaler appliance uses the 4-tuple of client IP address, client port, destination IP address, and destination port. When you enable the L2 Connection option, the Layer 2 parameters of the connection (channel number, MAC address, and VLAN ID) are used in addition to the normal 4-tuple.
- Add services representing the server pools in the domain, and bind them to the virtual server.
- Configure the firewall for each domain as a service, and bind all the firewall services to the shadow virtual server.

### To isolate network traffic by using the command line interface

At the command prompt, type the following commands:

```
1 add policy expression <expressionName> <listenPolicyExpression>
2
3 add lb vserver <name> <serviceType> <ip> <port> -l2conn ON -
 listenPolicy <expressionName>
4 <!--NeedCopy-->
```

Add a load balancing virtual server for each domain. This virtual server is for traffic of the same domain.

```
1 add lb vserver <name> ANY * * -l2conn ON -m MAC -listenPolicy <
 expressionName>
2 <!--NeedCopy-->
```

Add a shadow load balancing virtual server for each domain. This virtual server is for traffic of other domains.

#### Example:

```
1 add policy expression e110 client.vlan.id==110
2 add policy expression e210 client.vlan.id==210
```

```
3 add policy expression e310 client.vlan.id==310
4 add policy expression e11 client.vlan.id==11
5 add policy expression e22 client.vlan.id==22
6 add policy expression e33 client.vlan.id==33
7
8 add lb vserver LB-VIP1 HTTP 10.1.1.254 80 -persistenceType NONE -
 listenPolicy e11
9 -cltTimeout 180 -l2Conn ON
10
11 add lb vserver LB-VIP2 HTTP 10.2.2.254 80 -persistenceType NONE -
 listenPolicy e22
12 -cltTimeout 180 -l2Conn ON
13
14 add lb vserver LB-VIP3 HTTP 10.3.3.254 80 -persistenceType NONE -
 listenPolicy e33
15 -cltTimeout 180 -l2Conn ON
16
17
18 add lb vserver FW-VIP-1 ANY * * -persistenceType NONE -lbMethod
 ROUNDROBIN - listenPolicy e110 -Listenpriority 1 -m MAC -cltTimeout
 120
19
20 add lb vserver FW-VIP-2 ANY * * -persistenceType NONE -lbMethod
 ROUNDROBIN - listenPolicy e210 -Listenpriority 2 -m MAC -cltTimeout
 120
21
22 add lb vserver FW-VIP-3 ANY * * -persistenceType NONE -lbMethod
 ROUNDROBIN - listenPolicy e310 -Listenpriority 3 -m MAC -cltTimeout
 120
23
24
25 add service RD-1 10.1.1.1 ANY * -gslb NONE -maxClient 0 -maxReq 0 -cip
 DISABLED
26 -usip NO -useproxyport NO -sp ON -cltTimeout 120 -svrTimeout 120 -CKA
 NO -TCPB NO -CMP NO
27
28 add service RD-2 10.2.2.1 ANY * -gslb NONE -maxClient 0 -maxReq 0 -cip
 DISABLED
29 -usip NO -useproxyport NO -sp ON -cltTimeout 120 -svrTimeout 120 -CKA
 NO -TCPB NO -CMP NO
30
31 add service RD-3 10.3.3.1 ANY * -gslb NONE -maxClient 0 -maxReq 0 -cip
 DISABLED
32 -usip NO -useproxyport NO -sp ON -cltTimeout 120 -svrTimeout 120 -CKA
 NO -TCPB NO -CMP NO
33
34
35 bind lb vserver FW-VIP-1 RD-1
36
37 bind lb vserver FW-VIP-2 RD-2
38
39 bind lb vserver FW-VIP-3 RD-3
40 <!--NeedCopy-->
```

### To isolate network traffic by using the configuration utility

1. Add services representing the servers, as described in [Creating a Service](#).
2. Add each firewall as a service:
  - a) Navigate to **Traffic Management > Load Balancing > Services**.
  - b) Create a service, specifying the protocol as ANY, server as firewall's IP address, and port as 80.
3. Configure a load balancing virtual server.
4. Configure the shadow load balancing virtual server.
5. For each network domain, repeat steps 3 and 4.
6. From the Load Balancing Virtual Servers pane, open the virtual servers that you created and verify the settings.

## Use case 12: Configure Citrix Virtual Desktops for load balancing

May 2, 2023

For an improved performance in the delivery of virtual desktop applications, you can integrate the NetScaler appliance with Citrix Virtual Desktops and use the NetScaler load balancing feature to distribute the load across the Desktop Delivery Controller (DDC) servers.

Generally, you use Citrix Virtual Desktops in situations where applications are not compatible with running on a terminal server or virtual apps, or if each virtual desktop has unique requirements. In such cases, you need one desktop host for each user that connects. However, the hosts can be pooled so that you need only one host for each currently connected user.

The core application service deployed for Citrix Virtual Desktops is the Desktop Delivery Controller (DDC). The DDC is installed on a server, and its main function is to register desktop hosts and broker client connections to them.

The DDC also authenticates users and manages the assembly of the users' virtual desktop environments by controlling the state of the desktops, and starting and stopping the desktops.

Generally, multiple DDCs are installed to enhance availability.

The following figure shows the topology of a NetScaler appliance working with Citrix Virtual Desktops.

**Note:**

Although you can use the HTTP protocol, we recommend that you use SSL for communication between the client and the NetScaler appliance. You can use the HTTP protocol for communication between the NetScaler and the DDC servers even though you use the SSL protocol for communication with the client.

**To configure load balancing for Citrix Virtual Desktops by using the GUI**

1. Create a service.
  - a) Navigate to **Configuration > Traffic Management > Load Balancing > Services** and click **Add**.
  - b) Create a service by specifying a name, an IP address, a port, and a protocol type and then click **OK**.
2. Create a load balancing virtual server.

- a) Navigate to **Configuration > Traffic Management > Load Balancing > Virtual Servers** and click **Add**.
  - b) Create a virtual server by specifying a name, an IP address, a port, and a protocol type and then click **OK**.
3. Bind the service to the load balancing virtual server.
  4. Navigate to **Configuration > Traffic Management > Load Balancing > Virtual Servers** and select a server.
    - a) Click **Edit**.
    - b) In the **Services and Service Groups**, click **>** and click **Add Binding**.
    - c) Select the service that you want to bind and enter the weight value.
    - d) Click **Bind**.

### To configure load balancing for Citrix Virtual Desktops by using the command line interface

- To create a service, at the command prompt, type:

```
1 add service <name> <serverName> <serviceType> <port>
2 <!--NeedCopy-->
```

#### Example:

```
1 add service Service-HTTP-1 192.0.2.5 HTTP 80
2 <!--NeedCopy-->
```

- To create a virtual server, at the command prompt, type:

```
1 add lb vserver <name> <serviceType> <ip> <port>
2 <!--NeedCopy-->
```

#### Example:

**add lb vserver** Vserver-LB-1 HTTP 10.102.29.60 80

- To bind a service to a load balancing virtual server, at the command prompt, type:

```
1 bind lb vserver <name> <serviceName>
2 <!--NeedCopy-->
```

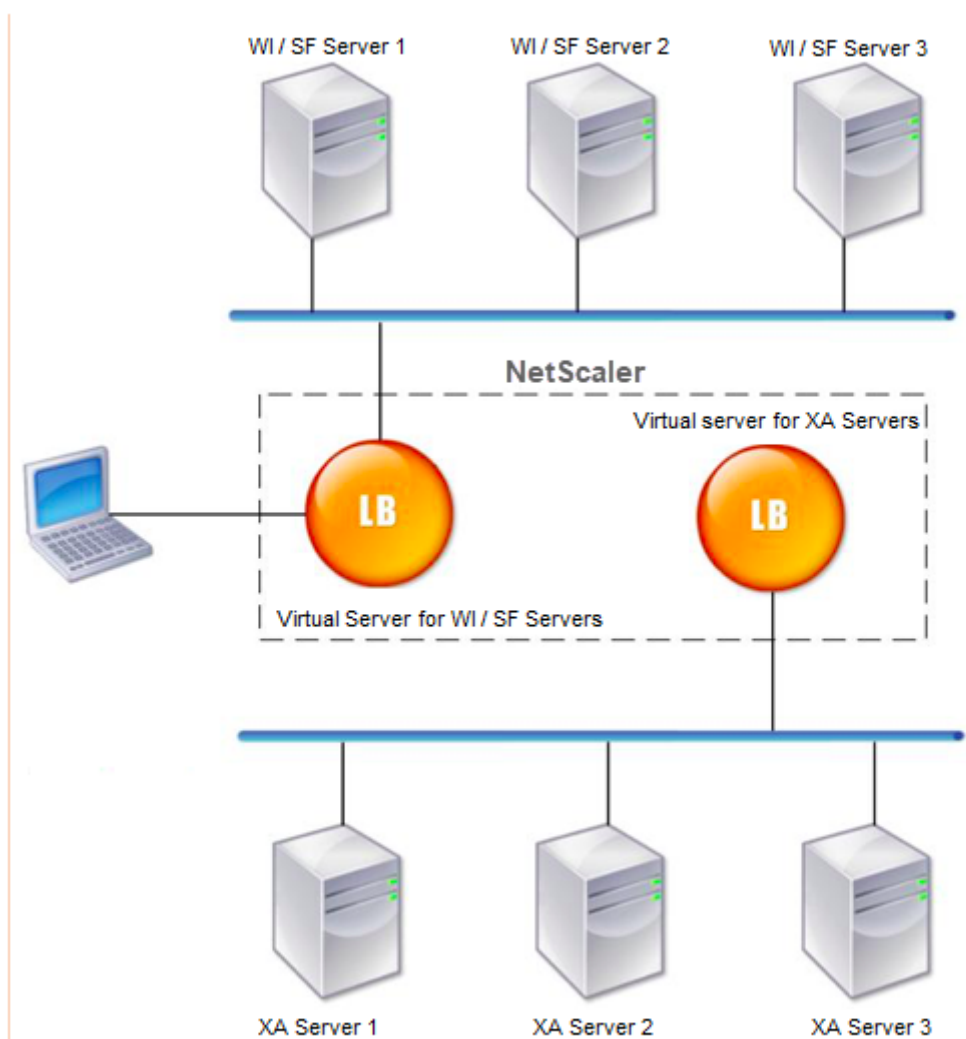

#### Example:

```
1 bind lb vserver Vserver-LB-1 Service-HTTP-1
2 <!--NeedCopy-->
```

## Use case 13: Configure Citrix Virtual Apps for load balancing

May 2, 2023

For efficient delivery of applications, you can integrate the NetScaler appliance with Citrix Virtual Apps and use the NetScaler load balancing feature to distribute the load across the Citrix Virtual Apps server farms. The following figure is a topology diagram of such a setup.

The Web Interface servers provide secure access to Citrix Virtual Apps application resources through the user’s Web browser. The Web Interface client presents to the users all the resources, such as applications, content, and desktops that are made available in the Citrix Virtual Apps server farms. Users can access the published resources through a standard Web browser or through the Citrix online plug-in.

The Web browser on the user's device sends information to the Web server, which communicates with the servers on the server farm to provide the user with access to the resources.

The Web Interface and the XML Broker are complementary services. The Web Interface provides users with access to applications, and the XML Broker evaluates the user's permissions to determine which applications appear in the Web Interface.

The XML service is installed on all the servers in the server farm. The XML service specified in the Web Interface functions as an XML broker. Based on the user credentials passed by the Web Interface server, the XML Broker server sends a list of applications accessible to the user.

In large enterprises where multiple Web Interface servers and XML Broker servers are deployed, Citrix recommends load balancing these servers by using the NetScaler appliance. Configure one virtual server to load balance the Web Interface servers and another for the XML Broker servers. The load balancing method and other features can be configured on the virtual server as required.

#### Note

Although you can use the HTTP protocol, Citrix recommends that you use SSL for communication between the client and the NetScaler. You can use the HTTP protocol for communication between the NetScaler and the WI servers even though you use the SSL protocol for communication with the client.

### To configure load balancing for Citrix Virtual Apps by using the GUI

1. Create a service.
  - a) Navigate to **Configuration > Traffic Management > Load Balancing > Services** and click **Add**.
  - b) Create a service by specifying a name, an IP address, a port, and a protocol type and then click **OK**.
2. Create a load balancing virtual server.
  - a) Navigate to **Configuration > Traffic Management > Load Balancing > Virtual Servers** and click **Add**.
  - b) Create a virtual server by specifying a name, an IP address, a port, and a protocol type and then click **OK**.
3. Bind the service to the load balancing virtual server.
4. Navigate to **Configuration > Traffic Management > Load Balancing > Virtual Servers** and select a server.
  - a) Click **Edit**.
  - b) In the **Services and Service Groups**, click **>** and click **Add Binding**.

- c) Select the service you want to bind and enter the weight value.
- d) Click **Bind**.

## To configure load balancing for Citrix Virtual Apps by using the command line interface

- To create a service, at the command prompt, type:

```
1 add service <name> <serverName> <serviceType> <port>
2 <!--NeedCopy-->
```

### Example:

```
1 add service Service-HTTP-1 192.0.2.5 HTTP 80
2 <!--NeedCopy-->
```

- To create a virtual server, at the command prompt, type:

```
1 add lb vserver <name> <serviceType> <ip> <port>
2 <!--NeedCopy-->
```

### Example:

```
1 add lb vserver Vserver-LB-1 HTTP 10.102.29.60 80
2 <!--NeedCopy-->
```

- To bind a service to a load balancing virtual server, at the command prompt, type:

```
1 bind lb vserver <name> <serviceName>
2 <!--NeedCopy-->
```

### Example:

```
1 bind lb vserver Vserver-LB-1 Service-HTTP-1
2 <!--NeedCopy-->
```

## Use case 14: ShareFile wizard for load balancing Citrix ShareFile

May 2, 2023

You can configure load balancing for Citrix ShareFile using the wizard. The Citrix ShareFile wizard helps in setting up the load balancing configuration for the ShareFile site based on the type of content requested. The content switching server directs the request based on whether it is a StorageZone, CIFS, or a SharePoint request. The content switching is based on policies. The wizard auto generates the policies to identify whether the request is for StorageZone, CIFS, or SharePoint. The

content switching virtual server uses these policies to direct the request to the correct load balancing server.

A typical data flow can be depicted as shown in the following diagram.

Figure 1. ShareFile Data Load Balancing

You can view the load balancing virtual servers that the ShareFile wizard creates by navigating to **Traffic Management > Virtual Servers** and **Services > Virtual Servers**. You cannot manually remove the virtual servers created using the ShareFile wizard. Use the wizard to remove the virtual servers.

NetScaler uses the LDAP authentication for SharePoint or CIFS request. Hash authentication is used for authenticating requests for StorageZones.

### To configure a NetScaler appliance for load balancing Citrix ShareFile

1. In the navigation pane, click **Traffic Management**.
2. Under **Citrix ShareFile** section, click **Setup NetScaler for ShareFile**.
3. On the **Setup Content Switching for ShareFile** page, provide the following information:
  - IP Address: IP address of the content switching virtual server.
  - Name: Name of the content switching virtual server.
  - If you want to set up load balancing for CIFS or SharePoint, click the **StorageZone Connector for Network File Shares/SharePoint** check box and then click **Continue**. By default, the **ShareFile Data** check box is selected.

#### ← Setup Content Switching for ShareFile

**Load Balancing Virtual Server Configuration**

Enter a public IP address and a name for the content switching virtual server.

IP Address\*

10 . 20 . 30 . 4
i

Name\*

ShareFile

ShareFile Data

StorageZones Connector for network file shares and SharePoint

Continue

Cancel

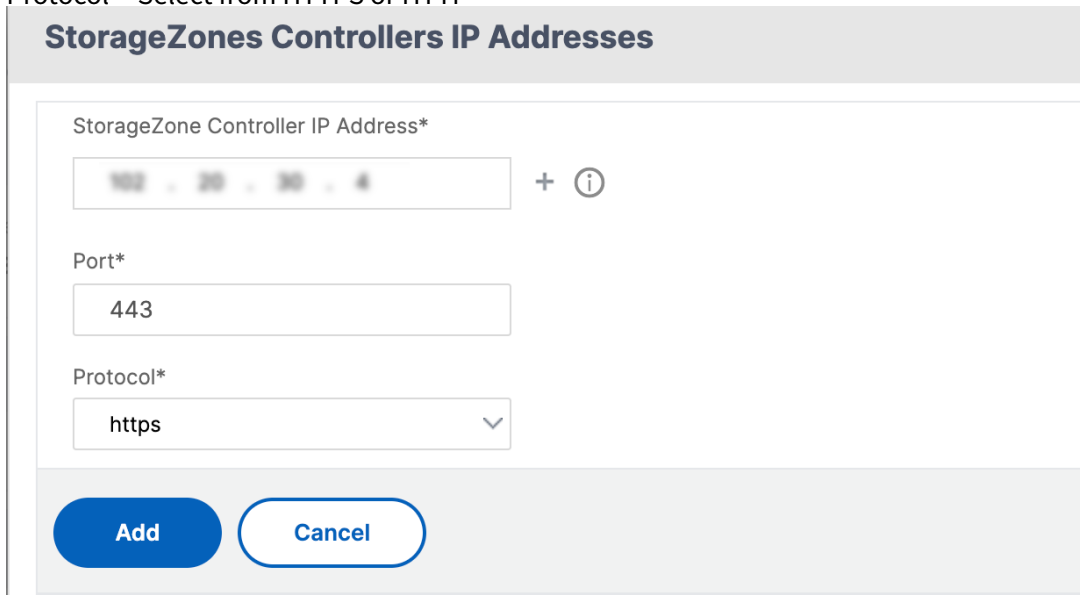

4. Provide a valid certificate. If you have a certificate, click **Choose Certificate** and from the drop-down list select the certificate. If you have to install a certificate, click **Install Certificate** and pro-

vide the Certificate-Key pair.

5. Click **Continue**.
6. In the **Add New StorageZone Controller** dialog box, specify the values of the following parameters:

- StorageZone Controller IP Address—IP address
- Port—Port number. The default value is 443.
- Protocol—Select from HTTPS or HTTP

7. Click **Create** and then click **Done**. The wizard automatically creates a service and autogenerates the name of the service.
8. If you chose load balancing for CIFS or SharePoint in step 4.c, then specify the values for LDAP Authentication Settings:

- NetScaler AAA virtual server IP Address—IP address of NetScaler AAA virtual server
- LDAP Server IP Address—IP Address of the LDAP server
- Port—Port number. The default value is 389
- Timeout—The time-out value in minutes
- Single sign-on Domain—Single sign-on domain name
- Base DN—Base domain name
- Administrator Bind DN—LDAP account name with the domain name, for example, admin-

strator@domainname.com

- Logon Name—Logon name is the sAMAccountName
- Password and Confirm Password—Enter the password and confirm the password

### LDAP Authentication Settings

**Configure New**

AAA Virtual Server IP Address\*

Password\*

Confirm Password\*  
 ⓘ

9. Click **Continue** and then click **Done**.

### To remove load balancing configuration for ShareFile

1. In the navigation pane, click **Traffic Management**.
2. Under **Citrix ShareFile** section, click **Remove ShareFile Configuration**.

## Use case 15: Configure layer 4 load balancing on the NetScaler appliance

October 8, 2023

The layer 4 load balancer (TCP and UDP ports) uses information provided in the networking transport layer for routing client requests across the server groups.

When a layer 4 connection is established between a client and a server, it has a packet view of traffic exchanged between them. The layer 4 load balancer makes its routing decisions based on the address information extracted from the first few packets in the TCP stream, and doesn't inspect the packet content. Therefore, the layer 4 load balancing is also called as connection-based load balancing.

The layer 4 load balancer monitors the health of a server. Traffic is not routed to the server if it is DOWN.

The layer 4 load balancing is useful for various applications that uses TCP or UDP payloads. Such protocols exchange data as TCP payload and don't have a specific structure to follow.

### To configure layer 4 load balancing using the command line interface

At the command prompt, type:

```
1 add service <name> <serverName> <serviceType> <port>
2 add lb vserver <name> <serviceType> <ip> <port>
3 bind lb vserver <name> <serviceName>
4 <!--NeedCopy-->
```

#### Example:

```
1 add service TCPservice 192.0.2.3 TCP 1
2 add lb vserver TCPserver TCP 192.0.2.4 1
3 bind lb vserver TCPserver TCPservice
4 <!--NeedCopy-->
```

## To configure layer 4 load balancing using the GUI

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Click **Add** to create a service.
3. Specify the required details in **Service Name** and **IP Address**.
4. Select either **TCP** or **UDP** in **Protocol**.
5. Click **OK**.
6. Click **Done**.

A service is created.

When you create a service using UDP as the transport layer protocol, a ping monitor (built-in monitor) is automatically bound to the service. When you create a service using TCP as the transport layer protocol, a **tcp\_default** monitor is automatically bound to the service.

For the load balancing setup, you can bind your service to a different type of monitor or multiple monitors. For advance monitoring requirements you can use the **tcp-ecv** monitor and configure the request and response messages.

7. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
  8. Click **Add** to create a new virtual server.
- When the load balancing is configured, you can connect to the load-balanced website, application, or server through the virtual server's IP address or FQDN.
9. Specify the required details in **Name**, **IP Address Type**, and **IP Address**.
  10. Select either **TCP** or **UDP** in **Protocol**.
  11. Type a port number (0–1023 based on the type of service) in **Port**.
  12. Click **OK**.

13. Click **No Load Balancing Virtual Server Service Binding** in **Services and Service Groups**.
14. In the **Service Binding** page, select **Click to Select** in **Select Service**.
15. Select the service to be bound and click **Select**.
16. Click **Bind** to bind the service to the virtual server.
17. Click **Continue**.
18. Click **Done**.

The layer 4 load balancing virtual server configuration is completed.

## Troubleshooting

May 2, 2023

If the load balancing does not work as expected after you have configured it, you can use some common tools to access NetScaler resources and diagnose the problem.

### Resources for Troubleshooting Load Balancing

For best results, use the following resources to troubleshoot a content switching issue on a NetScaler appliance:

- Latest ns.conf file
- Relevant `newslog` files
- Ethereal packet traces recorded on the appliance and relevant client, if possible
- The ns.log file

In addition to the above resources, the following tools expedite troubleshooting:

- A browser add-on tool that can display HTTP headers. This can be used to troubleshoot persistence related issues.
- The Wireshark application customized for the NetScaler trace files.

### Troubleshooting Load Balancing Issues

- **Issue**

CPU usage reaches 100% when a user monitor is bound to a service that is bound to a virtual server on which the -m MAC option is enabled.

- **Resolution**

Bind a non-user monitor to the service.

- **Issue**

I created a user script for monitoring, but it is not working.

- **Resolution**

Check the number of arguments in the script. The limit is 512. A script with more than 512 arguments might not work properly. Use the nsumon-debug.pl script from the CLI to debug the script.

- **Issue**

I see a lot of monitor probes, and they seem to be increasing the network traffic unnecessarily. Is there a way to off the monitor probes?

**Resolution**

You can set off the monitor probe connections, by disabling the monitor or setting the value of the healthMonitor parameter in the set service command to NO. With the NO option, the appliance shows the service as UP at all times.

- **Issue**

I have set up monitors for services, but connections are still directed to servers that are DOWN.

**Resolution**

You probably need to decrease the monitor probe intervals. The NetScaler appliance does not detect the DOWN state until the monitor sends a probe.

- **Issue**

A metric bound to the monitor is present in the local and custom metric tables.

**Resolution**

Add the local prefix to the metric name if the metric is chosen from the local metric table. However, if the metric is chosen from the custom table, you don't need to add any prefix.

- **Issue**

The monitor probes to a service are not reaching the service.

**Resolution**

Check whether you have set a limit on the number of connections for a service. If yes, exempt monitor-probe connections from this limit by setting the monitorSkipMaxClient parameter to ENABLED.

- **Issue**

I am able to ping the servers, but the state of the services is always shown as DOWN.

**Resolution**

Check the type of monitors configured. For example, if a server is not configured for SSL and you use an HTTPS monitor, the state of the service is marked as DOWN. In this case using a TCP monitor must change the state of the service to UP.

- **Issue**

Setting a weight for load monitors does not help in deciding the state of the service.

**Resolution**

Load monitors cannot decide the state of the service. Therefore, setting a weight on the load monitors is inappropriate.

- **Issue**

A service is not stable.

**Resolution**

Consider troubleshooting the following components:

- Verify that a correct server is bound to the service.
- Verify the type of monitor bound to the service.
- Verify the reasons for the monitor failures. You can open a service from the Services page and verify the details for the number of probes, failures, and last response status for the monitor in the Monitors tab of the Configure service dialog box. To display the details, click the monitor configured.
- If it is a custom monitor, bind a TCP or ping monitor to the service and verify the status of the monitor. If this resolves the issue, there is some problem with the custom monitor and the monitor requires further investigation.
- You can record packet traces on the NetScaler appliance and verify the monitor probes and server response for further investigation.

- **Issue**

The virtual IP (VIP) address is not stable or its status is displayed as DOWN.

**Resolution**

Consider troubleshooting the following components:

- Verify that the load balancing feature is licensed.
- Verify that the feature is enabled.
- Verify that an appropriate service is bound to the virtual server.
- If the status of the VIP address is displayed as DOWN, verify that an administrator has enabled the service. If it is not, the status of the service must be Out-Of-Service. In such a case, you must enable the service and verify if the issue is resolved.
- Verify the service(s) bound to the virtual server and complete the troubleshooting steps mentioned for service not stable issue.
- If the VIP address is not stable, all the services bound to the virtual server must fail. Therefore, verify if all the services are failing at the same time. If it is so, there is a network issue between the NetScaler appliance and the servers.

- **Issue**

The site is experiencing uneven load balancing.

**Resolution**

Consider troubleshooting the following components:

- Verify the load balancing method configured on the appliance.
- Verify weights associated with the services are as expected.
- If the load balancing method is other than round robin, verify the number of connections to the server logged in the `newslog` file. You can run the following command to verify the number on the `newslog` file:

```
nsconmsg -K <newslog_file> -s ConLb=2 -d oldconmsg
```

Verify the services for the specific virtual server and check for the Response time, Open Established connections (OE), number of requests, Persistent requests and persistent rate (P) to troubleshoot the issue further.

- If the load balancing method is round robin, verify the persistent requests as mentioned in the preceding step. Additionally, verify if the service is not stable. If it is not, complete the troubleshooting steps mentioned for service not stable issue
- Verify if persistency is configured on the appliance.
- Verify if any service is not stable. If yes, complete the troubleshooting steps mentioned for service not stable issue.

**• Issue**

The service status is displayed as DOWN.

**Resolution**

Consider troubleshooting the following components:

- Verify whether a SNIP address is configured.
- Verify that appropriate monitors are bound to the service.
- If custom monitors are bound to the service, bind a TCP or ping monitor to the service and verify the status of the monitor. If this resolves the issue, there is some problem with the custom monitor and the monitor requires further investigation.
- Verify if the status of service is displayed as DOWN for the server that is in another subnet. If yes, verify if Use Subnet IP (USNIP) resolves the issue because this can be due to the MIP address being unable to communicate to the server.

**• Issue**

There is an issue with the response time.

**Resolution**

Consider troubleshooting the following components:

- Verify the server response time from the service stats either by running the following command:

```
nsconmsg -K <newslog_file> -s ConLb=2 -d oldconmsg
```

- Check for service not stable and service status being displayed as DOWN issues.

- **Issue**

One of the servers is serving more requests than the other load balanced servers.

**Resolution**

Consider troubleshooting the following components:

- Verify the load balancing method. Use the round robin method to distribute the client request equally regardless of the load on the servers.
- Determine whether persistence is enabled for the load balancing configuration. If persistence is enabled, a given server might be carrying a heavier load to maintain its session, especially if the persistence sessions are long.
- Verify whether weights are assigned to each service. Assigning proper weights helps in proper load distribution.

- **Issue**

Connections to a specific load balanced server are stalled. For example, all connections to one Outlook server might be stalled.

**Resolution**

Consider troubleshooting the following components:

- Verify the load balance method. If it is round robin, consider changing the method to least connections.
- Consider reducing the monitor time-out period. A shorter timeout period helps in marking a service as DOWN sooner, which would help in directing the traffic to the server which is functional.
- If the connections are stalled for a long period, a surge queue might build. Consider flushing the surge queue to avoid a sudden spike in load on the server.
- If the servers are working at their maximum level, consider adding a new server for better performance.

- **Issue**

A majority of the connections are directed to a particular server, even when the least connections method for load balancing is configured.

**Resolution**

Determine whether persistence is configured and is of type source IP. If source IP persistence is configured even with the least connections method, the requests go to a specific server. The server's IP address is required for maintaining the session information. Consider using HTTP Cookies based persistence.

- **Troubleshooting Tips**

For other issues, consider the following tips to troubleshoot an issue not listed above:

- If multiple load monitors are bound to a service, the load on the service is the sum of all the values on the load monitors bound to it. For load balancing to work properly, you must bind the same set of monitors to all the services.
- If you disable a load monitor bound to the service and the service is bound to a virtual server, the virtual server uses the round robin method for load balancing.
- When you bind a service to a virtual server where the load balancing method is CUSTOMLOAD and the service status is UP, the virtual server uses the initial round robin method for load balancing. It continues to be in round robin if the service has no custom load monitors, or if the status of at least one of the custom load monitors is not UP.
- All the services that are bound to a virtual server where the load balancing method is CUSTOMLOAD, the services must have load monitors bound to them.
- The CUSTOMLOAD load balancing method also follows the startup round robin.
- If you disable a metric-based binding and this is the last active metric, the specific virtual server uses the round robin method for load balancing. A metric is disabled by setting the metric threshold to zero.
- When a metric bound to a monitor crosses the threshold value, that particular service is not considered for load balancing. If all the services have reached the threshold, the virtual server uses the round robin method for load balancing and an error message "5xx - server busy error" is displayed.
- A maximum of 10 metrics from a custom table can be bound to the monitor.
- The OIDs must be scalar variables.
- For successful load balancing, the interval must be as low as possible. If the interval is high, the time period for retrieving the load value increases. As a result, load balancing takes place using improper values.
- A user cannot modify the local table.

## Load balancing FAQs

May 2, 2023

## **What are the various load balancing policies I can create on the NetScaler appliance**

You can create the following types of load balancing policies on the NetScaler appliance:

- Least Connections
- Round Robin
- Least response time
- Least bandwidth
- Least packets
- URL hashing
- Domain name hashing
- Source IP address hashing
- Destination IP address hashing
- Source IP - Destination IP hashing
- Token
- LRTM

## **Can I achieve the Web farm security by implementing load balancing using the NetScaler appliance?**

Yes. You can achieve Web farm security by implementing load balancing using the NetScaler appliance. NetScaler appliance enables you to implement the following options of the load balancing feature:

- **IP Address hiding:** Enables you to install the actual servers to be on private IP address space for security reasons and for IP address conservation. This process is transparent to the end-user because the NetScaler appliance accepts requests on behalf of the server. While in the address hiding mode, the appliance completely isolates the two networks. Therefore, a client can access a service running on the private subnet, such as FTP or a Telnet server, through a different VIP on the appliance for that service.
- **Port Mapping:** Enables the actual TCP services to be hosted on non-standard ports for security reasons. This process is transparent to the end-user as the NetScaler appliance accepts requests on behalf of the server on the standard advertised IP address and port number.

## **What are the various devices that I can use to load balance with a NetScaler appliance?**

You can load balance the following devices with a NetScaler appliance:

- Server farms
- Caches or Reverse Proxies
- Firewall devices

- Intrusion detection systems
- SSL offload devices
- Compression devices
- Content Inspection servers

### **Why do I implement the load balancing feature for the website?**

You can implement the Load balancing feature for the website to take the following advantages:

- Reduce the response time: When you implement the load balancing feature for the website, one of the major benefits is the boost you can look forward to in load time. With two or more servers sharing the load of the web traffic, each of the servers runs less traffic load than a single server alone. This means there are more resources available to fulfill the client requests. This results in a faster website.
- Redundancy: Implementing the load balancing feature introduces a bit of redundancy. For example, if the website is balanced across three servers and one of them does not respond at all, the other two can keep running and the website visitors do not even notice any downtime. Any load balancing solution immediately stops sending traffic to the back-end server that is not available.

### **Why do I need to disable the Mac Based Forwarding (MBF) option for Link Load Balancing (LLB)?**

- If you enable the MBF option, the NetScaler appliance considers that the incoming traffic from the client and the outgoing traffic to the same client flow through the same upstream router. However, the LLB feature requires the best path to be chosen for the return traffic.
- Enabling the MBF option breaks this topology design by sending the outgoing traffic through the router that forwarded the incoming client traffic.

## **Networking**

May 2, 2023

The following topics provide a conceptual reference and instructions for configuring the various networking components on the NetScaler appliance.

IP Addressing	Learn the various types of NetScaler owned IP addresses and how to create, customize, and remove them.
Interfaces	Configure some of the basic network configurations that must be done to get started.
Access Control Lists (ACLs)	Configure the different types of Access Control Lists and how to create, customize, and remove them.
IP Routing	Learn and configure the routing functionality of the NetScaler appliance, both static and dynamic.
Internet Protocol version 6 (IPv6)	Learn how the NetScaler appliance supports IPv6.
Traffic Domains	Learn and configure traffic domains to segment network traffic for different applications.
VXLAN	Learn and configure VXLANs to meet the scalability needs in your datacenter.

---

## IP Addressing

May 2, 2023

Before you can configure the NetScaler appliance, you must assign the NSIP address, also known as the Management IP address. You can also create other NetScaler-owned IP addresses for abstracting servers and establishing connections with the servers. In this type of configuration, the appliance serves as a proxy for the abstracted servers. You can also proxy connections by using network address translations (INAT and RNAT). When proxying connections, the appliance can behave either as a bridging (Layer 2) device or as a packet forwarding (Layer 3) device. To make packet forwarding more efficient, you can configure static ARP entries. For IPv6, you can configure neighbor discovery (ND).

## Configuring NetScaler-owned IP addresses

May 2, 2023

The NetScaler-owned IP addresses—NSIP address, Virtual IP Addresses (VIPs), Subnet IP Addresses (SNIPs), and Global Server Load Balancing Site IP Addresses (GSLBIPs)—exist only on the NetScaler appliance. The NSIP uniquely identifies the NetScaler on your network, and it provides access to the appliance. A VIP is a public IP address to which a client sends requests. The NetScaler terminates the client connection at the VIP and initiates a connection with a server. This new connection uses a SNIP or a MIP as the source IP address for packets forwarded to the server. If you have multiple data centers that are geographically distributed, each data center can be identified by a unique GSLBIP. You can configure some NetScaler-owned IP addresses to provide access for management applications.

## Configuring the NSIP address

May 2, 2023

The NSIP address is the IP address at which you access the NetScaler appliance for management purposes. The appliance can have only one NSIP, which is also called the management IP address. You must add this IP address when you configure the NetScaler for the first time. You cannot remove an NSIP address. For security reasons, the NSIP should be a non-routable IP address on your organization's LAN.

If you modify this address, you must reboot the NetScaler appliance. If the subnet address of the new NSIP address is different from the previous one, you must add a default route for this subnet so that the new NSIP address becomes reachable from other networks on the LAN.

### Important

Configuring the NSIP address is mandatory.

Changing the NSIP address of a NetScaler appliance consists of the following tasks:

- Change the NSIP address.
- Add a default route for the subnet address of the NSIP address, if one is not present.
- Save the configuration.
- Restart the appliance.

## Command Line Procedures

To change the NSIP address by using the CLI:

At the command prompt, type:

- **set ns config -IPAddress** <ip\_addr> **-netmask** <netmask>
- **show ns config**

To add a default route by using the CLI:

At the command prompt, type:

- **add route 0 0** <gateway IP address>
- **show route**

To save the configuration by using the CLI:

At the command prompt, type:

- **save config**

To restart the NetScaler appliance by using the CLI:

At the command prompt, type:

- **reboot**

## GUI Procedures

To configure the NSIP address by using the GUI:

1. Click the gear icon in the top-right corner of the **Configuration** page.
2. Click the **NSIP address** pane.
3. On the **NSIP address** page, set the following parameters, and then click **Done**:
  - NSIP address
  - Netmask

To add a default route by using the GUI:

Navigate to **System > Network > Routes** and, on the **Basic** tab, add a default route with the following parameter settings, and then click **Create**.

- Network (set to zero)
- Netmask (set to zero)
- Gateway (IP address of the gateway)

To restart the NetScaler by using the GUI:

1. On the **System Information** tab page of the **System** node, click **Reboot**.
2. When prompted to reboot, select **Save Configuration** to make sure that you do not lose any configurations.

## Sample configuration

In the following example, the NSIP address of a NetScaler appliance is changed to 192.0.2.90, which has a different subnet address (192.0.2.0/24) than the previous NSIP address. Therefore, a default route is added for this subnet, so that the new NSIP address becomes reachable from other networks.

```
1 > set nsconfig -ipAddress 192.0.2.90 -netmask 255.255.255.0
2
3 Warning: The configuration must be saved and the system rebooted for
 these settings to take effect
4 > add route 0 0 192.0.2.1
5
6 Warning: The configuration must be saved and the system rebooted for
 these settings to take effect
7 > save config
8
9 Done
10 > reboot
```

## Configuring and Managing Virtual IP (VIP) Addresses

May 2, 2023

Configuration of a virtual server IP (VIP) address is not mandatory during initial configuration of the NetScaler. When you configure load balancing, you assign VIP addresses to virtual servers.

For more information about configuring a load balancing setup, see [Load Balancing](#).

In some situations, you need to customize VIP attributes or enable or disable a VIP address. A VIP address is usually associated with a virtual server, and some of the VIP attributes are customized to meet the requirements of the virtual server. You can host the same virtual server on multiple NetScaler appliances residing on the same broadcast domain, by using ARP and ICMP attributes. After you add a VIP (or any IP address), the appliance sends, and then responds to, ARP requests. VIPs are the only NetScaler-owned IP addresses that can be disabled. When a VIP address is disabled, the virtual server using it goes down and does not respond to ARP, ICMP, or L4 service requests. As an alternative to creating VIP addresses one at a time, you can specify a consecutive range of VIP addresses.

To create a VIP address by using the CLI:

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type <type>
- show ns ip <IPAddress>

**Example:**

```
1 > add ns ip 10.102.29.59 255.255.255.0 -type VIP
2 Done
3 <!--NeedCopy-->
```

To create a range of VIP addresses by using the CLI:

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type <type>
- show ns ip <IPAddress>

**Example:**

```
1 > add ns ip 10.102.29.[60-64] 255.255.255.0 -type VIP
2 ip "10.102.29.60" added
3 ip "10.102.29.61" added
4 ip "10.102.29.62" added
5 ip "10.102.29.63" added
6 ip "10.102.29.64" added
7 Done
8 <!--NeedCopy-->
```

To enable or disable an IPv4 VIP address by using the CLI:

At the command prompt, type one of the following sets of commands to enable or disable a VIP and verify the configuration:

- enable ns ip <IPAddress>
- show ns ip <IPAddress>
- disable ns ip <IPAddress>
- show ns ip <IPAddress>

**Example:**

```
1 > enable ns ip 10.102.29.79
2 Done
3 > show ns ip 10.102.29.79
4
5 IP: 10.102.29.79
6 Netmask: 255.255.255.255
7 Type: VIP
8 state: Enabled
9 arp: Enabled
10 icmp: Enabled
11 vserver: Enabled
12 management access: Disabled
13 telnet: Disabled
14 ftp: Disabled
15 ssh: Disabled
16 gui: Disabled
```

```
17 snmp: Disabled
18 Restrict access: Disabled
19 dynamic routing: Disabled
20 hostroute: Disabled
21 Done
22 > disable ns ip 10.102.29.79
23 Done
24 > show ns ip 10.102.29.79
25
26 IP: 10.102.29.79
27 Netmask: 255.255.255.255
28 Type: VIP
29 state: Disabled
30 arp: Enabled
31 icmp: Enabled
32 vserver: Enabled
33 management access: Disabled
34 telnet: Disabled
35 ftp: Disabled
36 ssh: Disabled
37 gui: Disabled
38 snmp: Disabled
39 Restrict access: Disabled
40 dynamic routing: Disabled
41 hostroute: Disabled
42
43 Done
44 <!--NeedCopy-->
```

To configure a VIP address by using the GUI:

Navigate to **System > Network > IPs > IPV4s**, and add a new IP address or edit an existing address.

To create a range of VIP addresses by using the GUI:

1. Navigate to **System > Network > IPs > IPV4s**.
2. In the **Action** list, select **Add Range**.

To enable or disable a VIP address by using the GUI:

1. Navigate to **System > Network > IPs > IPV4s**.
2. Do one of the following:
  - Select a VIP address.
  - Hold down the **Ctrl** key and select multiple server address entries.
  - Hold down the **Shift** key and select a range of server address entries.
  - Select all the addresses by selecting the checkbox on the left side of the header row.
3. From the **Action** list, select **Disable** or **Enable**.

## Detecting a NetScaler Appliance in a UDP Load Balancing Setup through TTL Updates

The following table displays how a NetScaler appliance handles the TTL value of received packets in different functionalities.

Functionality	TTL value
Virtual Server	TTL is set to 255 when forwarding the request to the backend servers. TTL is decremented by 1 when forwarding the response to the client.
L2 Mode	TTL is not changed.
L3 Mode	TTL is set to 255.
INAT	TTL is set to 255 when forwarding the request to the backend server. TTL is decremented by 1 when forwarding the response to the client.

Some enterprises/scenarios running a monitoring application requires the NetScaler appliance of a load balancing setup to be detected as one of the hop in a traceroute. A NetScaler appliance of a load balancing setup is not detected in a traceroute because the appliance, by default, sets the TTL value to 255 instead of decrementing it when forwarding the request to a backend server.

To meet this requirement, **Decrement TTL** parameter of a VIP address can be used. This parameter applies to all UDP virtual servers using this VIP.

When you enable the **Decrement TTL** parameter of a VIP, the NetScaler appliance decrements the TTL value by 1 instead of setting it to 255 when forwarding requests, which are received on the UDP virtual servers that uses this VIP.

Monitoring applications using traceroute data can now detect the presence of a NetScaler appliance of a UDP load balancing setup.

### Before You Begin

Before you begin configuring a NetScaler appliance to be detected in a traceroute of a load balancing setup, note the following points:

- Decrement TTL parameter is supported only for UDP load balancing virtual servers.
- Decrement TTL parameter is supported for IPv4 VIP as well as IPv6 VIP (VIP6) addresses.
- Decrement TTL parameter is supported for standalone NetScaler appliances as well as for high availability (HA) and cluster setups.

## Configuration Steps

Configuring a NetScaler appliance to be detected in a traceroute of a UDP load balancing setup consists of the following tasks:

- Create a UDP load balancing configuration
- Enable the Decrement TTL parameter for the VIP address

## CLI Procedures

To enable the decrement TTL option for a VIP address by using the CLI:

- To enable the decrement TTL option for a VIP address while adding the VIP address, at the command prompt, type:
  - **add ns ip** <ip> <mask> **-type VIP -decrementTTL ENABLED**
  - **show ns ip** <VIP address>
- To enable the decrement TTL option for an existing VIP address, at the command prompt, type:
  - **set ns ip** <ip> <mask> **-decrementTTL ENABLED**
  - **show ns ip** <VIP address>

To enable the decrement TTL option for a VIP6 address by using the CLI:

- To enable the decrement TTL option for a VIP6 address while adding the VIP6 address, at the command prompt, type:
  - **add ns ip6** <IP6/prefix> <mask> **-type VIP -decrementTTL ENABLED**
  - **show ns ip6** <VIP6/prefix>
- To enable the decrement TTL option for an existing VIP6 address, at the command prompt, type:
  - **set ns ip6** <ip6/prefix> <mask> **-decrementTTL ENABLED**
  - **show ns ip6** <VIP6 address>

```
1 > add ns ip 203.0.113.30 -type VIP -decrementTTL ENABLED
2 Done
3
4 > add ns ip6 2001:DB8:5001::30 -type VIP -decrementTTL ENABLED
5 Done
6 <!--NeedCopy-->
```

## GUI Procedures

To enable the decrement TTL option for a VIP address by using the GUI:

Navigate to **System > Network > IPs > IPv4s**, and enable the **Decrement TTL** parameter while adding a new VIP address or editing an existing address.

To enable the decrement TTL option for a VIP6 address by using the GUI:

Navigate to **System > Network > IPs > IPv6s**, and enable the **Decrement TTL** parameter while adding a new VIP6 address or editing an existing address.

## Configuring ARP response Suppression for Virtual IP addresses (VIPs)

May 2, 2023

You can configure the NetScaler appliance to respond or not respond to ARP requests for a Virtual IP (VIP) address on the basis of the state of the virtual servers associated with that VIP.

For example, if virtual servers V1, of type HTTP, and V2, of type HTTPs, share VIP address 10.102.29.45 on a NetScaler appliance, you can configure the appliance to not respond to any ARP request for VIP 10.102.29.45 if both V1 and V2 are in the DOWN state.

The following three options are available for configuring ARP-response suppression for a virtual IP address.

- **NONE.** The NetScaler appliance responds to any ARP request for the VIP address, irrespective of the state of the virtual servers associated with the address.
- **ONE VSERVER.** The NetScaler appliance responds to any ARP request for the VIP address if at least one of the associated virtual servers is in UP state.
- **ALL VSERVER.** The NetScaler appliance responds to any ARP request for the VIP address if all of the associated virtual servers are in UP state.

Following table shows the sample behavior of NetScaler appliance for a VIP configured with two virtual servers:

Associated virtual servers for a VIP	STATE 1	STATE 2	STATE 3	STATE 4
<b>NONE</b>				
V1	UP	UP	DOWN	DOWN
V2	UP	DOWN	UP	DOWN
Respond to an ARP request for this VIP?	Yes	Yes	Yes	Yes
<b>ONE VSERVER</b>				

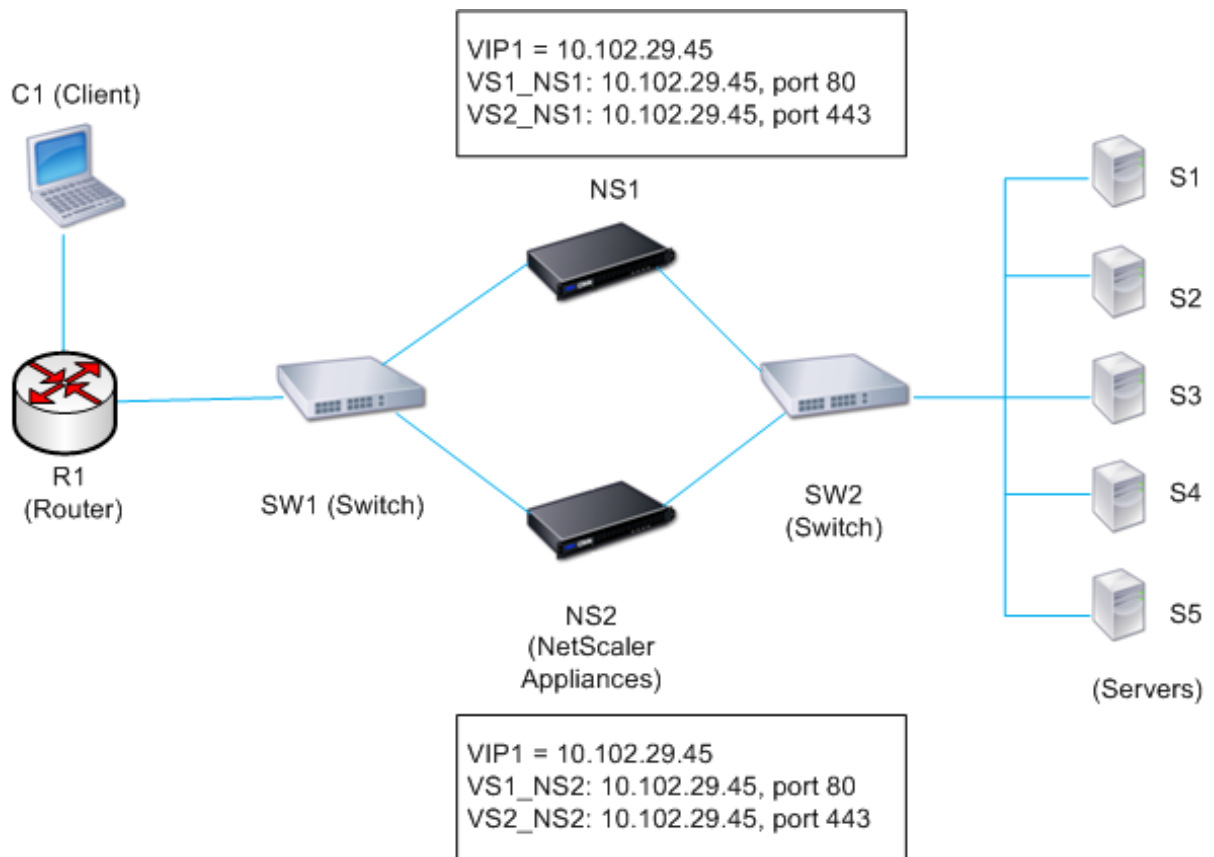

Associated virtual servers for a VIP	STATE 1	STATE 2	STATE 3	STATE 4
V1	UP	UP	DOWN	DOWN
V2	UP	DOWN	UP	DOWN
Respond to an ARP request for this VIP?	Yes	Yes	Yes	No
<b>ALL VSERVER</b>				
V1	UP	UP	DOWN	DOWN
V2	UP	DOWN	UP	DOWN
Respond to an ARP request for this VIP?	Yes	No	No	No

Consider an example where you want to test the performance of two virtual servers, V1 and V2, which have the same VIP address but are of different types and are each configured on NetScaler appliances NS1 and NS2. Let’s call the shared VIP address *VIP1*.

V1 load balances servers S1, S2, and S3. V2 load balances servers S4 and S5.

On both NS1 and NS2, for VIP1, the ARP suppression parameter is set to ALL\_VSERVER. If you want to test the performance of V1 and V2 on NS1, you must manually disable V1 and V2 on NS2, so that NS2 does not respond to any ARP request for VIP1.

Figure 1.

The execution flow is as follows:

1. Client C1 sends a request to V1. The request reaches R1.
2. R1 does not have an APR entry for the IP address (VIP1) of V1, so R1 broadcasts an ARP request for VIP1.
3. NS1 replies with source MAC address MAC1 and source IP address VIP1. NS2 does not reply to the ARP request.
4. SW1 learns the port for VIP1 from the ARP reply and updates its bridge table, and R1 updates the ARP entry with MAC1 and VIP1.
5. R1 forwards the packet to address VIP1 on NS1.
6. NS1's load balancing algorithm selects server S2, and NS1 opens a connection between one of its SNIP addresses and S2. When S2 sends a response to the client, the response returns by the same path.
7. Now you want to test the performance of V1 and V2 on NS2, so you enable V1 and V2 on NS2 and disable them on NS1. NS2 now broadcasts an ARP message for VIP1. In the message, MAC2 is the source MAC address and VIP1 is the source IP address.
8. SW1 learns the port number for reaching MAC2 from the ARP broadcast and updates its bridge table to send subsequent client requests for VIP1 to NS2. R1 updates its ARP table.
9. Now suppose the ARP entry for VIP1 times out in the ARP table of R1, and client C1 sends a request for V1. Because R1 does not have an APR entry for VIP1, it broadcasts an ARP request

for VIP1.

10. NS2 replies with a source MAC address and VIP1 as the source IP address. NS1 does not reply to the ARP request.

To configure ARP response suppression by using the CLI:

At the command prompt, type:

- **set ns ip -arpResponse** <arpResponse>]
- **sh ns ip** <IPAddress>

**Example:**

```
1 > set ns ip 10.102.29.96 -arpResponse ALL_VSERVERS
2 Done
3 <!--NeedCopy-->
```

To configure ARP response suppression by using the GUI:

1. Navigate to **System > Network > IPs > IPV4s**.
2. Open an IP address entry and select the type of ARP Response.

## Configuring Subnet IP Addresses (SNIPs)

May 2, 2023

A subnet IP address (SNIP) is a NetScaler owned IP address that is used by the NetScaler to communicate with the servers.

The NetScaler uses the subnet IP address as a source IP address to proxy client connections to servers. It also uses the subnet IP address when generating its own packets, such as packets related to dynamic routing protocols, or to send monitor probes to check the health of the servers. Depending on your network topology, you might have to configure one or more SNIPs for different scenarios.

To configure a SNIP address on a NetScaler, you add the SNIP address and then enable global Use Subnet IP (USNIP) mode. As an alternative to creating SNIPs one at a time, you can specify a consecutive range of SNIPs.

To configure a SNIP address by using the CLI:

At the command prompt, type:

- **add ns ip** <IPAddress> <netmask> -type SNIP
- **show ns ip** <IPAddress>

**Example:**

```
1 > add ns ip 10.102.29.203 255.255.255.0 -type SNIP
2 Done
3 <!--NeedCopy-->
```

To create a range of SNIP addresses by using the CLI:

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type SNIP
- show ns ip <IPAddress>

**Example:**

```
1 > add ns ip 10.102.29.[205-209] 255.255.255.0 -type SNIP
2 ip "10.102.29.205" added
3 ip "10.102.29.206" added
4 ip "10.102.29.207" added
5 ip "10.102.29.208" added
6 ip "10.102.29.209" added
7 Done
8 <!--NeedCopy-->
```

To enable or disable USNIP mode by using the CLI:

At the command prompt, type one of the following commands:

- enable ns modeUSNIP
- disable ns modeUSNIP

To configure a SNIP address by using the GUI:

Navigate to System > Network > IPs > IPV4s, and add a new SNIP address or edit an existing address.

To create a range of SNIP addresses by using the GUI:

1. Navigate to System > Network > IPs > IPV4s.
2. In the Action list, select Add Range.

To enable or disable USNIP mode by using the CLI:

At the command prompt, type one of the following commands:

- enable ns mode USNIP
- disable ns mode USNIP

To enable or disable USNIP mode by using the GUI:

1. Navigate to System > Settings, in Modes and Features group, click Change modes.
2. Select or clear the Use Subnet IP option.

## Using SNIPs for a Directly Connected Server Subnet

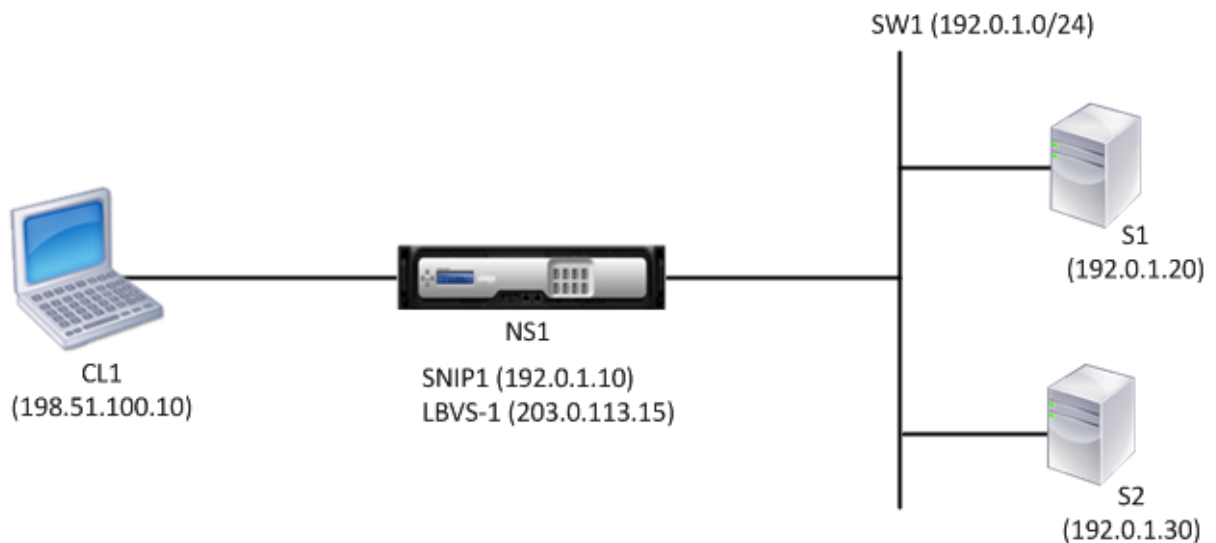

To enable communication between the NetScaler and a server that is either connected directly to the NetScaler or connected through only an L2 switch, you must configure a subnet IP address that belongs to the subnet of the server. You must configure at least one subnet IP address for each directly connected subnet, except for the directly connected management subnet that is connected through NSIP.

Consider an example of a load balancing setup in which load balancing virtual server LBVS1 on NetScaler NS1 is used to load balance servers S1 and S2, which are connected to NS1 through L2 switch SW1. S1 and S2 belong to the same subnet.

SNIP address SNIP1, which belongs to the same subnet as S1 and S2, is configured on NS1. As soon as SNIP1 is configured, NS1 broadcasts ARP packets for SNIP1.

Services SVC-S1 and SVC-S2 on NS1 represent S1 and S2. As soon as these services are configured, NS1 broadcasts ARP requests for S1 and S2 to resolve IP-to-MAC mapping. After S1 and S2 respond, NS1 sends them monitoring probes at regular intervals, from address SNIP1, to check their health.

For more information about configuring load balancing on a NetScaler, see [Load Balancing](#).

Following is the traffic flow in this example:

1. Client C1 sends a request packet to LBVS-1. The request packet has:
  - Source IP = IP address of the client (198.51.100.10)
  - Destination IP = IP address of LBVS-1 (203.0.113.15)
2. LBVS1 of NS1 receives the request packet.
3. LBVS1's load balancing algorithm selects server S2.
4. Because S2 is directly connected to NS1, and SNIP1 (192.0.1.10) is the only IP address on NS1 that belongs to the same subnet as S2, NS1 opens a connection between SNIP1 and S2.

5. NS1 sends the request packet to S2 from SNIP1. The request packet has:
  - Source IP = SNIP1 (192.0.1.10)
  - Destination IP = IP address of S2 (192.0.1.30)
6. S2's response returns by the same path.

### **Using SNIPs for Server Subnets Connected through a Router**

To enable communication between the NetScaler and servers in subnets connected through a router, you must configure at least one subnet IP address that belongs to the subnet of the directly connected interface to the router. The ADC uses this subnet IP address to communicate with servers in subnets that can be reached through the router.

Consider an example of a load balancing setup in which load balancing virtual server LBVS1 on NetScaler NS1 is used to load balance servers S1, S2, S3, and S4, which are connected to NS1 through router R1.

S1 and S2 belong to same subnet, 192.0.2.0/24, and are connected to R1 through L2 switch SW1. S3 and S4 belong to a different subnet, 192.0.3.0/24, and are connected to R1 through L2 switch SW2.

NetScaler NS1 is connected to router R1 through subnet 192.0.1.0/24. SNIP address SNIP1, which belongs to the same subnet as the directly connected interface to the router (192.0.1.0/24), is configured on NS1. NS1 uses this address to communicate with servers S1 and S2, and with servers S3 and S4.

For more information about configuring load balancing on a NetScaler, see [Load Balancing](#).

As soon as address SNIP1 is configured, NS1 broadcasts ARP announcement packets for SNIP1.

NS1's routing table consists of route entries for S1, S2, S3, and S4 through R1. These route entries are either static route entries or advertised by R1 to NS1, using dynamic routing protocols.

Services SVC-S1, SVC-S2, SVC-S3, and SVC-S4 on NS1 represent servers S1, S2, S3, and S4. NS1 finds, in its routing tables, that these servers are reachable through R1. NS1 sends them monitoring probes at regular intervals, from address SNIP1, to check their health.

For more information about IP routing on a NetScaler, see [IP Routing](#).

Following is the traffic flow in this example:

1. Client C1 sends a request packet to LBVS-1. The request packet has:
  - Source IP = IP address of the client (198.51.100.10)
  - Destination IP = IP address of LBVS-1 (203.0.113.15)
2. LBVS1 of NS1 receives the request packet.
3. LBVS1's load balancing algorithm selects server S3.
4. NS1 checks its routing table and finds that S3 is reachable through R1. SNIP1 (192.0.1.10) is the only IP address on NS1 that belongs to the same subnet as router R1, NS1 opens a connection between SNIP1 and S3 through R1.
5. NS1 sends the request packet to R1 from SNIP1. The request packet has:
  - Source IP address = SNIP1 (192.0.1.10)
  - Destination IP address = IP address of S3 (192.0.3.20)
6. The request reaches R1, which checks its routing table and forwards the request packet to S3.
7. S3's response returns by the same path.

### Using SNIPs for Multiple Server Subnets (VLANs) on an L2 Switch

When you have multiple server subnets (VLANs) on an L2 switch that is connected to a NetScaler, you must configure at least one SNIP address for each of the server subnets, so that the NetScaler can

communicate with these server subnets.

Consider an example of a load balancing setup in which load balancing virtual server LBVS1 on NetScaler NS1 is used to load balance servers S1 and S2, which are connected to NS1 through L2 switch SW1. S1 and S2 belong to different subnets and are part of VLAN 10 and VLAN20, respectively. The link between NS1 and SW1 is a trunk link and is shared by VLAN10 and VLAN20.

For more information about configuring load balancing on a NetScaler, see [Load Balancing](#).

Subnet IP addresses SNIP1 (for reference purposes only) and SNIP2 (for reference purposes only) are configured on NS1. NS1 uses SNIP1 (on VLAN 10) to communicate with server S1, and SNIP2 (on VLAN 20) to communicate with S2. As soon as SNIP1 and SNIP2 are configured, NS1 broadcasts ARP announcement packets for SNIP1 and SNIP2.

For more information about configuring VLANs on a NetScaler, see [Configuring a VLAN](#).

Services SVC-S1 and SVC-S2 on NS1 represent servers S1 and S2. As soon as these services are configured, NS1 broadcasts ARP requests for them. After S1 and S2 respond, NS1 sends them monitoring probes at regular intervals to check their health. NS1 sends monitoring probes to S1 from address SNIP1, and to S2 from address SNIP2.

Following is the traffic flow in this example:

1. Client C1 sends a request packet to LBVS-1. The request packet has:
  - Source IP = IP address of the client (198.51.100.10)
  - Destination IP = IP address of LBVS-1 (203.0.113.15)
2. LBVS1 of NS1 receives the request packet.
3. LBVS1's load balancing algorithm selects server S2.
4. Because S2 is directly connected to NS1, and SNIP2 (192.0.2.10) is the only IP address on NS1 that belongs to the same subnet as S2, NS1 opens a connection between SNIP2 and S2.
 

Note: If S1 is selected, NS1 opens a connection between SNIP1 and S1.
5. NS1 sends the request packet to S2 from SNIP2. The request packet has:

- Source IP = SNIP1 (192.0.2.10)
  - Destination IP = IP address of S2 (192.0.2.20)
6. S2's response returns by the same path.

## Configuring GSLB Site IP Addresses (GSLBIP)

May 2, 2023

A GSLB site IP (GSLBIP) address is an IP address associated with a GSLB site. It is not mandatory to specify a GSLBIP address when you initially configure the NetScaler appliance. A GSLBIP address is used only when you create a GSLB site.

For more information about creating a GSLB site IP address, see [Global Server Load Balancing](#).

## Removing a NetScaler-owned IP address

May 2, 2023

You can remove any IP address except the NSIP. The following table provides information about the processes you must follow to remove the various types of IP addresses. Before removing a VIP, remove the associated virtual server.

---

IP address type	Implications
Subnet IP address (SNIP)	If IP address being removed is the last IP address in the subnet, the associated route is deleted from the route table. If the IP address being removed is the gateway in the corresponding route entry, the gateway for that subnet route is changed to another NetScaler-owned IP address.
Virtual Server IP address (VIP)	Before removing a VIP, you must first remove the virtual server associated with it. For information about removing the virtual server, see <a href="#">Load Balancing</a> .

IP address type	Implications
GSLB-Site-IP address	Before removing a GSLB site IP address, you must remove the site associated with it. For information about removing the site, see <a href="#">Global Server Load Balancing</a> .

To remove an IP address by using the CLI:

At the command prompt, type:

```
rm ns ip <IPAddress>
```

**Example:**

```
1 > rm ns ip 10.102.29.54
2 Done
3 <!--NeedCopy-->
```

To remove an IP address by using the GUI:

Navigate to **System > Network > IPs > IPV4s**, delete the IP address.

## Configuring Application Access Controls

May 2, 2023

Application access controls, also known as management access controls, form a unified mechanism for managing user authentication and implementing rules that determine user access to applications and data. You can configure SNIPs to provide access for management applications. Management access for the NSIP is enabled by default and cannot be disabled. You can, however, control it by using ACLs.

For information about using ACLs, see [Access Control Lists \(ACLs\)](#).

The NetScaler appliance does not support management access to VIPs.

The following table provides a summary of the interaction between management access and specific service settings for Telnet.

Management Access	Telnet (State Configured on the NetScaler)	Telnet (Effective State at the IP Level)
Enable	Enable	Enable

Management Access	Telnet (State Configured on the NetScaler)	Telnet (Effective State at the IP Level)
Enable	Disable	Disable
Disable	Enable	Disable
Disable	Disable	Disable

The following table provides an overview of the IP addresses used as source IP addresses in outbound traffic.

Application/ IP	NSIP	SNIP	VIP
ARP	Yes	Yes	No
Server side traffic	No	Yes	No
RNAT	No	Yes	Yes
ICMP PING	Yes	Yes	No
Dynamic routing	Yes	Yes	Yes

The following table provides an overview of the applications available on these IP addresses.

Application/ IP	NSIP	SNIP	VIP
SNMP	Yes	Yes	Yes
System access	Yes	Yes	No

You can access and manage the NetScaler by using applications such as Telnet, SSH, GUI, and FTP.

**Note:** Telnet and FTP are disabled on the NetScaler for security reasons. To enable them, contact the customer support. After the applications are enabled, you can apply the controls at the IP level.

To configure the NetScaler to respond to these applications, you need to enable the specific management applications. If you disable management access for an IP address, existing connections that use the IP address are not terminated, but no new connections can be initiated.

Also, the non-management applications running on the underlying FreeBSD operating system are open to protocol attacks, and these applications do not take advantage of the NetScaler appliance's attack prevention capabilities.

You can block access to these non-management applications on a SNIP or NSIP. When access is blocked, a user connecting to a NetScaler by using the SNIP or NSIP is not be able to access the non-management applications running on the underlying operating system.

To configure management access for an IP address by using the CLI:

At the command prompt, type:

```
set ns ip <IPAddress> -mgmtAccess <value> -**telnet** <value> -**ftp** <value> -**gui** <value>
-**ssh** <value> -**snmp** <value> -**restrictAccess** (**ENABLED** | **DISABLED**)
```

**Example:**

```
1 > set ns ip 10.102.29.54 -mgmtAccess enabled -restrictAccess ENABLED
2 Done
3 <!--NeedCopy-->
```

To enable management access for an IP address by using the GUI:

1. Navigate to **System > Network > IPs > IPV4s**.
2. Open an IP address entry, and select the **Enable Management Access control** to support the listed applications option.

**Enable secure access to NetScaler GUI using a subnet IP address(SNIP)**

Secure access to NetScaler GUI is enabled by default for the NetScaler IP (NSIP). You can also enable secure access to the NetScaler appliance by using a subnet IP address of the appliance.

After configuring an SNIP address for secure access to a high availability pair, the secure access is available to the primary appliance, if you access the SNIP address.

**NetScaler CLI procedure**

To enable secure access to NetScaler GUI using a subnet IP address(SNIP) by using the CLI:

At the command prompt, type:

```
set ns ip <SNIP_Address> -type SNIP -gui SECUREONLY -mgmtAccess ENABLED
```

**Example:**

```
1 > set ns ip 203.0.113.99 -mgmtAccess enabled -restrictAccess ENABLED
2
3 Done
4 <!--NeedCopy-->
```

## How the NetScaler Proxies Connections

May 2, 2023

When a client initiates a connection, the NetScaler appliance terminates the client connection, initiates a connection to an appropriate server, and sends the packet to the server. The appliance does not perform this action for service type UDP or ANY.

For more information about service types, see [Load Balancing](#).

You can configure the NetScaler to process the packet before initiating the connection with a server. The default behavior is to change the source and destination IP addresses of a packet before sending the packet to the server. You can configure the NetScaler to retain the source IP address of the packets by enabling Use Source IP mode.

### How the Destination IP Address Is Selected

Traffic sent to the NetScaler appliance can be sent to a virtual server or to a service. The appliance handles traffic to virtual servers and services differently. The NetScaler terminates traffic received at a virtual server IP (VIP) address and changes the destination IP address to the IP address of the server before forwarding the traffic to the server, as shown in the following diagram.

Figure 1. Proxying Connections to VIPs

**Svr: Server**  
**NS: NetScaler**  
**NSVIP: NetScaler VIP**  
**MIP: NetScaler Mapped IP**

Packets destined for a service are sent directly to the appropriate server, and the NetScaler does not modify the destination IP addresses. In this case, the NetScaler functions as a proxy.

**How the Source IP Address Is Selected**

When the NetScaler appliance communicates with the physical servers or peer devices, by default, it does not use the IP address of the client. NetScaler maintains a pool of subnet IP addresses (SNIPs), and selects an IP address from this pool to use as the source IP address of a connection to the physical server. Depending on the subnet in which the physical server is placed, NetScaler selects a specific SNIP address.

**Note:** If the Use Source IP (USIP) option is enabled, appliance uses the IP address of the client.

## Enable Use Source IP Mode

May 2, 2023

When the NetScaler appliance communicates with the physical servers or peer devices, by default, it uses one of its own IP addresses as the source IP. The appliance maintains a pool of subnet IP addresses (SNIPs), and selects an IP address from this pool to use as the source IP address for a connection to the physical server. The decision of selecting a SNIP address depends on the subnet in which the physical server resides.

If necessary, you can configure the NetScaler appliance to use the client's IP address as source IP. Some applications need the actual IP address of the client. The following use cases are a few examples:

- Client's IP address in the web access log is used for billing purposes or usage analysis.
- Client's IP address is used to determine the country of origin of the client or the originating ISP of the client. For example, many search engines such as Google provide content relevant to the location to which the user belongs.
- The application must know the client's IP address to verify that the request is from a trustworthy source.
- Sometimes, even though an application server does not need the client's IP address, a firewall placed between the application server and the NetScaler may need the client's IP address for filtering the traffic.

Enable Use Source IP mode (USIP) mode if you want the NetScaler to use the client's IP address for communication with the servers.

The following figure shows how the appliance uses IP addresses in USIP mode.

## Before you begin

Before you enable USIP mode, note the following points:

- Enable USIP in the following situations:
  - Load balancing of Intrusion Detection System (IDS) servers
  - SMTP load balancing
  - Stateless connection failover
  - Sessionless load balancing
  - If you use the Direct Server Return (DSR) mode
- The USIP global setting applies only to services that are created after the USIP global setting is made. In other words, the USIP global setting does not apply to the existing services when the USIP global setting is made. For example, Disabling USIP globally does not disable USIP on the existing services. But it stops the subsequently created services from having USIP enabled automatically.

To enable or disable USIP on a set of existing services, you need to enable or disable USIP on each of these services.

- When USIP is enabled, you must set server's gateway to one of the NetScaler owned IP addresses (of type Subnet IP (SNIP)) so that server's response always go through the NetScaler appliance.
- If you enable USIP, set the idle timeout for server connections to a value lower than the default value, so that idle connections are cleared quickly on the server side.
- For transparent cache redirection, if you enable USIP, enable L2CONN also.
- Because HTTP connections are not reused when USIP is enabled, a large number of server-side connections may accumulate. Idle server connections can block connections for other clients. Therefore, set limits on maximum number of connections to a service. Citrix also recommends setting the HTTP server time-out value, for a service on which USIP is enabled, to a value lower than the default, so that idle connections are cleared quickly on the server side.
- As an alternative to USIP mode, you have the option of inserting the client's IP address (CIP) in the request header of the server-side connection for an application server that needs the client's IP address.
- In earlier NetScaler releases, USIP mode had the following source-port options for server-side connections:
  - **Use the client's port.** With this option, connections cannot be reused. For every request from the client, a new connection is made with the physical server.

- **Use proxy port.** With this option, connection reuse is possible for all requests from the same client.

In the later NetScaler releases, if USIP is enabled, the default is to use a proxy port for server-side connections and not reuse connections. Not reusing connections may not affect the speed of establishing connections.

By default, the Use Proxy Port option is enabled if the USIP mode is enabled.

**Note:** If you enable the USIP mode, it is recommended to enable the Use Proxy Port option.

For more information about the Use Proxy Port option, see [Configure the source port for server-side connections](#).

## Configuration Steps

Enable Use Source IP mode (USIP) mode if you want NetScaler to use the client's IP address for communication with the servers. By default, USIP mode is disabled. USIP mode can be enabled globally on the NetScaler or on a specific service. If you enable it globally, USIP is enabled by default for all subsequently created services. If you enable USIP for a specific service, the client's IP address is used only for the traffic directed to that service.

## CLI procedures

To globally enable or disable USIP mode by using the CLI:

At the command prompt, type one of the following commands:

- **enable ns mode USIP**
- **disable ns mode USIP**

To enable USIP mode for a service by using the CLI:

At the command prompt, type:

```
set service <name>@ -**usip** (**YES** | **NO**)
```

### Example:

```
1 > set service Service-HTTP-1 -usip YES
2 Done
3 <!--NeedCopy-->
```

## GUI procedures

### To globally enable USIP mode by using the GUI:

1. Navigate to **System > Settings**, in **Modes and Features** group, click **Change Modes**.
2. Select the **Use Source IP** option.

### To enable USIP mode for a service by using the GUI:

1. Navigate to **Traffic Management > Load Balancing > Services**, and edit a service.
2. In **Advanced Settings**, select **Service Settings**, and select **Use Source IP Address**.

## Configuring Network Address Translation

May 2, 2023

Network address translation (NAT) involves modification of the source and/or destination IP addresses and/or the TCP/UDP port numbers of IP packets that pass through the NetScaler appliance. Enabling NAT on the appliance enhances the security of your private network, and protects it from a public network such as the Internet, by modifying your networks source IP addresses when data passes through the NetScaler. Also, with the help of NAT entries, your entire private network can be represented by a few shared public IP addresses. The NetScaler supports the following types of network address translation:

- **Inbound NAT (INAT)**. The NetScaler replaces the destination IP address in the packets generated by the client with the private IP address of the server.
- **Reverse NAT (RNAT)**. The NetScaler replaces the source IP address in the packets generated by the servers with the public NAT IP addresses.

## Inbound Network Address Translation

May 2, 2023

When a client sends a packet to a NetScaler appliance that is configured for Inbound Network Address Translation (INAT), the appliance translates the packet's public destination IP address to a private destination IP address and forwards the packet to the server at that address.

The following configurations are supported:

- **IPv4-IPv4 Mapping:** A public IPv4 address on the NetScaler appliance listens to connection requests on behalf of a private IPv4 server. The NetScaler appliance translates the packet's public destination IP address to the destination IP address of the server. Then the appliance forwards the packet to the server at that address.
- **IPv4-IPv6 Mapping:** A public IPv4 address on the NetScaler appliance listens to connection requests on behalf of a private IPv6 server. The NetScaler appliance creates an IPv6 request packet with the IP address of the IPv6 server as the destination IP address.
- **IPv6-IPv4 Mapping:** A public IPv6 address on the NetScaler appliance listens to connection requests on behalf of a private IPv4 server. The NetScaler appliance creates an IPv4 request packet with the IP address of the IPv4 server as the destination IP address.
- **IPv6-IPv6 Mapping:** A public IPv6 address on the NetScaler appliance listens to connection requests on behalf of a private IPv6 server. The NetScaler appliance translates the packet's public destination IP address to the destination IP address of the server. Then the appliance forwards the packet to the server at that address.

When the appliance forwards a packet to a server, the source IP address assigned to the packet is determined as follows:

- If use subnet IP (USNIP) mode is enabled and use source IP (USIP) mode is disabled, the appliance uses a subnet IP address (SNIP) as the source IP address.
- If USIP mode is enabled, and USNIP mode is disabled the appliance uses the client IP (CIP) address as the source IP address.
- If both USIP and USNIP modes are enabled, USIP mode takes precedence.
- You can also configure the NetScaler to use a unique IP address as the source IP address, by setting the proxyIP parameter.
- If none of the above modes are enabled and a unique IP address has not been specified, the NetScaler attempts to use a MIP as the source IP address.
- If both USIP and USNIP modes are enabled and a unique IP address has been specified, the order of precedence is as follows: USIP-unique IP-USNIP-MIP-Error.

To protect the NetScaler from DoS attacks, you can enable TCP proxy. However, if other protection mechanisms are used in your network, you can disable them.

## Configure INAT rules

You can create, modify, or remove an INAT entry.

### CLI procedures

To create an INAT entry by using the CLI:

At the command prompt, type the following commands to create an INAT entry and verify its configuration:

- **add inat** <name> <publicIP> <privateIP> [-**tcpproxy** (\*\*ENABLED\*\* | \*\*DISABLED\*\*)] [-**ftp** (\*\*ENABLED\*\* | \*\*DISABLED\*\*)] [-**usip** (\*\*ON\*\* | \*\*OFF\*\*)] [-**usnip** (\*\*ON\*\* | \*\*OFF\*\*)] [-**proxyIP** <**ip\_addr**> ipv6\_addr<\*>]
- **show inat** [<name>]

**Example:**

```
1 > add inat ip4-ip4 172.16.1.2 192.168.1.1 -proxyip 10.102.29.171
2 Done
3 <!--NeedCopy-->
```

To modify an INAT entry by using the CLI:

To modify an INAT entry, type the `set inat` command, the name of the entry, and the parameters to be changed, with their new values.

To remove an INAT configuration by using the CLI:

At the command prompt, type:

- **rm inat** <name>

**Example:**

```
1 > rm inat ip4-ip4
2 Done
3 <!--NeedCopy-->
```

**GUI procedures**

To configure an INAT entry by using the GUI:

Navigate to **System > Network > Routes > INAT**, and add an INAT entry or edit an existing INAT entry.

To remove an INAT configuration by using the GUI:

Navigate to **System > Network > Routes > INAT**, delete the INAT configuration.

**Connection failover for INAT rules**

Connection failover or connection mirroring enables the primary node to duplicate connection and persistence information to the secondary node in a high availability. The state information of the connection is shared with the secondary node regularly when connection mirroring is enabled.

Enabling connection failover provides more reliability but it comes at the cost of some system time being used up for sharing the state information. The connection data is synchronized to the standby unit with every packet or flow state update. Hence, it must be used only at places where connection level reliability is of prime importance.

NetScaler appliance high availability setups support connection failover for INAT connections. The primary node sends INAT mappings and other INAT related connection information to the secondary node at regular intervals. The secondary appliance uses the mapping and connection information only in the event of a failover.

When a failover occurs, the new primary node has information about the INAT connections established before the failover. Hence, it continues to serve those connections even after the failover.

From the client's perspective the failover is transparent. During the transition period, the client and server might experience a brief disruption and retransmissions. Connection failover can be enabled per INAT rule.

For enabling connection failover on an INAT rule, you enable the `connFailover` parameter of that specific RNAT rule by using CLI.

### CLI procedure

To enable connection failover for an INAT rule by using the CLI:

To enable connection failover while adding an INAT rule, at the command prompt, type:

- `add inat <name> <publicIP> <privateIP> [-tcpproxy (**ENABLED** | **DISABLED**)] [-ftp ( **ENABLED** | **DISABLED**)] [-usip ( **ON** | **OFF**)] [-usnip ( **ON** | **OFF**)] [-proxyIP <ip_addr|ipv6_addr>] -connfailover (**ENABLED** | **DISABLED**)`
- `show inat <name>`

To enable connection failover while modifying an existing INAT rule, at the command prompt, type:

---

```
set inat -connfailover (ENABLED DISABLED)
```

---

- 
- `show inat <name>`

## Coexistence of INAT and Virtual Servers

May 2, 2023

If both INAT and RNAT are configured, the INAT rule takes precedence over the RNAT rule. If RNAT is configured with a network address translation IP (NAT IP) address, the NAT IP address is selected as the source IP address for that RNAT client.

The default public destination IP in an INAT configuration is the virtual IP (VIP) address of the NetScaler device. Virtual servers also use VIPs. When both INAT and a virtual server use the same IP address, the Vserver configuration overrides the INAT configuration.

Following are a few sample configuration setup scenarios and their effects.

Case	Result
You have configured a virtual server and a service to send all data packets received on a specific NetScaler port to the server directly. You have also configured INAT and enabled TCP. Configuring INAT in this manner sends all data packets received through a TCP engine before sending them to the server.	All packets received on the NetScaler, except those received on the specified port, pass through the TCP engine.
You have configured a virtual server and a service to send all data packets of service type TCP, that are received on a specific port on the NetScaler, to the server after passing through the TCP engine. You have also configured INAT and disabled TCP. Configuring INAT in this manner sends the data packets received directly to the server.	Only packets received on the specified port pass through the TCP engine.
You have configured a virtual server and a service to send all data packets received to either of two servers. You are attempting to configure INAT to send all data packets received to a different server.	The INAT configuration is not allowed.
You have configured INAT to send all received data packets directly to a server. You are attempting to configure a virtual server and a service to send all data packets received to two different servers.	The vserver configuration is not allowed.

## Stateless NAT46

May 2, 2023

The stateless NAT46 feature enables communication between IPv4 and IPv6 networks through IPv4 to IPv6 packet translation, and vice versa, without maintaining any session information on the NetScaler appliance.

For a stateless NAT46 configuration, the appliance translates an IPv4 packet to IPv6 or an IPv6 packet to IPv4 as defined in RFCs 6145 and 2765.

A stateless NAT46 configuration on the NetScaler appliance has the following components:

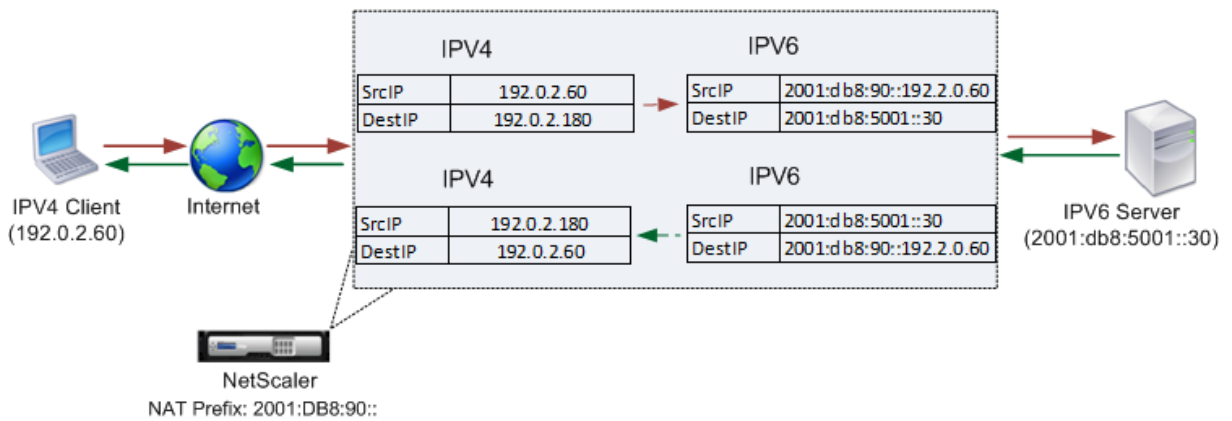

- **IPv4-IPv6 INAT entry.** An INAT entry defining a 1:1 relationship between an IPv4 address and an IPv6 address. In other words, an IPv4 address on the appliance listens to connection requests on behalf of an IPv6 server. An IPv4 request packet for this IPv4 address is translated into an IPv6 packet, and then the IPv6 packet is sent to the IPv6 server.

The appliance translates an IPv6 response packet into an IPv4 response packet with its source IP address field set as the IPv4 address specified in the INAT entry. The translated packet is then sent to the client.

- **NAT46 IPv6 prefix.** A global IPv6 prefix of length 96 bits ( $128-32=96$ ) configured on the appliance. During IPv4 packet to IPv6 packet translation, the appliance sets the source IP address of the translated IPv6 packet to a concatenation of the NAT46 IPv6 prefix [96 bits] and the IPv4 source address [32 bits] that was received in the request packet.

During IPv6 packet to IPv4 packet translation, the appliance sets the destination IP address of the translated IPv4 packet to the last 32 bits of the destination IP address of the IPv6 packet.

Consider an example in which an enterprise hosts site `www.example.com` on server S1, which has an IPv6 address. To enable communication between IPv4 clients and IPv6 server S1, NetScaler appliance NS1 is deployed with a stateless NAT46 configuration that includes an IPv4-IPv6 INAT entry for server S1, and a NAT46 Prefix. The INAT entry includes an IPv4 address at which the appliance listens to connection requests from IPv4 clients on behalf of the IPv6 server S1.

The following table lists the settings used in this example:

Entities	Name	Value
IP address of the client	Client_IPv4 (for reference purposes only)	192.0.2.60
IPv6 address of the server	Sevr_IPv6 (for reference purposes only)	2001:DB8:5001::30
IPv4 address defined in the INAT entry for IPv6 server S1	Map-Sevr-IPv4 (for reference purposes only)	192.0.2.180
IPv6 prefix for NAT 46 translation	NAT46_Prefix (for reference purposes only)	2001:DB8:90::

Following is the traffic flow in this example:

1. IPv4 Client CL1 sends a request packet to the Map-Sevr-IPv4 (192.0.2.180) address on the NetScaler appliance.
2. The appliance receives the request packet and searches the NAT46 INAT entries for the IPv6 address mapped to the Map-sevr-IPv4 (192.0.2.180) address. It finds the Sevr-IPv6 (2001:DB8:5001::30) address.
3. The appliance creates a translated IPv6 request packet with:
  - Destination IP address field = Sevr-IPv6 = 2001:DB8:5001::30
  - Source IP address field = Concatenation of NAT Prefix (First 96 bits) and Client\_IPv4 (last 32 bits) = 2001:DB8:90::192.0.2.60
4. The appliance sends the translated IPv6 request to Sevr-IPv6.
5. The IPv6 server S1 responds by sending an IPv6 packet to the NetScaler appliance with:
  - Destination IP address field = Concatenation of NAT Prefix (First 96 bits) and Client\_IPv4 (last 32 bits)= 2001:DB8:90::192.0.2.60

- Source IP address field = Sevr-IPv6 = 2001:DB8:5001::30
6. The appliance receives the IPv6 response packet and verifies that its destination IP address matches the NAT46 prefix configured on the appliance. Because the destination address matches the NAT46 prefix, the appliance searches the NAT46 INAT entries for the IPv4 address associated with the Sevr-IPv6 address (2001:DB8:5001::30 ). It finds the Map-Sevr-IPv4 address (192.0.2.180).
  7. The appliance creates an IPv4 response packet with:
    - Destination IP address field = The NAT46 prefix stripped from the destination address of the IPv6 response = Client\_IPv4 (192.0.2.60)
    - Source IP address field = Map-Sevr-IPv4 address (192.0.2.180)
  8. The appliance sends the translated IPv4 response to client CL1.

### **Limitations of Stateless NAT46**

The following limitations apply to stateless NAT46:

- Translation of IPv4 options is not supported.
- Translation of IPv6 routing headers is not supported.
- Translation of hop-by-hop extension headers of IPv6 packets is not supported.
- Translation of ESP and EH headers of IPv4 packets is not supported.
- Translation of multicast packets is not supported.
- Translation of destination option headers and source routing headers is not supported.
- Translation of fragmented IPv4 UDP packets that do not contain UDP checksum is not supported.

### **Configure Stateless NAT46**

Creating the required entities for stateless NAT46 configuration on the NetScaler appliance involves the following procedures:

1. Create an IPv4-IPv6 mapping INAT entry with stateless mode enabled.
2. Create a NAT46 IPv6 prefix.

### **CLI procedures**

To configure an INAT mapping entry by using the CLI:

At the command prompt, type:

- `add inat <name> <publicIPv4> <privateIPv6> -mode STATELESS`

- show inat <name>

To create an NAT46 prefix by using the CLI:

At the command prompt, type:

---

```
set inatparam -nat46v6Prefix <ipv6_addr *>
```

---

- 
- show inatparam

**Example:**

```
1 > add inat exmpl-com-stls-nat46 192.0.2.180
2 2001:DB8:5001::30 -mode stateless
3 Done
4
5 > set inatparam -nat46v6Prefix 2001:DB8:90::/96
6 Done
7 <!--NeedCopy-->
```

**GUI procedures**

To create an INAT mapping entry by using the GUI:

1. Navigate to System > Network > Routes > INAT.
2. Add a new INAT entry, or edit an existing INAT entry.
3. Set the following parameters:
  - Name\*
  - Public IP Address\*
  - Private IP Address\* (Select the IPv6 check box and enter the address in IPv6 format.)
  - Mode (Select Stateless from the drop down list.)

\* A required parameter

To create a NAT46 prefix by using the GUI:

Navigate to **System > Network**, in the **Settings** group, click **Configure INAT Parameters**, and set the **Prefix** parameter.

## Setting Global Parameters for Stateless NAT46

The appliance provides some optional global parameters for stateless NAT46 configurations.

To set global parameters for stateless NAT46 by using the CLI:

At the command prompt, type:

---

```
set inatparam [-nat46IgnoreTOS (YES NO)] [-nat46ZeroChecksum (ENABLED DISABLED)] [-nat46v6Mtu
```

---

- 
- **show inatparam**

### Example:

```
1 > set inatparam -nat46IgnoreTOS YES -nat46ZeroChecksum DISABLED -
 nat46v6Mtu 1400 -nat46FragHeader DISABLED
2 Done
3 <!--NeedCopy-->
```

To set global parameters for stateless NAT46 by using the GUI:

Navigate to **System > Network**, in the **Settings** group, click **Configure INAT Parameters**.

## DNS64

May 2, 2023

The NetScaler DNS64 feature responds with a synthesized DNS AAAA record to an IPv6 client sending an AAAA request for an IPv4-only domain. The DNS64 feature is used with the NAT64 feature to enable seamless communication between IPv6-only clients and IPv4-only servers. DNS64 enables discovery of the IPv4 domain by the IPv6 only clients, and NAT64 enables communication between the clients and servers.

For synthesizing an AAAA record, the NetScaler appliance fetches a DNS A record from a DNS server. The DNS64 prefix is a 96-bit IPv6 prefix configured on the NetScaler appliance. The NetScaler appliance synthesizes the AAAA record by concatenation of the DNS64 Prefix (96 bits) and the IPv4 address (32 bits).

For enabling communication between IPv6 clients and IPv4 servers, a NetScaler appliance with DNS64 and NAT64 configuration can be deployed either on the IPv6 client side or on the IPv4 server side. In both cases, the DNS64 configuration on the NetScaler appliance is similar and includes a load balancing virtual server acting as a proxy server for DNS servers. If the NetScaler appliance is deployed on the

client side, the load balancing virtual server must be specified, on the IPv6 client, as the nameserver for a domain.

Consider an example where a NetScaler appliance with DNS64 and NAT64 configuration is configured on the IPv4 side. In this example, an enterprise hosts site `www.example.com` on server S1, which has an IPv4 address. To enable communication between IPv6 clients and IPv4 server S1, NetScaler appliance NS1 is deployed with a DNS64 and stateful NAT64 configuration.

The DNS64 configuration includes DNS load balancing virtual server LBVS-DNS64-1, on which the DNS64 option is enabled. A DNS64 policy named DNS64-Policy-1, and an associated DNS64 action named DNS64-Action-1, are also configured on NS1, and DNS64-Policy-1 is bound to LBVS-DNS64-1. LBVS-DNS64-1 acts as a DNS proxy server for DNS servers DNS-1 and DNS-2.

When traffic arriving at LBVS-DNS64-1 matches the conditions specified in DNS64-Policy-1, the traffic is processed according to the settings in DNS64-Action-1. DNS64-Action-1 specifies the DNS64 prefix used, with the A record received from a DNS server, to synthesize an AAAA record.

The global DNS parameter `cacherecords` is enabled on the NetScaler appliance, so the appliance caches DNS records. This setting is necessary for the DNS64 to work properly.

The following table lists the settings used in the above example: [DNS64 example settings](#).

Following is the traffic flow in this example:

1. IPv6 client CL1 sends a DNS AAAA request for the IPv6 address of the site `www.example.com`.
2. The request is received by the DNS load balancing virtual server LBVS-DNS64-1 on NetScaler appliance NS1.
3. NS1 checks its DNS cache records for the requested AAAA record and finds that AAAA record for the site `www.example.com` does not exist in the DNS cache.
4. LBVS-DNS64-1's load balancing algorithm selects DNS server DNS-1 and forwards the AAAA request to it.
5. Because the site `www.example.com` is hosted on an IPv4 server, the DNS server DNS-1 does not have any AAAA record for the site `www.example.com`.
6. DNS-1 sends either an empty DNS AAAA response or an error message to LBVS-DNS64-1.
7. Because DNS64 option is enabled on LBVS-DNS64-1 and the AAAA request from CL1 matches the condition specified in DNS64-Policy-1, NS1 sends a DNS A request to DNS-1 for the IPv4 address of `www.example.com`.
8. DNS-1 responds by sending the DNS A record for `www.example.com` to LBVS-DNS64-1. The A record includes the IPv4 address for `www.example.com`.
9. NS1 synthesizes an AAAA record for the site `www.example.com` with:
  - IPv6 address for site `www.example.com` = Concatenation of DNS64 Prefix (96 bits) specified in the associated DNS64action, and IPv4 address of DNS A record (32 bits) = `2001:DB8:300::192.0.2.60`

10. NS1 sends the synthesized AAAA record to IPv6 client CL1. NS1 also caches the A record into its memory. NS1 uses the cached A record to synthesize AAAA records for subsequent AAAA requests.

### **Points to Consider for a DNS64 Configuration**

Before configuring DNS64 on a NetScaler appliance, consider the following points:

- The DNS64 feature of the NetScaler appliance is compliant with RFC 6174.
- The DNS64 feature of the NetScaler appliance does not support DNSSEC. The NetScaler appliance does not synthesize an AAAA record from a DNSSEC response received from a DNS server. A response is classified as a DNSSEC response, only if it contains RRSIG records.
- The NetScaler appliance supports DNS64 prefix of length of only 96 bits.
- Though the DNS64 feature is used with the NAT64 feature, the DNS64 and NAT64 configurations are independent on the NetScaler appliance. For a particular flow, you must specify the same IPv6 prefix value for the DNS64 prefix and the NAT64 prefix parameters, so that the synthesized IPv6 addresses received by the client are routed to the particular NAT64 configuration. For more information on configuring NAT64 on a NetScaler appliance, see [Stateful NAT64](#).
- The following are the different cases of DN64 processing by the NetScaler appliance:
  - If the AAAA response from the DNS server includes AAAA records, then each record in the response is checked for the set of exclusion rule configured on the NetScaler appliance for the particular DNS64 configuration. The NetScaler removes the IPv6 addresses, whose prefix matches the exclusion rule, from the response. If the resulting response includes at least one IPv6 record, the NetScaler appliance forwards this response to the client, else, the appliance synthesizes a AAAA response from the A record of the domain and sends it to the IPv6 client.
  - If the AAAA response from the DNS server is an empty answer response, the appliance requests for A resource records with the same domain name or searches in its own records if the appliance is an authentic domain name server for the domain. If the request results in an empty answer or error, the same is forwarded to the client.
  - If the response from the DNS server includes RCODE=1 (format error), the NetScaler appliance forwards the same to the client. If there is no response before the timeout, the NetScaler appliance sends a response with RCODE=2 (server failure) to the client.
  - If the response from the DNS server includes a CNAME, the chain is followed until the terminating A or AAAA record is reached. If the CNAME does not have any AAAA resource records, the NetScaler appliance fetches the DNS A record to be used for synthesizing AAAA record.

The CNAME chain is added to the answer section along with the synthesized AAAA record and then sent to the client.

- The DNS64 feature of the NetScaler appliance also supports responding to PTR request. When a PTR request for a domain of an IPv6 address is received on the appliance and the IPv6 address matches any of the configured DNS64 prefix, the appliance creates a CNAME record mapping the IP6-ARPA domain into the corresponding IN-ADDR. ARPA domain and the newly formed IN-ADDR.ARPA domain is used for resolution. The appliance searches the local PTR records and if the records are not present, the appliance sends a PTR request for IN-ADDR.ARPA domain to the DNS server. The NetScaler appliance uses the response from the DNS server to synthesize response for the initial PTR request.

## Configuration Steps

Creating the required entities for stateful NAT64 configuration on the NetScaler appliance involves the following procedures:

- **Add DNS services.** DNS services are logical representation of DNS servers for which the NetScaler appliance acts as a DNS proxy server. For more information on setting optional parameters of a service, see [Load Balancing](#).
- **Add DNS64 action and DNS64 policy and then bind the DNS64 action to the DNS64 policy.** A DNS64 policy specifies conditions to be matched against traffic for DNS64 processing according to the settings in the associated DNS64 action. The DNS64 action specifies the mandatory DNS64 prefix and the optional exclude rule and mapped rule settings.
- **Create a DNS load balancing virtual server and bind the DNS services and the DNS64 policy to it.** The DNS load balancing virtual server acts as a DNS proxy server for DNS servers represented by the bound DNS services. Traffic arriving at the virtual server is matched against the bound DNS64 policy for DNS64 processing. For more information on setting optional parameters of a load balancing virtual server, see [Load Balancing](#).

**Note:** The CLI has separate commands for these two tasks, but the GUI combines them in a single dialog box.

**Enable caching of DNS records.** Enable the global parameter for the NetScaler appliance to cache DNS records, which are obtained through DNS proxy operations. For more information on enabling caching of DNS records, see [Domain Name System](#).

### CLI procedures

To create a service of type DNS by using the CLI:

At the command prompt, type:

- add service <name> <IP> <serviceType> <port> ...

To create a DNS64 action by using the CLI:

At the command prompt, type:

- add dns action64 <actionName> -Prefix <ipv6\_addr|\*> [-mappedRule <expression>] [-excludeRule <expression>]

To create a DNS64 policy by using the CLI:

At the command prompt, type:

- add dns policy64 <name> -rule <expression> -action <string>

To create a DNS load balancing virtual server by using the CLI:

At the command prompt, type:

- add lb vserver <name> DNS <IPAddress> <port> -dns64 ( ENABLED | DISABLED ) [-bypassAAAA ( YES | NO )] ...

To bind the DNS services and the DNS64 policy to the DNS load balancing virtual server by using the CLI:

At the command prompt, type:

- bind lb vserver <name> <serviceName> ...
- bind lb vserver <name> -policyName <string> -priority <positive\_integer> ...

## GUI procedures

To create a service of type DNS by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Services, and add a new service.
2. Set the following parameters:
  - Service Name\*
  - Server\*
  - Protocol\* (Select DNS from the drop down list.)
  - Port\*

To create a DNS64 action by using the GUI:

Navigate to Traffic Management > DNS > Actions, on the DNS Actions64 tab, add a new DNS64 action.

To create a DNS64 policy by using the GUI:

Navigate to Traffic Management > DNS > Policies, on the DNS Policies64 tab, add a new DNS64 policy.

To create a DNS load balancing virtual server and bind the DNS services and the DNS64 policy to it by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and add a new virtual server.
2. Set the following parameters:
  - Name\*
  - IP Address\*
  - Protocol\* (Select DNS from the drop down list.)
  - Port\*
3. Select the Enable DNS64 option.
4. In the Services pane, bind the service to the virtual server.
5. In the Policies pane, bind the policy to the virtual server.

### Sample Configuration

```
1 > add service SVC-DNS-1 203.0.113.50 DNS 53
2 Done
3
4 > add service SVC-DNS-2 203.0.113.60 DNS 53
5 Done
6
7 > add dns Action64 DNS64-Action-1 -Prefix 2001:DB8:300::/96
8 Done
9
10 > add dns Policy64 DNS64-Policy-1 -rule "CLIENT.IPv6.SRC.IN_SUBNET
11 (2001:DB8:5001::/64)"
12 -action DNS64-Action-1
13 Done
14
15 > add lb vserver LBVS-DNS64-1 DNS 2001:DB8:9999::99 53 -dns64 ENABLED
16 Done
17
18 > bind lb vserver LBVS-DNS64-1 SVC-DNS-1
19 Done
20
21 > bind lb vserver LBVS-DNS64-1 SVC-DNS-2
22 Done
23
24 > bind lb vserver LBVS-DNS64-1 -policyname DNS64-Policy-1 -priority 2
25 Done
26 <!--NeedCopy-->
```

## Stateful NAT64 Translation

May 2, 2023

The stateful NAT64 feature enables communication between IPv6 clients and IPv4 servers through IPv6 to IPv4 packet translation, and vice versa, while maintaining session information on the NetScaler appliance.

A stateful NAT64 configuration on the NetScaler appliance has the following components:

- **NAT64 rule**—An entry consisting of an ACL6 rule and a netprofile, which consists of a pool of NetScaler owned SNIP Addresses.
- **NAT64 IPv6 Prefix**—A global IPv6 prefix of length 96 bits ( $128-32=96$ ) configured on the appliance.

Note: Currently the NetScaler appliance supports only one prefix to be used commonly with all NAT 64 rules.

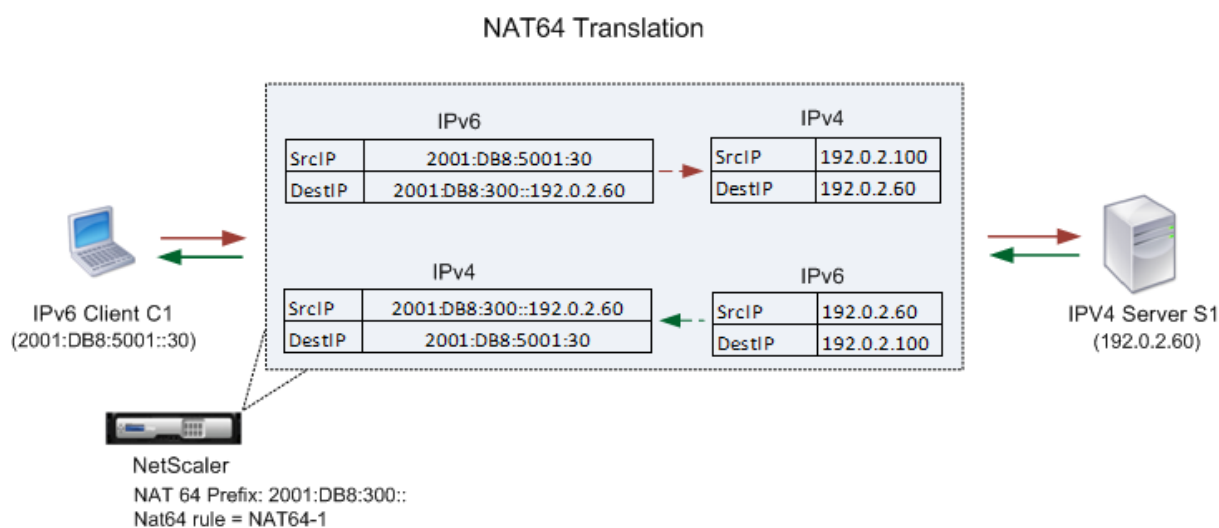

The NetScaler appliance considers an incoming IPv6 packet for NAT64 translation when all of the following conditions are met:

- The incoming IPv6 packet matches the ACL6 rule bound to a NAT64 rule.
- The destination IP address of the IPv6 packet matches the NAT64 IPv6 prefix.

When an IPv6 request packet received by the NetScaler appliance matches an ACL6 defined in a NAT64 rule and the destination IP of the packet matches the NAT64 IPv6 prefix, the NetScaler appliance considers the IPv6 packet for translation.

The appliance translates this IPv6 packet to an IPv4 packet with a source IP address matching one of the IP address bound to the netprofile defined in the NAT64 rule, and a destination IP address consisting of the last 32 bits of the destination IPv6 address of the IPv6 request packet. The NetScaler appliance creates a NAT64 session for this particular flow and forwards the packet to the IPv4 server. Subsequent responses from the IPv4 server and requests from the IPv6 client are translated accordingly by the appliance, on the basis of information in the particular NAT64 session.

Consider an example in which an enterprise hosts site `www.example.com` on server S1, which has an IPv4 address. To enable communication between IPv6 clients and IPv4 server S1, NetScaler appliance NS1 is deployed with a stateful NAT64 configuration that includes a NAT64 rule and a NAT64 prefix. A mapped IPv6 address of server S1 is formed by concatenating the NAT64 IPv6 prefix [96 bits] and the IPv4 source address [32 bits]. This mapped IPv6 address is then manually configured in the DNS servers. The IPv6 clients get the mapped IPv6 address from the DNS servers to communicate with IPv4 server S1.

The following table lists the settings used in this example: [Stateful NAT64 translation example settings](#).

Following is the traffic flow in this example:

1. IPv6 client CL1 sends a request packet to Map-Sevr-IPv6 (2001:DB8:300::192.0.2.60) address.
2. The NetScaler appliance receives the request packet. If the request packet matches the ACL6 defined in the NAT64 rule, and the destination IP address of the packet matches the NAT64 IPv6 prefix, the NetScaler considers the IPv6 packet for translation.
3. The appliance creates a translated IPv4 request packet with:
  - Destination IP address field containing the NAT64 prefix stripped from the destination address of the IPv6 request (Sevr\_IPv4 = 192.0.2.60)
  - Source IP address field containing one of the IPv4 address bound to Netprofile-1(in this case, 192.0.2.100)
4. The NetScaler appliance creates a NAT64 session for this flow and sends the translated IPv4 request to server S1.
5. IPv64 server S1 responds by sending an IPv4 packet to the NetScaler appliance with:
  - Destination IP address field containing 192.0.2.100
  - Source IP address field containing the address ofSevr\_IPv4(192.0.2.60)
6. The appliance receives the IPv4 response packet, searches all the session entries, and finds that the IPv6 response packet matches the NAT64 session entry created in step 4. The appliance considers the IPv4 packet for translation.
7. The appliance creates a translated IPv6 response packet with:
  - Destination IP address field=Client\_IPv6=2001:DB8:5001::30

- Source IP address field = Concatenation of NAT64 Prefix (First 96 bits) and Sevr\_IPv4 (last 32 bits) =2001:DB8:300::192.0.2.60

8. The appliance sends the translated IPv6 response to client CL1.

## Limitations of Stateful NAT64

The following limitations apply to stateful NAT64:

- Translation of IPv4 options is not supported.
- Translation of IPv6 routing headers is not supported.
- Translation of hop-by-hop extension headers of IPv6 packets is not supported.
- Translation of ESP and EH headers of IPv6 packets is not supported.
- Translation of multicast packets is not supported.
- Packets of Stream Control Transmission Protocol (SCTP), Datagram Congestion Control Protocol (DCCP), and IPSec, are not translated.

## Configuring Stateful NAT64

Creating the required entities for stateful NAT64 configuration on the NetScaler appliance involves the following procedures:

1. Add an ACL6 rule with action ALLOW.
2. Add an ipset, which binds multiple IP addresses.
3. Add a netprofile and bind the ipset to it. If you want to bind only one IP address, you need not create an ipset entity. In that case, bind the IP address directly to the netprofile.
4. Add a NAT64 rule, which includes binding the ACL6 rule and the netprofile to the NAT 64 rule.
5. Add a NAT64 IPv6 prefix.

### CLI procedures

To add an ACL6 rule by using the CLI:

At the command prompt, type:

- `add ns acl6 <acl6name> <acl6action> ...`

To add an IPset and bind multiple IPs to it by using the CLI:

At the command prompt, type:

- `add ipset <name>`
- `bind ipset <name> <IPaddress ...>`

To add a netprofile by using the CLI:

At the command prompt, type:

- add netprofile <name> -srcIP <IPaddress or IPset>

To add a NAT64 rule by using the CLI:

At the command prompt, type:

- add nat64 <name> <acl6name> -netProfile <string>

To add a NAT64 prefix by using the CLI:

At the command prompt, type:

---

```
set ipv6 -natprefix <ipv6_addr *>
```

---

•

**Example:**

```
1 > add acl6 ACL6-1 ALLOW -srcIPv6 2001:DB8:5001::30
2 Done
3
4 > apply acls6
5 Done
6
7 > add ip 192.0.2.100 255.255.255.0 - type SNIP
8 Done
9
10 > add ip 192.0.2.102 255.255.255.0 - type SNIP
11 Done
12
13 > add ipset IPset-1
14 Done
15
16 > bind ipset IPset-1 192.0.2.100 192.0.2.102
17 IPAddress "192.0.2.100" bound
18 IPAddress "192.0.2.102" bound
19 Done
20
21 > add netprofile Netprofile-1 -srcIP IPset-1
22 Done
23
24 > add nat64 NAT64-1 ACL6-1 -netprofile Netprofile-1
25 Done
26
27 > set ipv6 -natprefix 2001:DB8:300::/96
28 Done
29 <!--NeedCopy-->
```

## GUI procedures

To add a NAT64 rule by using the GUI:

Navigate to System > Network > Routes > NAT64, and add a new NAT64 rule, or edit an existing rule.

To add a NAT64 prefix by using the GUI:

Navigate to System > Network, in the Settings group, click Configure INAT Parameters, and set the Prefix parameter.

## RNAT

May 2, 2023

In Reverse Network Address Translation (RNAT), the NetScaler appliance replaces the source IP addresses in the packets generated by the servers with public NAT IP addresses. By default, the appliance uses a SNIP address as the NAT IP address. You can also configure the appliance to use a unique NAT IP address for each subnet. You can also configure RNAT by using Access Control Lists (ACLs). Use Source IP (USIP), Use Subnet IP (USNIP), and Link Load Balancing (LLB) modes affect the operation of RNAT. You can display statistics to monitor RNAT.

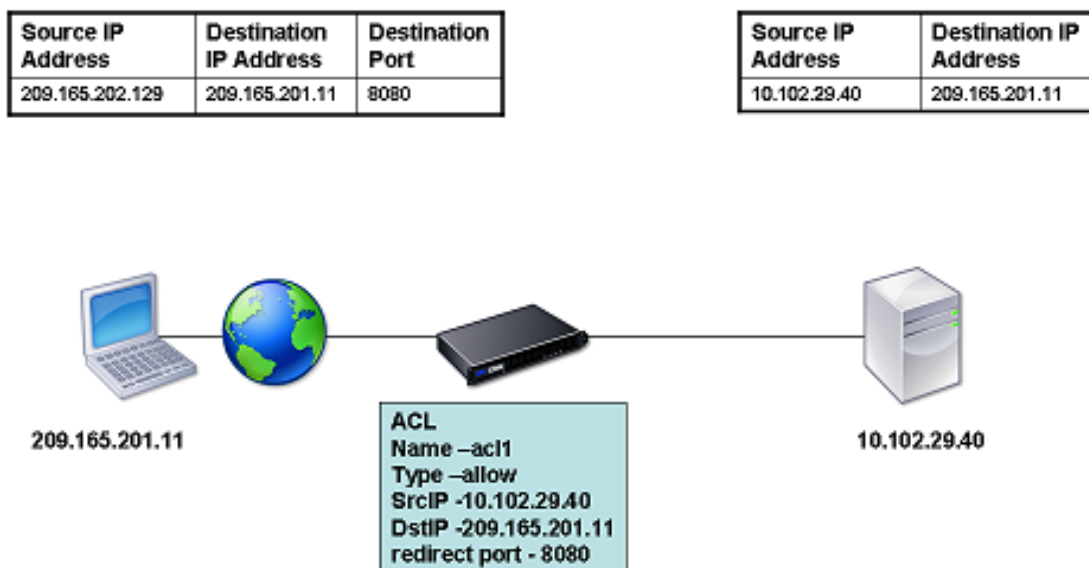

**Note:** The ephemeral port range for RNAT on the NetScaler appliance is 1024-65535.

You can use either a network address or an extended ACL as the condition for an RNAT entry:

- **Using a Network address.** When you use a network address, RNAT processing is performed on all of the packets coming from the specified network.
- **Using Extended ACLs.** When you use ACLs, RNAT processing is performed on all packets that match the ACLs. To configure the NetScaler appliance to use a unique IP address for traffic that matches an ACL, you must perform the following three tasks:
  1. Configure the ACL.
  2. Configure RNAT to change the source IP address and Destination Port.
  3. Apply the ACL.

The following diagram illustrates RNAT configured with an ACL.

Figure 1. RNAT with an ACL

You have the following basic choices for the type of NAT IP address:

- **Using a SNIP as the NAT IP Address.** When using a SNIP as the NAT IP address, the NetScaler appliance replaces the source IP addresses of server-generated packets with the a SNIP. Therefore, the SNIP address must be a public IP address. If Use Subnet IP (USNIP) mode is enabled, the NetScaler can use a subnet IP address (SNIP) as the NAT IP address.
- **Using a Unique IP Address as the NAT IP Address.** When using a unique IP address as the NAT IP address, the NetScaler appliance replaces the source IP addresses of server-generated packets with the unique IP address specified. The unique IP address must be a public NetScaler-owned IP address. If multiple NAT IP addresses are configured for a subnet, NAT IP selection uses the round robin algorithm.

This configuration is illustrated in the following diagram.

Figure 2. Using a Unique IP Address as the NAT IP Address

## Before you begin

Before configuring a RNAT rule, consider the following points:

- When RNAT and Use Source IP (USIP) are both configured on the NetScaler appliance, RNAT takes precedence. In other words, the source IP address of the packets, which matches a RNAT rule, is replaced according to the setting in the RNAT rule.
- In a topology where the NetScaler appliance performs both Link Load Balancing (LLB) and RNAT for traffic originating from the server, the appliance selects the source IP address based on the router. The LLB configuration determines selection of the router. For more information about LLB, see [Link Load Balancing](#).

## Configure RNAT

The following instructions provide separate command-line procedures for creating RNAT entries that use different conditions and different types of NAT IP addresses. In the GUI, all of the variations can be configured in the same dialog box, so there is only one procedure for GUI users.

### CLI procedures

To create an RNAT rule by using the CLI:

At the command prompt, to create the rule and verify the configuration, type:

- `add rnat <name> (<network> | (<aclname> [-redirectPort <port>]))`
- `bind rnat <name> <natIP>@ ...`
- `show rnat`

To modify or remove an RNAT rule by using the CLI:

- To modify an RNAT rule:  
`set rnat <name> (<aclname> [-redirectPort <port>])`
- To remove an RNAT rule, type the command.  
`rm rnat <name>`

Use the following command to verify the configuration:

- `show rnat`

#### Examples:

```
1 A network address as the condition and a SNIP address as the NAT IP
 address:
2
3 > add rnat RNAT-1 192.168.1.0 255.255.255.0
4 Done
5
6 A network address as the condition and a unique IP address as the NAT
 IP address:
7
8 > add rnat RNAT-2 192.168.1.0 255.255.255.0
9 Done
10
11 > bind rnat RNAT-2 -natip 10.102.29.50
12 Done
13
14 If instead of a single NAT IP address you specify a range, RNAT entries
 are created with all the NetScaler-owned IP addresses, except the
 NSIP, that fall within the range specified:
15
16 > add rnat RNAT-3 192.168.1.0 255.255.255.0
17 Done
18
19 > bind rnat RNAT-3 -natip 10.102.29.[50-110]
20 Done
21
22
23 An ACL as the condition and a SNIP address as the NAT IP address:
24
25 > add rnat RNAT-4 acl1
26 Done
27
```

```

28 An ACL as a condition and a unique IP address as the NAT IP address:
29
30 > add rnat RNAT-4 acl1
31 Done
32
33 > bind rnat RNAT-4 -natip 10.102.29.50
34 Done
35
36 If instead of a single NAT IP address you specify a range, RNAT entries
 are created with all the NetScaler-owned IP addresses, except the
 NSIP, that fall within the range specified:
37
38 > add rnat RNAT-5 acl1
39 Done
40
41 > bind rnat RNAT-5 -natip 10.102.29.[50-70]
42 Done
43
44 <!--NeedCopy-->

```

## GUI procedures

To create an RNAT entry by using the GUI:

Navigate to **System > Network > NATs**, click the **RNAT** tab, and add a new RNAT rule, or edit an existing rule.

## Monitor RNAT

You can display RNAT statistics to troubleshoot issues related to IP address translation.

The following table describes the statistics associated with RNAT and RNAT IP.

Statistic	Description
Bytes received	Bytes received during RNAT sessions
Bytes sent	Bytes sent during RNAT sessions
Packets received	Packets received during RNAT sessions
Packets sent	Packets sent during RNAT sessions
Syn sent	Requests for connections sent during RNAT sessions
Current sessions	Currently active RNAT sessions

To view RNAT statistics by using the CLI:

At the command prompt, type:

- **stat rnat**

**Example:**

```
1 > stat rnat
2
3 RNAT summary
4
5 Rate (/s) Total
6 Bytes Received 0 0
7 Bytes Sent 0 0
8 Packets Received 0 0
9 Packets Sent 0 0
10 Syn Sent 0 0
11 Current RNAT sessions -- 0
12 Done
13 >
14 <!--NeedCopy-->
```

To monitor RNAT by using the GUI:

Navigate to **System > Network > NATs**, click the **RNAT** tab, and then click **Statistics**.

## Configure RNAT6

Reverse Network Address Translation (RNAT) rules for IPv6 packets are called RNAT6s. When an IPv6 packet generated by a server matches the conditions specified in the RNAT6 rule, the appliance replaces the source IPv6 address of the IPv6 packet with a configured NAT IPv6 address before forwarding it to the destination. The NAT IPv6 address is one of the NetScaler owned SNIP6 or VIP6 addresses.

When configuring an RNAT6 rule, you can specify either an IPv6 prefix or an ACL6 as the condition:

- **Using a IPv6 network address.** When you use an IPv6 prefix, the appliance performs RNAT processing on those IPv6 packets whose IPv6 address matches the prefix.
- **Using ACL6s.** When you use an ACL6, the appliance performs RNAT processing on those IPv6 packets that match the conditions specified in the ACL6.

You have one of the following options to set the NAT IP address:

- Specify a set of NetScaler owned SNIP6 and VIP6 addresses for an RNAT6 rule. The NetScaler appliance uses any one of the IPv6 addresses from this set as a NAT IP address for each session. The selection is based on the round robin algorithm and is done for each session.
- Do not specify any NetScaler owned SNIP6 or VIP6 address for an RNAT6 rule. The NetScaler appliance uses any one of the NetScaler owned SNIP6 or VIP6 addresses as a NAT IP address.

The selection is based on the next hop network to which an IPv6 packet that matches the RNAT rule is destined.

### CLI procedures

To create an RNAT6 rule by using the CLI:

At the command prompt, to create the rule and verify the configuration, type:

- **add rnat6** <name> (<network> | (<acl6name> [-<redirectPort> <port>]))
- **bind rnat6** <name> <natIP6>@ ...
- **show rnat6**

To modify or remove an RNAT6 rule by using the CLI:

- To modify an RNAT6 rule whose condition is an ACL6, type the **set rnat6** <name> command, followed by a new value for the **redirectPort** parameter.
- To remove an RNAT6 rule, type the **clear rnat6** <name> command.

### GUI procedures

To configure an RNAT6 rule by using the GUI:

Navigate to **System > Network > NATs**, click the **RNAT6** tab, and add a new RNAT6 rule, or edit an existing rule.

### Monitor RNAT6

You can display statistics related to the RNAT6 feature to monitor the performance or to troubleshoot problems related to RNAT6 feature. You can display a summary of statistics of the RNAT6 rules or of a particular RNAT6 rule. The statistical counters reflect events since the NetScaler appliance was last restarted. All these counters are reset to 0 when the NetScaler appliance is restarted.

The following lists some of the statistics counters associated with the RNAT6 feature:

- **Bytes received** - Total bytes received during RNAT6 sessions.
- **Bytes sent** - Total number of bytes sent during RNAT6 sessions.
- **Packets received** - Total number of packets received during RNAT6 sessions.
- **Packets sent** - Total number of packets sent during RNAT6 sessions.
- **Syn sent** - Total number of requests for connections sent during RNAT6 sessions
- **Current sessions** - Currently active RNAT6 sessions

To display a summarized statistics of all RNAT6 rules by using the CLI:

At the command prompt, type:

- **stat rnat6**

To display statistics for a specified RNAT6 rule by using the CLI:

At the command prompt, type:

- **stat rnat6** [<rnat6 rule name>]

To display RNAT6 statistics by using the GUI:

Navigate to **System > Network > NATs**, click the **RNAT6** tab, and then click **Statistics**.

```
1 > stat rnat6
2
3 RNAT6 summary
4
5 Rate (/s) Total
6
7 Bytes Received 178 20644
8
9 Bytes Sent 178 20644
10
11 Packets Received 5 401
12
13 Packets Sent 5 401
14
15 Syn Sent 0 2
16
17 Current RNAT6 sessions -- 1
18
19 Done
20
21 <!--NeedCopy-->
```

## Log Start Time and Connection Closure Reasons in RNAT Log Entries

For diagnosing or troubleshooting problems related to RNAT, the NetScaler appliance logs RNAT sessions whenever they are closed.

A log message for an RNAT session consists of the following information:

- NetScaler owned IP address (NSIP address or SNIP address) from which the log message is sourced
- Time stamp of log creation
- Protocol of the RNAT session
- Source IP address

- RNAT IP address
- Destination IP address
- Start time of the RNAT session
- Closing time of the RNAT session
- Total bytes sent by the NetScaler appliance for this RNAT session
- Total bytes received by the NetScaler appliance for this RNAT session
- Reason for closure of the RNAT session. The NetScaler appliance logs closure reason for TCP RNAT sessions that do not use the TCP proxy (TCP proxy disabled) of the appliance. The following are the type of closure reasons that are logged for TCP RNAT sessions:
  - **TCP FIN.** The RNAT session was closed because of a TCP FIN sent by either the source or destination device.
  - **TCP RST.** The RNAT session was closed because of a TCP Reset that was sent by either the source or destination device.
  - **TIMEOUT.** The RNAT session timed out.

The following table shows some sample log entries for RNAT sessions.

Type of Entry	Sample Log Entry
Sample log entry for UDP RNAT session	Dec 1 15:28:12 10.102.53.114 12/01/2015:15:28:12 GMT 0-PPE-0 : default UDP NAT\_OTHERCONN\_DELINK 154 0 : Source 1.2.2.5:23431 - Destination 192.168.123.122:22 - NatIP 192.168.123.1:4045 - Destination 192.168.123.122:22 - Start Time 12/01/2015:15:26:58 GMT - Delink Time 12/01/2015:15:28:12 GMT - Total\_bytes\_send 2511 - Total\_bytes\_recv 3725
Sample log entry for TCP RNAT session. The log entry shows that the session closed because of TCP Reset	Dec 1 15:29:59 10.102.53.114 12/01/2015:15:27:59 GMT 0-PPE-0 : default TCP NAT\_OTHERCONN\_DELINK 152 0 : Source 1.2.2.5:33826 - Destination 192.168.123.122:22 - NatIP 192.168.123.1:2384 - Destination 192.168.123.122:22 - Start Time 12/01/2015:15:27:40 GMT - Delink Time 12/01/2015:15:27:59 GMT - Total\_bytes\_send 2147 - Total\_bytes\_recv 3257 - Closure Reason TCP RST

Type of Entry	Sample Log Entry
Sample log entry for TCP RNAT session. The log entry shows that the session timed out	Dec 1 15:30:12 10.102.53.114 12/01/2015:15:30:12 GMT 0-PPE-0 : default TCP NAT\_OTHERCONN\_DELINK 155 0 : Source 1.2.2.5:64976 - Destination 192.168.123.115:22 - NatIP 192.168.123.1:19636 - Destination 192.168.123.115:22 - Start Time 12/01/2015:15:27:25 GMT - Delink Time 12/01/2015:15:30:12 GMT - Total\_bytes\_send 0 - Total\_bytes\_recv 0 - Closure Reason TIMEOUT

## Stateful Connection Failover for RNAT

Connection failover helps prevent disruption of access to applications deployed in a distributed environment. The NetScaler appliance now supports stateful connection failover for connections related to RNAT rules in a NetScaler High Availability (HA) setup. In an HA setup, connection failover (or connection mirroring) refers to the process of keeping an established TCP or UDP connection active when a failover occurs.

The primary appliance sends messages to the secondary appliance to synchronize current information about the RNAT connections. The secondary appliance uses this connection information only in the event of a failover. When a failover occurs, the new primary NetScaler appliance has information about the connections established before the failover and hence continues to serve those connections even after the failover. From the client's perspective this failover is transparent. During the transition period, the client and server may experience a brief disruption and retransmissions.

Connection failover can be enabled per RNAT rule. For enabling connection failover on an RNAT rule, you enable the `connFailover` (Connection Failover) parameter of that specific RNAT rule by using either CLI or GUI.

To enable connection failover for a RNAT rule by using the CLI:

At the command prompt, type:

- `set rnat <name> -connfailover (ENABLED | DISABLED)`
- `show rnat`

To enable connection failover for a RNAT rule by using the GUI:

1. Navigate to **System > Network > NATs**, and then click the **RNAT** tab.
2. Select **Connection Failover** while adding a new RNAT rule, or while editing an existing rule.

## Reserving the source port for RNAT connections to servers

For a request hitting an RNAT configuration that has one or more RNAT IP addresses and Use Proxy port parameter disabled, the NetScaler appliance uses one of the RNAT IP address and the source port of the RNAT request for connecting to servers. Prior to the 13.0 47.x build, RNAT connection (using the RNAT client's source port) to the server fails if the same source port is already been used in some other connections.

- **Source port less than 1024.** By default, the NetScaler appliance reserves the first 1024 ports of any NetScaler owned IP address (including RNAT IP addresses). Prior to 13.0 47.x build, RNAT connection (using the RNAT client's source port) to the server fails if the source port of the RNAT request is less than or equal to 1024. With the 13.0 47.x build, RNAT connection (using the RNAT client's source port) to the server succeeds even if the source port of the RNAT request is less than or equal to 1024.
- **Source port greater than 1024.** Prior to the 13.0 47.x build, RNAT connection (using the RNAT client's source port) to the server fails if the same source port is already been used in some other connections. With 13.0 47.x build, you can specify a range of RNAT client source ports in the [Retain Source Port range](#) (`retainsourceportrange`) parameter as part of an RNAT configuration. The NetScaler appliance reserves these RNAT client source ports on the RNAT IP address to be used only for RNAT connection to servers.

## Removing RNAT Sessions

You can remove any unwanted or inefficient RNAT sessions from the NetScaler appliance. The appliance immediately releases resources (such as the port of the NAT IP address, and memory) allocated for these sessions, making the resources available for new sessions. The appliance also drops all the subsequent packets related to these removed sessions. You can remove all or selected RNAT sessions from the NetScaler appliance.

To clear all RNAT sessions by using the CLI:

At the command prompt, type:

- **flush rnatsession**

To clear selective RNAT sessions by using the CLI:

At the command prompt, type:

- `flush rnatsession ((-network <ip_addr> -netmask <netmask>) | -natIP <ip_addr> | -aclname <string>)`

To clear all or selective RNAT sessions by using the GUI:

1. Navigate to **System > Network > NATs**, and then click the **RNAT** tab.
2. In the **Actions** Menu, click **Flush RNAT Sessions** to remove all or selective RNAT sessions (for example, removing RNAT sessions with a specific RNAT IP, or belonging to a specific Network or ACL based RNAT rule).

### Sample Configurations:

```
1 Clear all RNAT sessions existing on a NetScaler appliance
2
3 > flush rnatsession
4
5 Done
6
7 Clear all RNAT sessions belonging to network based RNAT rules that
8 has 203.0.113.0/24 network as the matching condition.
9
10 > flush rnatsession -network 203.0.113.0 -netmask 255.255.255.0
11
12 Done
13
14 Clear all RNAT sessions with RNAT IP 192.0.2.90.
15
16 > flush rnatsession -natIP 192.0.2.90
17
18 Done
19
20 Clear all RNAT sessions belonging to ACL based RNAT rules that has
21 ACL-RNAT-1 as the matching condition.
22
23 > flush rnatsession -aclname ACL-RNAT-1
24
25 Done
26 <!--NeedCopy-->
```

## Configuring Prefix-Based IPv6-IPv4 Translation

May 2, 2023

Prefix-based translation is a process of translating packets sent from private IPv6 servers into IPv4 packets, using an IPv6 prefix configured in the NetScaler appliance. This prefix has a length of 96 bits (128-32=96). The IPv6 servers embed the destination IP address of the IPv4 servers or hosts in the last 32 bits of the destination IP address field of the IPv6 packets. The first 96 bits of the destination IP address field are set as the IPv6 NAT prefix.

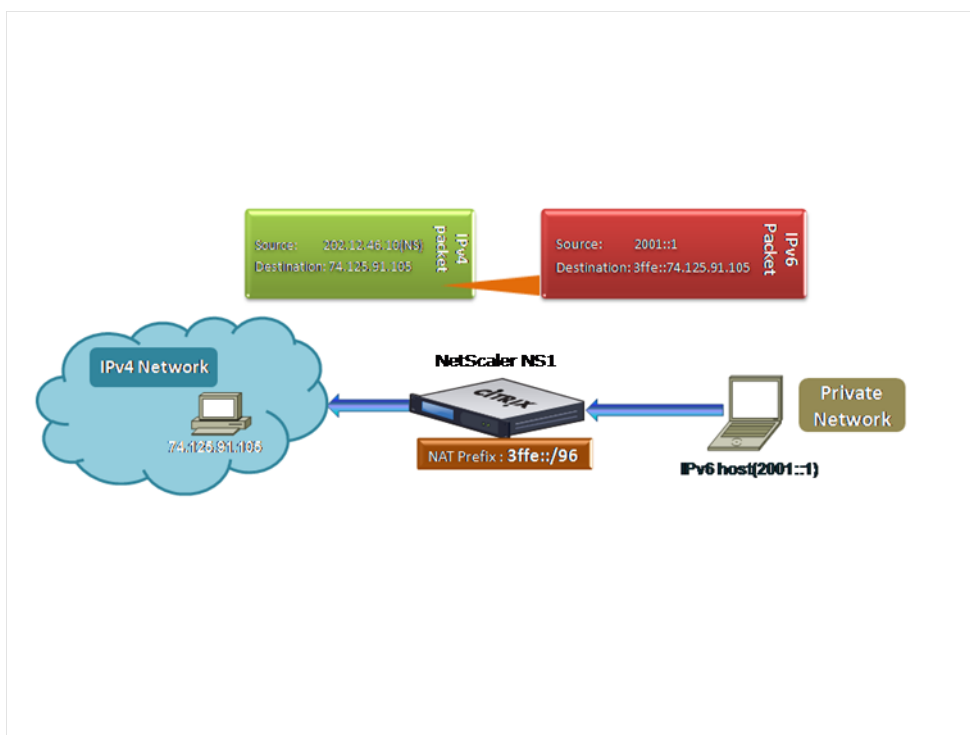

The NetScaler appliance compares the first 96 bits of the destination IP address of all the incoming IPv6 packets to the configured prefix. If there is a match, the NetScaler appliance generates an IPv4

packet and sets the destination IP address as the last 32 bits of the destination IP address of the matched IPv6 packet. IPv6 packets addressed to this prefix have to be routed to the NetScaler so that the IPv6-IPv4 translation is done by the NetScaler.

In the following diagram, 3ffe::/96 is configured as the IPv6 NAT prefix on NetScaler NS1. The IPv6 host sends an IPv6 packet with destination IP address 3ffe::74.125.91.105. NS1 compares the first 96 bits of the destination IP address of all the incoming IPv6 packets to the configured prefix, and they match. NS1 then generates an IPv4 packet and sets the destination IP address as 74.125.91.105.

Figure 1. IPv6-IPv4 Prefix-Based Translation

To configure prefix-based IPv6-IPv4 translation by using the CLI:

At the command prompt, type:

```
set ipv6 [-natprefix <ipv6_addr *>]
```

- 
- show ipv6

**Example:**

```
1 > set ipv6 -natprefix 3ffe::/96
2 Done
3 <!--NeedCopy-->
```

To configure prefix-based IPv6-IPv4 translation by using the GUI:

Navigate to System > Network, in the Settings group, click Configure INAT Parameters, and set the Prefix parameter.

## IP Prefix NAT

May 2, 2023

The NetScaler appliance supports translating a part of the source IP address instead of the complete address of packets received on the appliance. IP prefix NAT includes changing one or more octets or bits of the source IP address.

The NetScaler appliance supports IP prefix NAT for load balancing configurations of the following types: ANY, UDP, DNS, TCP, and HTTP.

### **Use Case: Zonification of Clients for a Deployment of a NetScaler appliance and an Optimization Device**

IP prefix NAT is very useful in a deployment that includes a NetScaler appliance and an optimization device (for example, Citrix ByteMobile). This type of deployment has different geographically located client networks, which share the same network address. The NetScaler appliance must send the traffic received from each of the client networks to the optimization device before forwarding to the destination.

The device sends the optimized traffic back to the NetScaler appliance. Because the optimization requirement is different for traffic from each client network, the optimization device must recognize the client network of each packet that it receives. The solution is to segregate traffic from each client network into a different zone by using VLANs. IP prefix NAT with a different setting is configured for each zone. The NetScaler appliance translates the last octet of the source IP address of every packet, and the translated octet value is different for each zone.

Consider an example of two zones, Z1 and Z2, sharing network address 192.0.2.0/24. On the NetScaler appliance, IP prefix NAT entities named natrule-1 and natrule-2 are configured for these two zones. Before the appliance forwards a packet from Z1, natrule-1 translates the last octet of the packet's source IP address to 100. Similarly, for packets from Z2, natrule-2 translates the last octet of the source IP address to 200. For two clients, CL1-Z1 in zone Z1 and CL1-Z2 in zone Z2, each with IP address 192.0.2.30, the NetScaler appliance translates the source IP address of CL1-Z1's packets to 100.0.2.30 and of CL1-Z2's packets to 200.0.2.30. The optimization device to which the NetScaler appliance sends the translated packets is configured to use a packet's source IP address to recognize the zone, so it applies the appropriate optimization configured for the zone from which the packet originated.

## Configuration Steps

Configuring IP prefix NAT consists of the following steps:

- **Create a net profile and set the NAT Rule parameter of a net profile.** A NAT rule specifies two IP addresses and a net mask. The first IP address (specified by IP Address parameter) is the source IP address that is to be translated with the second one (specified by IP Rewrite parameter). The net mask specifies the part of the source IP address that is to be translated with the same part of the second IP address.
- **Bind the net profile to load balancing virtual servers or services.** A net profile with NAT rule setting can be bound to a virtual server or service of type ANY, UDP, DNS, TCP, and HTTP. After binding a net profile to a virtual server or service, the NetScaler appliance matches the source IP address of the incoming packets related to the virtual server or service with the NAT rule setting. The NetScaler then performs IP prefix NAT for packets that match the NAT rule.

To configure IP prefix NAT translation by using the command line:

At the command prompt, type:

- **bind netProfile** <name> (-natRule <ip\_addr> <netmask> <rewritelp>)
- **show netprofile** <name>

To configure IP prefix NAT by using the GUI:

1. Navigate to **System > Network > Net Profiles**.
2. Set the following parameters under NAT Rules while adding or modifying NetProfiles.
  - IP Address
  - Netmask
  - Rewrite IP

## Sample configuration

In the following sample configuration, net profile PARTIAL-NAT-1 has IP prefix NAT settings and is bound to load balancing virtual server LBVS-1, which is of type ANY. For packets received on LBVS-1 from 192.0.0.0/8, the NetScaler appliance translates the last octet of the packet's source IP address to 100. For example, a packet with source IP address 192.0.2.30 received on LBVS-1, the NetScaler appliance translates the source IP address to 100.0.2.30 before sending it one of the bound servers.

```
1 > add netprofile PARTIAL-NAT-1
2 Done
3
4 > bind netprofile PARTIAL-NAT-1 -natrule 192.0.0.0 255.0.0.0 100.0.0.0
5 Done
```

```
6
7 > add lb vserver LBVS-1 ANY 203.0.113. 61 * -netprofile PARTIAL-NAT-1
8 Done
9 <!--NeedCopy-->
```

## Static ARP

May 2, 2023

You can add static ARP entries to and remove static ARP entries from the ARP table. After adding an entry, you should verify the configuration. If the IP address, port, or MAC address changes after you create a static ARP entry, you must remove or manually adjust the static entry. Therefore, creating static ARP entries is not recommended unless necessary.

To add a static ARP entry by using the CLI:

At the command prompt, type:

- **add arp -IPAddress** <ip\_addr> **-mac**<mac\_addr> **-ifnum** <interface\_name>
- **show arp** <IPAddress>

### Example:

```
1 > add arp -ip 10.102.29.6 -mac 00:24:e8:73:ca:ec -ifnum 1/1
2 Done
3 <!--NeedCopy-->
```

To remove a static ARP entry by using the CLI:

At the command prompt, type the **rm arp** command and the IP address.

To add a static ARP entry by using the GUI:

Navigate to **System > Network > ARP Table**, and add a static ARP entry.

## Specify a VLAN in a Static ARP Entry

In a static ARP entry, you can specify the VLAN through which the destination device is accessible. This feature is useful when the interface specified in the static ARP entry is part of multiple tagged VLANs and the destination is accessible through one of the VLANs. The NetScaler appliance includes the specified VLAN ID in the outgoing packets matching the static ARP entry. If you don't specify a VLAN ID in an ARP entry, and the specified interface is part of multiple tagged VLANs, the appliance assigns the interface's native VLAN to the ARP entry.

For example, say NetScaler interface 1/2 is part of native VLAN 2 and of tagged VLANs 3 and 4, and you add a static ARP entry for network device A, which is part of VLAN 3 and is accessible through interface 1/2. You must specify VLAN 3 in the ARP entry for network device A. The NetScaler appliance then includes tagged VLAN 3 in all the packets destined to network device A, and sends them from interface 1/2.

If you don't specify a VLAN ID, the NetScaler appliance assigns native VLAN 2 for the ARP entry. Packets destined to device A are dropped in the network path, because they do not specify tagged VLAN 3, which is the VLAN for device A.

To specify a VLAN in a static ARP entry by using the CLI:

At the command prompt, type:

- **add arp -IPAddress** <ip\_addr> **-mac**<mac\_addr> **-ifnum** <interface\_name> [**-vlan** <positive\_integer>]
- **show arp** <IPAddress>

**Example:**

```
1 > add arp -ip 198.51.100.91 -mac 36:db:4b:f6:12:15 -ifnum 1/2 -vlan 3
2 Done
3 <!--NeedCopy-->
```

## Set the Timeout for Dynamic ARP Entries

September 21, 2020

You can globally set an aging time (time-out value) for dynamically learned ARP entries. The new value applies only to ARP entries that are dynamically learned after the new value is set. Previously existing ARP entries expire after the previously configured aging time. You can specify an ARP time-out value of from 1 through 1200 seconds.

To set the time-out for dynamic ARP entries by using the CLI:

At the command prompt, type:

- **set arpparam -timeout** <positive\_integer>]
- **show arpparam**

**Example:**

```
1 > set arpparam -timeout 500
2 Done
3 <!--NeedCopy-->
```

To set the time-out for dynamic ARP entries to its default value by using the CLI:

At the command prompt, type:

- **unset arpparam**
- **show arpparam**

**Example:**

```
1 > unset arpparam
2 Done
3 <!--NeedCopy-->
```

To set the time-out for dynamic ARP entries by using the GUI:

Navigate to **System > Network**, in the **Settings** group, click **Configure ARP Global Parameters**, and set the **ARP Table Entry Timeout** parameter.

## Neighbor Discovery

May 2, 2023

Neighbor discovery (ND) is one of the most important protocols of IPv6. It is a message-based protocol that combines the functionality of the Address Resolution Protocol (ARP), Internet Control Message Protocol (ICMP), and Router Discovery. ND allows nodes to advertise their link layer addresses and obtain the MAC addresses or link layer addresses of the neighboring nodes. This process is performed by the Neighbor Discovery protocol (ND6).

Neighbor discovery can perform the following functions:

- **Router Discovery:** Enables a host to discover the local routers on an attached link and automatically configure a default router.
- **Prefix Discovery:** Enables the host to discover the network prefixes for local destinations.  
**Note:** The NetScaler appliance does not support Prefix Discovery.
- **Parameter Discovery:** Enables a host to discover additional operating parameters, such as MTU and the default hop limit for outbound traffic.
- **Address Autoconfiguration:** Enables hosts to automatically configure IP addresses for interfaces both with and without stateful address configuration services such as DHCPv6. The NetScaler does not support Address Autoconfiguration for Global IPv6 addresses.
- **Address Resolution:** Equivalent to ARP in IPv4, enables a node to resolve a neighboring node's IPv6 address to its link-layer address.

- **Neighbor Unreachability Detection:** Enables a node to determine the reachability state of a neighbor.
- **Duplicate Address Detection:** Enables a node to determine whether an NSIP address is already in use by a neighboring node.
- **Redirect:** Equivalent to the IPv4 ICMP Redirect message, enables a router to redirect the host to a better first-hop IPv6 address to reach a destination.

**Note:** The NetScaler appliance does not support IPv6 Redirect.

## Configuration Steps

Configuring neighbor discovery consists of the following tasks:

- Adding IPv6 neighbors
- (Optional) Removing IPv6 neighbors

## CLI procedures

To add an IPv6 neighbor by using the CLI:

At the command prompt, type:

- **add nd6** <neighbor> <mac> <ifnum> [-vlan <integer>]
- **sh nd6**

### Example:

```

1 > add nd6 2001::1 00:04:23:be:3c:06 1/1 -vlan 1
2 Done
3
4 > show nd6
5 Neighbor MAC-Address(Vlan, Interface) State
6 ----- -
7 1) ::1 00:d0:68:0b:58:da(1, LO/1) REACHABLE
8 PERMANENT
9 2) fe80::2d0:68ff:fe0b:58da 00:d0:68:0b:58:da(1, LO/1) REACHABLE
10 PERMANENT
11 3) 2001::1 00:04:23:be:3c:06(1, 1/1) REACHABLE
12 STATIC
13 Done
14 <!--NeedCopy-->

```

To remove a neighbor discovery entry by using the CLI:

At the command prompt, type:

- **rm nd6** <Neighbor> -vlan <VLANID>

**Example:**

```
1 rm nd6 3ffe:100:100::1 -vlan 1
2 <!--NeedCopy-->
```

To remove all neighbor discovery entries by using the CLI:

At the command prompt, type:

- **clear nd6**

**GUI procedures**

To add an IPv6 neighbor by using the GUI:

Navigate to **System > Network > IPv6 Neighbors**, and add a new IPv6 neighbor.

To remove a neighbor discovery entry by using the GUI:

Navigate to **System > Network > IPv6 Neighbors**, delete the IPv6 neighbor.

To remove all neighbor discovery entries by using the GUI:

Navigate to **System > Network > IPv6 Neighbors**, and click **Clear**.

**IP Tunnels**

May 2, 2023

An IP Tunnel is a communication channel, that can be created by using encapsulation technologies, between two networks that do not have a routing path. Every IP packet that is shared between the two networks is encapsulated within another packet and then sent via the tunnel.

The NetScaler appliance implements IP Tunneling in the following ways:

- **NetScaler as an Encapsulator (Load Balancing with DSR Mode):** Consider an organization that has multiple data centers across different countries, where the NetScaler maybe at one location and the back-end servers are located in a different country. In essence, the NetScaler and the back-end servers are on different networks and are connected via a router.

When you configure Direct Server Return (DSR) on this NetScaler, the packet sent from the source subnet is encapsulated by the NetScaler and sent via a router and tunnel to the appropriate back-end server. The back-end server decapsulates the packet and responds directly to the client, without allowing the packet to pass via the NetScaler.

- **NetScaler as a Decapsulator:** Consider an organization having multiple data centers each having NetScalers and back-end servers. When a packet is sent from data center A to data center B it is usually sent via an intermediary, say a router or another NetScaler. The NetScaler processes the packet and then forwards the packet to the back-end server. However, if an encapsulated packet is sent, the NetScaler must be able to decapsulate the packet before sending it to the back-end servers. To enable the NetScaler to function as a decapsulator, a tunnel is added between the router and the NetScaler. When the encapsulated packet, with additional header information, reaches the NetScaler, the data packet is decapsulated i.e. the additional header information is removed, and the packet is then forwarded to the appropriate back-end servers. The NetScaler can also be used as a decapsulator for the Load Balancing feature, specifically in scenarios when the number of connections on a vserver exceeds a threshold value and all the new connections are then diverted to a back-up vserver.

The IP Tunnel feature is available with a NetScaler Premium edition license. For more information about NetScaler edition licenses and NetScaler features matrix, see [NetScaler Editions data sheet](#).

## Configure IP Tunnels

Configuring IP tunnels on a NetScaler appliance consists of creating IP tunnel entities. An IP tunnel entity specifies the local and remote tunnel end-point IP addresses and the protocol to be used for the IP tunnel.

**Note:** While configuring an IP tunnel in a cluster setup, the local IP address must be a striped SNIP address.

### CLI procedures

To create an IP tunnel by using the CLI:

At the command prompt type:

- **add iptunnel** <name> <remote> <remoteSubnetMask> <local> -**type** -**protocol** (**ipoverip** | **GRE**)
- **show iptunnel**

To remove an IP tunnel by using the CLI:

To remove an IP tunnel, type the **rm iptunnel** command and the name of the tunnel.

To create an IPv6 tunnel by using the CLI:

At the command prompt type:

- **add ip6tunnel** <name> <remotelp> <local>

- **show ip6tunnel**

To remove an IPv6 tunnel by using the CLI:

To remove an IPv6 tunnel, type the **rm ip6tunnel** command and the name of the tunnel.

### GUI procedures

To create an IP Tunnel by using the GUI:

Navigate to **System > Network > IP Tunnels**, add a new IP tunnel.

To create an IPv6 Tunnel by using the GUI:

Navigate to **System > Network > IP Tunnels > IPv6 Tunnels**, and add a new IPv6 tunnel.

### Customizing IP Tunnels Globally

By globally specifying the source IP address, you can assign a common source IP address across all tunnels. Also, because fragmentation is CPU-intensive, you can globally specify that the NetScaler appliance drop any packet that requires fragmentation. Alternatively, if you would like to fragment all packets as long as a CPU threshold value is not reached, you can globally specify the CPU threshold value.

### CLI procedures

To globally customize IP tunnels by using the CLI:

At the command prompt, type:

- **set ipTunnelParam** **-srcIP** <sourceIPAddress> **-srcIPRoundRobin** ( **YES** | **NO** ) **-dropFrag** [**YES** | **NO**] **-dropFragCpuThreshold** <Positive integer>

- **show ipTunnelParam**

#### Example:

```
1 > set iptunnelparam -srcIP 12.12.12.22 -dropFrag Yes -
 dropFragCpuThreshold 50
2 Done
3
4 > set iptunnelparam -srcIPRoundRobin YES -dropFrag Yes -
 dropFragCpuThreshold 50
5 Done
6 <!--NeedCopy-->
```

To globally customize IPv6 tunnels by using the CLI:

At the command prompt, type:

- **set ip6tunnelparam** **srcIP** <IPv6Address> **srcIPRoundRobin** ( **YES** | **NO** ) **dropFrag** [**YES** | **NO**] **dropFragCpuThreshold** <Positive integer>
- **show ip6tunnelparam**

### GUI procedures

To globally customize IP tunnels by using the GUI:

Navigate to **System > Network**, in the Settings group, click **IPv4 Tunnel Global Settings**.

1. Navigate to **System > Network**, in the **Settings** group, click **IPv6 Tunnel Global Settings**.
2. In the **Configure IP Tunnel Global Parameters** dialog box, set the parameters.

To globally customize IPv6 tunnels by using the GUI:

1. Navigate to **System > Network**, in the **Settings** group, click **IPv6 Tunnel Global Settings**.
2. In the **Configure IP Tunnel Global Parameters** dialog box, set the parameters.

### GRE Payload Options in a GRE IP Tunnel

For a configured GRE IP tunnel, the NetScaler appliance encapsulates the entire Layer 2 packet, including the Ethernet header and the VLAN header (dot1q VLAN tag). IP GRE tunnels between NetScaler appliances and some 3rd party devices might not be stable, because these 3rd party devices are not programmed to process some or the Layer 2 packet headers. To configure a stable IP GRE tunnel between a NetScaler appliance and a 3rd party device, you can use the GRE payload parameter of the GRE IP tunnel command set. GRE payload setting can also be applied to a GRE with IPsec tunnel.

You can set the GRE payload parameter to do one of the following before the packet is sent through the GRE tunnel:

- **Ethernet with DOT1Q.** Carry the Ethernet header as well the VLAN header. This is the default setting. For a tunnel bound to a netbridge, inner Ethernet header and VLAN header contains information from the ARP and bridge table of the NetScaler appliance. For a tunnel set as a next hop to a PBR rule, Inner Ethernet destination MAC address is set to zero and the VLAN header specifies the default VLAN. The encapsulated (GRE) packet sent from the NetScaler tunnel end point has the following format:

Outer Ethernet Header	Outer IP Header	GRE Header	Inner Ethernet	Inner VLAN header	Inner IP/IPv6/ARP header	Inner TCP/UDP Header	Payload
-----------------------	-----------------	------------	----------------	-------------------	--------------------------	----------------------	---------

- **Ethernet.** Carry the Ethernet header but drop the VLAN header. Because the packets do not carry any VLAN information in the tunnel, for a tunnel with this setting and bound to a netbridge, you must bind an appropriate VLAN to the netbridge so that on receiving any packets on the tunnel, the NetScaler can forward these packet to the specified VLAN. If the tunnel is set as a next hop in a PBR rule, the NetScaler routes the packets that are received on the tunnel. The encapsulated (GRE) packet sent from the NetScaler tunnel end point has the following format:

Outer Ethernet header	Outer IP header	GRE Header	Inner Ethernet header	Inner IP/IPv6/ARP header	Inner TCP/UDP header	Payload
-----------------------	-----------------	------------	-----------------------	--------------------------	----------------------	---------

- **IP.** Drop the Ethernet header as well as the VLAN header. Because tunnels with this setting do not carry Layer 2 headers, these tunnels cannot be bound to a netbridge but can be set as a next hop in a PBR rule. The peer tunnel endpoint device on receiving the packet either consumes or routes it. The encapsulated (GRE) packet sent from the NetScaler tunnel end point has the following format:

<b>Outer Ethernet header</b>	<b>Outer IP header</b>	<b>GRE header</b>	<b>Inner IP/IPv6 header</b>	<b>Inner TCP/UDP header</b>	<b>Payload</b>
------------------------------	------------------------	-------------------	-----------------------------	-----------------------------	----------------

To drop Layer 2 headers of packets in a GRE IP tunnel by using the CLI:

- **add iptunnel** <name> <remote> <remoteSubnetMask> <local> [-**protocol** <GRE> [-**vlan** <positive\_integer>]] [-**grepayload** <grepayload>] [-**ipsecProfileName** <string>]
- **show iptunnel** <tunnelname>

**Example:**

```

1 > add iptunnel IPTUNNEL-1 203.0.113.133 255.255.255.0 198.51.100.15 -
 protocol GRE -grepayload Ethernet -ipsecProfileName IPTUNNEL-IPSEC
 -1
2 Done
3 <!--NeedCopy-->

```

**IPv6 Traffic through GRE IPV4 Tunnels**

The NetScaler appliance supports transferring IPv6 traffic through an IPV4 GRE tunnel. This feature can be used for enabling communication between Isolated IPv6 networks without upgrading the IPv4 infrastructure between them.

For configuring this feature, you associate a PBR6 rule with the configured IPv4 GRE tunnel through which you want the NetScaler to send and receive IPv6 traffic. The source IPv6 address and destination IPv6 address parameters of the PBR6 rule specify the IPv6 networks whose traffic is to traverse the IPv4 GRE tunnel.

**Note:** IPSec protocol is not supported on GRE IPv4 tunnels that are configured to transfer IPv6 packets.

To create a GRE IPv4 tunnel by using the CLI:

At the command prompt, type:

- **add ipTunnel** <name> <remote> <remoteSubnetMask> <local> **-protocol GRE**
- **show ipTunnel** <name>

To associate a PBR6 rule with a GRE IPv4 tunnel by using the CLI:

- **add ns pbr6** <pbrName> **ALLOW** **-srcIPv6** <network-range> **-dstIPv6** <network-range> **-ipTunnel** <tunnelName>
- **show pbr**

### Sample configuration

In the following sample configuration, GRE IP tunnel TUNNEL-V6onV4 is created with remote tunnel endpoint IP address 10.10.6.30 and local tunnel endpoint IP address 10.10.5.30. The tunnel is then bound to pbr6 PBR6-V6onV4. The srcIPv6 specifies the IPv6 network connected to the local endpoint and destIPv6 specifies the IPv6 network connected to the remote endpoint. The traffic from these IPv6 networks are allowed to traverse through the GRE IPv4 tunnel.

```
1 > add ipTunnel TUNNEL-V6onV4 10.10.6.30 255.255.255.255 10.10.5.30 -
 protocol GRE
2 -ipsecProfileName None
3 Done
4 > add ns pbr6 PBR6-V6onV4 ALLOW -srcIPv6 = 2001:0db8:1::1-2001:0db8
 :1::255 -destIPv6 =
5 1-2001:0db8:4::255 -ipTunnel TUNNEL-V6onV4
6 <!--NeedCopy-->
```

### Send Response Traffic Through an IP-IP Tunnel

You can configure a NetScaler appliance to send response traffic through an IP-IP tunnel instead of routing it back to the source. By default, when the appliance receives a request from another NetScaler or a third-party device through an IP-IP tunnel, it routes the response traffic instead of sending it through the tunnel. You can use policy based routes (PBRs) or enable MAC-Based Forwarding (MBF) to send the response through the tunnel.

In a PBR rule, specify the subnets at both end points whose traffic is to traverse the tunnel. Also set the next hop as the tunnel name. When response traffic matches the PBR rule, the NetScaler appliance sends the traffic through the tunnel.

Alternatively, you can enable MBF to meet this requirement, but the functionality is limited to traffic for which the NetScaler appliance stores session information (for example, traffic related to load balancing or RNAT configurations). The appliance uses the session information to send the response traffic through the tunnel.

### CLI procedures

To create a PBR rule and associate the IP-IP tunnel to it by using the CLI:

At the command prompt, type:

- **add ns pbr** <pbr\_name> **ALLOW** -**srcIP**=<local\_subnet\_range> -**destIP**=<remote\_subnet\_range> -**ipTunnel** <tunnel\_name>
- **apply ns pbrs**
- **show ns pbr** <pbr\_name>

To enable MAC-based forwarding by using the CLI:

At the command prompt, type:

- **enable ns mode MBF**
- **show ns mode**

### GUI procedures

To create a PBR rule and associate the IP-IP tunnel to it by using the GUI:

1. Navigate to **System > Network > PBRs**. On the **PBRs** tab, create a **PBR** rule.
2. While creating the PBR, set the **Next Hop Type** to **IP tunnel** and **IP Tunnel Name** to the configured IP-IP tunnel name.

To enable MAC-based forwarding by using the GUI:

1. Navigate to **System > Settings**, in **Modes and Features**, click **Configure Modes**.
2. On the **Configure Modes** page, select **MAC-based forwarding**.

### Sample configuration

Consider an example of an IPIP tunnel, NS1-NS2-IPIP, which is set up between two NetScaler appliances NS1 and NS2.

By default, for any request that NS2 receives through the tunnel, it routes the response traffic to the source instead of sending it (to NS1) through the tunnel.

You can configure policy based routes (PBRs) or enable MAC-Based Forwarding (MBF) on NS2 for enabling it to send the response through the tunnel.

In the following sample configuration on NS2, NS1-NS2-IPIP is an IPIP tunnel and NS1-NS2-IPIP-PBR is a PBR rule. For requests (with inner source IP address in the range 10.102.147.0-10.102.147.255 and inner destination IP address in the range 10.102.147.0-10.102.147.255) received by NS2 through the tunnel, NS2 sends the corresponding response through the tunnel (to NS1) instead of routing it to the source. The functionality is limited to the traffic that matches the PBR rule.

```
1 > add iptunnel NS1-NS2-IPIP 192.0.2.99 255.255.255.255 203.0.113.99 -
 protocol IPIP
2
3 Done
4 > add pbr NS1-NS2-IPIP-PBR -srcIP 10.102.147.0-10.102.147.255 -destIP
 10.20.1.0-10.20.1.255 -ipTunnel NS1-NS2-IPIP
5
6 Done
7 > apply pbrs
8
9 Done
10 <!--NeedCopy-->
```

Alternatively, MBF can be enabled on NS2. The functionality is limited to traffic for which NS2 stores session information (for example, traffic related to load balancing or RNAT configurations).

```
1 > enable ns mode MBF
2
3 Done
4 <!--NeedCopy-->
```

## Class E IPv4 packets

May 2, 2023

By default, the NetScaler appliance drops any packets if they contain any class E IPv4 address in the source IP or the destination IP fields. If your setup is using class E IPv4 addresses, you can configure the NetScaler appliance to process class E IPv4 packets.

### Before you begin

Before you begin configuring a NetScaler appliance to process class E IPv4 packets, note the following points:

- NetScaler appliances do not support configuring any NetScaler owned IPv4 address (for example, SNIP and VIP) in the class E range. NetScaler appliances only support processing of class E IPv4 packets.
- A NetScaler appliance internally uses class E IPv4 addresses for the IPv6 feature. The NetScaler appliance does not support both features (processing class E IPv4 packets and IPv6 support) working at the same time. The NetScaler appliance imposes a restriction to not enable the IPv6 feature when processing of class E IPv4 packets is enabled, and vice versa.

## Configuration steps

Configuring a NetScaler appliance to process class E IPv4 packets consist of the task of enabling the **IPv4 Class E address clients (allowClassEIPv4)** Layer 3 parameter.

## CLI procedures

To configure the NetScaler appliance to process Class E IPv4 packets by using the CLI:

At the command prompt, type:

```
set l3param -allowClassEIPv4 (ENABLED DISABLED)
```

- 
- **show l3param**

## Sample Configuration:

```
1 > set l3param -allowClassEIPv4 ENABLED
2
3 Done
4
5 > sh l3param
6
7 Network L3 related Configuration Parameters
8
9 icmpgen_rate_threshold : 100
10
11 srcnat : ENABLED
12
13 override_rnat : DISABLED
14
15 drop_df_flag : DISABLED
16
17 .
18
```

```
19 .
20
21 .
22
23 IPv6DynamicRouting : DISABLED
24
25 allowClassEIPv4 : ENABLED
26
27 Done
28 <!--NeedCopy-->
```

## GUI procedures

To configure the NetScaler appliance to process Class E IPv4 packets by using the GUI:

1. Navigate to **System > Network**, and then in the **Settings** section, click **Configure Layer 3 Parameters**.
2. Select **IPv4 Class E address clients** and click **OK**.

## Monitor the free ports available on a NetScaler appliance for a new back-end connection

May 2, 2023

For communication with the physical servers or other peer devices, the NetScaler appliance uses a Citrix owned IP address as the source IP address. The NetScaler appliance maintains a pool of its IP addresses, and dynamically selects an IP address while connecting with a server. Depending on the subnet in which the physical server is placed, the appliance decides which IP address to use. This address pool is used for sending traffic and monitor probes.

You can display the total number of free ports available on the NetScaler owned IP addresses for a new back-end connection. This information helps you in deciding the need for more NetScaler owned IP addresses if the free ports available are nearing exhaustion.

You can provide the following information for the NetScaler appliance to calculate the total number of free ports available for a new back-end connection:

- Citrix owned IP address (optional)
- Destination IP address
- Destination port
- TCP or non-TCP protocol

When you specify all the information except specifying a Citrix owned IP address:

- The NetScaler appliance performs a route lookup for finding all the NetScaler owned IP addresses that can connect to the destination IP address. The appliance then finds and displays the total number of free ports available on these NetScaler owned IP addresses for the specified new back-end connection.

**Note:**

The NetScaler appliance does not perform ECMP lookup, or LLB lookup path, or PBR lookup path for finding the NetScaler owned IP addresses that can connect to the destination IP address.

When you specify all the information including specifying a Citrix owned IP address:

- The NetScaler appliance displays the number of free ports available on the specified IP address for the specified new back-end connection.

### Before you begin

Before you display the total number of free ports available for a new back-end connection, make note of the following points:

- The NetScaler appliance does not perform ECMP lookup, or LLB lookup path, or PBR lookup path for finding the NetScaler owned IP addresses that can connect to the destination IP address.
- The NetScaler appliance does not support displaying free ports available on a link local IP address.

### Steps for displaying the number of free ports available on a NetScaler appliance for a new back-end connection

To display the total number of free ports available on a NetScaler appliance for a new back-end connection:

At the command prompt type:

---

```
• show portallocation ipv6_addr>] -destIP <ip_addr ipv6_addr> -destPort
 [-srcIP <ip_addr -**protocol** <1 for TCP, 0 for
 non-TCP protocol>
```

---

**Example - total number of free ports available on a standalone NetScaler appliance:**

```
1 > show portallocation -destip 198.51.100.30 -destport 80 -protocol 1
2
3 Freeports available : 64505
4 Done
5
6
7 > show portallocation -srcip 192.0.2.30 -destip 198.51.100.30 -destport
8 80 -protocol 1
9 Freeports available for IPAddress 192.0.2.30 : 20505
10 Done
11 <!--NeedCopy-->
```

### Example - total number of free ports available on a Cluster setup:

The following example output displays the total number of free ports available on each node of a two node cluster setup.

```
1 > show portallocation -destip 198.51.100.30 -destport 80 -protocol 1
2
3 Node Id: 1
4 Freeports available : 32321
5
6 Node Id: 0
7 Freeports available : 32184
8
9 Done
10 <!--NeedCopy-->
```

## Monitor the ports usage on a NetScaler appliance for back-end connections using SNMP

You can use the `PORT-ALLOC-EXCEED` SNMP alarm to monitor the ports usage on a NetScaler appliance for back-end connections.

`PORT-ALLOC-EXCEED` SNMP alarm includes the `high-threshold` and `normal-threshold` parameters, which specify the total allocated ports of the NetScaler owned IP addresses as percentages. For example, if the `high-threshold` parameter is set to 90, the NetScaler appliance generates and sends trap messages when the following event happens:

- when the port allocation percentage exceeds 90 percent on any of the NetScaler owned IP address for the back-end connections

The SNMP alerts help you in deciding the need for more NetScaler owned IP addresses if the free ports available are nearing exhaustion.

To Monitor the ports usage on a NetScaler appliance for back-end connections using SNMP

At the command prompt type:

```

• set snmp alarm (DISABLED) -severity state (DISABLED) -thresholdValue
PORT-ALLOC-EXCEED (ENABLED) normalValue -time
-logging (ENABLED

```

```

• sh snmp alarm PORT-ALLOC-EXCEED

```

**Example:**

```

1 > set snmp alarm PORT-ALLOC-EXCEED -logging ENABLED -severity Major -
 state ENABLED -thresholdValue 90 -time 1200
2 Done
3
4 > sh snmp alarm port-alloc-EXCEED
5
6 Alarm Alarm Threshold Normal Threshold Time
 State Severity Logging
7 -----
8 1) PORT-ALLOC-EXCEED 80 80 7200
 ENABLED Major ENABLED
9 Done
10
11 <!--NeedCopy-->

```

For more information on configuring SNMP alarms and SNMP trap listeners, see [Configuring the NetScaler to generate SNMP traps](#).

## Interfaces

May 2, 2023

Before you begin configuring interfaces, decide whether your configuration can use MAC-based forwarding mode, and either enable or disable this system setting accordingly. The number of interfaces in your configuration is different for the different models of the NetScaler appliance. In addition to configuring individual interfaces, you can logically group interfaces, using VLANs to restrict data flow within a set of interfaces, and you can aggregate links into channels. In a high availability setup, you can configure a virtual MAC address if necessary. If you use L2 mode, you might want to modify the aging of the bridge table.

When your configuration is complete, decide whether you should enable the system setting for path MTU discovery. NetScaler appliances can be deployed in active-active mode using VRRP. An active-active deployment, in addition to preventing downtime, makes efficient use of all the NetScaler appli-

ances in the deployment. You can use the Network Visualizer tool to view the network configuration of a NetScaler deployment and configure interfaces, channels, VLANs, and bridge groups.

## Configuring MAC-Based Forwarding

May 2, 2023

With MAC-based forwarding (MBF) enabled, when a request reaches the NetScaler appliance, the appliance remembers the source MAC address of the frame and uses it as the destination MAC address for the resulting replies. MAC-based forwarding can be used to avoid multiple-route/ARP lookups and to avoid asymmetrical packet flows. MAC-based forwarding may be required when the NetScaler is connected to multiple stateful devices, such as VPNs or firewalls, because it ensures that the return traffic is sent to the same device that the initial traffic came from.

MAC-based forwarding is useful when you use VPN devices, because it guarantees that all traffic flowing through a VPN passes back through the same VPN device.

The following topology diagram illustrates the process of MAC-based forwarding.

Figure 1. MAC-Based Forwarding Mode

When MAC-based forwarding (MBF) is enabled, the NetScaler caches the MAC address of:

- The source (a transmitting device such as router, firewall, or VPN device) of the inbound connection.
- The server that responds to the requests.

When a server replies through the NetScaler appliance, the appliance sets the destination MAC address of the response packet to the cached address, ensuring that the traffic flows in a symmetric manner, and then forwards the response to the client. The process bypasses the route table lookup and ARP lookup functions. However, when the NetScaler initiates a connection, it uses the route and ARP tables for the lookup function. In a direct server return configuration, you must enable MAC-based forwarding.

For more information about direct server return configurations, see [Load Balancing](#).

Some deployment topologies may require the incoming and outgoing paths to flow through different routers. MAC-based forwarding would break this topology design.

MBF should be disabled in the following situations:

- **When a server uses network interface card (NIC) teaming without using LACP (802.1ad Link Aggregation).** To enable MAC-based forwarding in this situation, you must use a layer 3 device between the NetScaler and server.  
Note: MBF can be enabled when the server uses NIC teaming with LACP, because the virtual interface uses one MAC address.
- **When firewall clustering is used.** Firewall clustering assumes that ARP is used to resolve the MAC address for inbound traffic. Sometimes the inbound MAC address can be a non-clustered MAC address and should not be used for inbound packet processing.

When MBF is disabled, the appliance uses L2 or L3 connectivity to forward the responses from servers to the clients. Depending on the route table, the routers used for outgoing connection and incoming connection can be different. In the case of reverse traffic (response from the server):

- If the source and destination are on different IP subnets, the appliance uses the route lookup to locate the destination.
- If the source is on the same subnet as the destination, the NetScaler looks up the ARP table to locate the network interface and forwards the traffic to it. If the ARP table does not exist, the NetScaler requests the ARP entries.

To enable or disable MAC-based forwarding by using the CLI:

At the command prompt, type:

- **enable ns mode MBF**
- **disable ns mode MBF**

To enable or disable MAC-based forwarding by using the GUI:

1. Navigate to **System > Settings**, in the **Modes and Features** group, click **Configure modes**.
2. Select or clear the **MAC-based forwarding** option.

## MAC based forwarding for a load balancing setup

Some load balancing setups require that the NetScaler appliance bypasses the global MBF (if enabled) for these setups and instead use the route/ARP lookups for sending packets to the destination.

The MBF parameter of a net profile is used to enable or disable MBF for a specific load balancing configuration. MBF can be set for the client side as well as the server side of a load balancing configuration by binding net profiles (MBF enabled or disabled) to the virtual server and the services.

For example, if a net profile with MBF disabled is bound to the virtual server of a load balancing configuration, the NetScaler appliance bypasses the global MBF (if enabled) and instead use the route/ARP lookups for sending response packets to clients.

## Before you begin

Before you begin configuring MBF for a load balancing configuration, note the following points:

- In a load balancing configuration, the client side (virtual server) and the server side (service/service groups) can have different MBF settings.
- A load balancing configuration inherits global MBF setting if MBF is not set explicitly in the net profiles bound to the virtual server and the services.
- In a load balancing configuration, server side (service) inherits client side MBF setting of net profile bound to the virtual server if no net profile is bound to the service.
- In a load balancing configuration with direct server return mode, client side inherits the MBF setting in the net profile bound to the service.
- In a content switching configuration, client side takes the MBF setting in the net profile bound to the content switching virtual server instead of from the target load balancing virtual server.

## Limitations

Before you begin configuring MBF for a load balancing configuration, note the following limitations:

- MBF setting for load balancing configurations is not supported in a cluster setup.
- For a load balancing virtual server with MAC mode or L2Conn settings, MBF is enabled irrespective of the MBF setting in the bound net profile to the virtual server.
- The NetScaler appliance does not support setting MBF for load balancing monitors using net profile. In other words, the MBF setting of a net profile is not applied to the monitors to which the net profile is bound. The global MBF setting is applied to monitors irrespective of the MBF setting of the bound net profile.

## Configure MBF for load balancing configuration

Configuring MBF for a load balancing configuration consists of the following tasks:

- Enable MBF parameter in a net profile.
- Bind the net profile to a load balancing virtual server or services.

To enable MBF in a net profile by using the CLI:

- To enable MBF while adding a net profile, at the command prompt, type:
  - `**add netProfile** <name> -**MBF** ( **ENABLED** | **DISABLED** )`
  - `show netprofile <name>`
- To enable MBF in an existing net profile, at the command prompt, type:
  - `**set netProfile** <name> -**MBF** ( **ENABLED** | **DISABLED** )`
  - `show netprofile <name>`

To enable MBF in a net profile by using GUI\*\*

1. Navigate to **System > Network > Net Profiles**.
2. Enable the **MBF** parameter while adding or modifying a net profile.

In the following sample configuration, net profile NETPROFILE-MBF-LBVS has MBF enabled and is bound to load balancing virtual server LBVS-1. Also, net profile NETPROFILE-MBF-SVC has MBF enabled and is bound to a load balancing service SVC-1.

```
1 > add netprofile NETPROFILE-MBF-LBVS -MBF ENABLED
2
3 Done
4
5 > add netprofile NETPROFILE-MBF-SVC -MBF ENABLED
6
7 Done
8
9 > set lb vserver LBVS-1 -netprofile NETPROFILE-MBF-LBVS
10
11 Done
12
13 > set service SVC-1 -netprofile NETPROFILE-MBF-SVC
14
15 Done
16
17 <!--NeedCopy-->
```

## Configure network interfaces

November 7, 2023

Network interfaces in the NetScaler appliance are numbered in `<slot><port>` notation. After configuring your interfaces, display the interfaces and their settings to verify the configuration. You can also display this information to troubleshoot a problem in the configuration.

To manage the network interfaces, you can do the following:

- Enable some interfaces and disable others.
- Reset an interface to renegotiate its settings.
- Clear the accumulated statistics for an interface.

To verify the configuration, you can display the interface settings. You can display the statistics for an interface to evaluate its health.

### Set the network interface parameters

The network interface configuration is neither synchronized nor propagated. For an HA pair, you must perform the configuration on each unit independently.

#### Note:

In an HA setup, if the `tag all` parameter is enabled, then the HA packets are also tagged with the VLAN traffic. However, there might be issues with the high availability communication. Therefore, it is recommended to configure NSVLAN or HA SYNC VLAN for HA traffic.

- For NSVLAN configuration, see [Configuring NSVLAN](#).
- For HA SYNC VLAN configuration, see [Configure HA SYNC VLAN](#).

To set the network interface parameters by using the CLI:

At the command prompt, type:

```
1 - set interface <id> [-speed <speed>] [-duplex <duplex>] [-flowControl
 <flowControl>] [-autoneg (DISABLED | ENABLED)] [-haMonitor (ON |
 OFF)] [(ON | OFF)] [-tagall (ON | OFF)] [-lacpMode <lacpMode
 >] [-lacpKey<positive_integer>] [-lacpPriority <positive_integer>]
 [-lacpTimeout (LONG | SHORT)] [-ifAlias <string>] [-throughput <
 positive_integer>][-bandwidthHigh <positive_integer> [-
 bandwidthNormal <positive_integer>]]
2 - show interface [<id>]
3 <!--NeedCopy-->
```

#### Example:

```
1 > set interface 1/8 -duplex full
2 Done
3 <!--NeedCopy-->
```

To set the network interface parameters by using the GUI:

Navigate to **System > Network > Interfaces**, select the network interface that you want to modify (for example, 1/8), click **Edit**, and then set the parameters.

## Setting the receive ring size and ring type for an interface

You can increase the receive ring size and ring type for IX, F1X, F2X, or F4X interfaces on NetScaler MPX and SDX platforms.

An increased ring size provides more cushion to handle burst traffic, but might impact the performance. A ring size of up to 8192 is supported for IX interfaces. A ring size of up to 4096 is supported for F1X, F2X, and F4X interfaces. The default ring size remains 2048.

Interface ring types are elastic by default. They increase or decrease in size based on packet arrival rate. You can configure the ring type as “fixed” in which case the ring size does not change based on traffic rate.

**Note:** This feature is supported from release 13.0 build 41.x, and supported on platforms that have IX, F1X, F2X, or F4X interfaces.

Use the `show hardware` command to identify whether your appliance has IX, F1X, F2X, or F4X interfaces.

### Examples:

The following model has 16 F1X (10G) interfaces and 4 F4X (40G) interfaces.

```
1 > sh hardware
2 Platform: NSMPX-25000-40G 20*CPU+16*F1X+4*F4X+2*E1K+2*CVM N3
 250040
3 Manufactured on: 12/16/2016
4 CPU: 2800MHZ
5 Host Id: 234913926
6 Serial no: N43RJCRV3X
7 Encoded serial no: N43RJCRV3X
8 Netscaler UUID: 336a32d6-2cfa-11e8-bf01-00e0ed5dd23c
9 BMC Revision: 4.08
10 Done
11 <!--NeedCopy-->
```

The following model has 2 1X (10G) interfaces.

```
1 > sh hardware
2 Platform: NSMPX-10500 8*CPU+2*E1K+8*E1K+2*IX+8*CVM 1620 760100
```

```

3 Manufactured on: 12/27/2010
4 CPU: 2832MHZ
5 Host Id: 1707114630
6 Serial no: 7VZZV1ZXJ4
7 Encoded serial no: 7VZZV1ZXJ4
8 Netscaler UUID: eb1bfd72-5176-11e7-ba18-00e0ed1b0d12
9 Done
10 <!--NeedCopy-->

```

To configure ring size and ring type by using the CLI

At the command line, type:

```

1 set interface <id> -ringsize <positive_integer> -ringtype (Elastic |
 Fixed)
2 <!--NeedCopy-->

```

### Parameters:

#### ringsize:

The receive ring size of the interface. A higher number provides more buffers to handle incoming traffic.

Default value: 2048

Minimum value: 512

Maximum value: 16384

#### ringtype:

The receive ring type of the interface. A fixed ring type preallocates the configured number of buffers irrespective of traffic rate. In contrast, an elastic ring, expands and shrinks based on incoming traffic rate.

Possible values: Elastic, Fixed

Default value: Elastic

### Example:

```

1 > set interface 40/2 -ringsize 4096 -ringtype Fixed
2 Done
3 > show interface 40/2
4
5 1) Interface 40/2 (40G Ethernet, CR4, 40 Gbit) #21 flags=0xc020 <
 ENABLED, UP, UP, autoneg, HAMON, HEARTBEAT, 802.1q> MTU=1500, native
 vlan=10, MAC=00:e0:ed:75:14:2a, uptime 119h26m32s
6 Requested: media AUTO, speed AUTO, duplex AUTO, fctl OFF,
 throughput 0
7 Actual: media UTP, speed 40000, duplex FULL, fctl OFF,
 throughput 40000
8 LLDP Mode: NONE, LR Priority: 1024
9 RX: Pkts(1443972660032) Bytes(1457207315336105) Errs(0) Drops
 (53319) Stalls(0)

```

```

10 TX: Pkts(1452311431262) Bytes(1458534011197761) Errs(0) Drops
 (788) Stalls(0)
11 NIC: InDisc(0) OutDisc(0) Fctls(0) Stalls(0) Hangs(0) Muted(0)
12 Bandwidth thresholds are not set.
13 Rx Ring: Configured size=4096, Actual size=4096, Type: Fixed
14 Done
15 <!--NeedCopy-->

```

The last line shows the configured and actual ring size, and the ring type.

To configure ring size and ring type by using the GUI:

1. Navigate to **System > Network > Interfaces**.
2. Select your interface and click **Edit**.
3. In **Ring Size**, specify one of the following:
  - **IX interfaces:** 512, 1024, 2048, 4096, or 8192.
  - **F1X, F2X, or F4X interfaces:** 512, 1024, 2048, or 4096.
4. In **Ring Type**, select Elastic or Fixed.
5. Click **OK**.

## Enable and disable network interfaces

By default, the network interfaces are enabled. Disable any network interface that is not connected to the network, so that it cannot send or receive packets. Disabling a network interface that is connected to the network in a high availability setup can cause a failover.

For more information about high availability, see [High Availability](#).

To enable or disable a network interface by using the CLI:

At the command prompt, type:

```

1 - enable interface <interface_num>
2 - show interface <interface_num>
3 - disable interface <interface_num>
4 - show interface <interface_num>
5 <!--NeedCopy-->

```

### Example:

```

1 > enable interface 1/8
2 Done
3 > show interface 1/8
4 Interface 1/8 (Gig Ethernet 10/100/1000 Mbits) #2
5 flags=0x4004000 <ENABLED, DOWN, BOUND to LA/1, down, autoneg,
 802.1q>

```

```
6 MTU=1514, MAC=00:d0:68:15:fd:3d, downtime 906h58m40s
7 Requested: media UTP, speed AUTO, duplex FULL, fctl OFF,
 throughput 0
8 RX: Pkts(0) Bytes(0) Errs(0) Drops(0) Stalls(0)
9 TX: Pkts(0) Bytes(0) Errs(0) Drops(0) Stalls(0)
10 NIC: InDisc(0) OutDisc(0) Fctls(0) Stalls(0) Hangs(0) Muted(0)
11 Bandwidth thresholds are not set.
12 Done
13 <!--NeedCopy-->
```

To enable or disable a network interface by using the GUI:

1. Navigate to **System > Network > Interfaces**.
2. Select the network interface and, in the **Action** list, select Enable or Disable.

### Reset network interfaces

Network interface settings control properties such as duplex and speed. To renegotiate the settings of a network interface, you must reset it.

To reset a network interface by using the CLI:

At the command prompt, type:

```
1 - reset interface <interface_num>
2 - show interface <interface_num>
3 <!--NeedCopy-->
```

#### Example:

```
1 > reset interface 1/8
2 Done
3 <!--NeedCopy-->
```

To reset a network interface by using the GUI:

1. Navigate to **System > Network > Interfaces**.
2. Select the network interface and, in the **Action** list, select **Reset Interface**.

### Monitor a network interface

You can display network interface statistics to monitor parameters and use the information to check the health of the network interface. You can monitor parameters, such as packets sent and packets received, throughput, Link Aggregate Control Protocol (LACP) data units, and errors. You can clear the statistics of a network interface to monitor its statistics from the time the statistics are cleared.

To display the statistics of the network interfaces by using the CLI:

At the command prompt, type:

```
1 - stat interface <interface_num>
2 <!--NeedCopy-->
```

**Example:**

```
1 > stat interface 1/8
2 Done
3 <!--NeedCopy-->
```

To clear a network interface's statistics by using the CLI:

At the command prompt, type:

```
1 - clear interface <interface_num>
2 <!--NeedCopy-->
```

**Example:**

```
1 > clear interface 1/8
2 Done
3 <!--NeedCopy-->
```

To display the statistics of an Interface by using the GUI:

Navigate to **System > Network > Interfaces**, select the network interface, and click **Interface Statistics**.

To clear a network interface's statistics by using the GUI:

1. Navigate to **System > Network > Interfaces**.
2. Select the network interface and, in the **Action** list, select **Clear Statistics**.

## Configuring Forwarding Session Rules

May 2, 2023

By default, the NetScaler appliance does not create session entries for traffic that it only forwards (L3 mode). For a case in which a client request that the appliance forwards to a server results in a response that has to return by the same path, you can create a forwarding-session rule. A forwarding-session rule creates forwarding-session entries for traffic that originates from or is destined for a particular network and is forwarded by the NetScaler. You can create forwarding session rules for IPv4 traffic as well as IPv6 traffic.

When configuring an IPv4 forwarding-session rule, you can specify either an IPv4 network address or an extended ACL as the condition for identifying IPv4 traffic for which to create a forwarding-session entry:

- **Network address.** When you specify an IPv4 network address, the appliance creates forwarding sessions for IPv4 traffic whose source or destination matches the network address.
- **Extended ACL rule.** When you specify an extended ACL rule, the appliance creates forwarding sessions for IPv4 traffic that matches the conditions specified in the extended ACL rule.

When configuring an IPv6 forwarding-session rule, you can specify either an IPv6 prefix or an ACL6 as the condition for identifying IPv6 traffic for which to create a forwarding-session entry:

- **IPv6 prefix.** When you specify an IPv6 prefix, the appliance creates forwarding sessions for IPv6 traffic whose source or destination matches the IPv6 prefix.
- **ACL6 rule.** When you specify an ACL6 rule, the appliance creates forwarding sessions for IPv6 traffic that matches the conditions specified in the ACL6 rule.

To create an IPv4 forwarding session rule by using the CLI:

At the command prompt, type the following commands to create a forwarding-session rule and verify the configuration:

- `add forwardingSession <name> [<network> <netmask> ] | [-aclname <string>] -connfailover (ENABLED | DISABLED)`
- `show forwardingSession`

**Example:**

```
1 A network address as the condition:
2
3 > add forwardingSession fs-nw-1 10.102.105.51 255.255.255.255
4 Done
5
6 An ACL as the condition:
7
8 > add forwardingSession fs-acl-1 acl1
9 Done
10 <!--NeedCopy-->
```

To configure an IPv4 forwarding session rule by using the GUI:

Navigate to System > Network > Forwarding Sessions, add a new IPv4 forwarding session, or edit an existing forwarding session.

To create an IPv6 forwarding session rule by using the CLI:

- At the command prompt, type the following commands to create a forwarding-session rule and verify the configuration:
  - `add forwardingSession <name> [<IPv6 prefix> ] | [-acl6name <string>]`
  - `show forwardingSession`

**Example:**

```
1 An IPv6 prefix as the condition:
2
3 > add forwardingSession fsv6-pfx-1 3ffe::/64
4 Done
5
6 An ACL6 rule as the condition:
7
8 > add forwardingSession fsv6-acl6-1 - acl6name ACL6-FS
9 Done
10 <!--NeedCopy-->
```

To configure an IPv6 forwarding session rule by using the GUI:

Navigate to System > Network > Forwarding Sessions, add a new IPv6 forwarding session, or edit an existing forwarding session.

### Assigning an ACL rule to an Existing Forwarding Session Rule

You can assign an ACL rule to a Network-address/IPv6-prefix based forwarding session rule, in which case it becomes an ACL based forwarding session rule. You can also change an existing ACL rule to another ACL rule in an ACL based forwarding session rule. After the existing related forwarding session entries (if any) have timed out, the rules start using the newly assigned ACL to identify IPv4/IPv6 traffic for which to create a forwarding-session entry.

To assign an extended ACL rule to an existing IPv4 forwarding session rule by using the CLI:

At the command prompt, type

- `set forwardingSession <name> [-aclname <string>]`
- `show forwardingSession <name>`

To assign an ACL6 rule to an existing IPv6 forwarding session rule by using the CLI:

At the command prompt, type

- `set forwardingSession <name> [-acl6name <string>]`
- `show forwardingSession <name>`

#### Example:

```
1 > add forwardingSession FS-1 -aclname ACL-9
2 Done
3
4 > add forwardingSession FS6-1 - acl6name ACL6-9
5 Done
```

## Disabling Steering for Forwarding Sessions on a Cluster Setup

The default behavior of a NetScaler cluster is for the node that receives traffic (flow receiver) to direct the traffic to another node (flow processor), which processes the traffic. Directing the traffic from flow receiver to flow processor occurs over the cluster backplane and is called steering.

Steering can be an overhead for real-time processing or when the setup includes high-latency links.

Steering for forwarding sessions can now be disabled so that the processing becomes local to the flow receiver. That is, the flow receiver becomes the flow processor.

### Before you begin

Note the following points before configuring forwarding session rules in a cluster setup:

- You must configure linksets to be used for forwarding sessions.
- You must enable MAC Based Forwarding (MBF) on the cluster setup.

### Configuring Forwarding Session Rules in a Cluster Setup

Disabling steering for forwarding session rules in a cluster setup can be done at the following two levels:

- **Specific forwarding session rule level.** Enable the Process Local parameter while adding a new forwarding session rule or editing an existing forwarding session rule.
- **Global level.** Enable the Process Local parameter while adding a new cluster instance or editing an existing cluster instance. The global setting takes precedence over the forwarding session rule setting.

**CLI procedures** To disable steering for a forwarding session rule on a cluster setup by using the CLI:

At the command prompt, type one of the following sets of commands:

- If adding a new forwarding session rule:
  - **add forwardingSession** <name> ((<network> [<netmask>]) | **-acl6name** <string> | **-aclname** <string>) **-processLocal ENABLED**
  - **show forwardingSession** <name>
- If reconfiguring an existing forwarding session rule:
  - **set forwardingSession** <name> **-processLocal ENABLED**
  - **show forwardingSession** <name>

To disable steering for all (global level) forwarding session rules on a cluster setup by using the CLI:

At the command prompt, type one of the following sets of commands:

- If adding a new cluster instance:
  - **add cluster instance** <clid> **-processLocal Enabled**
  - **show cluster instance** <clid>
- If reconfiguring an existing cluster instance:
  - **set cluster instance** <clid> **-processLocal Enabled**
  - **show cluster instance** <clid>

### Sample configuration:

Following are two examples of disabling steering at the forwarding session rule level, and an example of disabling steering at the global level.

```
1 An IPv4 forwarding session rule:
2
3 > add forwardingSession FWD-SESSN-PROCSS-LOCL-IPV4-1 10.102.105.51
 255.255.255.255 -processLocal Enabled
4 Done
5
6 An IPv6 forwarding session rule:
7
8 > add forwardingSession FWD-SESSN-PROCSS-LOCL-IPV6-1 - acl6name ACL6-
 FWD-SESSN-1 -processLocal Enabled
9 Done
10
11 A cluster setup, with an instance ID 10, has steering disabled at
 global level:
12
13 > set cluster instance 10 -processLocal Enabled
14 Done
15 <!--NeedCopy-->
```

**GUI procedures** To disable steering for a forwarding session rule on a cluster setup by using the GUI:

Navigate to **System > Network > Forwarding Sessions**, select **Process Local** while adding a new forwarding session rule or editing an existing forwarding session rule.

To disable steering for all (global level) forwarding session rules on a cluster setup by using the GUI:

Navigate to **System > Cluster**, and select **Process Local** while adding a cluster configuration or modifying an existing cluster configuration.

## Understanding VLANs

May 2, 2023

A NetScaler appliance supports Layer 2 port and IEEE 802.1q tagged VLANs. VLAN configurations are useful when you need to restrict traffic to certain groups of stations. You can configure a network interface as a part of multiple VLANs by using IEEE 802.1q tagging.

You can configure VLANs and bind them to IP subnets. The NetScaler then performs IP forwarding between these VLANs (if it is configured as the default router for the hosts on these subnets).

The NetScaler supports the following types of VLANs:

- **Port-Based VLANs.** The membership of a port-based VLAN is defined by a set of network interfaces that share a common, exclusive Layer 2 broadcast domain. You can configure multiple port-based VLANs. By default, all network interfaces on the NetScaler are members of VLAN 1.

If you apply 802.1q tagging to the port, the network interface belongs to a port-based VLAN. Layer 2 traffic is bridged within a port-based VLAN, and Layer 2 broadcasts are sent to all members of the VLAN if Layer 2 mode is enabled. When you add an untagged network interface as a member of a new VLAN, it is removed from its current VLAN.

- **Default VLAN.** By default, the network interfaces on the NetScaler are included in a single, port-based VLAN as untagged network interfaces. This VLAN is the default VLAN. It has a VLAN ID (VID) of 1. This VLAN exists permanently. It cannot be deleted, and its VID cannot be changed.

When you add a network interface to a different VLAN as an untagged member, the network interface is automatically removed from the default VLAN. If you unbind a network interface from its current port-based VLAN, it is added to the default VLAN again.

- **Tagged VLANs.** 802.1q tagging (defined in the IEEE 802.1q standard) allows a networking device (such as the NetScaler) to add information to a frame at Layer 2 to identify the VLAN membership of the frame. Tagging allows network environments to have VLANs that span multiple devices. A device that receives the packet reads the tag and recognizes the VLAN to which the frame belongs. Some network devices do not support receiving both tagged and untagged packets on the same network interface—in particular, Force10 switches. In such cases, you need to contact customer support for assistance.

The network interface can be a tagged or untagged member of a VLAN. Each network interface is an untagged member of one VLAN only (its native VLAN). This network interface transmits the frames for the native VLAN as untagged frames. A network interface can be a part of more than one VLAN if the other VLANs are tagged.

When you configure tagging, be sure to match the configuration of the VLAN on both ends of the link. The port to which the NetScaler connects must be on the same VLAN as the NetScaler

network interface.

**Note:** This VLAN configuration is neither synchronized nor propagated, therefore you must perform the configuration on each unit in an HA pair independently.

## Applying Rules to Classify Frames

VLANs have two types of rules for classifying frames:

- **Ingress rules.** Ingress rules classify each frame as belonging only to a single VLAN. When a frame is received on a network interface, the following rules are applied to classify the frame:
  - If the frame is untagged, or has a tag value equal to 0, the VID of the frame is set to the port VID (PVID) of the receiving interface, which is classified as belonging to the native VLAN. (PVIDs are defined in the IEEE 802.1q standard.)
  - If frame has a tag value equal to FFF, the frame is dropped.
  - If the VID of the frame specifies a VLAN of which the receiving network interface is not a member, the frame is dropped. For example, if a packet is sent from a subnet associated with VLAN ID 12 to a subnet associated with VLAN ID 10, the packet is dropped. If an untagged packet with VID 9 is sent from the subnet associated with VLAN ID 10 to a network interface PVID 9, the packet is dropped.
- **Egress Rules.** The following egress rules are applied:
  - If the VID of the frame specifies a VLAN of which the transmission network interface is not a member, the frame is discarded.
  - During the learning process (defined by the IEEE 802.1q standard), the Src MAC and VID are used to update the bridge lookup table of the NetScaler.
  - A frame is discarded if its VID specifies a VLAN that does not have any members. (You define members by binding network interfaces to a VLAN.)

## VLANs and Packet Forwarding on the NetScaler

The forwarding process on the NetScaler appliance is similar to that on any standard switch. However, the NetScaler performs forwarding only when Layer 2 mode is on. The key features of the forwarding process are:

- Topology restrictions are enforced. Enforcement involves selecting each network interface in the VLAN as a transmission port (depending on the state of the network interface), bridging restrictions (do not forward on the receiving network interface), and MTU restrictions.
- Frames are filtered on the basis of information in the bridge table lookup in the forwarding database (FDB) table of the NetScaler. The bridge table lookup is based on the destination MAC and

the VID. Packets addressed to the MAC address of the NetScaler are processed at the upper layers.

- All broadcast and multicast frames are forwarded to each network interface that is a member of the VLAN, but forwarding occurs only if L2 mode is enabled. If L2 mode is disabled, the broadcast and multicast packets are dropped. This is also true for MAC addresses that are not currently in the bridging table.
- A VLAN entry has a list of member network interfaces that are part of its untagged member set. When forwarding frames to these network interfaces, a tag is not inserted in the frame.
- If the network interface is a tagged member of this VLAN, the tag is inserted in the frame when the frame is forwarded.

When a user sends any broadcast or multicast packets without the VLAN being identified, that is, during duplicate address detection (DAD) for NSIP or ND6 for the next hop of the route, the packet is sent out on all the network interfaces, with appropriate tagging based on either the Ingress and Egress rules. ND6 usually identifies a VLAN, and a data packet is sent on this VLAN only. Port-based VLANs are common to IPv4 and IPv6. For IPv6, the NetScaler supports prefix-based VLANs.

## Configuring a VLAN

May 2, 2023

You can implement VLANs in the following environments:

- Single subnet
- Multiple subnets
- Single LAN
- VLANs (no tagging)
- VLANs (802.1q tagging)

If you configure VLANs that have only untagged network interfaces as their members, the total number of possible VLANs is limited to the number of network interfaces available in the NetScaler. If more IP subnets are required with a VLAN configuration, 802.1q tagging must be used.

When you bind a network interface to a VLAN, the network interface is removed from the default VLAN. If the network interfaces need to be a part of more than one VLAN, you can bind the network interfaces to the VLANs as tagged members.

You can configure the NetScaler to forward traffic between VLANs at Layer 3. In this case, a VLAN is associated with a single IP subnet. The hosts in a VLAN that belong to a single subnet use the same subnet mask and one or more default gateways connected to that subnet. Configuring Layer 3 for a VLAN is optional. Layer 3 is used for IP forwarding (inter-VLAN routing). Each VLAN has a unique IP

address and subnet mask that define an IP subnet for the VLAN. In an HA configuration, this IP address is shared with the other NetScaler appliances. The NetScaler forwards packets between configured IP subnets (VLANs).

When you configure the NetScaler, you must not create overlapping IP subnets. Doing so impedes Layer 3 functionality.

Each VLAN is a unique Layer 2 broadcast domain. Two VLANs, each bound to separate IP subnets, cannot be combined into a single broadcast domain. Forwarding traffic between two VLANs requires a Layer 3 forwarding (routing) device, such as the NetScaler appliance.

## Configuring VLANs in an HA Setup

VLAN configuration for a high-availability setup requires that the NetScaler appliances have the same hardware configuration, and the VLANs configured on them must be mirror images.

The correct VLAN configuration is implemented automatically when the configuration is synchronized between the NetScaler appliances. The result is identical actions on all the appliances. For example, adding network interface 0/1 to VLAN2 adds this network interface to VLAN 2 on all the appliances participating in the high-availability setup.

Note: If you use network-interface-specific commands in an HA setup, the configurations you create are not propagated to the other NetScaler appliance. You must perform these commands on each appliance in an HA pair to ensure that the configuration of the two appliances in the HA pair remains synchronized.

## Creating or Modifying a VLAN

To configure a VLAN, you create a VLAN entity, and then bind network interfaces and IP addresses to the VLAN. If you remove a VLAN, its member interfaces are added to the default VLAN.

### CLI procedures

To create a VLAN by using the CLI:

At the command prompt, type:

- `add vlan <id> [-aliasName <string>] [-ipv6DynamicRouting (ENABLED | DISABLED)]`
- `sh vlan <id>`

### Example:

```
1 > add vlan 2 -aliasName "Network A" Done
2 <!--NeedCopy-->
```

To bind an interface to a VLAN by using the CLI:

At the command prompt, type:

- `bind vlan <id> -ifnum <slot/port>`
- `sh vlan <id>`

**Example:**

```
1 > bind vlan 2 -ifnum 1/8 Done
2 <!--NeedCopy-->
```

To bind an IP address to a VLAN by using the CLI:

At the command prompt, type:

- `bind vlan <id> -IPAddress <IPAddress> <netMask>`
- `sh vlan <id>`

**Example:**

```
1 > bind vlan 2 -IPAddress 10.102.29.54 255.255.255.0 Done
2 <!--NeedCopy-->
```

To remove a VLAN by using the CLI:

At the command prompt, type:

- `rm vlan <id>`

## GUI procedures

To configure a VLAN by using the GUI:

1. Navigate to System > Network > VLANs, add a new VLAN, or edit an existing VLAN.
2. To bind an IP address to a VLAN, under IP Bindings, select the Active option corresponding to the IP address that you want to bind to the VLAN (for example, 10.102.29.54). The Type column displays the IP address type (such as mapped IP, virtual IP, or subnet IP) for each IP address in the IP Address column.
3. To bind a network interface to a VLAN, under Interface Bindings, select the Active option corresponding to the interface that you want to bind to the VLAN.

## Monitoring VLANs

You can display VLAN statistics such as packets received, bytes received, packets sent, and bytes sent, and use the information to identify anomalies and or debug a VLAN.

To view the statistics of a VLAN by using the CLI:

At the command prompt, type:

- `stat vlan <vlanID>`

### Example:

```
1 stat vlan 2
2 <!--NeedCopy-->
```

To view the statistics of a VLAN by using the GUI:

1. Navigate to System > Network > VLANs.
2. Select the VLAN, and click Statistics.

## Configuring VLANs on a Single Subnet

May 2, 2023

Before configuring a VLAN on a single subnet, make sure that Layer 2 Mode is enabled.

The following figure shows a single subnet environment

Figure 1. VLAN on a Single Subnet

In the above figure:

1. The default router for the NetScaler and the servers is Router 1.
2. Layer 2 mode must be enabled on the NetScaler for the NetScaler to have direct access to the servers.
3. For this subnet, a virtual server can be configured for load balancing on the NetScaler appliance.

To configure a VLAN on a single subnet, follow the procedures described in [Configuring a VLAN](#).

## Configuring VLANs on Multiple Subnets

September 21, 2020

To configure a single VLAN across multiple subnets, you must add a VIP for the VLAN and configure the routing appropriately. The following figure shows a single VLAN configured across multiple subnets.

Figure 1. Multiple Subnets in a Single VLAN

To configure a single VLAN across multiple subnets, perform the following tasks:

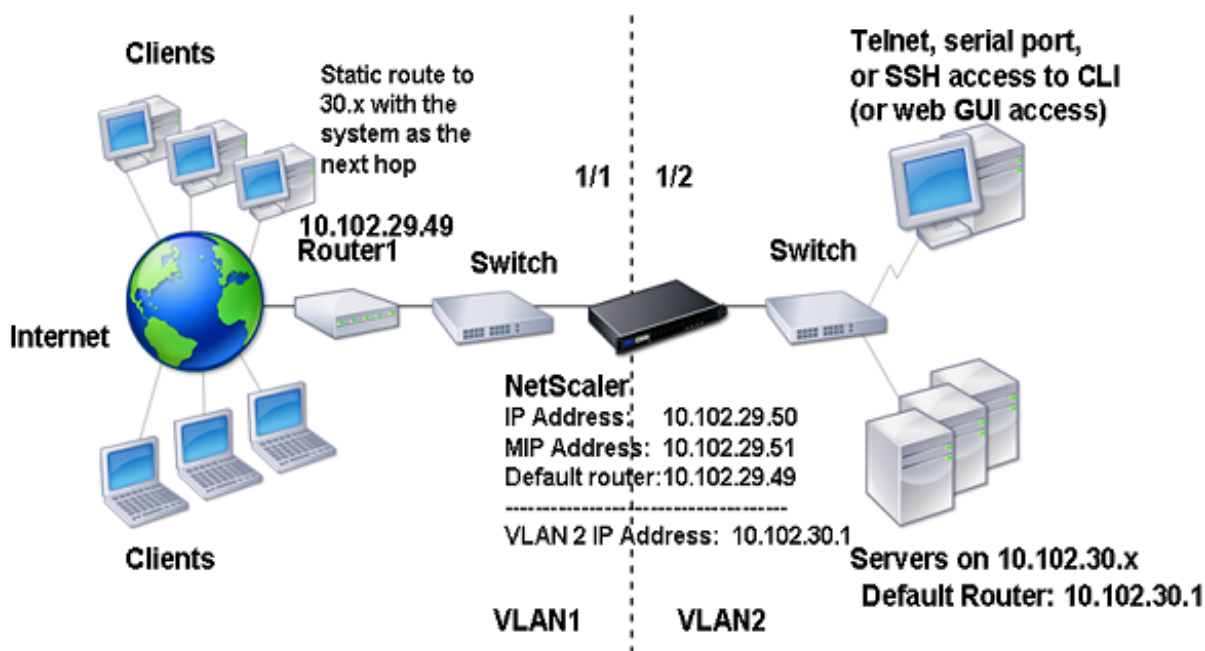

1. Disable Layer 2 mode. For the procedure to disable Layer 2 mode, see [Packet forwarding modes](#).
2. Add a VIP address. For the procedure to add a VIP address, see [Configuring and Managing Virtual IP Addresses \(VIPs\)](#).
3. Configure RNAT rule. For the procedure to configure the RNAT ID, see [Configuring RNAT](#).

## Configuring Multiple Untagged VLANs across Multiple Subnets

May 2, 2023

In environments with multiple untagged VLANs across multiple subnets, a VLAN is configured for each IP subnet. A network interface is bound to one VLAN only. The following figure shows this configuration.

Figure 1. Multiple Subnets with VLANs - No Tagging

To implement the configuration shown in the above figure, perform the following tasks:

1. Add VLAN 2.
2. Bind the 1/2 network interface of the NetScaler to VLAN 2 as an untagged network interface.
3. Bind the IP address and subnet mask to VLAN 2.

For procedures on these tasks, see [Configuring a VLAN](#).

## Configuring Multiple VLANs with 802.1q Tagging

May 2, 2023

For multiple VLANs with 802.1q tagging, each VLAN is configured with a different IP subnet. Each network interface is in one VLAN. One of the VLANs is set up as tagged. The following figure shows this configuration.

Figure 1. Multiple VLANs with IEEE 802.1q Tagging

To implement the configuration shown in the above figure, perform the following tasks:

1. Add VLAN 2.
2. Bind the 1/2 network interface of the NetScaler to VLAN 2 as an untagged network interface.
3. Bind the IP address and netmask to VLAN 2.
4. Add VLAN 3.
5. Bind the 1/2 network interface of the NetScaler to VLAN 3 as a tagged network interface.
6. Bind the IP address and netmask to VLAN 3.

For procedures on these tasks, see [Configuring a VLAN](#).

## Associate an IP Subnet with a NetScaler Interface by Using VLANs

May 2, 2023

By default, a NetScaler appliance does not provide any differentiation between network interfaces. The appliance functions more like a network hub than a switch. This can lead to Layer 3 network loops where duplicated traffic is transmitted on multiple interfaces.

In such scenarios, depending on network design, it is possible that a request could be transmitted on one interface and the corresponding response is received on a different interface.

For example, a SYN packet sent on one interface and the SYN-ACK response received on a different interface can result in a failed connection, as the appliance expects to receive the SYN-ACK on the same interface that sent the original SYN packet.

To resolve such issues, the appliance can use internal or external VLANs, to associate specific subnets with interfaces.

## Before you begin

Before you begin associating an IP Subnet with a NetScaler interface by using VLANs, note the following points:

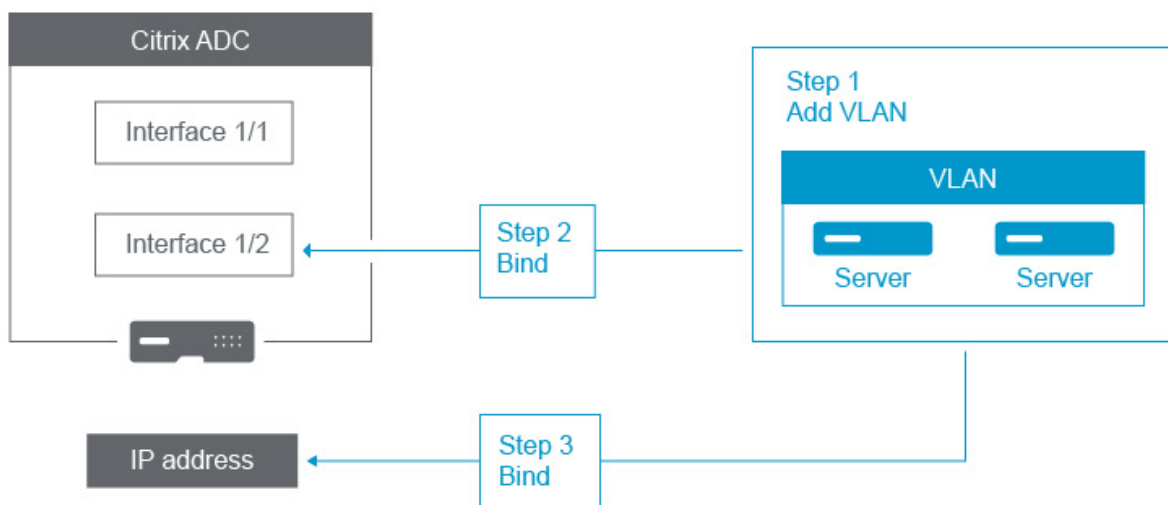

- The network connectivity might be accidentally lost when associating a VLAN to the subnet or interface that is currently being used to access the NetScaler GUI or command line interface. Therefore, in such scenarios, it is highly recommended that the change is made by accessing the command line interface through the serial console of a physical NetScaler appliance or through the virtual serial console of a NetScaler VPX.
- NetScaler management interfaces lack certain hardware optimization features which makes them less desirable for use with production data traffic. As such, it is recommended that the NetScaler be configured to only use the management interfaces for management (NSIP) traffic. In the default configuration, there is no logical differentiation between the management interfaces and data interfaces on a hardware NetScaler. In order to accomplish this goal, it is recommended that the NSIP be on a separate VLAN from data traffic, which allows management traffic to be on a separate interface.

Although the concept is the same, to change the VLAN associations of the subnet that contains the NSIP address, you must configure NSVLAN instead of the below instructions. Such changes will also require a reboot of the NetScaler in order to take effect. For more information, see [Configuring NSVLAN](#).

- On NetScaler SDX, it is highly recommended that the NSIP of each instance be on the same subnet and VLAN as the SDX's SVM (Management Service GUI) and XenServer. The SVM communicates with instances via the network. If the SVM, XenServer, and instances are not on the same VLAN and subnet, management traffic must flow outside of the SDX. In this situation, network issues can cause Instance state to show up as yellow or red and can prevent the management and configuration changes of the NetScaler instances.

## Configuration Steps

Associate an IP subnet with a NetScaler Interface consists of the following tasks:

**Add a VLAN.** While adding a VLAN, if you are tagging the VLAN, then you must select a VLAN number that is defined in the network switch for the associated switch port. If the VLAN is untagged and is internal to the appliance, then it is recommended that you select the VLAN number that is available in the switch configuration for easy reference.

**Bind an interface to the VLAN.** While binding, if you are using Link Aggregation, associate the VLAN with the LA channel (for example, LA/1) instead of the physical interface. The VLAN must be associated with only one network interface.

If you want to tag the traffic on the interface, use the tagged (Tag) option. Else, the traffic leaves the appliance untagged and is associated with the native VLAN of the switch port.

**Bind an IP address to the VLAN.** While binding, if you bind more than one IP address from the same subnet, an error occurs. When an IP address is associated with a VLAN, all IP addresses in that subnet are automatically associated with the VLAN.

### Note:

In a high availability (HA) setup, these VLAN configurations are added automatically from the

primary node to the secondary node during HA synchronization. For more information about high availability setups, see [High Availability](#).

### CLI procedures

To add a VLAN by using the CLI:

At the command prompt, type:

- **add vlan** <id>
- **sh vlan** <id>

To bind an interface to a VLAN by using the CLI:

At the command prompt, type:

- **bind vlan** <id> **-ifnum** <slot/port>
- **sh vlan** <id>

To bind an IP address to a VLAN by using the CLI:

At the command prompt, type:

- **bind vlan** <id> **-IPAddress** <IPAddress> <netMask>
- **sh vlan** <id>

### Example:

```
1 > add vlan 100
2
3 > bind vlan 100 -ifnum 1/1
4
5 > bind vlan 100 -ipAddress 10.0.1.0 255.255.255.0
6 <!--NeedCopy-->
```

### GUI procedures

To configure a VLAN by using the GUI:

1. Navigate to **System > Network > VLANs**, add a new VLAN.
2. To bind a network interface to a VLAN, under **Interface Bindings**, select the **Active** option corresponding to the interface that you want to bind to the VLAN.
3. To bind an IP address to a VLAN, under **IP Bindings**, select the **Active** option corresponding to the IP address that you want to bind to the VLAN (for example, 10.102.29.54). The **Type** column displays the IP address type for each IP address in the **IP Address** column.

## NetScaler appliance networking and VLAN best practices

May 2, 2023

A NetScaler appliance uses VLANs to determine which interface must be used for which traffic. In addition, NetScaler appliance does not participate in Spanning Tree. Without the proper VLAN configuration, the NetScaler appliance is unable to determine which interface to use, and it can function more like a HUB than a switch or a router. In other words, the NetScaler appliance can use all interfaces for each conversation.

### Symptoms of VLAN misconfiguration

VLAN misconfiguration issue can manifest itself in many forms, including performance issues, inability to establish connections, randomly disconnected sessions, and in severe situations, network disruptions seemingly unrelated to the NetScaler appliance itself. The NetScaler appliance may also report MAC moves, muted interfaces, and/or management interface transmit or receive buffer overflows, depending on the exact nature of the interaction with your network.

**MAC Moves (counter `nic_tot_bdg_mac_moved`):** This issue indicates that the NetScaler appliance is using more than one interface to communicate with the same device (MAC address), because it could not properly determine which interface to use.

**Muted interfaces (counter `nic_err_bdg_muted`):** This issue indicates that the NetScaler appliance has detected that it is creating a routing loop due to VLAN configuration issues, and as such, it has shut down one or more of the offending interfaces in order to prevent a network outage.

**Interface buffer overflows, typically referring to management interfaces (counter `nic_err_tx_overflow`):** This issue can be caused if too much traffic is being transmitted over a management interface. Management interfaces on the NetScaler appliance is not designed to handle large volumes of traffic, which may result from network and VLAN misconfigurations triggering the NetScaler appliance to use a management interface for production data traffic. This often occurs because the NetScaler appliance has no way to differentiate traffic on the VLAN / subnet of the NSIP (NSVLAN) from regular production traffic. It is highly recommended that the NSIP be on a separate VLAN and subnet from any production devices such as workstations and servers.

**Orphan ACKs (counter `tcp_err_orphan_ack`):** This issue indicates that the NetScaler appliance received an ACK packet that it was not expecting, typically on a different interface than the ACK'd traffic originated from. This situation can be caused by VLAN misconfigurations where the NetScaler appliance transmits on a different interface than the target device would typically use to communicate with the NetScaler appliance (often seen in conjunction with MAC moves)

**High rates of retransmissions or retransmit give ups (counters: `tcp_err_retransmit_giveups`,**

**tcp\_err\_7th\_retransmit, various other retransmit counters):** The NetScaler appliance attempts to retransmit a TCP packet a total of 7 times before it gives up and terminates the connection. While this situation can be caused by network conditions, it often occurs as a result of VLAN and interface misconfiguration.

**High Availability Split Brain:** Split Brain is a condition where both high availability nodes believe they are Primary, leading to duplicate IP addresses and loss of NetScaler appliance functionality. This is caused when the two high availability nodes cannot communicate with each-other using high availability Heartbeats on UDP Port 3003 using the NSIP, across any interface. This is typically caused by VLAN misconfigurations where the native VLAN on the NetScaler appliance interfaces does not have connectivity between NetScaler appliances.

### **Best practices for VLAN and network configurations**

1. Each subnet must be associated with a VLAN.
2. More than one subnet can be associated with the same VLAN (depending on your network design).
3. Each VLAN should be associated to only one interface (for purposes of this discussion, a LA channel counts as a single interface).
4. If you require more than one subnet to be associated with an interface, the subnets must be tagged.
5. Contrary to popular belief, the Mac-Based-Forwarding (MBF) feature on the NetScaler appliance is not designed to mitigate this type of issue. MBF is designed primarily for the DSR (Direct Server Return) mode of the NetScaler appliance, which is rarely used in most environments (it is designed to allow traffic to purposely bypass the NetScaler appliance on the return path from the back-end servers). MBF may hide VLAN issues in some instances, but it should not be relied-upon to resolve this type of problem.
6. Every interface on NetScaler appliance requires a native VLAN (unlike Cisco, where native VLANs are optional), although the TagAll setting on an interface can be used so that no untagged traffic leaves the interface in question.
7. The native VLAN can be tagged if necessary for your network design (this is the TagAll option for the interface).
8. The VLAN for the subnet of your NetScaler appliance's NSIP is a special case. This is called the NSVLAN. The concepts are the same but the commands to configure it are different and changes to the NSVLAN require a reboot of the NetScaler appliance to take effect. If you attempt to bind a VLAN to a SNIP that shares the same subnet as the NSIP, you get "Operation not permitted." This is because you have to use the NSVLAN commands instead. Also, on some firmware versions, you

cannot set an NSVLAN if that VLAN number exists using `add VLAN` command. Simply remove the VLAN and then set the NSVLAN again.

9. High availability Heartbeats always use the Native VLAN of the respective interface (optionally tagged if the TagAll option is set on the interface).
10. There must be communication between at least one set of Native VLAN(s) on the two nodes of an high availability pair (this can be direct or via a router). The native VLANs are used for high availability heartbeats. If the NetScaler appliances cannot communicate between native VLANs on any interface, this will lead to high availability failovers and possibly a split-brain situation where both NetScaler appliances think they are primary (leading to duplicate IP addresses, amongst other things).
11. The NetScaler appliance does not participate in spanning tree. As such, it is not possible to use spanning tree to provide for interface redundancy when using a NetScaler appliance. Instead, use a form of Link Aggregation (LACP or manual LAG) for this purpose.

Note: If you want to have link aggregation between multiple physical switches, you must have the switches configured as a virtual switch, using a feature such as Cisco's Switch Stack.

12. The high availability synchronization and command Propagation, by default, use the NSIP/NSVLAN. To separate these out to a different VLAN, you can use the SyncVLAN option of the `set HA node` command.
13. There is nothing built-in to the NetScaler appliance default configuration that denotes that a management interface (0/1 or 0/2) is restricted to management traffic only. This restriction must be enforced by the end user through VLAN configuration. The management interfaces are not designed to handle data traffic, so your network design must take this point into account. Management interfaces, contained on the NetScaler appliance motherboard, lack various off-loading features such as CRC offload, larger packet buffers, and other optimizations, making them much less efficient in handling large amounts of traffic. To separate production data and management traffic, the NSIP must not be on the same subnet/VLAN as your data traffic.
14. If it is desired to use a management interface to carry management traffic, it is best practice that the Default Route be on a subnet other than the subnet of the NSIP (NSVLAN).

In many configurations, the default route is relied-upon for workstation communication (in an internet scenario). If the default route is on the same subnet as the NSIP, then the ADC appliance can use the management interface to send and receive data traffic. This use of data traffic can overload the management interface.

15. Also, an SDX-the SVM, XenServer, and all NetScaler instance NSIPs must be on the same VLAN and subnet. There is no **backplane** in the SDX appliance that allows for communication between SVM/Xen/Instances. If they are not on the same VLAN/subnet/interface, traffic between them must leave the physical hardware, be routed on your network, and return.

This configuration can lead to obvious connectivity issues between the instances and SVM and as such, is not recommended. A common symptom of this is a Yellow Instance State indicator in the SVM for the VPX instance in question, and the inability to use the SVM to reconfigure a VPX instance.

16. If some VLANs are bound to subnets and some are not, during a high availability failover, GARP packets are not be sent for any IP addresses on any of the subnets that are not bound to a VLAN. This configuration can cause dropped connections and connectivity issues during high availability failovers. This issue is caused because the NetScaler appliance cannot notify the network MAC ownership IP addresses change on non-VMAC-configured NetScaler appliances.

Symptoms of this are that during/after a high availability failover, the `ip_tot_floating_ip_err` counter increments on the former primary NetScaler appliance for more than a few seconds, indicating that the network did not receive or process GARP packets and the network is continuing to transmit data to the new secondary NetScaler appliance.

## Configuring NSVLAN

May 2, 2023

NSVLAN is a VLAN to which the NetScaler management IP (NSIP) address's subnet is bound. The NSIP subnet is available only on interfaces that are associated with NSVLAN. By default, NSVLAN is VLAN 1, but you can designate a different VLAN as NSVLAN. If you do so, you must reboot the NetScaler appliance for the change to take effect. After the reboot, NSIP subnet traffic is restricted to the new NSVLAN.

The traffic from the NetScaler IP subnet can be tagged (802.1q) with the VLAN ID specified for NSVLAN. You must configure the attached switch interface to tag and allow this same VLAN ID on the connected interface. If you remove your NSVLAN configuration, the NSIP subnet is automatically bound to VLAN 1, restoring the default NSVLAN.

### To configure NSVLAN by using the CLI:

At the command prompt, type:

---

```
set ns config -nsvlan -**ifnum** ...[-**tagged** NO]]
(YES
```

---

- 
- **show ns config**

**Note:**

The configuration takes effect after the NetScaler appliance is restarted.

**Example:**

```
1 > set ns config -nsvlan 300 -ifnum 1/1 1/2 1/3 -tagged YES
2 Done
3
4 > save config
5 Done
6 <!--NeedCopy-->
```

**To restore the default NSVLAN configuration by using the CLI:**

At the command prompt, type:

- **unset ns config -nsvlan**
- **show ns config**

**Example:**

```
1 > unset ns config -nsvlan
2 Done
3 <!--NeedCopy-->
```

**To configure NSVLAN by using the GUI:**

Navigate to **System > Settings**, in the **Settings** group, click **Change NSVLAN Settings**.

**Setting the MTU on the NSVLAN**

By default, the MTU of the NSVLAN is set to 1500 bytes. You can modify this setting to optimize throughput and network performance. For example, you can configure the NSVLAN to process jumbo frames.

To set the MTU of the NSVLAN by using the CLI:

At the command prompt, type:

- **set vlan <id> -mtu <positive\_integer>**
- **show vlan <id>**

To set the MTU of the NSVLAN by using the GUI:

Navigate to **System > Network > VLANs**, open the NSVLAN, and set the **Maximum Transmission Unit** parameter.

**Sample configuration:**

In the following sample configuration, VLAN 100 is the NSVLAN.

```
1 > set ns config -nsvlan 100 -ifnum 1/1 -tagged no
2
3 Warning: The configuration must be saved and the system rebooted for
 these settings to take effect
4
5 > set vlan 100 -mtu 1600
6
7 Done
8
9 > sh vlan
10
11 1) VLAN ID: 1
12

```

## Configuring Allowed VLAN List

May 2, 2023

NetScaler accepts and sends tagged packets of a VLAN on an interface if the VLAN is explicitly configured on the NetScaler appliance and the interface is bound to the VLAN. Some deployments (for example, Bump in the wire) require the NetScaler appliance to function as a transparent device to accept and forward tagged packets related to a large number of VLANs. For this requirement, configuring and managing a large number of VLANs is not a feasible solution.

Allowed VLAN list on an interface specifies a list of VLANs. The interface transparently accepts and sends tagged packets related to the specified VLANs without the need for explicitly configuring these

VLANs on the appliance.

## Points to Consider before Configuring Allowed VLAN List

Consider the following points before configuring allowed VLAN list

- In a high availability setup, allowed VLAN list is not propagated or synchronized. Therefore, you have to configure allowed VLAN list on both the nodes.
- The traffic of a native VLAN might leak to the non-member interfaces that specifies the native VLAN in its allowed VLAN list.
- A Maximum of 60 VLAN ranges can be specified as part of allowed VLAN list for an interface.
- The NetScaler appliance does not support allowed VLAN list on interfaces that are part of link aggregation channels or redundant interface sets. For more information on redundant interface set, see [Redundant Interface Set](#).
- Allowed VLAN list is not supported on a NetScaler cluster configuration.
- The NetScaler appliance does not support allowed VLAN list for Bridge groups.
- The NetScaler appliance does not support allowed VLAN list for VXLANs.

## Configuring Allowed VLAN List

To configure allowed VLAN list by using the CLI:

At the command prompt, type:

- **set interface** <id> **-trunkmode** (ON|OFF) **-trunkAllowedVlan** <int[-int]> ...
- **show interface** <id>

To configure allowed VLAN list by using the GUI:

Navigate to **System > Network > Interfaces**, select a network interface, click **Edit**, and then set the following parameters:

- Trunk Mode
- Trunk Allowed VLAN

### Sample Configuration:

In the following sample configuration, VLANS in the ranges 100-120, 190-200, and 300-330 are specified as part of allowed VLAN list for interface 1/2.

```
1 > set int 1/2 -trunkmode on -trunkallowedVlan 100-120 190-200 300-330
2
3 Done
4
5 > sh int 1/2
```

```
6
7 1) Interface 1/2 (Gig Ethernet 10/100/1000 Mbits) #6
8 flags=0xc020
9
10 <ENABLED, UP, UP, AUTONEG OFF, HEARTBEAT, 802.1q, trunkmode>
11
12 Trunk Allowed Vlans: 100-120 190-200 300-330
13
14 Done
15
16 <!--NeedCopy-->
```

## Configuring Bridge Groups

May 2, 2023

Typically, when you want to merge two or more VLANs into a single domain, you change the VLAN configuration on all the devices in the separate domains. This can be a tedious task. To more easily merge multiple VLANs into a single broadcast domain, you can use bridge groups.

The bridge groups feature works the same way as a VLAN. Multiple VLANs can be bound to a single bridge group, and all VLANs bound to same bridge group form a single broadcast domain. You can bind only Layer 2 VLANs to a bridge group. For Layer 3 functionality, you must assign an IP address to a bridge group.

In Layer 2 mode, a broadcast packet received on an interface belonging to a particular VLAN is bridged to other VLANs that belong to the same bridge group. In the case of a unicast packet, the NetScaler appliance searches its bridge table for the learned MAC addresses of all the VLANs belonging to same bridge group.

In Layer 3 forwarding mode, an IP subnet is bound to a bridge group. The NetScaler accepts incoming packets belonging to the bound subnet and forwards the packets only on VLANs that are bound to the bridge group.

IPv6 routing can be enabled on a configured bridge group.

### Note

Bridge Group feature and Bridge BPDU mode cannot work together.

## Configuration steps

Perform the following steps to configure a bridge group:

- Enable Layer 2 mode

- Add a bridgegroup and bind VLANs to the bridgegroup

### CLI procedures

To enable Layer 2 mode by using the CLI:

At the command prompt, type:

- **enable ns mode l2**
- **show ns mode**

To add a bridge group and bind VLANs by using the CLI:

At the command prompt, type:

- **add bridgegroup** <id> [-**ipv6DynamicRouting** ( **ENABLED** | **DISABLED** )]
- **bind bridgegroup** <id> -**vlan** <positive\_integer>
- **show bridgegroup** <id>

#### Example:

```
1 > add bridgegroup 12
2 Done
3 <!--NeedCopy-->
```

To remove a bridge group by using the CLI:

At the command prompt, type:

- **rm bridgegroup** <id>

#### Example:

```
1 rm bridgegroup 12
2 <!--NeedCopy-->
```

### GUI Procedures

To configure a bridge group by using the GUI:

Navigate to **System > Network > Bridge Groups**, add a new bridge group and bind VLANs to the bridgegroup, or edit an existing bridge group.

## Configuring virtual MACs

September 21, 2020

The primary and secondary nodes in a high availability (HA) setup share the virtual MAC address floating entity. The primary node owns the floating IP addresses (such as MIP, SNIP, and VIP) and responds to ARP requests for these IP addresses with its own MAC address. Therefore, the ARP table of an external device, such as an upstream router, is updated with the floating IP address and the MAC address of the primary node.

When a failover occurs, the secondary node takes over as the new primary node. The former secondary node uses Gratuitous ARP (GARP) to advertise the floating IP addresses that it had learned from the old primary node. The MAC address that the new primary node advertises is the MAC address of its own network interface. Some devices (a few routers) do not accept these GARP messages. Therefore, these external devices retain the IP address-to-MAC address mapping that the old primary node had advertised. This can result in a GSLB site going down.

Therefore, you must configure a virtual MAC on both nodes of an HA pair. This means that both nodes have identical MAC addresses. When a failover occurs, the MAC address of the secondary node remains unchanged, and the ARP tables on the external devices do not need to be updated.

For the procedures to configure a virtual MAC, see [Configuring Virtual MAC Addresses](#).

## Configuring Link Aggregation

May 2, 2023

Link aggregation combines data coming from multiple ports into a single high-speed link. Configuring link aggregation increases the capacity and availability of the communication channel between the NetScaler appliance and other connected devices. An aggregated link is also referred to as a “channel.” You can configure the channels manually, or you can use Link Aggregation Control Protocol (LACP). You cannot apply LACP to a manually configured channel, nor can you manually configure a channel created by LACP.

When a network interface is bound to a channel, the channel parameters have precedence over the network interface parameters. (That is, the network interface parameters are ignored.) A network interface can be bound only to one channel.

When a network interface is bound to a channel, it drops its VLAN configuration. When network interfaces are bound to a channel, either manually or by LACP, they are removed from the VLANs that they originally belonged to and added to the default VLAN. However, you can bind the channel back to the old VLAN, or to a new one. For example, if you bind the network interfaces 1/2 and 1/3 to a VLAN with ID 2, and then bind them to a channel LA/1, the network interfaces are moved to the default VLAN, but you can bind them back to VLAN 2.

## Configuring Link Aggregation Manually

When you create a link aggregation channel, its state is DOWN until you bind an active interface to it. You can modify a channel at any time. You can remove channels, or you can enable/disable them.

### CLI procedures

To create a link aggregation channel by using the CLI:

At the command prompt, type:

- `add channel <id> [-ifnum <interfaceName> ...] [-state ( ENABLED | DISABLED )] [-speed <speed>] [-flowControl <flowControl>] [-haMonitor ( ON | OFF )] [-tagall ( ON | OFF )] [-ifAlias <string>] [-throughput <positive_integer>] [-bandwidthHigh <positive_integer>] [-bandwidthNormal <positive_integer>]`
- `show channel`

### Example:

```
1 > add channel LA/1 -ifnum 1/8
2 Done
3 <!--NeedCopy-->
```

To bind an interface to or unbind an interface from an existing link aggregation channel by using the CLI:

At the command prompt, type one of the following commands:

- `bind channel <id> <interfaceName>`
- `unbind channel <id> <interfaceName>`

### Example:

```
1 bind channel LA/1 1/8
2 <!--NeedCopy-->
```

To modify a link aggregation channel by using the CLI:

At the command prompt, type the

`set channel` command, the channel ID, and the parameters to be changed, with their new values.

To remove a link aggregation channel by using the CLI:

**Important:** When a channel is removed, the network interfaces bound to it induce network loops that decrease network performance. You must disable the network interfaces before you remove the channel.

At the command prompt, type:

- `rm channel <id>`

**Example:**

```
1 > rm channel LA/1
2 Done
3 <!--NeedCopy-->
```

**GUI procedures**

To configure a link aggregation channel by using the GUI:

Navigate to System > Network > Channels, add a new channel, or edit an existing channel.

To remove a link aggregation channel by using the GUI:

**Important:**

When a channel is removed, the network interfaces bound to it induce network loops that decrease network performance. You must disable the network interfaces before you remove the channel.

Navigate to System > Network > Channels, select the channel that you want to remove and click Delete.

**Configuring Link Aggregation by Using the Link Aggregation Control Protocol**

The Link Aggregation Control Protocol (LACP) enables network devices to exchange link aggregation information by exchanging LACP Data Units (LACPDU). Therefore, you cannot enable LACP on network interfaces that are members of a channel that you created manually.

When using LACP to configure link aggregation, you use different commands and parameters for modifying link aggregation channels than you do for creating link aggregation channels. To remove a channel, you must disable LACP on all interfaces that are part of the channel.

**Note:** In an High Availability configuration, LACP configurations are neither propagated nor synchronized.

**Configuring the LACP System Priority**

The LACP system priority determines which peer device of an LACP LA channel can have control over the LA channel. This number is globally applied to all LACP channels on the appliance. The lower the value, the higher the priority.

To configure the LACP system priority by using the CLI:

At the command prompt, type the following commands to set the priority for a standalone appliance and verify the configuration:

- `set lacp -sysPriority <positive_integer>`
- `show lacp`

**Example:**

```
1 set lacp -sysPriority 50
2 <!--NeedCopy-->
```

To set the priority for a specific cluster node, log on to the cluster IP address and at the command prompt, type the following commands:

- `set lacp -sysPriority <positive_integer> -ownerNode <positive_integer>`
- `show lacp`

**Example:**

```
1 set lacp -sysPriority 50 -ownerNode 2
2 <!--NeedCopy-->
```

To configure the LACP system priority by using the GUI:

1. Navigate to System > Network > Interfaces and, in the Action list, select Set LACP.
2. Specify the system priority and the owner node (applicable only for a cluster setup).

## Creating Link Aggregation Channels

For creating a link aggregation channel by using LACP, you need to enable LACP and specify the same LACP key on each interface that you want to be the part of the channel. For example, if you enable LACP and set the LACP Key to 3 on interfaces 1/1 and 1/2, a link aggregation channel LA/3 is created and interfaces 1/1 and 1/2 are automatically bound to it.

**Note:**

- When enabling LACP on a network interface, you must specify the LACP Key.
- By default, LACP is disabled on all network interfaces.

To create an LACP channel by using the CLI:

At the command prompt, type:

- `set interface <id> [-lacpMode <lacpMode>] [-lacpKey<positive_integer>] [-lacpPriority <positive_integer>] [-lacpTimeout (LONG | SHORT )]`
- `show interface [<id>]`

To create an LACP channel by using the GUI:

Navigate to System > Network > Interfaces, open the network interface, and set the parameters.

### Modifying Link aggregation Channels

After you have created an LACP channel by specifying interfaces, you can modify properties of the channel.

To modify an LACP channel by using the CLI:

At the command prompt, type:

- `set channel <id> [-ifnum <interfaceName> ...] [-state ( ENABLED | DISABLED )] [-speed <speed>] [-flowControl <flowControl>] [-haMonitor ( ON | OFF )] [-ifAlias <string>] [-throughput <positive_integer>] [-tagall ( ON | OFF )] [-bandwidthHigh <positive_integer> [-bandwidthNormal <positive_integer>]]`
- `show channel`

#### Example:

```
1 > set channel LA/3 -state ENABLED -speed 10000
2 Done
3 <!--NeedCopy-->
```

To modify an LACP channel by using the GUI:

Navigate to System > Network > Channels, and modify an existing LACP channel.

### Removing a Link Aggregation Channel

To remove a link aggregation channel that was created by using LACP, you need to disable LACP on all the interfaces that are part of the channel.

To remove an LACP channel by using the CLI:

At the command prompt, type:

- `set interface <id> -lacpMode Disable`
- `show interface [<id>]`

To remove an LACP channel by using the GUI:

Navigate to System > Network > Interfaces, open the network interface, and clear the Enable LACP option.

## Link Redundancy using LACP channels

Link Redundancy using LACP channels enables the NetScaler to divide an LACP channel into logical subchannels, with one subchannel active and the others in standby mode. If the active subchannel fails to meet a minimum threshold of throughput, one of the standby subchannels becomes active and takes over.

A subchannel is created from links that are part of the LACP channel and are connected to a particular device. For example, for an LACP channel with four interfaces on a NetScaler, with two of the interfaces connected to device A and the other two connected to device B, the ADC creates two logical subchannels, one subchannel with two links to device A, and another subchannel with two links to device B.

To configure link redundancy for an LACP channel, set the `lrMinThroughput` parameter, which specifies the minimum throughput threshold (in Mbps) to be met by the active subchannel. Setting this parameter automatically creates the subchannels. When the maximum supported throughput of the active channel falls below the `lrMinThroughput` value, link failover occurs and a standby subchannel becomes active.

If you unset the `lrMinThroughput` parameter of an LACP channel, or set the value to zero, link redundancy for that channel is disabled, which is the default setting.

### Example

Consider an example of link redundancy configured between NetScaler NS1 and switches SW1 and SW2.

NS1 is connected to network device NW-A through SW1 and SW2.

On NS1, LACP channel LA/1 is created from interfaces 1/1, 1/2, 1/3, and 1/4. Interfaces 1/1 and 1/2 of

NS1 are connected to SW1, and interfaces 1/3 and 1/4 are connected to SW2. Each of the four links supports a maximum throughput of 1000Mbps.

When the `lrMinThroughput` parameter is set to some value (say 2000), NS1 creates two logical subchannels from LA/1, one subchannel (say subchannel 1) using interfaces 1/1 and 1/2 (connected to SW1), and the other subchannel (subchannel 2) using interfaces 1/3 and 1/4 (connected to SW2).

NS1 applies an algorithm to make one subchannel (say subchannel 1) active and put the other on standby. NS1 and network device NW-A are accessible to each other through only the active subchannel.

Say subchannel 1 is active, and its maximum supported throughput falls below the `lrMinThroughput` value (for example, one of its links fails, and the maximum supported throughput falls to 1000 Mbps). Subchannel 2 becomes active and takes over.

### **Link Redundancy using LACP channels in a High Availability setup**

In a high availability (HA) configuration, if you want to configure throughput (throughput parameter) based HA failover and link redundancy (`lrMinThroughput` parameter) on an LACP channel, you must set the throughput parameter to a value less than or equal to that of the `lrMinThroughput` parameter.

The maximum supported throughput of an LACP channel is calculated as the maximum supported throughput of the active subchannel.

If the throughput parameter value is equal to or less than the `lrminthroughput` parameter value, HA failover occurs when both of the following conditions exist at the same time:

- None of the subchannels' maximum supported throughput meet the `lrMinThroughput` parameter value.
- The maximum supported throughput of the LACP channel does not meet the throughput parameter value

Consider an example of an HA setup that has NetScalers NS1 and NS2, with switches SW1 and SW2. NS1 is connected to NS2 through SW1 and SW2.

On NS1, LACP channel LA/1 is created from interfaces 1/1, 1/2, 1/3, and 1/4. Interfaces 1/1 and 1/2 of NS1 are connected to SW1, and interfaces 1/3 and 1/4 are connected to SW2. Each of the four links supports a maximum throughput of 1000 Mbps.

Following are the LACP-parameter settings in this example:

Parameter	Value
Throughput	2000
lrminthroughput	2000

NS1 forms two subchannels from LA/1, one subchannel (say subchannel 1) using interfaces 1/1 and 1/2 (connected to SW1), and the other subchannel (subchannel 2) using interfaces 1/3 and 1/4 (connected to SW2). Each of the two subchannels supports a maximum throughput of 2000 Mbps. Applying an algorithm, NS1 makes one subchannel (say subchannel 1) active and the other standby.

Say subchannel 1 is active, and its maximum supported throughput falls below the lrMinThroughput value (for example, one of its links fails, and maximum supported throughput falls to 1000 Mbps). Subchannel 2 becomes active and takes over. HA failover does not occur, because the maximum supported throughput of the LACP channel is not less than the throughput parameter value:

Maximum supported throughput of the LACP channel = Maximum supported throughput of the active channel = Maximum supported throughput of subchannel 2 = 2000 Mbps

If subchannel 2's maximum supported throughput also falls below the lrminthroughput value (for example, one of its links fails, and the maximum supported throughput falls to 1000 Mbps), HA failover occurs, because the maximum supported throughput of the LACP channel is then less than the throughput parameter value:

### Configure Link Redundancy using LACP channels

To configure link redundancy for a LACP channel by using the CLI:

At the command prompt, type the following commands to configure the channel and verify the configuration:

- **set channel** <id> -lrMinThroughput <positive\_integer>
- **show channel**

**Example:**

```
1 > set channel la/1 -lrMinThroughput 2000
2 Done
3 > set channel la/2 -throughput 2000 -lrMinThroughput 2000
4 Done
5 <!--NeedCopy-->
```

To configure link redundancy for a LACP channel by using GUI

1. Navigate to System > Network > Channels.
2. In the details pane, select an LACP channel for which you want to configure link redundancy, and then click Edit.
3. In the Configure LACP channel dialog box, set the lrMinThroughput parameter.
4. Click Close.

## Redundant Interface Set

May 22, 2023

**Note**

Link redundancy configuration is not supported on a NetScaler VPX instance hosted on a NetScaler SDX appliance.

A redundant interface set is a set of interfaces where one of the interfaces is active and the remaining ones are standby. If the active interface fails, one of the standby interfaces takes over and becomes active.

The following are the main benefits of using redundant interface sets:

- A redundant interface set ensures connection reliability between the NetScaler appliance and a peer device by providing backup links between them.
- Unlike link redundancy using LACP, no configuration is required on the peer device for a redundant interface set. To the peer device, the redundant interface set appear as individual interfaces and not as a set or collection.
- In a high availability configuration (HA), redundant interface sets can minimize the number the HA failovers.

**Note**

Redundant Interface Set was formerly known as ‘NIC bundling’ when first introduced in 10.5 release.

**How a Redundant Interface Set Works**

For a redundant interface set, the NetScaler appliance derives a MAC address based on an internal algorithm and assigns it to the redundant interface set. This MAC address is shared by all the member interfaces and is used only by the active interface at a time. The active interface broadcasts GARP messages, which contain the MAC address assigned to the redundant interface set and not the interface’s own physical MAC address. When the current active interface fails and is taken over by another interface, the new active interface sends GARP messages. The peer device updates its forwarding table with the new active interface information. The standby interfaces do not send any GARP messages. The standby interfaces do not send any packets and they drop any packets they receive.

In a redundant interface set, selection of the member interface as active is based on either of the following factors:

- **Redundant interface priority.** This is a parameter of an interface and it defines the priority of the interface in a redundant interface set for the active member selection. This parameter specifies a positive integer. Lower the value higher the priority of active member selection. The member interface with the highest priority (lowest value) is selected as the active interface of the redundant interface set.
- **Binding order of the member interfaces.** If all the member interfaces have the same redundant interface priority, the member interface that was bound first to the redundant interface set is selected as the active interface of the redundant interface set.

In a redundant interface set, active interface selection is triggered in one of the following events:

- When the current active interface fails or you disable it.
- When you set the priority of a standby interface to a value lower than that of the current active interface. The standby interface takes over as the active interface.
- When you bind an interface whose priority is lower than that of the current active interface. The newly bound interface takes over as the active interface.

**Points to Consider for Configuring Redundant Interface Sets**

Consider the following points before you configure a redundant interface set:

- In a standalone appliance or an appliance in a high availability setup, a link redundant set is specified in LR/X notation, where X can range from 1 to 4. For example, LR/1.

- In a high availability configuration, redundant interface set configurations do not propagate or synchronize to the secondary node.
- You can configure a maximum of four redundant interface sets on a NetScaler appliance.
- You can bind a maximum of 16 interfaces to a redundant interface set.
- Member interfaces of a redundant interface set cannot be bound to another redundant interface set.
- Member interfaces of a redundant interface set cannot be bound to a link aggregate (LA) channel.
- LA channels cannot be bound to a redundant interface set.
- Redundant interface sets cannot be bound to an LA channel.
- In a cluster setup:
  - Redundant interface sets cannot be bound to a cluster link aggregation.
  - A link redundant set is specified in N/LR/X notation (for example, 1/LR/3). Where:
    - N is the ID of the cluster node on which the redundant interface set is to be created.
    - X is a link-redundant set identifier on a cluster node. X can range 1–4.
  - A cluster link aggregation cannot be bound to a redundant interface set.
  - A redundant interface set can include only the interfaces of the node to which the redundant interface set belongs.
  - An Existing elink redundancy set configuration on a standalone appliance automatically changes to cluster notation (N/LR/X) after the appliance is added to a cluster setup.

## Configuration Steps

Configuring a redundant interface set on a NetScaler appliance consists of the following tasks:

- **Create a redundant interface set.** Use the channel command operation for creating a redundant interface set.

In a standalone appliance or an appliance in a high availability setup, a link redundant set is specified in LR/X notation, where X can range from 1 to 4. For example, LR/1.

In a cluster setup, a link redundant set is specified in N/LR/X (for example, 1/LR/3), where: N is the ID of the cluster node on which the redundant interface set is to be created; X is the link redundant set identifier on a cluster node. X can range 1–4.

- **Bind interfaces to the redundant interface set.** Associate the desired interfaces with the redundant interface set. An interface cannot be a part of multiple redundant interface sets.
- **(Optional) Set a redundant interface priority on the member interface.** Use the interface command operation for setting the redundant interface priority on a desired member interface of a redundant interface set.

To create a redundant interface set by using the CLI:

At the command prompt:

- add channel <ID>
- show channel <ID>

To bind interfaces to a redundant interface set by using the CLI:

At the command prompt:

- bind channel <ID> <ifnum>
- show channel <ID>

To set a redundant interface priority of an interface by using the CLI:

At the command prompt:

- set interface <ID> -lrsetpriority <positive\_integer>
- show interface <ID>

### Sample configuration 1:

In the following example, a redundant interface set LR/1 is created, and interfaces 1/1, 1/2, 1/3, and 1/4 are bound to LR/1. The redundant interface priority is set to a default value of 1024 for all these member interfaces. Output of the show channel command displays that the interface 1/1 is the current active interface for the redundant interface set lr/1.

```
1 > add channel lr/1
2 Done
3 > bind channel lr/1 1/1 1/2 1/3 1/4
4 Done
5 > show channel
6 1) Interface LR/1 (Link Redundant) #23
7 flags=0x100c020 <ENABLED, UP, LINKREDUNDANT, UP, HAMON, 802.1q>
8 MTU=1500, native vlan=1, MAC=36:97:a2:b7:6b:a9, uptime 0h00m00s
9 Requested: media NONE, speed AUTO, duplex NONE, fctl OFF,
10 throughput 0
11 Actual: throughput 1000

## Binding an SNIP address to an Interface

May 2, 2023

You can now bind a NetScaler owned SNIP address to an interface without using Layer 3 VLANs. Any packets related to the SNIP address will go only through the bound interface.

This feature can be useful in a scenario where the upstream switch does not support Link Aggregation channels and you want the NetScaler appliance to load balance traffic, originated from a server, across the four links to the upstream switch as shown in the following illustration.

The following tables describe the example settings for the scenario:

Entity	Name	Value
SNIP addresses on NS1	SNIP2 (for reference purpose only)	10.10.10.2
	SNIP3 (for reference purpose only)	
	SNIP4 (for reference purpose only)	
	SNIP5 (for reference purpose only)	
LLB virtual server on NS1	LLB_VSERVER1	-
Transparent monitor on NS1	TRANS_MON	-

Entity	Name	Value
LLB services on NS1	LLB_SVC2	10.10.10.240
		LLB_SVC3
		LLB_SVC4
		LLB_SVC5
MAC address of interface 1/2 on NS1	NS_MAC_2 (for reference purpose only)	00:e0:ed:0f:bc:e0
MAC address of interface 1/3 on NS1	NS_MAC_3 (for reference purpose only)	00:e0:ed:0f:bc:df
MAC address of interface 1/4 on NS1	NS_MAC_4 (for reference purpose only)	00:e0:ed:0f:bc:de
MAC address of interface 1/5 on NS1	NS_MAC_5 (for reference purpose only)	00:e0:ed:1c:89:53
IP address of Router R1	Router_IP (for reference purpose only)	10.10.10.1
MAC address of interface of R1	ROUTER_MAC1 (for reference purpose only)	00:21:a1:2d:db:cc

To configure the example settings:

1. Add four different SNIPs in different subnet ranges. This is for ARP to be resolved on four different links. For more information on creating a SNIP address, see [Configuring Subnet IP Addresses \(SNIPs\)](#).

**CLI example:**

```

1 > add ns ip 10.10.10.2 255.255.255.0 -type SNIP
2 Done
3 > add ns ip 10.10.10.3 255.255.255.128 -type SNIP
4 Done
5 > add ns ip 10.10.10.4 255.255.255.192 -type SNIP
6 Done
7 > add ns ip 10.10.10.5 255.255.255.224 -type SNIP
8 Done
9 <!--NeedCopy-->

```

2. Add four different dummy services in the added SNIP subnets. This is to ensure that the traffic is sent out with source IP as one of the four configured SNIPs. For more information on creating a service, see [Set up basic load balancing](#).

**CLI example:**

```
1 > add service LLB_SVC2 10.10.10.240 any *
2 Done
3 > add service LLB_SVC3 10.10.10.120 any *
4 Done
5 > add service LLB_SVC4 10.10.10.60 any *
6 Done
7 > add service LLB_SVC5 10.10.10.30 any *
8 Done
9 <!--NeedCopy-->
```

3. Add a transparent ping monitor for monitoring the gateway. Bind the monitor to each of the configured dummy services. This is to make the state of the services as UP. For more information on creating a transparent monitor, see [Configure monitors in a load balancing setup](#).

**CLI example:**

```
1 > add monitor TRANS_MON ping -destIP 10.10.10.1 -transparent YES
2 Done
3 > bind monitor TRANS_MON LLB_SVC2
4 Done
5 > bind monitor TRANS_MON LLB_SVC3
6 Done
7 > bind monitor TRANS_MON LLB_SVC4
8 Done
9 > bind monitor TRANS_MON LLB_SVC5
10 Done
11 <!--NeedCopy-->
```

4. Add a link load balancing (LLB) virtual server and bind the dummy services to it. For more information on creating an LLB virtual server, see [Configuring a Basic LLB Setup](#).

**CLI example:**

```
1 > add lb vserver LLB_VSERVER1 any
2 Done
3 > set lb vserver LLB_VSERVER1 -lbmethod ROUNDROBIN
4 Done
5 > bind lb vserver LLB_VSERVER1 LLB_SVC2
6 Done
7 > bind lb vserver LLB_VSERVER1 LLB_SVC2
8 Done
9 > bind lb vserver LLB_VSERVER1 LLB_SVC2
10 Done
11 > bind lb vserver LLB_VSERVER1 LLB_SVC2
12 Done
13 <!--NeedCopy-->
```

5. Add the LLB virtual server as the default LLB route. For more information on creating an LLB route see [Configuring a Basic LLB Setup](#).

**CLI example:**

```
1 > add lb route 0.0.0.0 0.0.0.0 LLB_VSERVER1
2 Done
3 <!--NeedCopy-->
```

6. Add an ARP entry for each of the dummy services with the MAC address of the gateway. This way the gateway is reachable through these dummy services. For more information on adding an ARP entry, see [Configuring Static ARP](#).

**CLI example:**

```
1 > add arp -ipaddress 10.10.10.240 -mac 00:21:a1:2d:db:cc -ifnum
 1/2
2 Done
3 > add arp -ipaddress 10.10.10.120 -mac 00:21:a1:2d:db:cc -ifnum
 1/3
4 Done
5 > add arp -ipaddress 10.10.10.60 -mac 00:21:a1:2d:db:cc -ifnum 1/4
6 Done
7 > add arp -ipaddress 10.10.10.30 -mac 00:21:a1:2d:db:cc -ifnum 1/5
8 Done
9 <!--NeedCopy-->
```

7. Bind a specific interface to an SNIP by adding an ARP entry for each of these SNIPs. This is to ensure that the response traffic will reach the same interface through which the request went out. For more information on adding an ARP entry, see [Configuring Static ARP](#).

**CLI example:**

```
1 > add arp -ipAddress 10.10.10.2 -mac 00:e0:ed:0f:bc:e0 -ifnum 1/2
2 Done
3 > add arp -ipAddress 10.10.10.3 -mac 00:e0:ed:0f:bc:df -ifnum 1/3
4 Done
5 > add arp -ipAddress 10.10.10.4 -mac 00:e0:ed:0f:bc:de -ifnum 1/4
6 Done
7 > add arp -ipAddress 10.10.10.5 -mac 00:e0:ed:1c:89:53 -ifnum 1/5
8 Done
9 <!--NeedCopy-->
```

## Monitor the Bridge Table and Changing the Aging time

May 2, 2023

NetScaler appliance bridges frames on the basis of bridge table lookup of the destination MAC address and the VLAN ID. However, the appliance performs forwarding only when Layer 2 mode is enabled.

The bridge table is dynamically generated, but you can display it, modify the aging time for the bridge table, and view bridging statistics. All the MAC entries in the bridge table are updated with the aging

time.

To set the aging time of bridge table entries by using the CLI:

At the command prompt, type:

- **set l2param -bridgeagetimeout** <positive\_integer>
- **show l2param**

**Example:**

```
1 > set l2param -bridgeagetimeout 90
2 Done
3 <!--NeedCopy-->
```

To view the statistics of a bridge table by using the CLI:

At the command prompt, type:

- **stat bridge**

To set the aging time of bridge table entries by using the GUI:

Navigate to **System > Network**. On the **Network** page, in the **Settings** section, click **Configure Layer2 Parameters** and set the **Timeout Value For The Bridge Table Entries (seconds)** parameter.

To view the statistics of a bridge table by using the GUI:

Navigate to **System > Network > Bridge Table**, select the MAC address, and click **Statistics**.

## NetScaler Appliances in Active-Active Mode Using VRRP

May 2, 2023

An active-active deployment, in addition to preventing downtime, makes efficient use of all the NetScaler appliances in the deployment. In active-active deployment mode, the same VIPs are configured on all NetScaler appliances in the configuration, but with different priorities, so that a given VIP can be active on only one appliance at a time.

The active VIP is called the master VIP, and the corresponding VIPs on the other NetScaler appliances are called the backup VIPs. If a master VIP fails, the backup VIP with the highest priority takes over and becomes the master VIP. All the NetScaler appliances in an active-active deployment use the Virtual Router Redundancy Protocol (VRRP) protocol to advertise their VIPs and the corresponding priorities at regular intervals.

NetScaler appliances in active-active mode can be configured so that no NetScaler is idle. In this configuration, different sets of VIPs are active on each NetScaler. For example, in the following diagram, VIP1, VIP2, VIP3, and VIP4 are configured on appliances NS1, NS2, and NS3. Because of their priorities, VIP1 and VIP 2 are active on NS1, VIP3 is active on NS2 and VIP 4 is active on NS3. If, for example, NS1 fails, VIP1 on NS3 and VIP2 on NS2 become active.

Figure 1. An Active-Active Configuration

The NetScaler appliances in the above diagram process traffic as follows:

1. Client C1 sends a request to VIP1. The request reaches R1.
2. R1 does not have an ARP entry for VIP1, so it broadcasts an ARP request for VIP1.
3. VIP1 is active in NS1, so NS1 replies with a source MAC address as the virtual MAC (for example virtual MAC1) associated with VIP1, and VIP1 as the source IP address.
4. SW1 learns the port for VIP1 from the ARP reply and updates its bridge table.
5. R1 updates the ARP entry with virtual MAC1 and VIP1.
6. R1 forwards the packet to the VIP1 on NS1.
7. NS1's load balancing algorithm selects server S2, and NS1 opens a connection between one of its SNIP addresses and S2.
8. S2 replies to the SNIP on the NetScaler.
9. NS1 sends S2's reply to the client. In the reply, NS1 inserts MAC address of the physical interface as the source MAC address and VIP1 as the source IP address.
10. Should NS1 fail, the NetScaler appliances use the VRRP protocol to select the VIP1 with the highest priority. In this case, VIP1 on NS3 becomes active, and the following two steps update the active-active configuration.
11. NS3 broadcasts a GARP message for VIP1. In the message, virtual MAC1 is the source MAC address and VIP1 is the source IP address.
12. SW1 learns the new port for virtual MAC1 from the GARP broadcast and updates its bridge table to send subsequent client requests for VIP1 to NS3. R1 updates its ARP table.

The priority of a VIP can be modified by health tracking. If you enable health tracking, you should make sure that preemption is also enabled, so that a VIP whose priority is lowered can be preempted by another VIP.

In some situations, traffic might reach a backup VIP. To avoid dropping such traffic, you can enable sharing, on a per-node basis, as you create an active-active configuration. Or you can enable the global send to master option. On a node on which sharing is enabled, it takes precedence over send to master.

## Health Tracking

Base priority (BP-range 1-255) ordinarily determines which VIP is the master VIP, but effective priority (EP) can also affect the determination.

For example, if a VIP on NS1 has a priority of 101 and same VIP on NS2 has a priority of 99, the VIP on NS1 is active. However, if two vservers are using the VIP on NS1 and one of them goes DOWN, health tracking can reduce the EP of VIP on NS1. VRRP then makes the VIP on NS2 the active VIP.

Following are the health tracking options for modifying EP:

- **NONE.** No tracking. EP = BP
- **ALL.** If all virtual servers are UP, then EP = BP. Otherwise, EP = 0.

- **ONE.** If at least one virtual server is UP, then EP = BP. Otherwise, EP = 0.
- **PROGRESSIVE.** If ALL virtual servers are UP, then EP = BP. If ALL virtual servers are DOWN then EP = 0. Otherwise EP = BP (1 - K/N), where N is the total number of virtual servers associated with the VIP and k is the number of virtual servers that are down.

**Note:** If you specify a value other than NONE, preemption should be enabled, so that the backup VIP with the highest priority becomes active if the priority of the master VIP is downgraded.

## Preemption

Preemption of an active VIP by another VIP that attains a higher priority is enabled by default, and normally should be enabled. In some cases, however, you may want to disable it. Preemption is a per-node setting for each VIP.

Preemption can occur in the following situations:

- An active VIP goes down and a VIP with a lower priority takes its place. If the VIP with the higher priority comes back online, it preempts the currently active VIP.
- Health tracking causes the priority of a backup VIP to become higher than that of the active VIP. The backup VIP then preempts the active VIP.

## Sharing

In the event that traffic reaches a backup VIP, the traffic is dropped unless the sharing option is enabled on the backup VIP. This behavior is a per node setting for each VIP and is disabled by default.

In the figure **An Active-Active Configuration** VIP1 on NS1 is active and VIP1 VIPs on NS2 and NS3 are backups. Under certain circumstances, traffic may reach VIP1 on NS2. If Sharing is enabled on NS2, this traffic is processed instead of dropped.

## Configuring Active-Active Mode

May 2, 2023

On each NetScaler appliance that you want to deploy in active-active mode, you must add a virtual MAC and bind the virtual MAC to a VIP. The virtual MAC for a given VIP must be same on each appliance. For example, if VIP 10.102.29.5, is created on the appliances, a virtual router ID (VRID) must be created on each NetScaler and bound to VIP 10.102.29.5 on each NetScaler. When you bind a virtual MAC to a VIP, the appliance sends VRRP advertisements to each VLAN that is bound to that VIP. The virtual MAC can be shared by different VIPs configured on the same NetScaler.

## Configuring IPv4 Active-Active Mode

Perform the following tasks on each of the NetScaler appliances to be included in the active-active configuration:

- **Add a virtual MAC address.** Add a virtual MAC address by adding a VRID. You can also specify a priority and enable or disable preemption and sharing on this VRID address.
- **Add a VIP address and associate the virtual MAC's VRID.** Add a VIP address and set the VRID parameter to the newly created VRID. The attributes of the VRID (for example, priority and preemption) are bound to this VIP address.

**Note:** The same VIP address must be added to all the other NetScaler appliances.

To add a virtual MAC address by using the CLI

At the command prompt, type:

- **add vrid** <id> [-priority <positive\_integer>] [-preemption (\*\*ENABLED\*\*|\*\*DISABLED\*\*)] [-sharing (\*\*ENABLED\*\*|\*\*DISABLED\*\*)] [-tracking <tracking>]
- **show vrid**

To add a VIP address by using the CLI:

At the command prompt, type:

- **add ns ip** <IPv4Address> -type VIP -vrid <value>
- **show ns ip**

To configure a virtual MAC by using the GUI:

1. Navigate to **System > Network > VMAC**, on the **VMAC** tab, add a new virtual MAC, or edit an existing virtual MAC.
2. Set the following parameters:
  - Virtual Router ID
  - Priority
  - Tracking
  - Preemption
  - Sharing

To configure a VIP address and associate the VRID to it by using the GUI:

1. Navigate to **System > Network > IPs**, on the **IPV4s** tab, add an IP address of type VIP.
2. While adding the IP address, select the virtual router ID from the **Virtual Router Id** drop down box.

### Sample Configuration:

The following sample configuration is for deploying NetScaler appliances NS1 and NS2 in IPv4 active-active mode. VIP address 203.0.113.10 is configured on both NS1 and NS2, with a different priority value on each appliance. On each appliance, this VIP address is bound to a virtual MAC address. 203.0.113.10 is master on NS2, because its priority (200) on NS2 is higher than on NS1 (100).

```
1 Settings on NS1
2
3 > add vrid 10 -Priority 100 -Preemption Enabled -sharing Enabled
4
5 Done
6
7 > add ns ip 203.0.113.10 -type VIP -vrid 10
8
9 Done
10
11 Settings on NS2
12
13 > add vrid 10 -Priority 200 -Preemption Enabled -sharing Enabled
14
15 Done
16
17 > add ns ip 203.0.113.10 -type VIP -vrid 10
18
19 Done
20 <!--NeedCopy-->
```

## Configuring IPv6 Active-Active Mode

Perform the following tasks on each of the NetScaler appliances to be included in the active-active configuration:

- **Add a virtual MAC6 address.** Add a virtual MAC6 address by adding a VRID6. You can also specify a priority and enable or disable preemption and sharing on this VRID6 address.
- **Add a VIP6 address.** Add a VIP6 address. Set the VRID6 parameter to the VRID6 of the newly created virtual MAC6. The attributes of the virtual MAC6 (for example, priority and preemption) are bound to this VIP6 address.

**Note:** The same VIP6 address must be added to all the other NetScaler appliances.

To add a virtual MAC6 address by using the CLI:

At the command prompt, type:

- **add vrid6** <id> [-\*\*priority\*\* <positive\_integer>] [-\*\*preemption\*\* ( \*\*ENABLED\*\* | \*\*DISABLED\*\* )] [-\*\*sharing\*\* ( \*\*ENABLED\*\* | \*\*DISABLED\*\* )]
- **show vrid6**

To add a VIP6 address by using the CLI:

At the command prompt, type:

- **add ns ip6** <IPv6Address> **-type** VIP **-vrid** <value>
- **show ns ip6**

To configure a virtual MAC6 by using the GUI:

1. Navigate to **System > Network > VMAC**, on the **VMAC6** tab, add a new virtual MAC6, or edit an existing **VMAC6**.
2. Set the following parameters:
  - Virtual Router ID
  - Priority
  - Preemption
  - Sharing

To configure a VIP6 address and associate the VRID to it by using the GUI:

1. Navigate to **System > Network > IPs**, on the **IPV6s** tab, add an IPv6 address of type VIP.
2. While adding the VIP6 address, select the VRID6 from the **Virtual Router Id** drop down box.

### Sample Configuration:

The following sample configuration is for deploying NetScaler appliances NS1 and NS2 in IPv6 active-active mode. VIP6 address 2001:db8::5001 is configured on both NS1 and NS2, with a different priority value on each appliance. On each appliance, this VIP6 address is bound to a virtual MAC6 address. 2001:db8::5001 is master on NS2, because it's priority (200) on NS2 is higher than on NS1 (100).

```
1 Settings on NS1
2 > add vrid6 10 - Priority 100 - Preemption Enable - sharing Enable
3
4 Done
5 > add ns ip6 2001:db8::5001 - type VIP - vrid6 10
6
7 Done
8 Settings on NS2
9 > add vrid6 10 - Priority 200 - Preemption Enable - sharing Enable
10
11 Done
12 > add ns ip6 2001:db8::5001 - type VIP - vrid6 10
13
14 Done
15 <!--NeedCopy-->
```

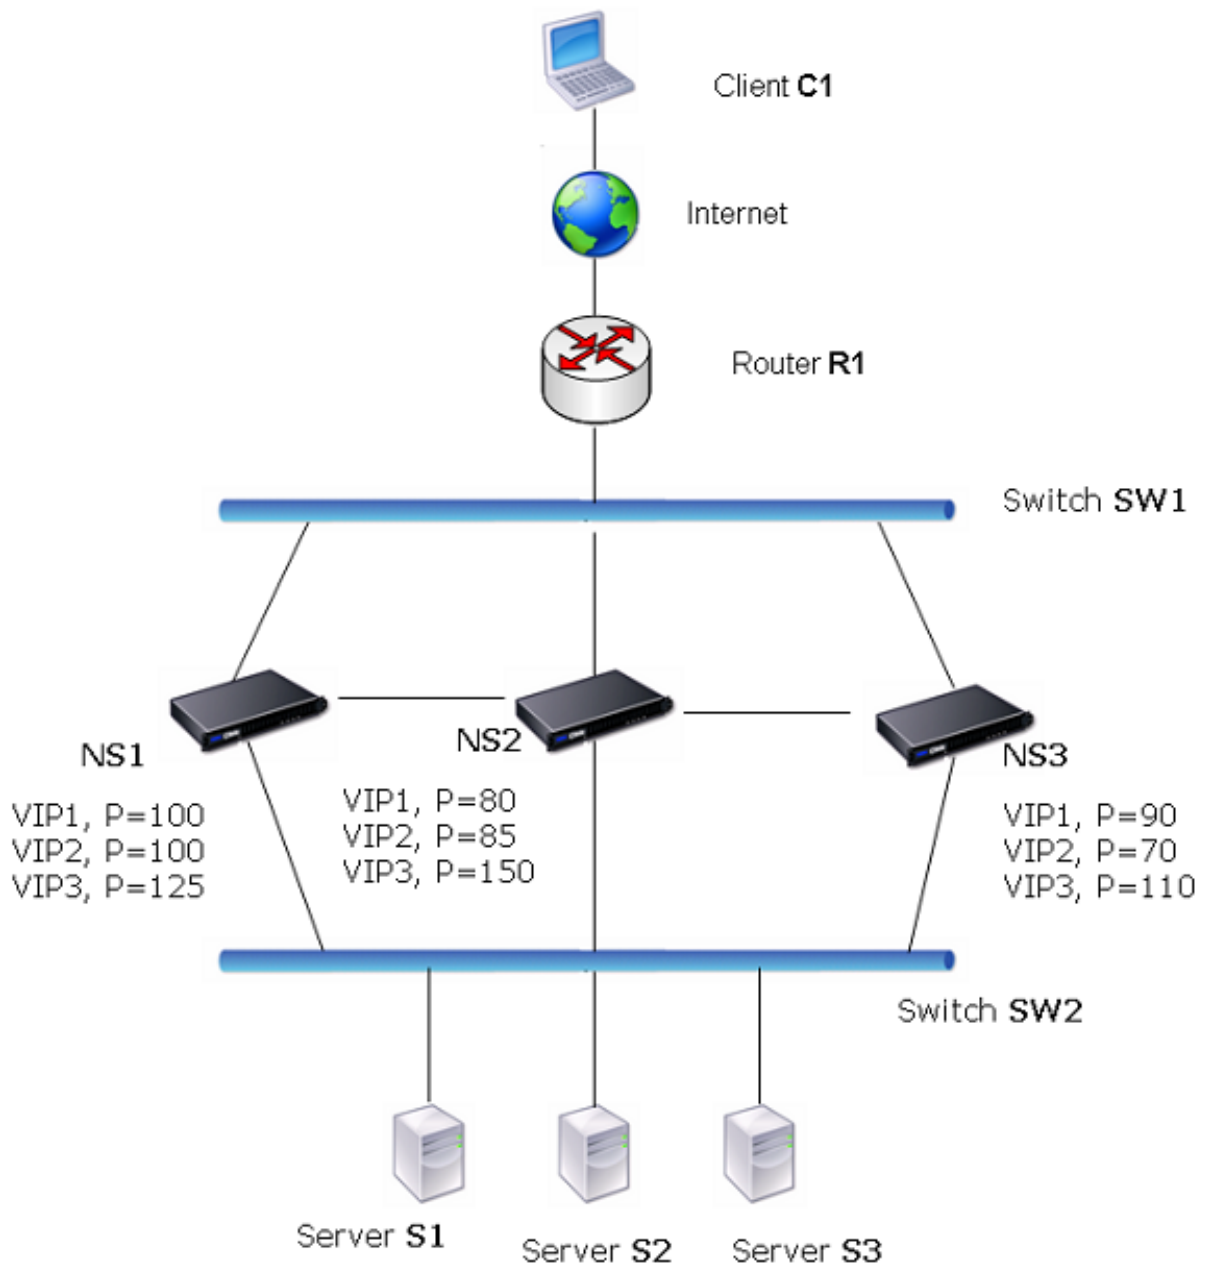

## Configuring Send to Master

May 2, 2023

Usually, the traffic destined to a VIP reaches the NetScaler appliance on which the VIP is active, because an ARP request with the VIP and a virtual MAC on that appliance has reached the upstream router. But in some cases, such as static routes configured on the upstream router for the VIP subnet, or a topology that blocks this route, the traffic can reach a NetScaler appliance on which the VIP is in backup state. If you want this appliance to forward the data packets to the appliance on which the VIP is active, you need to enable the send to master option. This behavior is a per node setting and is disabled by default.

For example, in the following diagram, VIP1 is configured on NS1, NS2, and NS3 and is active on NS1. Under certain circumstances, traffic for VIP1 (active on NS1) may reach VIP1 on NS3. When the send to master option is enabled on NS3, NS3 forwards the traffic to NS1 through NS2 by using route entries for NS1.

Figure 1. An Active-Active Configuration with Send to Master Option Enabled

To enable send to master by using the CLI:

At the command prompt, type:

```
set vrIDParam -sendToMaster (ENABLED DISABLED)
```

**Example:**

---

```
1 > set vrIDParam -sendToMaster ENABLED
2 Done
3 <!--NeedCopy-->
```

To enable send to master by using the GUI:

1. Navigate to **System > Network**, in the **Settings** group, click **Virtual Router Parameters**.
2. Select the **Send to Master** option.

## Configuring VRRP Communication Intervals

May 2, 2023

In an active-active deployment, all NetScaler nodes use the Virtual Router Redundancy Protocol (VRRP) to advertise their master VIP addresses and the corresponding priorities in VRRP advertisement packets (hello messages) at regular intervals.

VRRP uses the following communication intervals:

- **Hello Interval.** Interval between the VRRP hello messages that a node of a master VIP address sends to its peer nodes.
- **Dead Interval.** Time after which a node of a backup VIP address considers the state of the master VIP address as DOWN if VRRP hello messages are not received from the node of the master VIP address. After the dead interval, the backup VIP address takes over and becomes the master VIP address.

You can change these intervals to a desired value. Both of these communication intervals are per node setting for all VIP addresses in that node.

To configure VRRP communication intervals by using the CLI:

At the command prompt, type:

- **set vrIDParam** [-helloInterval <msecs>] [-deadInterval <secs>]
- **sh vrIDParam**

### Example:

```
1 > set vrIDParam -helloInterval 500 -deadInterval 2
2 Done
3 <!--NeedCopy-->
```

To configure VRRP communication intervals by using the GUI:

1. Navigate to **System > Network**, in the **Settings** group, click **Virtual Router Parameters**.

2. In **Configure Virtual Router Parameter**, set the **Hello Interval** and **Dead Interval** parameters.
3. Click **OK**.

### **Example 1: Nodes with the Same VRRP Dead Intervals**

Consider an active-active deployment consisting of NetScalers NS1, NS2, and NS3. Virtual IP addresses VIP1, VIP2, VIP3 are configured on each of these ADCs. Because of their priorities, VIP1 is active on NS1, VIP2 is active on NS2, and VIP3 is active on NS3.

As shown in the table below, the dead interval is set to the same value (2 seconds) on all the three nodes. The VRRP communication intervals (hello interval and dead interval) of a node apply to all the VRIDs configured on the node, and in turn, apply to all VIP addresses associated with the VRIDs on the node.

On each node, the VIP addresses that are active (master) on that node use the hello interval, and the dead interval is used by the VIP addresses that are inactive (backup) on that node. Preemption is disabled for the VIP addresses in all the three nodes.

The following table lists the settings used in this example: [VRRP interval example 1 settings](#).

The execution flow is as follows:

1. NS1 sends hello messages at a set hello interval of 400 ms to NS2 and NS3 for the VIP1 address, because VIP1 is active (the master) on NS1. Similarly, NS2 sends hello messages for VIP2, and NS3 sends hello messages for VIP3.

2. On NS1, the set dead interval applies to VIP2 and VIP3, because they are inactive (backups) on NS1. Similarly, on NS2, the set dead interval applies to VIP1 and VIP3, and on NS3, the set dead interval applies to VIP1 and VIP2.
3. If NS1 goes down, NS2 and NS3 consider NS1 to be down if they receive no hello messages from NS1 for 2 seconds (the dead interval). VIP1 on NS3 takes over and becomes active (master) because its VRID priority (60) is higher than that of VIP1 of NS2 (30).

### **Example 2: Nodes with Different VRRP Dead Intervals**

Consider a VRRP deployment similar to the deployment described in Example1 but with a different dead interval on each node (NS1, NS2, and NS3). Preemption is disabled for the VIP addresses in all the three nodes.

The following table lists the settings used in this example: [VRRP interval example 2 settings](#).

The execution flow is as follows when NS1 goes down:

1. NS2 considers NS1 to be down after not receiving any hello messages from NS1 for 2 seconds (NS2's dead interval).
2. VIP1 on NS2 takes over and becomes active (master). NS2 now starts sending hello messages

for VIP1.

Even though VIP1 on NS3 has a higher VRIP priority (60) than does VIP1 on NS2 (30), NS3's larger dead interval (3 seconds, vs. 2 seconds for NS2), prevents VIP1 on NS3 from taking over before VIP 1 on NS2 has already done so.

### **Example 3: Nodes with Different Dead Intervals and Preemption Enabled**

Consider a VRRP deployment similar to the deployment described in Example1 but with different dead intervals on the three nodes, NS1, NS2, and NS3, and with preemption enabled for the VIP1 address on NS3.

The following table lists the settings used in this example: [VRRP interval example 3 settings](#).

The execution flow is as follows when NS1 goes down:

1. NS2 considers NS1 to be down after not receiving any hello messages from NS1 for 2 seconds (NS2's set dead interval). At this time, NS3, with a dead interval of 3 seconds, does not consider NS1 to be down.

2. VIP1 on NS2 takes over and becomes active (master). NS2 now starts sending hello messages for VIP1.
3. Upon receiving hello messages from NS2 for VIP1, NS3 preempts NS2 for VIP1 because preemption is enabled for VIP1 of NS3 and the VRID priority (60) of VIP1 of NS3 is higher than that (30) of VIP1 of NS2.
4. VIP1 on NS3 takes over and becomes active (master). NS3 now starts sending hello messages for VIP1.

## Configuring Health Tracking based on Interface State

May 2, 2023

To ensure that a backup VIP address takes over as the master VIP before the node of the current master VIP address goes down completely, you can configure a node to change the priority of a VIP address when the state of an interface on the node changes. For example, the node reduces the priority of a VIP address when the state of an interface changes to DOWN, and increases the priority when the state of the interface changes to UP. This feature is a per node configuration for each VIP address.

### Example

Consider an active-active deployment consisting of NetScalers NS1, NS2, and NS3. Virtual IP addresses VIP1, VIP2, VIP3, and VIP4 are configured on each of these ADCs. Because of their priorities, VIP1 and VIP4 are active on NS1, VIP2 is active on NS2, and VIP3 is active on NS3.

To ensure that the active VIP addresses on NS1 are taken over by either NS2 or NS3 before NS1 goes down completely, interface-based health tracking is configured for the VIP1 and VIP4 addresses on NS1. Configuring interface-based health tracking for a VIP address includes associating the desired interfaces and setting the reduced priority (`trackifNumPriority`) parameter for the associated VRID of the VIP address. For example, on NS1, interfaces 1/2, 1/3, and 1/5 are associated to the VRID of VIP1, and reduced priority is set to 20.

Preemption is enabled for these VIP addresses in all three nodes.

The following table lists the settings used in this example: [Health tracking example settings](#).

\*  
Packet Interfaces = 1/2, 1/3, 1/5  
Reduced Priority = 20

\*\*  
Packet Interfaces = 1/5, 1/7  
Reduced Priority = 55

The execution flow is as follows on NS1 when multiple interface on NS1 goes down:

1. If interface 1/3 goes down, the priority of address VIP1 is reduced by 20 (VIP1's reduced priority value), because interface 1/3 is associated with VIP1:
  - Effective priority of VIP1 = (Current priority - reduced priority) = (90-20) = 70
2. Similarly, if interface 1/5 goes down, the priority of address VIP1 is further reduced:
  - Effective priority of VIP1 = (Current priority - reduced priority) = (70-20) = 50
3. At this point, the effective priority of VIP1 on NS1 is less than the priority of VIP1 on NS3. NS3 preempts NS1 for VIP1. VIP1 on NS3 takes over and becomes active (master).
4. Also, because interface 1/5 is also associated with VIP4, the priority of VIP4 is reduced by the VIP4's reduced priority value (55).
  - Effective priority of VIP4 = (250 - 55) = 195
5. If interface 1/7 goes down, the priority of VIP4 is further reduced:
  - Effective priority of VIP4 = (Current priority - reduced priority) = (195-55) = 145
6. At this point, the effective priority of VIP4 on NS1 is less than the priority of VIP4 on NS2. NS2 preempts NS1 for VIP4. VIP4 on NS3 takes over and becomes active (master). This configuration ensures that none of the four VIP addresses are active on NS1 before it completely goes down.

### Configuration Steps for IPv4 Active-Active Mode

To configure this feature on a node for a VIP address, you set the Reduced Priority (`trackifNumPriority`) parameter, and then associate the interfaces whose state is to be tracked for changing the priority of the VIP address. When any of the associated interface's state changes to DOWN or UP, the node reduces or increases the priority of the VIP address by the configured Reduced Priority (`trackifNumPriority`) value.

To set reduced priority and bind interfaces to the virtual router ID by using the CLI:

At the command prompt, type:

- **set vrID** <id> [**-trackifNumPriority** <positive\_integer>]
- **bind vrID** <id> **-trackifNum** <interface\_name>
- **show vrID** <id>

#### Example:

```
1 > set vrID 125 -trackifNumPriority 10
2 Done
3
4 > bind vrID 125 -trackifNum 1/4 1/5
```

```

5 Done
6 <!--NeedCopy-->

```

To set reduced priority and bind interfaces to the virtual router ID by using the GUI:

1. Navigate to **System > Network > VMAC**.
2. On the **VMACs** tab, select a virtual router ID, and click **Edit**.
3. Under **Configure virtual MAC**, set the **Reduced Priority** parameter.
4. Select the **Interfaces tracked for the VRID** option and, under **Associate Interfaces**, add interfaces to the virtual router ID.

### Configuration Steps for IPv6 Active-Active Mode

To configure this feature on a node for a VIP6 address, you set the Reduced Priority (`trackifNumPriority`) parameter, and then associate the interfaces whose state is to be tracked for changing the priority of the VIP6 address. When any of the associated interface's state changes to DOWN or UP, the node reduces or increases the priority of the VIP6 address by the configured Reduced Priority (`trackifNumPriority`) value.

To change the priority of a VIP address automatically by using the CLI:

At the command prompt, type one of the following sets of commands.

- If adding a new virtual MAC6:
  - **add vrID6** <id> [-**trackifNumPriority** <positive\_integer>]
  - **bind vrID6** <id> -**trackifNum** <interface\_name>
  - **show vrID6** <id>
- If reconfiguring an existing virtual MAC6:
  - **set vrID6** <id> [-**trackifNumPriority** <positive\_integer>]
  - **bind vrID6** <id> -**trackifNum** <interface\_name>
  - **show vrID6** <id>

#### Example:

```

1 > set vrID6 130 -trackifNumPriority 10
2 Done
3
4 > bind vrID6 130 -trackifNum 1/4 1/5
5 Done
6 <!--NeedCopy-->

```

## Delaying Preemption

May 2, 2023

By default, a backup VIP address preempts the master VIP address immediately after its priority becomes higher than that of the master VIP. When configuring a backup VIP address, you can specify an amount of time by which to delay the preemption. Preemption delay time is a per-node setting for each backup VIP address.

The preemption delay setting for a backup VIP does not apply in the following conditions:

- The node of the master VIP goes down. In this case, the backup VIP takes over as the master VIP after the dead interval set on the backup VIP's node.
- The priority of the master VIP is set to zero. The backup VIP takes over as the master VIP after the dead interval set on the backup VIP's node.

### Example: Delaying Preemption

Consider an active-active deployment consisting of NetScaler appliances NS1 and NS2. Virtual IP address VIP1 is configured on each of these appliances. Because of their priorities, VIP1 is master on NS2. Preemption is enabled and preemption delay time is set for VIP1 on these two nodes.

The following table lists the settings used in this example.

Entity and Parameters	Settings on NS1	Settings on NS2
VIP1 (for reference purposes only)	<b>IP address:</b> 192.0.1.10, <b>VRID:</b> 10, <b>Priority:</b> 100, <b>Preemption:</b> Enabled, <b>Preemption delay time:</b> 1000 seconds	<b>IP address:</b> 192.0.1.10, <b>VRID:</b> 10, <b>Priority:</b> 200, <b>Preemption:</b> Enabled, <b>Preemption delay time:</b> 2000 seconds
Dead Interval	1 Seconds	2 Seconds

Following are some examples of possible preemption behavior in this setup:

- If the priority of VIP1 on NS1 is set to a value (for example, 210) higher than that of VIP1 on NS2, VIP1 on NS1 takes over as master after its set preemption delay time (1000 secs).
- If a third node NS3 with the following VRRP settings is added to this deployment, VIP1 on NS3 becomes master after its set preemption delay time (3000 secs).
  - VIP1
    - \* VRID: 30

- ★ IP address:
  - ★ Priority = 300
  - ★ Preemption delay time = 3000 seconds
- If NS2 goes down, VIP1 on NS1 takes over as master after 1 second (set dead interval on NS1). Preemption delay time for VIP1 on NS1 does not apply in this case.
  - If NS2 goes down and NS1 restarts, VIP1 on NS1 becomes master 1 second (set dead interval on NS1) after NS1 comes up. Preemption delay time for VIP1 on NS1 does not apply in this case.
  - If the priority of VIP1 on NS2 is set to zero, VIP1 goes to standby mode. VIP1 on NS1 takes over as master after 1 second (set dead interval on NS1). Preemption delay time for VIP1 on NS1 does not apply in this case.

### Configuring Delay Preemption for IPv4 Active-Active Mode

To configure preemption delay time for a VIP address, you set the preemption delay timer parameter of the associated virtual MAC address. You can set this parameter when you add the address, or you can modify an existing virtual MAC address.

To configure preemption delay time by using the CLI:

- To set the preemption delay time while adding a virtual MAC, at the command prompt, type:
  - **add vrid <id> -preemptiondelaytimer <secs>**
  - **show vrid**
- To set the preemption delay time while modifying a virtual MAC, at the command prompt, type:
  - **set vrid <id> -preemptiondelaytimer <secs>**
  - **show vrid**

To configure preemption delay time by using the GUI:

1. Navigate to **System > Network > VMAC**.
2. On the **VMAC** tab. While adding a new virtual MAC, or editing an existing virtual MAC, set the **Preemption Delay Timer** parameter.

#### Sample configuration:

The following configuration uses the settings listed in table in section Example: Delaying Preemption.

```
1 Settings on NS1
2
3 > set vrid param -deadInterval 1
4
5 Done
6
```

```
7 > add ns ip 192.0.1.10 255.255.255.255 -type VIP
8
9 Done
10
11 > add vrid 10 -Priority 100 -Preemption Enable -
 preemptiondelaytimer 1000
12
13 Done
14
15 > bind ns ip 192.0.1.10 255.255.255.255 -vrid 10
16
17 Done
18
19 Settings on NS2
20
21 > set vrid param -deadInterval 2
22
23 Done
24
25 > add ns ip 192.0.1.10 255.255.255.255 -type VIP
26
27 Done
28
29 > add vrid 20 -Priority 200 -Preemption Enable -
 preemptiondelaytimer 2000
30
31 Done
32
33 > set ns ip 192.0.1.10 255.255.255.255 -vrid 10
34
35 Done
36 <!--NeedCopy-->
```

## Configuring Delay Preemption for IPv6 Active-Active Mode

To configure preemption delay time for a VIP6 address, you set the preemption delay timer parameter of the associated virtual MAC6 address. You can set this parameter when you add the virtual MAC6 address, or you can modify an existing virtual MAC6 address.

To configure preemption delay time by using the CLI:

- To set the preemption delay time while adding a virtual MAC6, at the command prompt, type:
  - **add vrid6** <id> -**preemptiondelaytimer** <secs>
  - **show vrid6**
- To set the preemption delay time while modifying a virtual MAC6, at the command prompt, type:
  - **set vrid6** <id> -**preemptiondelaytimer** <secs>
  - **show vrid6**

To configure preemption delay time by using the GUI:

1. Navigate to **System > Network > VMAC**.
2. On the **VMAC6** tab. While adding a virtual MAC6 address, or editing an existing virtual MAC6 address, set the **Preemption Delay Timer** parameter.

## Keeping a VIP Address in the Backup State

September 21, 2020

You can force a VIP address to always stay in backup state. This operation is helpful in maintenance or testing of a VRRP deployment.

When a VIP address is forced to stay in backup state, it does not participate in VRRP state transitions. Also, it cannot become master even if all other nodes go down.

To force a VIP address to stay in backup state, you set the priority of the associated virtual MAC address to zero. To ensure that none of the VIP addresses of a node handle traffic during a maintenance process on the node, set all the priorities to zero.

You can set the priority of a virtual MAC address while adding or modifying the address.

To force a VIP address to stay in the backup state by using the CLI:

- To set the priority while adding a virtual MAC, at the command prompt, type:
  - **add vrid <id> -priority 0**
  - **show vrid**
- To set the priority while modifying a virtual MAC, at the command prompt, type:
  - **set vrid <id> -priority 0**
  - **show vrid**

To force a VIP address to stay in backup state by using the GUI:

1. Navigate to **System > Network > VMAC**.
2. On the **VMAC** tab, while adding a new virtual MAC or editing an existing virtual MAC, set the **Priority** parameter to zero.

## Network Visualizer

May 2, 2023

The network visualizer shows a graphical view of all the interfaces, channels, VLANs, IP addresses, and bindings to VLANs on a NetScaler appliance. An enabled interface or channel has a black label. A disabled interface or channel has a red label.

This complete picture of the appliance's network connections can be useful for detecting flaws in the network design and for optimizing the network. It can also help a new administrator easily understand the appliance's network configuration.

To open the Network Visualizer:

Navigate to **System > Network**. In **Monitor Connections**, click **Network Visualizer**.

## Configuring Link Layer Discovery Protocol

May 2, 2023

The NetScaler supports the industry standard (IEEE 802.1AB) Link Layer Discovery Protocol (LLDP). LLDP is a layer 2 protocol that enables the NetScaler to advertise its identity and capabilities to the directly connected devices, and also learn the identity and capabilities of these neighbour devices.

**Note:**

Link Layer Discovery Protocol (LLDP) is supported only in NetScaler MPX platforms.

Using LLDP, the NetScaler transmits and receives information in the form of LLDP messages known as LLDP packet data units (LLDPUs). An LLDP is a sequence of type, length, value (TLV) information elements. Each TLV holds a specific type of information about the device that transmits the LLDPDU. The NetScaler sends the following TLVs in each LLDPDU:

- Chassis ID
- Port ID
- Time-to-live value
- System name
- System description
- Port description
- System capabilities
- Management address
- Port VLAN ID
- Link aggregation

**Note:** You cannot specify the TLVs to be sent in LLDP messages.

NetScaler interfaces support the following LLDP modes:

- **NONE.** The interface neither receives from nor transmits LLDP messages to the directly connected device.
- **TRANSMITTER.** The interface transmits LLDP messages to the directly connected device but does not receive LLDP messages from the directly connected device.
- **RECEIVER.** The interface receives LLDP messages from the directly connected device but does not transmit LLDP messages to the directly connected device.
- **TRANSCEIVER.** The interface transmits LLDP messages to and receives LLDP messages from the directly connected device.

The LLDP mode of an interface depends on the LLDP mode configured at the global and the interface levels. The following table shows the modes resulting from the available combinations of global- and interface-level settings: [Interface and global level LLDP modes](#).

Note the following points related to LLDP messages transmitted or received by the NetScaler:

- **Transmitting LLDP messages.** The NetScaler transmits LLDPUs from interfaces that are operating in either TRANSMITTER or TRANSCEIVER LLDP mode.

Following are the global LLDP transmitting parameters on the NetScaler:

- **Timer.** Interval, in seconds, between LLDPUs that the NetScaler sends to a directly connected device.
- **Holdtime Multiplier.** A multiplier for calculating the duration for which the receiving device stores the LLDP information in its database before discarding or removing it. The duration is calculated as the **Holdtime Multiplier** parameter value multiplied by the Timer parameter value.
- **Receiving LLDP Messages.** The NetScaler stores the LLDPDU information in its Management Information base (MIB). The stored LLDP information is classified or grouped under the ID of the interface that received the LLDPDU. The NetScaler retains this LLDP information for the duration specified in the received LLDPDU.

If the ADC receives another LLDPDU on an interface before the stored LLDP information for that interface is discarded, the ADC replaces the stored LLDP information for that interface with information in the new LLDPDU.

## Configuration Steps

Configuring LLDP on a NetScaler appliance consists of the following tasks:

1. **Set global level LLDP parameters.** In this task, you set the global LLDP parameters such as LLDP Timer, Hold Time Multiplier, and LLDP mode.
2. **Set the interface level LLDP parameters.** In this task, you set the LLDP mode for an interface.

3. **(Optional) Display neighbor-device information.** You can display the neighbor-device LLDP information collected on all of the NetScaler's interfaces, or just the LLDP information collected on specified interfaces. If you do not specify an interface, the information is shown for all interfaces.

Following are the prerequisites for configuring LLDP on a NetScaler:

1. Make sure that you understand the standard LLDP protocol (IEEE 802.1AB).
2. Verify that you have configured LLDP on the desired directly connected devices.

### CLI procedures

To set global level LLDP parameters by using the CLI:

At the command prompt, type:

- `set lldp param [-holdtimeTxMult <positive_integer>][-timer <positive_integer>] [-Mode <Mode>]`
- `show lldp param`

To configure an interface for LLDP by using the CLI:

At the command prompt, type:

- `set interface <id> -lldpmode <lldpmode>`
- `show interface <id>`

To display neighbor device information by using the CLI:

At the command prompt, type one of the following commands:

- `show lldp neighbors`
- `show lldp neighbors <ifnum>`

### GUI procedures

To set the global level LLDP parameters by using the GUI:

1. Navigate to System > Network, and click Configure LLDP Parameters.
2. Set the following parameters:
  - Hold Timer Multiplier
  - Timer
  - Mode

To configure an interface for LLDP by using the GUI:

Navigate to System > Network > Interfaces, open the interface, and set the LLDP mode parameter.

To display neighbor device information by using the GUI:

Navigate to System > Network > Interfaces and, in the Action list, select View LLDP Neighbors.

## LLDP Support in a Cluster Setup

In a cluster setup, the GUI and CLI display the LLDP neighbour configuration of all or specific cluster nodes when the GUI or CLI is accessed through the Cluster IP address (CLIP). Any change made to the global level LLDP mode is applied to the global level LLDP mode on each of the cluster nodes.

Consider an example of a cluster setup of three nodes, NS1, NS2, and NS3. Each of these nodes are connected to both routers Router-1 and Router-2. The following output is displayed when the **show lldp neighbor -summary** operation is performed on the Cluster CLI that is accessed through the Cluster IP address (CLIP) of the cluster setup. The output shows the LLDP neighbour information of all these nodes.

```

1 > show lldp neighbor -summary
2
3 Node Id: 1
4 -----
5 Interface ChassisId PortId System name
6 -----
7 1 1/1/1 fe:c7:3b:13:bd:11 1/1 Router-1
8
9 2 1/1/2 12:68:7b:9e:4c:11 1/1 Router-2
10
11 Node Id: 2
12 -----
13 Interface ChassisId PortId System name
14 -----
15 1 2/1/1 fe:c7:3b:13:bd:12 1/2 Router-1
16
17 2 2/1/2 12:68:7b:9e:4c:12 1/2 Router-2
18
19 Node Id: 3
20 -----
21 Interface ChassisId PortId System name
22 -----
23
24 1 3/1/1 fe:c7:3b:13:bd:13 1/3 Router-1
25
26 2 3/1/2 12:68:7b:9e:4c:13 1/3 Router-2
27
28 Done
29 <!--NeedCopy-->

```

## Jumbo Frames

May 2, 2023

NetScaler appliances support receiving and transmitting jumbo frames containing up to 9216 bytes of IP data. Jumbo frames can transfer large files more efficiently than it is possible with the standard IP MTU size of 1500 bytes.

A NetScaler appliance can use jumbo frames in the following deployment scenarios:

- Jumbo to Jumbo. The appliance receives data as jumbo frames and sends it as jumbo frames.
- Non-Jumbo to Jumbo. The appliance receives data as regular frames and sends it as jumbo frames.
- Jumbo to Non-Jumbo. The appliance receives data as jumbo frames and sends it as regular frames.

The NetScaler appliance supports jumbo frames in a load balancing configuration for the following protocols:

- TCP
- Any protocol over TCP (for example, HTTP)
- SIP
- RADIUS

## Configuring Jumbo Frames Support on a NetScaler Appliance

May 2, 2023

To enable the NetScaler appliance to support jumbo frames, you set the MTU to more than 1500 on interfaces or LA channels, and on VLANs on which you want the NetScaler appliance to support jumbo frames.

Points to consider before setting the MTU of interfaces, LA channels, or VLANs on a NetScaler appliance

1. When you create an LA channel, the channel takes the MTU of the first bound interface if no MTU is specified for the channel.
2. The MTU for a channel is propagated to all the bound interfaces.
3. When an interface is bound to the channel whose MTU is different from the interface's MTU, the interface goes onto the inactive list.

4. When you change the MTU of a member interface, the interface goes onto the inactive list.
5. When an interface is unbound from the channel, the interface retains the MTU value of the channel.
6. You can set the MTU for an interface, channel, or VLAN to a value in the range of 1500-9216.
7. You cannot set the MTU on the default VLAN. The NetScaler appliance uses the MTU of the interface through which it receives or sends data from or to the default VLAN.
8. For TCP based traffic on a load balancing configuration on a NetScaler appliance, MSSs are set accordingly at each end point for supporting jumbo frames:
  - For a connection between a client and a load balancing virtual server on the NetScaler appliance, the MSS on the NetScaler appliance is set in a TCP profile, which is then bound to the load balancing virtual server.
  - For a connection between the NetScaler appliance and a server, the MSS on NS1 is set in a TCP profile, which is then bound to the service representing the server on the NetScaler appliance.
  - By default, a TCP profile `nstcp_default_profile` is bound to all TCP based load balancing servers and services on the NetScaler appliance.
  - For supporting jumbo frames, you can either change the MSS value of the TCP profile `nstcp_default_profile`, or create a custom TCP profile and set its MSS accordingly, and then bind the custom TCP profile to the desired load balancing virtual servers and services.
  - The default MSS value of any TCP profile is 1460.

## CLI procedures

To set the MTU of an interface by using the CLI:

At the command prompt, type:

- `set interface <id> -mtu <positive_integer>`
- `show interface <id>`

### Example:

```
1 > set interface 10/1 - mtu 9000
2 Done
3 <!--NeedCopy-->
```

To set the MTU of a channel by using the CLI:

At the command prompt, type:

- `set channel <id> -mtu <positive_integer>`
- `show channel <id>`

**Example:**

```
1 > set channel LA/1 - mtu 9000
2 Done
3 <!--NeedCopy-->
```

To set the MTU of a VLAN by using the CLI:

At the command prompt, type:

- add vlan <id> -mtu <positive\_integer>
- show vlan <id>

**Example:**

```
1 > set vlan 20 - mtu 9000
2 Done
3 <!--NeedCopy-->
```

**GUI procedures**

To set the MTU of an interface by using the GUI:

Navigate to System > Network > Interfaces, open the interface, and set the Maximum Transmission Unit parameter.

To set the MTU of a channel by using the GUI:

Navigate to System > Network > Channels, open the channel, and set the Maximum Transmission Unit parameter.

To set the MTU of a VLAN by using the GUI:

Navigate to System > Network > VLANs, open the VLAN, and set the Maximum Transmission Unit parameter.

**Use Case 1 –Jumbo to Jumbo Setup**

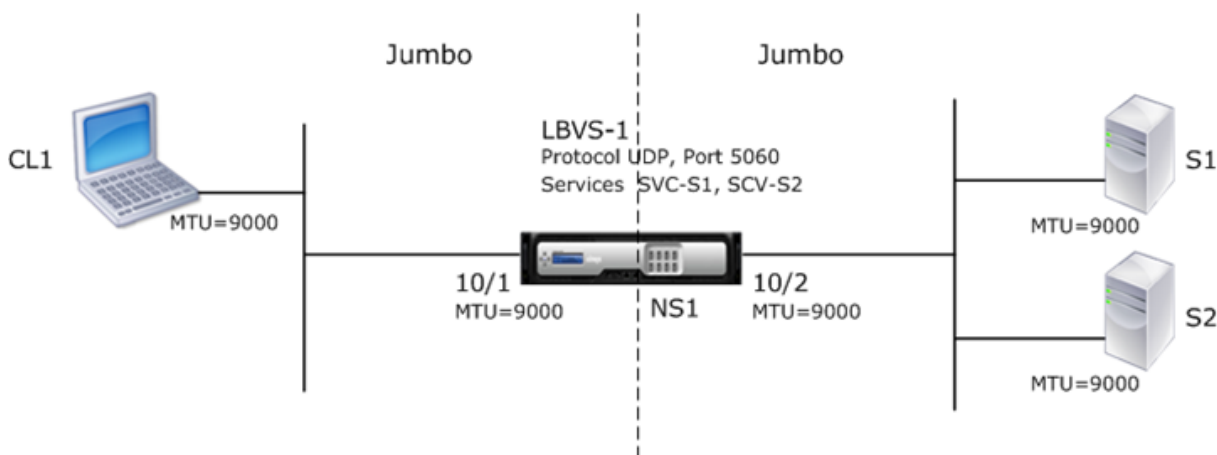

May 2, 2023

Consider an example of a jumbo to jumbo setup in which SIP load balancing virtual server LBVS-1, configured on NetScaler appliance NS1, is used to load balance SIP traffic across servers S1 and S2. The connection between client CL1 and NS1, and the connection between NS1 and the servers support jumbo frames.

Interface 10/1 of NS1 receives or sends traffic from or to client CL1. Interface 10/2 of NS1 receives or sends traffic from or to server S1 or S2. Interfaces 10/1 and 10/2 of NS1 are part of VLAN 10 and VLAN 20, respectively.

For supporting jumbo frames, the MTU is set to 9216, on NS1, for interfaces 10/1, 10/2, and VLANs VLAN 10, VLAN 20.

All other network devices, including CL1, S1, S2, in this setup example are also configured for supporting jumbo frames.

The following table lists the settings used in the example.

Entity	Name	Details
IP address of client CL1	-	192.0.2.10
IP address of servers	S1	198.51.100.19
	S2	
SNIP address on NS1		198.51.100.18
MTU specified for interfaces and VLANs on NS1	10/1	9000
	10/2	
	VLAN 10	
	VLAN 20	
Services on NS1 representing servers	SVC-S1	<b>IP address:</b> 198.51.100.19, <b>Protocol:</b> SIP, <b>Port:</b> 5060
	SVC-S2	

Entity	Name	Details
Load balancing virtual server on VLAN 10	LBVS-1	<b>IP address:</b> 203.0.113.15, <b>Protocol:</b> SIP, <b>Port:</b> 5060, <b>Bound services:</b> SVC-S1, SVC-S2

Following is the traffic flow of CL1's request to NS1:

- CL1 creates a 20000-byte SIP request to send to LBVS-1 of NS1.
- CL1 sends the request data in IP fragments to LBVS-1. The size of each IP fragment is either equal to or less than the MTU (9000) set on the interface from which CL1 sends these fragments to NS1.
  - Size of the first IP fragment = [IP header + UDP header + SIP data segment] = [20 + 8 + 8972] = 9000
  - Size of the second IP fragment = [IP header + SIP data segment] = [20 + 8980] = 9000
  - Size of the last IP fragment = [IP header + SIP data segment] = [20 + 2048] = 2068
- NS1 receives the request IP fragments at interface 10/1. NS1 accepts these fragments, because the size of each of these fragments is equal to or less than the MTU (9000) of interface 10/1.
- NS1 reassembles these IP fragments to form the 20000-byte SIP request. NS1 processes this request.
- LBVS-1's load balancing algorithm selects server S1.
- NS1 sends the request data in IP fragments to S1. The size of each IP fragment is either equal or less than the MTU (9000) of the interface 10/2, from which NS1 sends these fragments to S1. The IP packets are sourced with a SNIP address of NS1.
  - Size of the first IP fragment = [IP header + UDP header + SIP data segment] = [20 + 8 + 8972] = 9000
  - Size of the second IP fragment = [IP header + SIP data segment] = [20 + 8980] = 9000
  - Size of the last IP fragment = [IP header + SIP data segment] = [20 + 2048] = 2068

Following is the traffic flow of S1's response to CL1 in this example:

- Server S1 creates a 30000-byte SIP response to send to the SNIP address of NS1.
- S1 sends the response data in IP fragments to the SNIP address of NS1. The size of each IP fragment is either equal to or less than the MTU (9000) set on the interface from which S1 sends these fragments to NS1.

- Size of the first IP fragment = [IP header + UDP header + SIP data segment] = [20 + 8 + 8972] = 9000
  - Size of the second and third IP fragment = [IP header + SIP data segment] = [20 + 8980] = 9000
  - Size of the last IP fragment=[IP header + SIP data segment] = [20 + 3068] = 3088
3. NS1 receives the response IP fragments at interface 10/2. NS1 accepts these fragments, because the size of each fragment is equal to or less than the MTU (9000) of interface 10/2.
  4. NS1 reassembles these IP fragments to form the 30000-byte SIP response. NS1 processes this response.
  5. NS1 sends the response data in IP fragments to CL1. The size of each IP fragment is either equal or less than the MTU (9000) of the interface 10/1, from which NS1 sends these fragments to CL1. The IP fragments are sourced with LBVS-1's IP address.
    - Size of the first IP fragment = [IP header + UDP header + SIP data segment] = [20 + 8 + 8972] = 9000
    - Size of the second and third IP fragment = [IP header + SIP data segment] = [20 + 8980] = 9000
    - Size of the last IP fragment=[IP header + SIP data segment] = [20 + 3068] = 3088

## Configuration Tasks

The following table list the tasks, NetScaler commands, and examples for creating the required configuration on the NetScaler appliance.

Task	NetScaler Command Syntax	Example
Set the MTU of the desired interfaces for supporting jumbo frames	set interface -mtu , show interface	set int 10/1 -mtu 9000 set int 10/2 -mtu 9000
Create VLANs and set the MTU of the desired VLANs for supporting jumbo frames	add vlan -mtu , show vlan	add vlan 10 -mtu 9000 add vlan 20 -mtu 9000
Bind interfaces to VLANs	bind vlan -ifnum , show vlan	bind vlan 10 -ifnum 10/1 bind vlan 20 -ifnum 10/2
Add a SNIP address	add ns ip -type SNIP, show ns ip	add ns ip 198.51.100.18 255.255.255.0 -type SNIP

Task	NetScaler Command Syntax	Example
Create services representing SIP servers	add service SIP_UDP , show service	add service SVC-S1 198.51.100.19 SIP_UDP 5060 add service SVC-S2 198.51.100.20 SIP_UDP 5060
Create SIP load balancing virtual servers and bind the services to it	add lb vserver SIP_UDP bind lb vserver , show lb vserver	add lb vserver LBVS-1 SIP_UDP 203.0.113.15 5060 bind lb vserver LBVS-1 SVC-S1 bind lb vserver LBVS-1 SVC-S2
Save the configuration	save ns config, show ns config	

## Use Case 2 –Non-Jumbo to Jumbo Setup

October 3, 2023

Consider an example of a regular to jumbo setup in which load balancing virtual server LBVS-1, configured on a NetScaler appliance NS1, is used to load balance traffic across servers S1 and S2. The connection between client CL1 and NS1 supports regular frames, and the connection between NS1 and the servers supports jumbo frames.

Interface 10/1 of NS1 receives or sends traffic from or to client CL1. Interface 10/2 of NS1 receives or sends traffic from or to server S1 or S2.

Interfaces 10/1 and 10/2 of NS1 are part of VLAN 10 and VLAN 20, respectively. For supporting only regular frames between CL1 and NS1, the MTU is set to the default value of 1500 for both interface 10/1 and VLAN 10

For supporting jumbo frames between NS1 and the servers, the MTU is set to 9000 for interface 10/2 and VLAN 20. Servers and all other network devices between NS1 and the servers are also configured for supporting jumbo frames.

Since HTTP traffic is based on TCP, MSSs are set accordingly at each end point for supporting jumbo frames.

- For supporting jumbo frames for the connection between a SNIP address of NS1 and S1 or S2, the MSS on NS1 is set accordingly in a custom TCP profile, which is bound to the services (SVC-S1 and SVC-S1 ) representing S1 and S2 on NS1.
- For supporting only regular frames for the connection between CL1 and virtual server LBVS-1 of NS1, default TCP profile nstcp\_default\_profile is used that is by default bound to LBVS-1 and has the MSS set to the default value of 1460.

The following table lists the settings used in this example.

Entity	Name	Details
IP address of client CL1		192.0.2.10
IP address of servers	S1	198.51.100.19
	S2	
SNIP address on NS1		198.51.100.18
MTU specified for interfaces and VLANs on NS1	10/1	1500
	10/2	
	VLAN 10	
	VLAN 20	
Default TCP profile	nstcp_default_profile	MSS:1460
Custom TCP profile	NS1-SERVERS-JUMBO	MSS: 8960
Services on NS1 representing servers	SVC-S1	IP address: 198.51.100.19, Protocol: HTTP, Port: 80, TCP profile: NS1-SERVERS-JUMBO (MSS: 8960)
	SVC-S2	

Entity	Name	Details
Load balancing virtual server on VLAN 10	LBVS-1	IP address = 203.0.113.15, Protocol: HTTP, Port:80, Bound services: SVC-S1, SVC-S2, TCP Profile: nstcp_default_profile (MSS:1460)

Following is the traffic flow of CL1's request to S1 in this example:

1. Client CL1 creates a 200-byte HTTP request to send to virtual server LBVS-1 of NS1.
2. CL1 opens a connection to LBVS-1 of NS1. CL1 and NS1 exchange their respective TCP MSS values while establishing the connection.
3. Because NS1's MSS is larger than the HTTP request, CL1 sends the request data in a single IP packet to NS1.

Size of the request packet = [IP Header + TCP Header + TCP Request] = [20 + 20 + 200] = 240

4. NS1 receives the request packet at interface 10/1 and then processes the HTTP request data in the packet.
5. LBVS-1's load balancing algorithm selects server S1, and NS1 opens a connection between one of its SNIP addresses and S1. NS1 and CL1 exchange their respective TCP MSS values while establishing the connection.
6. Because S1's MSS is larger than the HTTP request, NS1 sends the request data in a single IP packet to S1.

Size of the request packet = [IP Header + TCP Header + [TCP Request]] = [20 + 20 + 200] = 240

Following is the traffic flow of S1's response to CL1 in this example:

1. Server S1 creates an 18000-byte HTTP response to send to the SNIP address of NS1.
2. S1 segments the response data into multiples of NS1's MSS and sends these segments in IP packets to NS1. These IP packets are sourced from S1's IP address and destined to the SNIP address of NS1.

- Size of the first two packet = [IP Header + TCP Header + (TCP segment=NS1's MSS size)] = [20 + 20 + 8960] = 9000

- Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 80] = 120

3. NS1 receives the response packets at interface 10/2.

4. From these IP packets, NS1 assembles all the TCP segments to form the HTTP response data of 18000 bytes. NS1 processes this response.
5. NS1 segments the response data into multiples of CL1's MSS and sends these segments in IP packets, from interface 10/1, to CL1. These IP packets are sourced from LBVS-1's IP address and destined to CL1's IP address.
  - Size of all packets except the last one = [IP Header + TCP Header + (TCP payload=CL1's MSS size)] = [20 + 20 + 1460] = 1500
  - Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 480] = 520

### Configuration Tasks

The following table list the tasks, NetScaler commands, and examples for creating the required configuration on the NetScaler appliance.

Tasks	CLI Syntax	Examples
Set the MTU of the desired interfaces for supporting jumbo frames	set interface -mtu , show interface	set int 10/1 -mtu 1500 set int 10/2 -mtu 9000
Create VLANs and set the MTU of the desired VLANs for supporting jumbo frames	add vlan -mtu , show vlan	add vlan 10 -mtu 1500 add vlan 20 -mtu 9000
Bind interfaces to VLANs	bind vlan -ifnum , show vlan	bind vlan 10 -ifnum 10/1 bind vlan 20 -ifnum 10/2
Add a SNIP address	add ns ip -type SNIP, show ns ip	add ns ip 198.51.100.18 255.255.255.0 -type SNIP
Create services representing HTTP servers	add service HTTP , show service	add service SVC-S1 198.51.100.19 http 80, add service SVC-S2 198.51.100.20 http 80
Create HTTP load balancing virtual servers and bind the services to it	add lb vserver HTTP , bind lb vserver , show lb vserver	add lb vserver LBVS-1 http 203.0.113.15 80, bind lb vserver LBVS-1 SVC-S1, bind lb vserver LBVS-1 SVC-S2
Create a custom TCP profile and set its MSS for supporting jumbo frames	add tcpProfile -mss , show tcpProfile	add tcpprofile NS1-SERVERS-JUMBO -mss 8960

Tasks	CLI Syntax	Examples
Bind the custom TCP profile to the desired services	set service -tcpProfileName , show service	set service SVC-S1 -tcpProfileName NS1-SERVERS-JUMBO, set service SVC-S2 -tcpProfileName NS1-SERVERS-JUMBO
Save the configuration	save ns config, show ns config	

### Use Case 3 –Coexistence of Jumbo and Non-Jumbo flows on the Same Set of Interfaces

May 2, 2023

Consider an example in which load balancing virtual servers LBVS-1 and LBVS-2 are configured on NetScaler appliance NS1. LBVS-1 is used to load balance HTTP traffic across servers S1 and S2, and LBVS-2 is used to load balance traffic across servers S3 and S4.

CL1 is on VLAN 10, S1 and S2 are on VLAN20, CL2 is on VLAN 30, and S3 and S4 are on VLAN 40. VLAN 10 and VLAN 20 support jumbo frames, and VLAN 30 and VLAN 40 support only regular frames.

In other words, the connection between CL1 and NS1, and the connection between NS1 and server S1 or S2 support jumbo frames. The connection between CL2 and NS1, and the connection between NS1 and server S3 or S4 support only regular frames.

Interface 10/1 of NS1 receives or sends traffic from or to clients. Interface 10/2 of NS1 receives or sends traffic from or to the servers.

Interface 10/1 is bound to both VLAN 10 and VLAN 30 as a tagged interface, and interface 10/2 is bound to both VLAN 20 and VLAN 40 as a tagged interface.

For supporting jumbo frames, the MTU is set to 9216 for interfaces 10/1 and 10/2.

On NS1, the MTU is set to 9000 for VLAN 10 and VLAN 20 for supporting jumbo frames, and the MTU is set to the default value of 1500 for VLAN 30 and VLAN 40 for supporting only regular frames.

The effective MTU on a NetScaler interface for VLAN tagged packets is of the MTU of the interface or the MTU of the VLAN, whichever is lower. For example:

- The MTU of interface 10/1 is 9216. The MTU of VLAN 10 is 9000. On interface 10/1, the MTU of VLAN 10 tagged packets is 9000.

- The MTU of interface 10/2 is 9216. The MTU of VLAN 20 is 9000. On interface 10/2, the MTU of VLAN 20 tagged packets is 9000.
- The MTU of interface 10/1 is 9216. The MTU of VLAN 30 is 1500. On interface 10/1, the MTU of VLAN 30 tagged packets is 1500.
- The MTU of interface 10/2 is 9216. The MTU of VLAN 40 is 1500. On interface 10/2, the MTU of VLAN 40 tagged packets is 9000.

CL1, S1, S2, and all network devices between CL1 and S1 or S2 are configured for jumbo frames.

Since HTTP traffic is based on TCP, MSSs are set accordingly at each end point for supporting jumbo frames.

- For the connection between CL1 and virtual server LBVS-1 of NS1, the MSS on NS1 is set in a TCP profile, which is then bound to LBVS-1.
- For the connection between a SNIP address of NS1 and S1, the MSS on NS1 is set in a TCP profile, which is then bound to the service (SVC-S1) representing S1 on NS1.

The following table lists the settings used in this example: [Jumbo frames use case 3 example settings](#).

Following is the traffic flow of CL1's request to S1:

1. Client CL1 creates a 20000-byte HTTP request to send to virtual server LBVS-1 of NS1.
2. CL1 opens a connection to LBVS-1 of NS1. CL1 and NS1 exchange their TCP MSS values while establishing the connection.

3. Because NS1's MSS value is smaller than the HTTP request, CL1 segments the request data into multiples of NS1's MSS and sends these segments in IP packets tagged as VLAN 10 to NS1.
  - Size of the first two packets = [IP Header + TCP Header + (TCP segment=NS1 MSS)] = [20 + 20 + 8960] = 9000
  - Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 2080] = 2120
4. NS1 receives these packets at interface 10/1. NS1 accepts these packets because the size of these packets is equal to or less than the effective MTU (9000) of interface 10/1 for VLAN 10 tagged packets.
5. From the IP packets, NS1 assembles all the TCP segments to form the 20000-byte HTTP request. NS1 processes this request.
6. LBVS-1's load balancing algorithm selects server S1, and NS1 opens a connection between one of its SNIP addresses and S1. NS1 and CL1 exchange their respective TCP MSS values while establishing the connection.
7. NS1 segments the request data into multiples of S1's MSS and sends these segments in IP packets tagged as VLAN 20 to S1.
  - Size of the first two packets = [IP Header + TCP Header + (TCP payload=S1 MSS)] = [20 + 20 + 8960] = 9000
  - Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 2080] = 2120

Following is the traffic flow of S1's response to CL1:

1. Server S1 creates a 30000-byte HTTP response to send to the SNIP address of NS1.
2. S1 segments the response data into multiples of NS1's MSS and sends these segments in IP packets tagged as VLAN 20 to NS1. These IP packets are sourced from S1's IP address and destined to the SNIP address of NS1.
  - Size of first three packet = [IP Header + TCP Header + (TCP segment=NS1's MSS size)] = [20 + 20 + 8960] = 9000
  - Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 3120] = 3160
3. NS1 receives the response packets at interface 10/2. NS1 accepts these packets, because their size is equal to or less than the effective MTU value (9000) of interface 10/2 for VLAN 20 tagged packets.
4. From these IP packets, NS1 assembles all the TCP segments to form the 30000-byte HTTP response. NS1 processes this response.
5. NS1 segments the response data into multiples of CL1's MSS and sends these segments in IP packets tagged as VLAN 10, from interface 10/1, to CL1. These IP packets are sourced from LBVS's IP address and destined to CL1's IP address.

- Size of first three packet = [IP Header + TCP Header + [(TCP payload=CL1's MSS size)] = [20 + 20 + 8960] = 9000
- Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 3120] = 3160

## Configuration Tasks

Following table lists tasks, commands, and examples for creating the required configuration on the NetScaler appliance: [Jumbo frames use case 3 configuration tasks](#).

## NetScaler Support for Microsoft Direct Access Deployment

May 2, 2023

Microsoft Direct Access is a technology that enables remote users to seamlessly and securely connect to the enterprise's internal networks, without the need to establish a separate VPN connection. Unlike VPN connections, which require user intervention to open and close connections, a Direct Access-enabled client connects automatically to the enterprise's internal networks whenever the client connects to the Internet.

Manage-Out is a Microsoft Direct Access feature that allows administrators inside the enterprise network to connect to Direct Access clients outside the network and manage them (for example, performing administration tasks, such as scheduling service updates, and providing remote support).

In a Direct Access deployment, NetScaler appliances provide high availability, scalability, high performance, and security. NetScaler load balancing functionality sends client traffic through the most appropriate server. The appliances can also forward Manage-Out traffic through the right path to reach the client.

## Architecture

The architecture of a Microsoft Direct Access deployment consists of Direct Access enabled clients, Direct Access servers, application servers, and internal and external NetScaler appliances. Clients connect to an application server through a Direct Access server. An external NetScaler appliance load balance the client traffic to a Direct Access server, and an Internal NetScaler appliance forwards the client traffic from the Direct Access server to the destination application server. Direct Access is used for tunneling the client's IPv6 traffic over the IPv4 network. An IPv4 load balancing virtual server on the external NetScaler appliance load balances the client's tunneled traffic to one of the Direct Access servers. The Direct Access server extracts the IPv6 packets from the received client's IPv4 packets

and sends them to the destination application server through the internal NetScaler appliance. The Internal NetScaler appliance has forwarding session rules with the source route cache option enabled for storing Layer 2 and Layer 3 connection information about the client's traffic from the Direct Access Server. The NetScaler appliance stores the following Layer 2 and Layer 3 information in a table called the source route cache table:

- Source IP address of the received packet
- MAC address of the Direct Access server that sent the packet
- VLAN ID of the NetScaler appliance that received the packet
- Interface ID of the NetScaler appliance that received the packet

The NetScaler appliance uses the information in the source route cache table for forwarding a response to the same Direct Access server because it has the tunneling information to reach the client. Also, the Internal appliance uses the source route cache table to forward application server's Manage-out traffic to the appropriate Direct Access server to reach a particular client.

## Configuring the Internal NetScaler Appliance in a Microsoft Direct Access Deployment

To configure the Internal NetScaler appliance for forwarding an application server's response and manage-out traffic to the appropriate Direct Access Gateway, configure forwarding session rules. In each rule, set the `sourceroutecache` parameter to `ENABLED`.

To create a forwarding session rule by using the CLI:

At the command prompt, type:

- `add forwardingSession <name> ((<network> [<netmask>]) | -acl6name <string> | -aclname <string>) -sourceroutecache ( ENABLED | DISABLED )`
- **show forwardingSession** <name>

### Sample configuration:

In the following example, forwarding-session rule MS-DA-FW-1 is created on the internal NetScaler appliance. The forwarding session stores Layer 2 and Layer 3 information for any incoming IPv6 packets from a Direct Access server that matches source IPv6 prefix 2001:DB8::/96.

```
1 > add forwardingSession MS-DA-FW-1 2001:DB8::/96 -sourceroutecache -
 ENABLED
2 Done
```

## Displaying the Source Route Cache Table

You can display the source route cache table for monitoring or detecting any unwanted connections between direct access servers and application servers.

To display the source route cache table by using the CLI:

At the command prompt, type:

- **show sourceroutecachetable**

### Example:

```
1 > show sourceroutecachetable
2 SOURCEIP MAC VLAN INTERFACE
3 2001:DB8:5001:10 56:53:24:3d:02:eb 30 1/2
4 2001:DB8:5003:30 60:54:35:3e:04:bd 60 1/3
5 Done
```

## Clearing the Source Route Cache Table

You can clear all the entries from the source route cache table on a NetScaler appliance.

To clear the source route cache table by using the CLI:

At the command prompt, type:

- **flush ns sourceroutecachetable**

## Access Control Lists

May 2, 2023

Access Control Lists (ACLs) filter IP traffic and secure your network from unauthorized access. An ACL is a set of conditions that the NetScaler evaluates to determine whether to allow access. For example, the Finance department probably does not want to allow its resources to be accessed by other

departments, such as HR and Documentation, and those departments want to restrict access to their data.

When the NetScaler receives a data packet, it compares the information in the data packet with the conditions specified in the ACL and allows or denies access. The administrator of the organization can configure ACLs to function in the following processing modes:

- **ALLOW**—Process the packet.
- **BRIDGE**—Bridge the packet to the destination without processing it. The packet is directly sent by Layer 2 and Layer 3 forwarding.
- **DENY**—Drop the packet.

ACL rules are the first level of defense on the NetScaler.

NetScaler supports the following types of ACLs:

- **Simple ACLs** filter packets based on their source IP address and, optionally, their protocol, destination port, or traffic domain. Any packet that has the characteristics specified in the ACL is dropped.
- **Extended ACLs** filter data packets based on various parameters, such as source IP address, source port, action, and protocol. An extended ACL defines the conditions that a packet must satisfy for the NetScaler to process the packet, bridge the packet, or drop the packet.

## Nomenclature

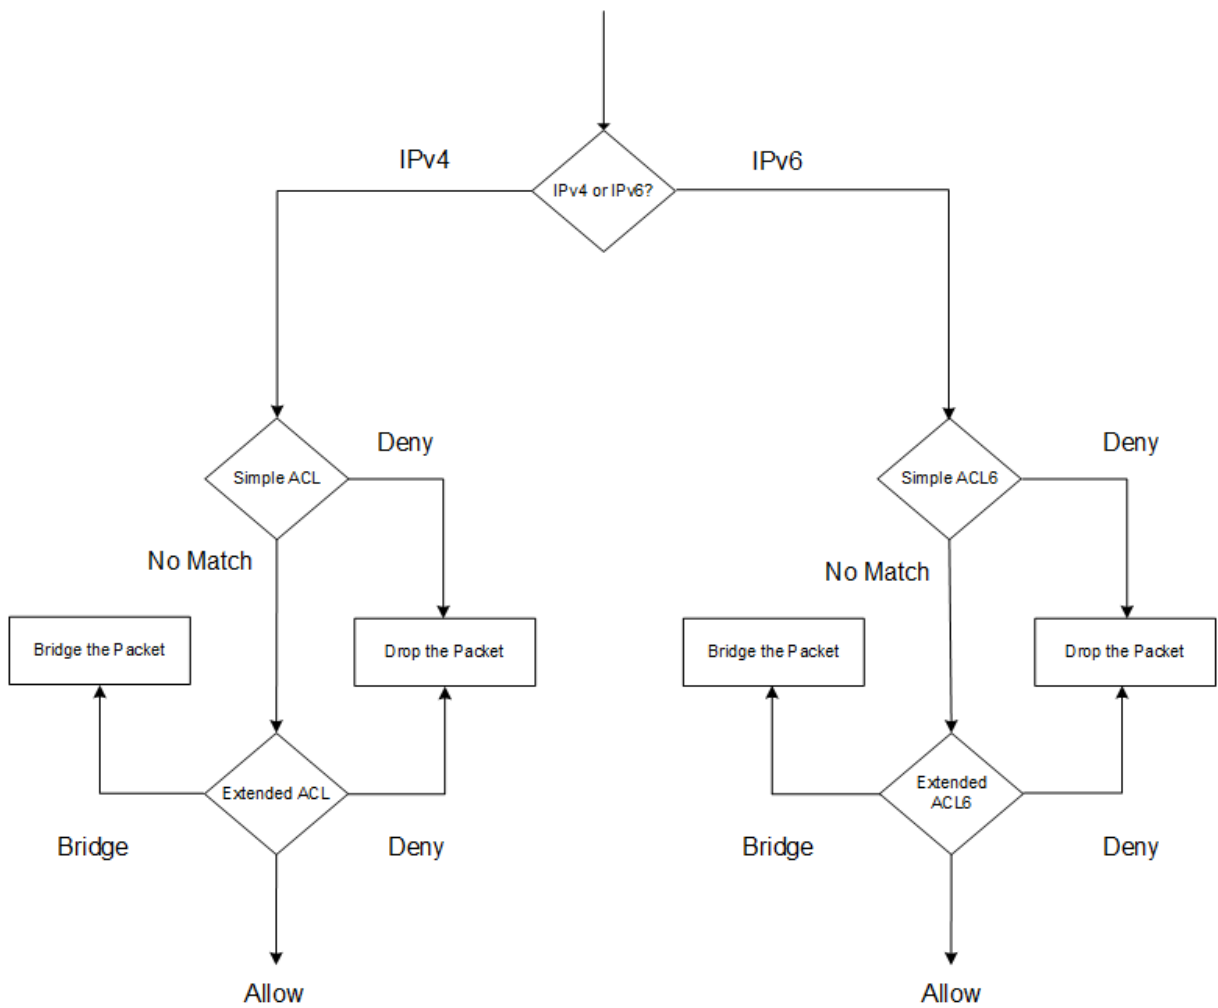

In the NetScaler user interfaces, the terms simple ACL and extended ACL refer to ACLs that process IPv4 packets. An ACL that processes IPv6 packets is called a simple ACL6 and or extended ACL6. When discussing both types, this documentation sometimes refers to both of them as simple ACLs or extended ACLs.

## ACL Precedence

If both simple and extended ACLs are configured, incoming packets are compared to the simple ACLs first.

The NetScaler first determines whether the incoming packet is an IPv4 or an IPv6 packet, and then compares the packet's characteristics to either simple ACLs or simple ACL6s. If a match is found, the packet is dropped. If no match is found, the packet is compared to extended ACLs or extended ACL6s. If that comparison results in a match, the packet is handled as specified in the ACL. The packet can be bridged, dropped, or allowed. If no match is found, the packet is allowed.

Figure 1. Simple and Extended ACLs Flow Sequence

## Simple ACLs and Simple ACL6s

May 2, 2023

A simple ACL or simple ACL6 uses few parameters and can be configured only to drop IP packets. Packets can be dropped based on their source IP address and, optionally, their protocol, destination port, or traffic domain.

When creating a simple ACL or simple ACL6, you can specify a time to live (TTL), in seconds, after which the ACL expires. ACLs with TTLs are not saved when you save the configuration. You can display simple ACLs and simple ACL6s to verify their configuration, and you can display their statistics.

## Configuring Simple ACLs and Simple ACL6s

Configuring a simple ACL or simple ACL6 on a NetScaler can include the following tasks.

- **Create simple ACLs or simple ACL6s.** Creating simple ACLs or simple ACL6s to drop (deny) packets based on their source IP address and, optionally, their protocol, destination port, or traffic domain.
- **Remove simple ACLs or simple ACL6s.** These ACLs cannot be modified once created. If you must modify a simple ACL or simple ACL6, you must remove it and create a one.

### CLI procedures

To create a simple ACL by using the CLI:

At the command prompt, type:

```
1 - ns simpleacl <aclname> DENY -srcIP <ip_addr> [-destPort <port> -
 protocol (TCP | UDP)] [-TTL \<positive_integer>]
2 - show ns simpleacl [\<aclname>]
3 <!--NeedCopy-->
```

#### Example:

```
1 > add simpleacl rule1 DENY -srcIP 10.102.29.5 -TTL 600
2 Done
3 <!--NeedCopy-->
```

To create a simple ACL6 by using the CLI:

At the command prompt, type:

```
1 - add ns simpleacl6 <aclname> DENY - srcIPv6 <ipv6_addr|null> [-
 destPort <port> -protocol (TCP | UDP)] [-TTL <positive_integer>]
2 - show ns simpleacl6 [<aclname>]
3 <!--NeedCopy-->
```

#### Example:

```
1 > add ns simpleacl6 rule1 DENY - srcIPv6 3ffe:192:168:215::82 -
 destPort 80 -Protocol TCP -TTL 9000
2 Done
3 <!--NeedCopy-->
```

To remove a single simple ACL by using the CLI:

At the command prompt, type:

- **rm ns simpleacl** <aclname>
- **show ns simpleacl**

To remove a single simple ACL6 by using the CLI:

At the command prompt, type:

- **rm ns simpleacl6**<aclname>
- **show ns simpleacl6**

To remove all simple ACLs by using the CLI:

At the command prompt, type:

- **clear ns simpleacl**
- **show ns simpleacl**

To remove all simple ACL6s by using the CLI:

At the command prompt, type:

- **clear ns simpleacl6**
- **show ns simpleacl6**

### GUI procedures

To create a simple ACL by using the GUI:

Navigate to **System > Network > ACLs** and, on the **Simple ACLs** tab, add a new simple ACL.

To create a simple ACL6 by using the GUI:

Navigate to **System > Network > ACLs** and, on the **Simple ACL6s** tab, add a new simple ACL6.

To remove a single simple ACL by using the GUI:

Navigate to **System > Network > ACLs** and, on the **Simple ACLs** tab, delete the simple ACL.

To remove a single simple ACL6 by using the GUI:

Navigate to **System > Network > ACLs** and, on the **Simple ACL6s** tab, delete the simple ACL6.

To remove all simple ACLs by using the GUI:

1. Navigate to **System > Network > ACLs**.
2. On the **Simple ACLs** tab, in the **Action** list, click **Clear**.

To remove all simple ACL6s by using the GUI:

1. Navigate to **System > Network > ACLs**.
2. On the **Simple ACL6s** tab, in the **Action** list, click **Clear**.

## Displaying Simple ACL and Simple ACL6 Statistics

You can display the simple ACL (or simple ACL6) statistics, which include the number of matches, the number of misses, and the number of simple ACLs configured.

The following table describes the statistics you can display for simple ACLs and simple ACL6s.

Statistics	Indicates
ACL match	Packets matching an ACL
ACL misses	Packets not matching any ACL
ACL count	Number of ACLs configured

### CLI procedures

To display simple ACL statistics by using the CLI:

At the command prompt, type:

- **stat ns simpleacl**

#### Example:

```

1 > stat ns simpleacl
2
3 SimpleACL Statistics
4
5 Rate (/s)
6 SimpleACL hits Total
7 SimpleACL misses 0
 51872
8 SimpleACLs count 2
9 Done
10 <!--NeedCopy-->
```

To display simple ACL6 statistics by using the CLI:

At the command prompt, type:

- **stat ns simpleacl6**

### GUI procedures

To display simple ACL statistics by using the GUI:

Navigate to **System > Network > ACLs** and, on the **Simple ACLs** tab, select the ACL and click **Statistics**.

To display simple ACL6 statistics by using the GUI:

Navigate to **System > Network > ACLs** and, on the **Simple ACL6s** tab, select the simple ACL6 and click **Statistics**.

## Terminating Established Connections

For a simple ACL or simple ACL6, the NetScaler blocks any new connections that match the conditions specified in the ACL. Packets related to existing connections that were established before the ACL was created are not blocked. To terminate previously established connections that match an existing ACL, you can run a flush operation from the CLI or the GUI.

Flush can be useful in the following cases:

- You receive a list of blacklisted IP addresses and want to completely block those IP addresses from accessing the NetScaler. In this case, you create simple ACLs or simple ACL6s to block any new connections from these IP addresses, and then flush any existing connections associated with those addresses.
- You want to terminate many connections from a particular network without taking the time to terminate them one by one.

### Before you begin

- When you run flush, the NetScaler searches through all of its established connections and terminates the connections that match the conditions specified in any of the simple ACLs configured on the ADC.
- If you plan to create more than one simple ACL and flush existing connections that match any of them, you can minimize the effect on performance by first creating all simple ACLs and then running flush only once.

### CLI procedures

To terminate all established IPv4 connections that match any of your configured simple ACLs by using the CLI:

At the command prompt, type:

- **flush simpleacl -estSessions**

To terminate all established IPv6 connections that match any of your configured simple ACL6s by using the CLI:

At the command prompt, type:

- **flush simpleacl6 -estSessions**

### GUI procedures

To terminate all established IPv4 connections that match any of your configured simple ACLs by using the GUI:

1. Navigate to **System > Network > ACLs**.
2. On the **Simple ACLs** tab, in the **Action** list, click **Flush**.

To terminate all established IPv6 connections that match any of your configured simple ACL6s by using the GUI:

1. Navigate to **System > Network > ACLs**.
2. On the **Simple ACL6s** tab, in the **Action** list, click **Flush**.

## Extended ACLs and Extended ACL6s

May 2, 2023

Extended ACLs and extended ACL6s provide parameters and actions not available with simple ACLs. You can filter data based on parameters such as source IP address, source port, action, and protocol. You can specify tasks to allow a packet, deny a packet, or bridge a packet.

Extended ACLs and ACL6s can be modified after they are created, and you can renumber their priorities to specify the order in which they are evaluated.

**Note:** If you configure both simple and extended ACLs, simple ACLs take precedence over extended ACLs.

The following actions can be performed on extended ACLs and ACL6s: Modify, Apply, Disable, Enable, Remove, and Renumber (the priority). You can display extended ACLs and ACL6s to verify their configuration, and you can display their statistics.

You can configure the NetScaler to log details for packets that match an extended ACL.

**Applying Extended ACLs and Extended ACL6s:** Unlike simple ACLs and ACL6s, extended ACLs and ACL6s created on the NetScaler do not work until they are applied. Also, if you make any changes to an extended ACL or ACL6, such as disabling the ACLs, changing a priority, or deleting the ACLs, you must

reapply the extended ACLs or ACL6s. You must reapply them after enabling logging. The procedure to apply extended ACLs or ACL6s reapplies all of them. For example, if you have applied extended ACL rules 1 through 10, and you then create and apply rule 11, the first 10 rules are applied afresh.

If a session has a DENY ACL related to it, that session is terminated when you apply the ACLs.

Extended ACLs and ACL6s are enabled by default. When they are applied, the NetScaler starts comparing incoming packets against them. However, if you disable them, they are not used until you reenable them, even if they are reapplied.

**Renumbering the priorities of Extended ACLs and Extended ACL6s:** Priority numbers determine the order in which extended ACLs or ACL6s are matched against a packet. An ACL with a lower priority number has a higher priority. It is evaluated before ACLs with higher priority numbers (lower priorities), and the first ACL to match the packet determines the action applied to the packet.

When you create an extended ACL or ACL6, the NetScaler automatically assigns it a priority number that is a multiple of 10, unless you specify otherwise. For example, if two extended ACLs have priorities of 20 and 30, respectively, and you want a third ACL to have a value between those numbers, you might assign it a value of 25. If you later want to retain the order in which the ACLs are evaluated but restore their numbering to multiples of 10, you can use the renumber procedure.

## Configuring Extended ACLs and Extended ACL6s

Configuring an extended ACL or ACL6 on a NetScaler consists of the following tasks.

- **Create an extended ACL or ACL6.** Create an extended ACL or ACL6 to either allow, deny, or bridge a packet. You can specify an IP address or range of IP addresses to match against the source or destination IP addresses of the packets. You can specify a protocol to match against the protocol of incoming packets.
- (Optional) **Modify an extended ACL or ACL6.** You can modify extended ACLs or ACL6s that you previously created. Or, if you want to temporarily take one out of use you can disable it, and later reenable it.
- **Apply extended ACLs or ACL6s.** After you create, modify, disable or reenable, or delete an extended ACL or ACL6, you must apply the extended ACLs or ACL6s to activate them.
- (Optional) **Renumber the priorities of extended ACLs or ACL6s.** If you have configured ACLs with priorities that are not multiples of 10 and want to restore the numbering to multiples of 10, use the renumber procedure.

### CLI procedures

#### To create an extended ACL by using the CLI:

At the command prompt, type:

- **add ns acl** <aclname> <aclaction> [-\*\*srcIP\*\* [<operator>] <srcIPVal>] [-\*\*srcPort\*\* [<operator>] <srcPortVal>] [-\*\*destIP\*\* [<operator>] <destIPVal>] [-\*\*destPort\*\* [<operator>] <destPortVal>] [-\*\*TTL\*\* <positive\_integer>] [-\*\*srcMac\*\* <mac\_addr>] [(**protocol** <protocol> [-established]) | **protocolNumber** <positive\_integer>] [-\*\*vlan\*\* <positive\_integer>] [-\*\*interface\*\* <interface\_name>] [-\*\*icmpType\*\* <positive\_integer>] [-\*\*icmpCode\*\* <positive\_integer>]] [-\*\*priority\*\* <positive\_integer>] [-\*\*state\*\* ( ENABLED | DISABLED )] [-\*\*logstate\*\* ( ENABLED | DISABLED )] [-\*\*ratelimit\*\* <positive\_integer>]]
- **show ns acl** [<aclName>]

#### To create an extended ACL6 by using the CLI:

At the command prompt, type:

- **add ns acl6** <acl6name> <acl6action> [-\*\*srcIPv6\*\* [<operator>] <srcIPv6Val>] [-\*\*srcPort\*\* [<operator>] <srcPortVal>] [-\*\*destIPv6\*\* [<operator>] <destIPv6Val>] [-\*\*destPort\*\* [<operator>] <destPortVal>] [-\*\*TTL\*\* <positive\_integer>] [-\*\*srcMac\*\* <mac\_addr>] [(**protocol** <protocol> [-established]) | **protocolNumber** <positive\_integer>] [-\*\*vlan\*\* <positive\_integer>] [-\*\*interface\*\* <interface\_name>] [-\*\*icmpType\*\* <positive\_integer>] [-\*\*icmpCode\*\* <positive\_integer>]] [-\*\*priority\*\* <positive\_integer>] [-\*\*state\*\* ( ENABLED | DISABLED )]
- **show ns acl6** [<aclName>]

#### To modify an extended ACL by using the CLI:

To modify an extended ACL, type the **set ns acl** command, the name of the extended ACL, and the parameters to be changed, with their new values.

#### To modify an extended ACL6 by using the CLI:

To modify an extended ACL6, type the **set ns acl6** command, the name of the extended ACL6, and the parameters to be changed, with their new values.

#### To disable or enable an extended ACL by using the CLI:

At the command prompt, type one of the following commands:

- **disable ns acl** <aclname>
- **enable ns acl** <aclname>

#### To disable or enable an extended ACL6 by using the CLI:

At the command prompt, type one of the following commands:

- **disable ns acl6** <aclname>
- **enable ns acl6** <aclname>

**To apply extended ACLs by using the CLI:**

At the command prompt, type:

- **apply ns acls**

**To apply extended ACL6s by using the CLI:**

At the command prompt, type:

- **apply ns acls6**

**To renumber the priorities of extended ACLs by using the CLI:**

At the command prompt, type:

- **renumber ns acls**

**To renumber the priorities of extended ACL6s by using the CLI:**

At the command prompt, type:

- **renumber ns acls6**

**GUI procedures**

**To configure an extended ACL by using the GUI:**

- Navigate to **System > Network > ACLs** and, on the **Extended ACLs** tab, add a new extended ACL or edit an existing extended ACL. To enable or disable an existing extended ACL, select it, and then select **Enable** or **Disable** from the **Action** list.

**To configure an extended ACL6s by using the GUI:**

- Navigate to **System > Network > ACLs** and, on the **Extended ACL6s** tab, add a new extended ACL6 or edit an existing extended ACL6. To enable or disable an existing extended ACL6, select it, and then select **Enable** or **Disable** from the **Action** list.

**To apply extended ACLs by using the GUI:**

- Navigate to **System > Network > ACLs** and, on the **Extended ACLs** tab, in the **Action** list, click **Apply**.

**To apply extended ACL6s by using the GUI:**

- Navigate to **System > Network > ACLs** and, on the **Extended ACL6s** tab, in the **Action** list, click **Apply**.

**To renumber the priorities of extended ACLs by using the GUI:**

- Navigate to **System > Network > ACLs** and, on the **Extended ACLs** tab, in the **Action** list, click **Renumber Priority (s)**.

**To renumber the priorities of extended ACL6s by using the GUI:**

- Navigate to **System > Network > ACLs** and, on the **Extended ACL6s** tab, in the **Action** list, click **Renumber Priority (s)**.

**Sample Configurations**

The following table shows examples of configuring extended ACL rules through the command line interface: [ACLs sample configurations](#).

**Logging extended ACLs**

You can configure the NetScaler to log details for packets that match extended ACLs.

In addition to the ACL name, the logged details include packet-specific information such as the source and destination IP addresses. The information is stored either in the syslog file or in the `nslog` file, depending on the type of global logging (`syslog` or `nslog`) enabled.

Logging must be enabled at both the global level and the ACL level. The global setting takes precedence.

To optimize logging, when multiple packets from the same flow match an ACL, only the first packet's details are logged, and the counter is incremented for every packet that belongs to the same flow. A flow is defined as a set of packets that have the same values for the source IP address, destination IP address, source port, destination port, and protocol parameters. To avoid flooding of log messages, the NetScaler performs internal rate limiting so that packets belonging to the same flow are not repeatedly logged. The total number of different flows that can be logged at any given time is limited to 10,000.

**Note:** You must apply ACLs after you enable logging.

**CLI procedures****To configure extended ACL Logging by using the CLI:**

At the command prompt, type the following commands to configure logging and verify the configuration:

- `set ns acl <aclName> [-logState (ENABLED | DISABLED)] [-rateLimit <positive_integer>]`

- **apply acls**
- **show ns acl** [<aclName>]

## GUI procedures

### To configure extended ACL Logging by using the GUI:

1. Navigate to **System > Network > ACLs** and, on the **Extended ACLs** tab, open the extended ACL.
2. Set the following parameters:
  - **Log State**—Enable or disable logging of events related to the extended ACL rule. The log messages are stored in the configured [syslog](#) or [auditlog](#) server.
  - **Log Rate Limit**—Maximum number of log messages to be generated per second. If you set this parameter, you must enable the Log State parameter.

## Sample configuration

```
1 > set ns acl restrict -logstate ENABLED -ratelimit 120
2 Warning: ACL modified, apply ACLs to activate change
3
4 > apply ns acls
5 Done
6 <!--NeedCopy-->
```

## Logging extended ACL6s

You can configure the NetScaler appliance to log details for packets that match an extended ACL6 rule. In addition to the ACL6 name, the logged details include packet-specific information, such as the source and destination IP addresses. The information is stored either in a `syslog` or `nslog` file, depending on the type of logging (`syslog` or `nslog`) that you have configured in the NetScaler appliance.

To optimize logging, when multiple packets from the same flow match an ACL6, only the first packet's details are logged. The counter is incremented for every other packet that belongs to the same flow. A flow is defined as a set of packets that have the same values for the following parameters:

- Source IP
- Destination IP
- Source port
- Destination port
- Protocol (TCP or UDP)

If an incoming packet is not from the same flow, a new flow is created. The total number of different flows that can be logged at any given time is limited to 10,000.

## CLI procedures

### To configure logging for an extended ACL6 rule by using the CLI:

- To configure logging while adding the extended ACL6 rule, at the command prompt, type:
  - **add acl6** <acl6Name> <acl6action> [-**logState** (ENABLED | DISABLED)] [-**rateLimit** <positive\_integer>]
  - **apply acls6**
  - **show acl6** [<acl6Name>]
- To configure logging for an existing extended ACL6 rule, at the command prompt, type:
  - **set acl6** <acl6Name> [-**logState** (ENABLED | DISABLED)] [-**rateLimit** <positive\_integer>]
  - **show acl6** [<acl6Name>]
  - **apply acls6**

## GUI procedures

### To configure extended ACL6 Logging by using the GUI:

1. Navigate to **System > Network > ACLs** and, then click the **Extended ACL6s** tab.
2. Set the following parameters while adding, or modifying an existing extended ACL6 rule.
  - **Log State**—Enable or disable logging of events related to the extended ACL6s rule. The log messages are stored in the configured syslog or **auditlog** server.
  - **Log Rate Limit**—Maximum number of log messages to be generated per second. If you set this parameter, you must enable the **Log State** parameter.

## Sample configuration

```
1 > set acl6 ACL6-1 -logstate ENABLED -ratelimit 120
2 Done
3
4 > apply acls6
5 Done
6 <!--NeedCopy-->
```

## Displaying extended ACLs and extended ACL6s statistics

You can display statistics of extended ACLs and ACL6s.

The following table lists the statistics associated with extended ACLs and ACL6s, and their descriptions.

---

Statistic	Specifies
Allow ACL matches	Packets matching ACLs with processing mode set to ALLOW. The NetScaler processes these packets.
NAT ACL matches	Packets matching a NAT ACL, resulting in a NAT session.
Deny ACL matches	Packets dropped because they match ACLs with processing mode set to DENY.
Bridge ACL matches	Packets matching a bridge ACL, which in transparent mode bypasses service processing.
ACL matches	Packets matching an ACL.
ACL misses	Packets not matching any ACL.
ACL Count	Total number of ACL rules configured by users.
Effective ACL Count	Total number of effective ACL configured internally. For an extended ACL with a range of IP addresses, the NetScaler appliance internally creates an extended ACL for each IP address. For example, for an extended ACL with 1000 IPv4 addresses (range or dataset), the NetScaler internally creates 1000 extended ACLs.

---

### CLI procedures

#### To display the statistics of all extended ACLs by using the CLI:

At the command prompt, type:

- **stat ns acl**

#### To display the statistics of all extended ACL6s by using the CLI:

At the command prompt, type:

- **stat ns acl6**

## GUI procedures

### To display the statistics of an extended ACL by using the GUI:

- Navigate to **System > Network > ACLs**, on the **Extended ACLs** tab, select the extended ACL, and click **Statistics**.

### To display the statistics of an extended ACL6 by using the GUI:

- Navigate to **System > Network > ACLs**, on the **Extended ACL6s** tab, select the extended ACL, and click **Statistics**.

## Stateful ACLs

A stateful ACL rule creates a session when a request matches the rule and allows the resulting responses even if these responses match a deny ACL rule in the NetScaler appliance. A stateful ACL offloads the work of creating more ACL rules/forwarding session rules for allowing these specific responses.

Stateful ACLs can be best used in an edge firewall deployment of a NetScaler appliance having the following requirements:

- The NetScaler appliance must allow requests initiated from internal clients and the related responses from the Internet.
- The appliance must drop the packets from the Internet that are not related to any client connections.

## Before you begin

Before you configure stateful ACL rules, note the following points:

- The NetScaler appliance supports stateful ACL rules and stateful ACL6 rules.
- In a high availability setup, the sessions for a stateful ACL rule are not synchronized to the secondary node.
- You cannot configure an ACL rule as stateful if the rule is bound to any NetScaler NAT configuration. Some examples of NetScaler NAT configurations are:
  - RNAT
  - Large Scale NAT (large scale NAT44, DS-Lite, large scale NAT64)
  - NAT64
  - Forwarding session
- You cannot configure an ACL rule as stateful if TTL and Established parameters are set for this ACL rule.

- The sessions created for a stateful ACL rule continue to exist until time out irrespective of the following ACL operations:
  - Remove ACL
  - Disable ACL
  - Clear ACL
- Stateful ACLs are not supported for the following protocols:
  - Active FTP
  - TFTP

### Configure stateful IPv4 ACL rules

Configuring a stateful ACL rule consists of enabling the stateful parameter of an ACL rule.

#### To enable the stateful parameter of an ACL rule by using the CLI:

- To enable the stateful parameter while adding an ACL rule, at the command prompt, type:
  - **add acl** <name> ALLOW **stateful** (ENABLED | DISABLED)
  - **apply acls**
  - **show acl** <name>
- To enable the stateful parameter of an existing ACL rule, at the command prompt, type:
  - **set acl** <name> **stateful** (ENABLED | DISABLED)
  - **apply acls**
  - **show acl** <name>

#### To enable the stateful parameter of an ACL rule by using the GUI:

1. Navigate to **System > Network > ACLs** and, on the **Extended ACLs** tab.
2. Enable the **Stateful** parameter while adding, or modifying an existing ACL rule.

### Sample configuration

```
1 > add acl ACL-1 allow -srcIP 1.1.1.1 -stateful Yes
2
3 Done
4
5 > apply acls
6
7 Done
8
9 > show acl
```

```
10
11 1) Name: ACL-1
12
13 Action: ALLOW Hits: 0
14
15 srcIP = 1.1.1.1
16
17 destIP
18
19 srcMac:
20
21 Protocol:
22
23 Vlan: Interface:

31 Log Status: DISABLED
32
33 Forward Session: NO
34
35 Stateful: YES
36 <!--NeedCopy-->
```

## Configure stateful ACL6 rules

Configuring a stateful ACL6 rule consists of enabling the stateful parameter of an ACL6 rule.

### To enable the stateful parameter of an ACL6 rule by using the CLI:

- To enable the stateful parameter while adding an ACL6 rule, at the command prompt, type:
  - **\*\*add acl6\*\*** <name> ALLOW -stateful ( ENABLED | DISABLD )
  - **apply acls6**
  - **show acl6** <name>
- To enable the stateful parameter of an existing ACL6 rule, at the command prompt, type:
  - **\*\*set acl6\*\*** <name> -stateful ( ENABLED | DISABLED )
  - **apply acls6**
  - **show acl6** <name>

### To enable the stateful parameter of an ACL6 rule by using the GUI:

1. Navigate to **System > Network > ACLs** and, on the **Extended ACL6s** tab.
2. Enable the **Stateful** parameter while adding, or modifying an existing ACL6 rule.

**Sample configuration**

```
1 > add acl6 ACL6-1 allow -srcipv6 1000::1 - stateful Yes
2
3 Done
4
5 > apply acls6
6
7 Done
8
9 > show acl6
10
11 1) Name: ACL6-1
12
13 Action: ALLOW Hits: 0
14
15 srcIPv6 = 1000::1
16

```

**Dataset based extended ACLs**

Many ACLs are required in an enterprise. Configuring and managing many ACLs is difficult and cumbersome when they require frequent changes.

A NetScaler appliance supports datasets in extended ACLs. Dataset is an existing feature of a NetScaler appliance. A dataset is an array of indexed patterns of types: number (integer), IPv4 address, or IPv6 address.

Dataset support in extended ACLs is useful for creating multiple ACL rules, which require common ACL parameters.

While creating an ACL rule, instead of specifying the common parameters, you can specify a dataset,

which includes these common parameters.

Any changes made in the dataset are automatically reflected in the ACL rules that are using this dataset. ACLs with datasets are easier to configure and manage. They are also smaller and easier to read than the conventional ACLs.

Currently, the NetScaler appliance supports only the following types of datasets for the extended ACLs:

- IPv4 address (for specifying the source IP address or the destination IP address or both for an ACL rule)
- number (for specifying the source port or the destination port or both for an ACL rule)

### **Before you begin**

Before configuring dataset based extended ACL rules, note the following points:

- Make sure that you are familiar with the dataset feature of a NetScaler appliance. For more information about datasets, see [Pattern sets and data sets](#).
- The NetScaler appliance supports datasets only for IPv4 extended ACLs.
- The NetScaler appliance supports only the following types of datasets for the extended ACLs:
  - IPv4 address
  - number
- The NetScaler appliance supports dataset based extended ACLs for all NetScaler set ups: stand-alone, high availability, and cluster.
- For an extended ACL with datasets containing ranges, the NetScaler appliance internally creates an extended ACL for each combination of the dataset values.
  - **Example 1:** For an IPv4 dataset based extended ACL with 1000 IPv4 addresses bound to the dataset, and the dataset is set to the source IP parameter, the NetScaler appliance internally creates 1000 extended ACLs.
  - **Example 2:** A dataset based extended ACL with following parameters set:
    - \* Source IP is set to a dataset containing 5 IP addresses.
    - \* Destination IP is set to a dataset containing 5 IP addresses.
    - \* Source port is set to a dataset containing 5 ports.
    - \* Destination port is set to a dataset containing 5 ports.

The NetScaler appliance internally creates 625 extended ACLs. Each of these internal ACLs contains a unique combination of the above mentioned four parameter values.

- The NetScaler appliance supports a maximum of 10K extended ACLs. For an IPv4 dataset based extended ACL with a range of IP addresses bound to the dataset, the NetScaler appliance stops creating internal ACLs once the total number of extended ACLs reaches the maximum limit.
- The following counters are present as part of the extended ACL statistics:
  - \* **ACL count.** Total number of ACL rules configured by users.
  - \* **Effective ACL count.** Total number of effective ACL rules that the NetScaler appliance configures internally.

For more information, see [Displaying extended ACL and extended ACL6s Statistics](#).

- The NetScaler appliance does not support `set` and `unset` operations for associating/dissociating datasets with the parameters of an extended ACL. You can set the ACL parameters to a dataset only during the `add` operation.

### Configure dataset based extended ACLs

Configuring a dataset based extended ACL rule consists of the following tasks:

- **Add a dataset.** A dataset is an array of indexed patterns of types: number (integer), IPv4 address, or IPv6 address. In this task, you create a type of dataset, for example, a dataset of type IPv4.
- **Bind values to the dataset.** Specify a value or a range of values to the dataset. The specified values must be of the same type as the dataset type. For example, you can specify an IPv4 address, or an IPv4 address range, or an IPv4 address range in CIDR notation to an IPv4 dataset.
- **Add an extended ACL and set ACL parameters to the dataset.** Add an extended ACL and set the required ACL parameters to the dataset. This setting results in the parameters set to the values specified in the dataset.
- **Apply extended ACLs.** Apply the ACLs to activate any new or modified extended ACLs.

#### To add a policy dataset by using the CLI:

At the command prompt, type:

- **add policy dataset** <name> <type>
- **show policy dataset**

#### To bind a pattern to the data set by using the CLI:

At the command prompt, type:

- **bind policy dataset** <name> <value> [-endRange <string>]
- **show policy dataset**

**To add an extended ACL and set the ACL parameters to the dataset by using the CLI:**

At the command prompt, type:

- **add ns acl** <aclname> <aclaction> [-srcIP [<operator>] <srcIPVal>] [-srcPort [<operator>] <srcPortVal>] [-destIP [<operator>] <destIPVal>] [-destPort [<operator>] <destPortVal>] ...
- **show acls**

**To apply extended ACLs by using the CLI:**

At the command prompt, type:

- **apply acls**

**Sample configuration**

In the following sample configuration of a dataset based extended ACL, two IPv4 datasets `DATASET_IP_ACL_1` and `DATASET_IP_ACL_2` are created. Two port datasets `DATASET_PORT_ACL_1` and `DATASET_PORT_ACL_2` are created.

Two IPv4 addresses: 192.0.2.30 and 192.0.2.60 are bound to `DATASET_IP_ACL_1`. Two IPv4 address ranges: (198.51.100.15 - 45) and (203.0.113.60-90) are bound to `DATASET_IP_ACL_2`. `DATASET_IP_ACL_1` is then specified to the `srcIP` parameter, and `DATASET_IP_ACL_2` to the `destIP` parameter of the extended ACL `ACL-1`.

Two port numbers: 2001 and 2004, are bound to `DATASET_PORT_ACL_1`. Two port ranges: (5001 - 5040) and (8001 - 8040) are bound to `DATASET_PORT_ACL_2`. `DATASET_IP_ACL_1` is then specified to the `srcIP` parameter, and `DATASET_IP_ACL_2` to the `destIP` parameter of the extended ACL `ACL-1`.

```

1 add policy dataset DATASET_IP_ACL_1 IPV4
2 add policy dataset DATASET_IP_ACL_2 IPV4
3
4 add policy dataset DATASET_PORT_ACL_1 NUM
5 add policy dataset DATASET_PORT_ACL_2 NUM
6
7 bind dataset DATASET_IP_ACL_1 192.0.2.30
8 bind dataset DATASET_IP_ACL_1 192.0.2.60
9 bind dataset DATASET_IP_ACL_2 198.51.100.15 -endrange 198.51.100.45
10 bind dataset DATASET_IP_ACL_2 203.0.113.1/24
11
12 bind dataset DATASET_PORT_ACL_1 2001
13 bind dataset DATASET_PORT_ACL_1 2004
14 bind dataset DATASET_PORT_ACL_2 5001 -endrange 5040
15 bind dataset DATASET_PORT_ACL_2 8001 -endrange 8040
16
17 add ns acl ACL-1 ALLOW -srcIP DATASET_IP_ACL_1 -destIP DATASET_IP_ACL_2
18 -srcPort DATASET_PORT_ACL_1 -destPort DATASET_PORT_ACL_2 -protocol TCP
19 <!--NeedCopy-->

```

## MAC Address Wildcard Mask for ACLs

September 21, 2020

A wildcard mask parameter has been introduced for extended ACLs and ACL6s and is used with the source MAC address parameter to define a range of MAC addresses to be match against the source MAC address of incoming packets.

Wild card masks specify which hexadecimal digits of the MAC address are used and which hexadecimal digits are ignored. The wildcard mask parameter specifies a series of ones and zeroes and has a length of 12 digits. Each digit is a mask for the corresponding hexadecimal digit of the MAC address. A zero digit in the wildcard mask indicates that the corresponding hexadecimal digit of the MAC address must be considered and a one digit indicates that the corresponding hexadecimal digit to be ignored.

The wildcard mask must meet the following conditions:

- Has only one series of zeroes
- Has only one series of ones
- Start with a series of zeroes

The following are some of the examples of valid wildcard masks:

- 000000111111
- 000000011111
- 000011111111

The following are some of the examples of invalid wildcard masks:

- 000000111100
- 111110000000
- 010101010101

For an ACL, a wildcard mask of 000000111111 for MAC address 96:fa:95:1d:67:4a defines the MAC address range 96:FA:95:00:00:00 - 96:FA:95:FF:FF:FF. This MAC address range is matched against the source MAC address of the incoming packets.

To specify a range of source MAC addresses in an ACL rule by using the CLI:

At the command prompt, type:

```
1 - add ns acl <name> <action> -srcMac <mac_addr> -srcMacMask <string>
2 - show ns acl <aclname>
3 <!--NeedCopy-->
```

### Example:

```

1 add ns acl ACL-1 ALLOW - protocol TCP - srcport 2000-3000 -srcMac 96:fa
 :95:1d:67:4a
2 - srcMacMask 0000000111111
3 Done
4 <!--NeedCopy-->

```

To specify a range of source MAC addresses in an ACL6 rule by using the CLI:

At the command prompt, type:

```

1 - add ns acl6 <name> <action> -srcMac <mac_addr> -srcMacMask <string>
2 - show ns acl6 <acl6name>
3 <!--NeedCopy-->

```

### Example:

```

1 > add ns acl6 ACL6-1 ALLOW -destIPv6 2001::45 -srcMac 96:fa:90:1d:67:4a
2 - srcMacMask 0000000001111
3 Done
4 <!--NeedCopy-->

```

## Blocking Traffic on Internal Ports

May 2, 2023

By default, a NetScaler appliance does not block some type of internal traffic even using ACL rules.

The following table lists the internal traffic types that a NetScaler appliance does not block even using ACL rules:

NetScaler Setup	Protocol	Destination Port	Destination IP address
All	TCP	3008–3011	NSIP or SNIP
All	TCP	179	NSIP or SNIP
All	UDP	520	NSIP or SNIP
High availability	UDP	3003	NSIP
High availability	TCP	22	NSIP
Cluster	UDP	7000	NSIP

This feature of not blocking the earlier mentioned types of traffic is specified by the default setting of the global Layer-3 `Implicit ACL Allow (implicitACLAllow)` parameter.

You can disable this parameter if you want to block the earlier mentioned traffic types using the ACL rules. An appliance in a high availability setup makes an exception for its partner (primary or secondary) node. It does not block traffic from that node.

**To disable or enable this parameter by using the CLI:**

At the command prompt, type:

---

```
set l3param -implicitACLAllow [ENABLED DISABLED]
```

---

- 
- **sh l3param**

**Note:** The parameter implicitACLAllow is enabled by default.

**Example:**

```
1 > set l3param -implicitACLAllow DISABLED
2 Done
3 <!--NeedCopy-->
```

## IP Routing

May 2, 2023

NetScaler appliances support both dynamic and static routing. Because simple routing is not the primary role of a NetScaler, the main objective of running dynamic routing protocols is to enable route health injection (RHI), so that an upstream router can choose the best among multiple routes to a topographically distributed virtual server.

Most NetScaler implementations use some static routes to reduce routing overhead. You can create backup static routes and monitor routes to enable automatic switchover in the event that a static route goes down. You can also assign weights to facilitate load balancing among static routes, create null routes to prevent routing loops, and configure IPv6 static routes. You can configure policy based routes (PBRs), for which routing decisions are based on criteria that you specify.

## Configuring Dynamic Routes

May 2, 2023

When a dynamic routing protocol is enabled, the corresponding routing process monitors route updates and advertises routes. Routing protocols enable an upstream router to use the equal cost multipath (ECMP) technique to load balance traffic to identical virtual servers hosted on two standalone NetScaler appliances. Dynamic routing on a NetScaler appliance uses three routing tables. In a high-availability setup, the routing tables on the secondary appliance mirror those on the primary.

For command reference guides and unsupported commands on dynamic routing protocol, see *Dynamic Routing Protocol Command Reference Guides and Unsupported Commands*.

The NetScaler supports the following protocols:

- Routing Information Protocol (RIP) version 2
- Open Shortest Path First (OSPF) version 2
- Border Gateway Protocol (BGP)
- Routing Information Protocol next generation (RIPng) for IPv6
- Open Shortest Path First (OSPF) version 3 for IPv6
- ISIS Protocol

You can enable more than one protocol simultaneously.

### **Routing Tables in NetScaler**

In a NetScaler appliance, the NetScaler kernel routing table, the FreeBSD kernel routing table, and the NSM FIB routing table each hold a different set of routes and serve a different purpose. They communicate with each other by using UNIX routing sockets. Route updates are not automatically propagated from one routing table to another. You must configure propagation of route updates for each routing table.

#### **NS Kernel Routing Table**

The NS kernel routing table holds subnet routes corresponding to the NSIP and to each SNIP and MIP. Usually, no routes corresponding to VIPs are present in the NS kernel routing table. The exception is a VIP added by using the `add ns ip` command and configured with a subnet mask other than 255.255.255.255. If there are multiple IP addresses belonging to the same subnet, they are abstracted as a single subnet route. In addition, this table holds a route to the loopback network (127.0.0.0) and any static routes added through the CLI (CLI). The entries in this table are used by the NetScaler in packet forwarding. From the CLI, they can be inspected with the `show route` command.

#### **FreeBSD Routing Table**

The sole purpose of the FreeBSD routing table is to facilitate initiation and termination of management traffic (telnet, ssh, etc.). In a NetScaler appliance, these applications are tightly coupled to FreeBSD,

and it is imperative for FreeBSD to have the necessary information to handle traffic to and from these applications. This routing table contains a route to the NSIP subnet and a default route. In addition, FreeBSD adds routes of type WasCloned(W) when the NetScaler establishes connections to hosts on local networks. Because of the highly specialized utility of the entries in this routing table, all other route updates from the NS kernel and NSM FIB routing tables bypass the FreeBSD routing table. Do not modify it with the route command. The FreeBSD routing table can be inspected by using the netstat command from any UNIX shell.

### Network Services Module (NSM) FIB

The NSM FIB routing table contains the advertisable routes that are distributed by the dynamic routing protocols to their peers in the network. It may contain:

- **Connected routes.** IP subnets that are directly reachable from the NetScaler. Typically, routes corresponding to the NSIP subnet and subnets over which routing protocols are enabled are present in NSM FIB as connected routes.
- **Kernel routes.** All the VIP addresses on which the -hostRoute option is enabled are present in NSM FIB as kernel routes if they satisfy the required RHI Levels. In addition, NSM FIB contains any static routes configured on the CLI that have the - advertise option enabled. Alternatively, if the NetScaler is operating in Static Route Advertisement (SRADV) mode, all static routes configured on the CLI are present in NSM FIB. These static routes are marked as kernel routes in NSM FIB, because they actually belong to the NS kernel routing table.
- **Static routes.** Normally, any static route configured in VTYSH is present in NSM FIB. If administrative distances of protocols are modified, this may not always be the case. An important point to note is that these routes can never get into the NS kernel routing table.
- **Learned routes.** If the NetScaler is configured to learn routes dynamically, the NSM FIB contains routes learned by the various dynamic routing protocols. Routes learned by OSPF, however, need special processing. They are downloaded to FIB only if the fib-install option is enabled for the OSPF process. This can be done from the router-config view in VTYSH.

### Dynamic Routing in a High Availability Setup

In a high availability setup, the primary node runs the routing process and propagates routing table updates to the secondary node. The routing table of the secondary node mirrors the routing table on the primary node.

### Non-Stop Forwarding

After failover, the secondary node takes some time to start the protocol, learn the routes, and update its routing table. But this does not affect routing, because the routing table on the secondary node

is identical to the routing table on the primary node. This mode of operation is known as non-stop forwarding.

### **Black Hole Avoidance Mechanism**

After failover, the new primary node injects all its VIP routes into the upstream router. However, that router retains the old primary node's routes for 180 seconds. Because the router is not aware of the failover, it attempts to load balance traffic between the two nodes. During the 180 seconds before the old routes expire, the router sends half the traffic to the old, inactive primary node, which is, in effect, a black hole.

To prevent this, the new primary node, when injecting a route, assigns it a metric that is slightly lower than the one specified by the old primary node.

### **Interfaces for Configuring Dynamic Routing**

To configure dynamic routing, you can use either the GUI or a command-line interface. The NetScaler supports two independent command-line interfaces: the CLI and the Virtual Teletype Shell (VTYSH). The CLI is the appliance's native shell. VTYSH is exposed by ZebOS. The NetScaler routing suite is based on ZebOS, the commercial version of GNU Zebra.

#### **Note:**

Citrix recommends that you use VTYSH for all commands except those that can be configured only on the CLI. Use of the CLI should generally be limited to commands for enabling the routing protocols, configuring host route advertisement, and adding static routes for packet forwarding.

### **Dynamic Routing Protocol Command Reference Guides and Unsupported Commands**

The following table lists command reference guide links, for various dynamic routing protocols, and unsupported commands on the NetScaler appliance: [Dynamic routing protocol reference guides and unsupported commands](#).

## **Configuring RIP**

May 2, 2023

Routing Information Protocol (RIP) is a Distance Vector protocol. The NetScaler supports RIP as defined in RFC 1058 and RFC 2453. RIP can run on any subnet.

After enabling RIP, you need to configure advertisement of RIP routes. For troubleshooting, you can limit RIP propagation. You can display RIP settings to verify the configuration.

## Enabling and Disabling RIP

Use either of the following procedures to enable or disable RIP. After you enable RIP, the NetScaler appliance starts the RIP process. After you disable RIP, the appliance stops the RIP process.

To enable or disable RIP routing by using the CLI:

At the command prompt, enter one of the following commands to enable or disable RIP:

- **enable ns feature RIP**
- **disable ns feature RIP**

To enable or disable RIP routing by using the GUI:

1. Navigate to **System > Settings**, in **Modes and Features** group, click **Change advanced features**.
2. Select or clear the **RIP Routing** option.

## Advertising Routes

RIP enables an upstream router to load balance traffic between two identical virtual servers hosted on two standalone NetScaler appliances. Route advertisement enables an upstream router to track network entities located behind the NetScaler.

To configure RIP to advertise routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router rip	Start the RIP routing process and enter configuration mode for the routing process.
redistribute static	Redistribute static routes.
redistribute kernel	Redistribute kernel routes.

### Example:

```
1 >VTYSH
2 NS# configure terminal
3 NS(config)# router rip
4 NS(config-router)# redistribute static
5 NS(config-router)# redistribute kernel
6 <!--NeedCopy-->
```

## Limiting RIP Propagations

If you need to troubleshoot your configuration, you can configure listen-only mode on any given interface.

To limit RIP propagation by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

---

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router rip	Start the RIP routing process and enter configuration mode for the routing process.
passive-interface <vlan_name>	Suppress routing updates on interfaces bound to the specified VLAN.

---

### Example:

```
1 >VTYSH
2 NS# configure terminal
3 NS(config)# router rip
4 NS(config-router)# passive-interface VLAN0
5 <!--NeedCopy-->
```

## Verifying the RIP Configuration

You can display the routing table and other RIP settings.

To view the RIP settings by using the VTYSH command line:

At the command prompt, type the following commands in the following order:

Command	Specifies
VTYSH	Display VTYSH command prompt.
sh rip	Display updated RIP routing table.
sh rip interface	Displays RIP information for the specified VLAN.

---

**Example:**

```
1 NS# VTYSH
2 NS# sh rip
3 NS# sh rip interface VLAN0
4 <!--NeedCopy-->
```

## Configuring OSPF

May 2, 2023

The NetScaler supports Open Shortest Path First (OSPF) Version 2 (RFC 2328). The features of OSPF on the NetScaler are:

- If a vserver is active, the host routes to the vserver can be injected into the routing protocols.
- OSPF can run on any subnet.
- Route learning advertised by neighboring OSPF routers can be disabled on the NetScaler.
- The NetScaler can advertise Type-1 or Type-2 external metrics for all routes.
- The NetScaler can advertise user-specified metric settings for VIP routes. For example, you can configure a metric per VIP without special route maps.
- You can specify the OSPF area ID for the NetScaler.
- The NetScaler supports not-so-stubby-areas (NSSAs). An NSSA is similar to an OSPF stub area but allows injection of external routes in a limited fashion into the stub area. To support NSSAs, a new option bit (the N bit) and a new type (Type 7) of Link State Advertisement (LSA) area have been defined. Type 7 LSAs support external route information within an NSSA. An NSSA area border router (ABR) translates a type 7 LSA into a type 5 LSA that is propagated into the OSPF domain. The OSPF specification defines only the following general classes of area configuration:
  - Type 5 LSA: Originated by routers internal to the area are flooded into the domain by AS boarder routers (ASBRs).
  - Stub: Allows no type 5 LSAs to be propagated into/throughout the area and instead depends on default routing to external destinations.

After enabling OSPF, you need to configure advertisement of OSPF routes. For troubleshooting, you can limit OSPF propagation. You can display OSPF settings to verify the configuration.

## Enabling and Disabling OSPF

To enable or disable OSPF, you must use either the CLI or the GUI. When OSPF is enabled, the NetScaler starts the OSPF process. When OSPF is disabled, the NetScaler stops the OSPF routing process.

To enable or disable OSPF routing by using the CLI:

At the command prompt, type one of the following commands:

1. **enable ns feature OSPF**
2. **disable ns feature OSPF**

To enable or disable OSPF routing by using the GUI:

1. Navigate to **System > Settings**, in **Modes and Features** group, click **Change advanced features**.
2. Select or clear the **OSPF Routing** option.

## Advertising OSPF Routes

OSPF enables an upstream router to load balance traffic between two identical virtual servers hosted on two standalone NetScaler appliances. Route advertising enables an upstream router to track network entities located behind the NetScaler.

To configure OSPF to advertise routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

---

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enters global configuration mode.
router OSPF	Start OSPF routing process and enter configuration mode for the routing process.
network A.B.C.D/M area <0-4294967295>	Enable routing on an IP network.
redistribute static	Redistribute static routes.
redistribute kernel	Redistribute kernel routes.

---

### Example:

```

1 >VTYSH
2 NS# configure terminal
3 NS(config)# router OSPF
4 NS(config-router)# network 10.102.29.0/24 area 0
5 NS(config-router)# redistribute static
6 NS(config-router)# redistribute kernel
7 <!--NeedCopy-->

```

## Limiting OSPF Propagations

If you need to troubleshoot your configuration, you can configure listen-only mode on any given VLAN.

To limit OSPF propagation by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router OSPF	Start OSPF routing process and enters configuration mode for the routing process.
passive-interface <vlan_name>	Suppress routing updates on interfaces bound to the specified VLAN.

### Example:

```

1 >VTYSH
2 NS# configure terminal
3 NS(config)# router OSPF
4 NS(config-router)# passive-interface VLAN0
5 <!--NeedCopy-->

```

## Verifying the OSPF Configuration

You can display current OSPF neighbors, and OSPF routes.

To view the OSPF settings by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
sh OSPF neighbor	Displays current neighbors.
sh OSPF route	Displays OSPF routes.

**Example:**

```

1 >VTYSH
2 NS# sh ip OSPF neighbor
3 NS# sh ip OSPF route
4 <!--NeedCopy-->

```

**Configuring Graceful Restart for OSPF**

In a non-INC high availability (HA) setup in which a routing protocol is configured, after a failover, routing protocols are converged and routes between the new primary node and the adjacent neighbor routers are learned. Route learning takes some time to complete. During this time, forwarding of packets is delayed, network performance might get disrupted, and packets might get dropped.

Graceful restart enables an HA setup during a failover to direct its adjacent routers to not remove the old primary node's learned routes from their routing databases. Using the old primary node's routing information, the new primary node and the adjacent routers immediately start forwarding packets, without disrupting network performance.

**Note:**

Graceful restart is not supported for high availability setups in INC mode.

To configure graceful restart for OSPF by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

Command	Example	Command Description
VTYSH	VTYSH	Enters VTYSH command prompt.
configure terminal	NS# configure terminal	Enters global configuration mode.

Command	Example	Command Description
router-id	NS(config)# router-id 1.1.1.1	Sets a router identifier for the NetScaler appliance. This identifier is set for all the dynamic routing protocols. The same ID must be specified in the other node in a high availability set up for graceful restart to work properly in the HA setup.
ospf restart grace-period <1-1800>	NS(config)# ospf restart grace-period 170	Specifies the grace period, in seconds, for which the routes are to be preserved in the helper devices. Default value: 120 seconds.
ospf restart helper max-grace-period <1-1800>	NS(config)# ospf restart helper max-grace-period 180	This is an optional command to limit the maximum grace period for which the NetScaler appliance will be in the helper mode. If the NetScaler appliance receives an opaque LSA with grace-period greater than the set helper max-grace-period, the LSA is discarded and the NetScaler is not placed in helper mode.
router ospf	NS(config)# router ospf	Starts OSPF routing process and enter configuration mode for the routing process.
network A.B.C.D/M area <0-4294967295>	NS(config-router)# network 192.0.2.0/24 area 0	Enables routing on an IP network.
capability restart graceful	NS(config-router)# capability restart graceful	Enables graceful restart on the OSPF routing process.
redistribute kernel	NS(config-router)# redistribute kernel	Redistributes kernel routes.

## Configuring BGP

May 2, 2023

The NetScaler appliance supports BGP (RFC 4271). The features of BGP on the NetScaler are:

- The NetScaler advertises routes to BGP peers.
- The NetScaler injects host routes to virtual IP addresses (VIPs), as determined by the health of the underlying virtual servers.
- The NetScaler generates configuration files for running BGP on the secondary node after failover in an HA configuration.
- This protocol supports IPv6 route exchanges.
- As-Override Support in Border Gateway Protocol

After enabling BGP, you need to configure advertisement of BGP routes. For troubleshooting, you can limit BGP propagation. You can display BGP settings to verify the configuration.

### Enabling and Disabling BGP

To enable or disable BGP, you must use either the CLI or the GUI. When BGP is enabled, the NetScaler appliance starts the BGP process. When BGP is disabled, the appliance stops the BGP process.

To enable or disable BGP routing by using the CLI:

At the command prompt, type one of the following commands:

- `enable ns feature BGP`
- `disable ns feature BGP`

To enable or disable BGP routing by using the GUI:

1. Navigate to System > Settings, in Modes and Features group, click Change advanced features.
2. Select or clear the BGP Routing option.

### Advertising IPv4 Routes

You can configure the NetScaler appliance to advertise host routes to VIPs and to advertise routes to downstream networks.

To configure BGP to advertise IPv4 routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
<b>VTYSH</b>	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router BGP <ASnumber>	BGP autonomous system. <ASnumber> is a required parameter. Possible values: 1 to 4,294,967,295.
Neighbor <IPv4 address> remote-as <as-number>	Update the IPv4 BGP neighbor table with the link local IPv4 address of the neighbor in the specified autonomous system.
Address-family ipv4	Enter address family configuration mode.
Neighbor <IPv4 address> activate	Exchange prefixes for the IPv4 router family between the peer and the local node by using the link local address.
redistribute kernel	Redistribute kernel routes.
redistribute static	Redistribute static routes.

**Example:**

```

1 >VTYSH
2 NS# configure terminal
3 NS(config)# router BGP 5
4 NS(config-router)# Neighbor 10.102.29.170 remote-as 100
5 NS(config-router)# Address-family ipv4
6 NS(config-router-af)# Neighbor 10.102.29.170 activate
7 NS(config-router)# redistribute kernel
8 NS(config-router)# redistribute static
9 <!--NeedCopy-->

```

**Advertising IPv6 BGP Routes**

Border Gateway Protocol (BGP) enables an upstream router to load balance traffic between two identical virtual servers hosted on two standalone NetScaler appliances. Route advertising enables an upstream router to track network entities located behind the NetScaler.

**Prerequisites for IPv6 BGP**

Before you begin configuring IPv6 BGP, do the following:

- Make sure that you understand the IPv6 BGP protocol.

- Enable the IPv6 feature.

### Configuration steps

To configure BGP to advertise IPv6 routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

---

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router BGP <ASnumber>	BGP autonomous system. <ASnumber> is a required parameter. Possible values: 1 to 4,294,967,295.
Neighbor <IPv6 address> remote-as <as-number>	Update the IPv6 BGP neighbor table with the link local IPv6 address of the neighbor in the specified autonomous system.
Address-family ipv6	Enter address family configuration mode.
Neighbor <IPv6 address> activate	Exchange prefixes for the IPv6 router family between the peer and the local node by using the link local address.
redistribute kernel	Redistribute kernel routes.
redistribute static	Redistribute static routes.

---

### Example:

```
1 >VTYSH
2 NS# configure terminal
3 NS(config)# router BGP 5
4 NS(config-router)# Neighbor a1bc::102 remote-as 100
5 NS(config-router)# Address-family ipv6
6 NS(config-router-af)# Neighbor a1bc::102 activate
7 NS(config-router)# redistribute kernel
8 NS(config-router)# redistribute static
9 <!--NeedCopy-->
```

### Verifying the BGP Configuration

You can use VTYSH to display BGP settings.

To view the BGP settings using the VTYSH command line

At the command prompt, type:

```
1 VTYSH
2 You are now in the VTYSH command prompt. An output similar to the
 following appears:
3 NS170#
4 At the VTYSH command prompt, type:
5 NS170# sh ip BGP
6 NS170# sh BGP
7 NS170# sh ip BGP neighbors
8 NS170# sh ip BGP summary
9 NS170# sh ip BGP route-map <map-tag>
10 <!--NeedCopy-->
```

## As-Override Support in Border Gateway Protocol

As a part of BGP loop prevention functionality, if a router receives a BGP packet containing the router's Autonomous System Number (ASN) in the Autonomous Systems (AS) path, the router drops the packet. The assumption is that the packet originated from the router and has reached the place from where it originated.

If an enterprise has several sites with a same ASN, BGP loop prevention causes the sites with an identical ASN to not get linked by another ASN. Routing updates (BGP packets) are dropped when another site receives them.

To solve this issue, BGP AS-Override functionality has been added to the ZebOS BGP routing module of the NetScaler.

With AS-Override enabled for a peer device, when the NetScaler appliance receives a BGP packet for forwarding to the peer, and the ASN of the packet matches that of the peer, the appliance replaces the ASN of the BGP packet with its own ASN number before forwarding the packet.

You can enable AS-Override for a specific neighbor or a group of neighbors (peer group) by using the VTYSH command line.

To configure BGP AS-Override for a IPv4 neighbor by using the VTYSH command line:

---

Command	Specifies
<b>configure terminal</b>	Enter global configuration mode.
<b>router BGP &lt;ASnumber&gt;</b>	BGP autonomous system. <ASnumber> is a required parameter.

Command	Specifies
<b>Neighbor</b> < IPv4 address> remote-as < as-number>	Update the IPv4 BGP neighbor table with the IPv4 address of the neighbor in the specified autonomous system.
<b>Neighbor</b> as-override	Enable BGP as-override for the specified neighbor.

```

1 > VTYSH NS# configure terminal
2 NS(config)# router BGP 200
3 NS(config-router)# Neighbor 192.0.2.100 remote-as 100
4 NS(config-router)# Neighbor 10.102.29.100 as-override
5 <!--NeedCopy-->

```

To configure BGP AS-Override for a IPv4 BGP peer group by using the VTYSH command line:

Command	Specifies
<b>configure terminal</b>	Enter global configuration mode.
<b>router BGP</b> < ASnumber>	BGP autonomous system. < ASnumber> is a required parameter.
<b>Neighbor</b> **peer-group**	Create a BGP peer group.
<b>Neighbor</b> **peer-group**	Associate neighbors to the specified peer group.
<b>Neighbor</b> remote-as < as-number>	Update the IPv4 BGP neighbor table with the IPv4 address of the neighbor in the specified autonomous system.
<b>Neighbor</b> as-override	Enable BGP as-override for all the neighbors that are associated with the specified peer group.

```

1 > VTYSH NS# configure terminal
2 NS(config)# router BGP 200
3 NS(config-router)# neighbor external-peers-1 peer-group
4 NS(config-router)# neighbor 192.0.2.101 peer-group external-peers-1
5 NS(config-router)# neighbor 192.0.2.102 peer-group external-peers-1
6 NS(config-router)# neighbor 192.0.2.103 peer-group external-peers-1
7 NS(config-router)# Neighbor external-peers-1 remote-as 100
8 NS(config-router)# Neighbor external-peers-1 as-override
9 <!--NeedCopy-->

```

To configure BGP AS-Override for an IPv6 neighbor by using the VTYSH command line:

Command	Specifies
<b>configure terminal</b>	Enter global configuration mode.
<b>router BGP</b> <ASnumber>	BGP autonomous system. <ASnumber> is a required parameter.
<b>Neighbor</b> <IPv6 address> remote-as <as-number>	Update the IPv4 BGP neighbor table with the IPv4 address of the neighbor in the specified autonomous system.
<b>Neighbor</b> as-override	Enable BGP as-override for the specified neighbor.
<b>Address-family ipv6</b>	Enter address family configuration mode.
<b>Neighbor</b> <IPv6 address> activate	Exchange prefixes for the IPv6 router family between the specified neighbor and the NetScaler by using the link local address.
<b>Neighbor</b> as-override	Enable BGP as-override for the specified neighbor.

```

1 > VTYSH NS# configure terminal
2 NS(config)# router BGP 200
3 NS(config-router)# Neighbor a1bc::102 remote-as 100
4 NS(config-router)# Neighbor a1bc::102 as-override
5 NS(config-router)# Address-family ipv6
6 NS(config-router-af)# Neighbor a1bc::102 activate
7 NS(config-router)# Neighbor a1bc::102 as-override
8 <!--NeedCopy-->

```

To configure BGP AS-Override for IPv6 peer group by using the VTYSH command line:

Command	Specifies
<b>configure terminal</b>	Enter global configuration mode.
<b>router BGP</b> <ASnumber>	BGP autonomous system. <ASnumber> is a required parameter.
<b>Neighbor</b> **peer-group**	Create a BGP peer group.
<b>Neighbor</b> **peer-group**	Associate a neighbor with the specified peer group.
<b>Neighbor</b> remote-as < as-number>	Update the IPv4 BGP neighbor table with the IPv4 address of the neighbor in the specified autonomous system.

Command	Specifies
<b>Neighbor</b> as-override	Enable BGP as-override for all the neighbors that are associated with the specified peer group.
<b>Address-family ipv6</b>	Enter address family configuration mode.
<b>Neighbor</b> activate	Exchange prefixes for the IPv6 router family between the neighbors of the specified peer group and the NetScaler by using the link local address.
<b>Neighbor</b> as-override	Enable BGP as-override for all the neighbors that are associated with the specified peer group.

```

1 > VTYSH NS# configure terminal
2 NS(config)# router BGP 200
3 NS(config-router)# neighbor external-peers-2 peer-group
4 NS(config-router)# neighbor 2001::1 peer-group external-peers-2
5 NS(config-router)# neighbor 2001::2 peer-group external-peers-2
6 NS(config-router)# Neighbor external-peers-2 remote-as 100
7 NS(config-router)# Neighbor external-peers-2 as-override
8 NS(config-router)# Address-family ipv6
9 NS(config-router-af)# Neighbor external-peers-2 activate
10 NS(config-router)# Neighbor external-peers-2 as-override
11 <!--NeedCopy-->

```

## Graceful Restart

In a non-INC high availability (HA) setup in which a routing protocol is configured, after a failover, routing protocols are converged and routes between the new primary node and the adjacent neighbor routers are learned. Route learning take some time to complete. During this time, forwarding of packets is delayed, network performance might get disrupted, and packets might get dropped.

Graceful restart enables an HA setup during a failover to direct its adjacent routers to not remove the old primary node's learned routes from their routing databases. Using the old primary node's routing information, the new primary node and the adjacent routers immediately start forwarding packets, without disrupting network performance.

### Note:

Graceful restart is not supported for high availability setups in INC mode.

## Configuring Graceful Restart for BGP

To configure graceful restart for BGP by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

Command	Example	Command Description
VTYSH	VTYSH	Enters VTYSH command prompt.
configure terminal	NS# configure terminal	Enters global configuration mode.
router-id	NS(config)# router-id 1.1.1.1	A router identifier for the NetScaler appliance. This identifier is set for all the dynamic routing protocols. The same identifier must be specified on the other node in a high availability setup for graceful restart to work properly.
router bgp	NS(config)# router bgp 5	Enters BGP configuration mode.
bgp graceful-restart	NS(config)# bgp graceful-restart	Enables graceful restart on the BGP routing process.
bgp graceful-restart restart-time <1-1800>	NS(config-router)# bgp graceful-restart restart-time 170	Specifies the grace period, in seconds, that the helper routers waits for a TCP connection from the new primary node after a failover. For this amount of time, the helper routers preserve the routes.
bgp graceful-restart stalepath-time <1-1800>	NS(config-router)# bgp graceful-restart stalepath-time 180	Specifies the time, in seconds, that the NetScaler appliance in helper mode retains the stale routes for restarting neighbor routers. The default value is 360 seconds.

Command	Example	Command Description
neighbor remote-as	NS(config-router)# neighbor 192.0.2.30 remote-as 2	Establishes BGP peering with the specified neighbor router device.
neighbor capability graceful-restart	NS(config-router)# neighbor 192.0.2.30 capability graceful-restart	Enables graceful restart with the specified neighbor.
redistribute kernel	NS(config-router)# redistribute kernel	Redistributes kernel routes.

### Configuring Graceful Restart for IPv6 BGP

To configure graceful restart for IPv6 BGP by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

Command	Example	Command Description
VTYSH	VTYSH	Enters VTYSH command prompt.
configure terminal	NS# configure terminal	Enters global configuration mode.
router-id	NS(config)# router-id 1.1.1.1	Sets a router identifier for the NetScaler appliance. This identifier is set for all the dynamic routing protocols. The same ID must be specified in the other node in a high availability setup for graceful restart to work properly.
router bgp	NS(config)# router bgp 5	Enters configuration mode for BGP protocol.
bgp graceful-restart	NS(config)# bgp graceful-restart	Enables graceful restart on the BGP routing process.

Command	Example	Command Description
<code>bgp graceful-restart restart-time &lt;1-1800&gt;</code>	<code>NS(config-router)# bgp graceful-restart restart-time 170</code>	Specifies the grace period, in seconds, that the helper routers waits for a TCP connection from the new primary node after a failover. For this amount of time, the helper routers preserve the routes. The default value is 360 seconds.
<code>bgp graceful-restart stalepath-time &lt;1-1800&gt;</code>	<code>NS(config-router)# bgp graceful-restart stalepath-time 180</code>	Specifies the time, in seconds, that the NetScaler appliance in helper mode retains the stale routes for restarting neighbor routers. The default value is 360 seconds.
<code>neighbor remote-as</code>	<code>NS(config-router)# neighbor 2001:db8::10 remote-as 2</code>	Establishes BGP peering with the specified neighbor router device.
<code>address-family ipv6</code>	<code>NS(config-router)#address-family ipv6</code>	Enters address family configuration mode.
<code>neighbor activate</code>	<code>NS(config-router-af)#neighbor 2001:db8::10 activate</code>	Enables the exchange of address family routes with the specified neighbor router device.
<code>neighbor capability graceful-restart</code>	<code>NS(config-router-af)#neighbor 2001:db8::10 capability graceful-restart</code>	Enables graceful restart with the specified neighbor router device.
<code>redistribute kernel</code>	<code>NS(config-router-af)#redistribute kernel</code>	Redistributes kernel routes.
<code>exit-address-family</code>	<code>NS(config-router-af)#exit-address-family</code>	Exits address family configuration mode.

### Configuring MD5 Authentication for IPv4 BGP

The NetScaler appliance supports MD5 authentication for Border Gateway Protocol (BGP). When authentication is enabled, any TCP segment belonging to BGP exchanged between the NetScaler appliance and its peer device is verified and accepted only if authentication is successful. For authentica-

tion to be successful, both the peers must be configured with the same MD5 password. If authentication fails, the BGP neighbor relationship is not being established. MD5 authentication support for BGP in the NetScaler appliance is compliant with RFC 2385.

### Before you Begin

Before you start configuring BGP MD5 authentication, consider the following points:

- Make sure that you understand the different components of BGP MD5 authentication, described in RFC 2385.
- BGP MD5 authentication is not supported for NetScaler admin partitions.
- BGP MD5 authentication is not supported for IPv6 BGP configurations.
- BGP MD5 authentication is supported for NetScaler cluster configurations as well as for high availability configurations.
- Because of the following issue in FreeBSD, Citrix recommends to set a low keep-live and hold-time values (for example, 5 and 15) and configure graceful restart for a BGP session in a Layer 2 high availability configuration. Otherwise, with MD5 authentication enabled, BGP might take a longer time to re-establish a connection with the neighbour after a failover.
  - Last ACK from FreeBSD does not contain md5 digest:
    - \* <https://forums.freebsd.org/threads/11170/>
    - \* <http://support.pfsense.narkive.com/povrH5HI/bgp-md5-weird-behavior-when-connection-closes>

### Configuration steps

To configure MD5 authentication for IPv4 BGP by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

---

Command	Specifies
<b>vtysh</b>	Displays VTYSH command prompt.
<b>configure terminal</b>	Enters global configuration mode.
<b>**router bgp **</b>	Enters configuration mode for BGP protocol. is a BGP autonomous system number and is a required parameter.
<b>**neighbor remote-as &lt; AS-number &gt;**</b>	Updates the IPv4 BGP table with the IPv4 address of the neighbor in the specified autonomous system.

Command	Specifies
<b>neighbor &lt; neighbour IPv4 address &gt; password &lt; password in double quotes&gt;</b>	Configures MD5 authentication for the specified neighbour with the specified MD5 password. For MD5 authentication to be successful, you must configure the same MD5 password on the NetScaler appliance and the neighbour appliance.

```

1 > vtysh
2
3 ns# configure terminal
4
5 ns(config)#router bgp 5
6
7 ns(config-router)#neighbor 20.20.20.138 remote-as 1
8
9 ns(config-router)#neighbor 20.20.20.138 password "secret"
10
11 ns(config-router)#redistribute kernel
12
13 ns(config-router)#exit
14
15 <!--NeedCopy-->

```

### Configure 4-byte BGP ASNs in asplain and asdot formats

The NetScaler appliance supports configuring and displaying 4-byte BGP autonomous system numbers (ASN) in asplain or asdot format as defined in RFC 5396.

- **asplain.** Decimal value notation where both 2-byte and 4-byte ASNs are represented in decimal value. For example, 65527 is a 2-byte ASN and 234567 is a 4-byte ASN.
- **asdot** Autonomous system dot notation where 2-byte ASNs are represented in decimal value (same as in asplain) and 4-byte ASNs are represented in a dot notation. For example, 65527 is a 2-byte ASN and 3.37959 is a 4-byte ASN. (3.37959 is asdot format for the 234567 decimal number).

### Examples of BGP ASN configuration in asplain and asdot formats

By default, the NetScaler appliance displays the BGP ASNs in asplain format, but you can configure to display in asdot format. You can configure local and remote BGP ASNs in asplain or asdot format.

The following lists some examples of BGP ASN configuration in asplain and asdot formats:

- Display BGP AS number in asplain format. By default, the NetScaler appliance displays the BGP AS number in asplain format.

```
1 ns#conf t
2 ns(config)# router bgp 196908
3 ns(config-router)# end
4 ns#
5 ns# sh run router bgp
6 !
7 router bgp 196908
8 !
9 <!--NeedCopy-->
```

- Display BGP AS number in asdot format. Run the `bgp asnotation-dot` command to display the BGP AS number in asdot format.

```
1 ns#conf t
2 ns(config)#router bgp 196908
3 ns(config-router)#bgp asnotation-dot
4 ns(config-router)#end
5 ns#
6 ns#sh run router bgp
7 !
8 router bgp 3.300
9 bgp asnotation-dot
10 !
11 <!--NeedCopy-->
```

- Configure and display BGP AS number in asdot format. Run the `bgp asnotation-dot` command to display the BGP AS number in asdot format.

```
1 ns# conf t
2 ns(config)# router bgp 3.300
3 ns(config-router)# bgp asnotation-dot
4 ns#
5 ns# sh run router bgp
6 !
7 router bgp 3.300
8 bgp asnotation-dot
9 !
10 <!--NeedCopy-->
```

- Display the BGP AS number back to asplain format from asdot format. Run the `bgp no asnotation-dot` command to display the BGP AS number back to asplain format.

```
1 ns#conf t
2 ns(config)#router bgp 3.300
3 ns(config-router)#no bgp asnotation-dot
4 ns(config-router)#end
5 ns#
6
7 ns#sh run router bgp
```

```
8 !
9 router bgp 196908
10 !
11 <!--NeedCopy-->
```

- Configure and display remote as-number in asdot format. Run the `bgp asnotation-dot` command. In the sample configuration, remote as-number 80000 is configured in asdot format 1.14464.

```
1 ns# conf t
2 ns(config)# router bgp 3.300
3 ns(config-router)# bgp asnotation-dot
4 ns(config-router)# neighbor 192.168.1.2 remote-as 1.14464
5 ns(config-router)#end
6 ns#
7 ns#
8 ns#sh run router bgp
9 !
10 router bgp 3.300
11 bgp asnotation-dot
12 neighbor 192.168.1.2 remote-as 1.14464
13 !
14 ns#
15 <!--NeedCopy-->
```

- Display the BGP local and remote AS numbers back to the asplain format from the asdot format. Run the `bgp no asnotation-dot` command.

```
1 ns#conf t
2 ns(config)#router bgp 3.300
3 ns(config-router)#no bgp asnotation-dot
4 ns(config-router)#end
5 ns#
6
7 ns#sh run router bgp
8 !
9 router bgp 196908
10 neighbor 192.168.1.2 remote-as 80000
11 !
12 ns#
13 <!--NeedCopy-->
```

**Note:**

Instead of configuring for individual BGP neighbors, the same asplain or asdot configuration can be used for BGP peer-groups as well.

## Configuring IPv6 RIP

May 2, 2023

IPv6 Routing Information Protocol (RIP) or RIPng is a Distance Vector protocol. This protocol is an extension of RIP to support IPv6. After enabling IPv6 RIP, you need to configure advertisement of IPv6 RIP routes. For troubleshooting, you can limit IPv6 RIP propagation. You can display IPv6 RIP settings to verify the configuration.

### Prerequisites for IPv6 RIP

Before you begin configuring IPv6 RIP, do the following:

- Make sure that you understand the IPv6 RIP protocol.
- Install the IPv6PT license on the NetScaler appliance.
- Enable the IPv6 feature.

### Advertising IPv6 RIP Routes

IPv6 RIP enables an upstream router to load balance traffic between two identical vservers hosted on two standalone NetScaler devices. Route advertisement enables an upstream router to track network entities located behind the NetScaler.

To configure IPv6 RIP to advertise IPv6 routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

---

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router ipv6 rip	Start IPv6 RIP routing process and enter configuration mode for the routing process.
redistribute static	Redistribute static routes.
redistribute kernel	Redistribute kernel routes.

---

### Example:

```
1 >VTYSH
2 NS# configure terminal
```

```

3 NS(config)# router ipv6 rip
4 NS(config-router)# redistribute static
5 NS(config-router)# redistribute kernel
6 <!--NeedCopy-->

```

## Limiting IPv6 RIP Propagations

If you need to troubleshoot your configuration, you can configure the listen-only mode on any given interface.

To limit IPv6 RIP propagation by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router ipv6 rip	Start IPv6 RIP routing process and enter configuration mode for the routing process.
passive-interface <vlan_name>	Suppress routing updates on interfaces bound to the specified VLAN.

### Example:

```

1 >VTYSH
2 NS# configure terminal
3 NS(config)# router ipv6 rip
4 NS(config-router)# passive-interface VLAN0
5 <!--NeedCopy-->

```

## Verifying the IPv6 RIP Configuration

You can use VTYSH to display the IPv6 RIP routing table and IPv6 RIP information for a specified VLAN.

To view the IPv6 RIP settings by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Commands	Specifies
VTYSH	Display VTYSH command prompt.
sh ipv6 rip	Display updated IPv6 RIP routing table.
sh ipv6 rip interface	Display IPv6 RIP information for the specified VLAN.

---

**Example:**

```
1 NS# VTYSH
2 NS# sh ipv6 rip
3 NS# sh ipv6 rip interface VLAN0
4 <!--NeedCopy-->
```

## Configuring IPv6 OSPF

May 2, 2023

IPv6 OSPF or OSPF version 3 (OSPF v3) is a link state protocol that is used to exchange IPv6 routing information. After enabling IPv6 OSPF, you need to configure advertisement of IPv6 OSPF routes. For troubleshooting, you can limit IPv6 OSPF propagation. You can display IPv6 OSPF settings to verify the configuration.

### Prerequisites for IPv6 OSPF

Before you begin configuring IPv6 OSPF, do the following:

- Make sure that you understand the IPv6 OSPF protocol.
- Install the IPv6PT license on the NetScaler appliance.
- Enable the IPv6 feature.

### Advertising IPv6 Routes

IPv6 OSPF enables an upstream router to load balance traffic between two identical vservers hosted on two standalone NetScaler devices. Route advertising enables an upstream router to track network entities located behind the NetScaler.

To configure IPv6 OSPF to advertise IPv6 routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Commands	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router ipv6 OSPF	Start IPv6 OSPF routing process and enter configuration mode for the routing process.
redistribute static	Redistribute static routes.
redistribute kernel	Redistribute kernel routes.

---

**Example:**

```
1 >VTYSH
2 NS# configure terminal
3 NS(config)# router ipv6 OSPF
4 NS(config-router)# redistribute static
5 NS(config-router)# redistribute kernel
6 <!--NeedCopy-->
```

**Limiting IPv6 OSPF Propagations**

If you need to troubleshoot your configuration, you use VTYSH to configure listen-only mode on any given VLAN.

To limit IPv6 OSPF propagation by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Commands	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router ipv6 OSPF	Start IPv6 OSPF routing process and enter configuration mode for the routing process.
passive-interface <vlan_name >	Suppress routing updates on interfaces bound to the specified VLAN.

---

**Example:**

```
1 >VTYSH
2 NS# configure terminal
3 NS(config)# router ipv6 OSPF
```

```

4 NS(config-router)# passive-interface VLAN0
5 <!--NeedCopy-->

```

## Verifying the IPv6 OSPF Configuration

You use VTYSH to display IPv6 OSPF current neighbors and IPv6 OSPF routes.

To view the IPv6 OSPF settings by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
sh ipv6 OSPF neighbor	Display current neighbors.
sh ipv6 OSPF route	Display IPv6 OSPF routes.

### Example:

```

1 >VTYSH
2 NS# sh ipv6 OSPF neighbor
3 NS# sh ipv6 OSPF route
4 <!--NeedCopy-->

```

## OSPFv3 Authentication

To ensure the integrity, data origin authentication, and data confidentiality of OSPFv3 packets, OSPFv3 authentication must be configured on OSPFv3 peers.

The NetScaler appliance supports OSPFv3 authentication and is partially compliant with RFC 4552. OSPFv3 authentication is based on the two IPsec protocols: Authentication Header (AH) and Encapsulating Security Payload (ESP). The NetScaler appliance supports only the AH protocol for OSPFv3 authentication.

OSPFv3 authentication uses manually defined IPsec Security Associations (SAs) between the OSPFv3 peers and does not rely on IKE protocol for forming dynamic SAs. Manual SAs define the security parameter Index (SPI) values, algorithms, and keys to be used between the peers. Manual SAs require no negotiation between the peers; therefore, the same SA must be defined on both the peers.

You can configure OSPFv3 authentication on a VLAN or for an OSPFv3 area. When you configure for a VLAN, the settings are applied to all the interfaces that are members of the VLAN. When you configure OSPFv3 authentication for an OSPF area, the settings are applied to all the VLANs in that area. The

settings are in turn applied to all the interfaces that are members of these VLANs. These settings do not apply to member VLANs on which you have configured OSPFv3 authentication directly.

Consider the following points and limitations before configuring OSPFv3 authentication on a NetScaler appliance:

- Make sure that you understand the different components of OSPFv3 authentication, described in RFC 4552.
- Only Authentication Header protocol is supported for OSPFv3 authentication. Encapsulating Security Payload (ESP) is not supported.
- You must define an SA with the same setting on the peer interface.
- Rekeying of manual keys is not supported.

To configure OSPFv3 authentication on a VLAN by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown: [OSPFv3 authentication VLAN commands](#).

**Example:**

```
1 > VTYSH NS# configure terminal
2 NS(config)# interface vlan2
3 NS(config-if)# ipv6 ospf authentication ipsec spi 256 md5 123456789
 ABCDEF0123456789ABCDEF0
4 <!--NeedCopy-->
```

To configure OSPFv3 authentication on an OSPF area by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown: [OSPFv3 authentication OSPF area commands](#).

**Example:**

```
1 > VTYSH NS# configure terminal
2 ns(config)#router ipv6 ospf 30
3 ns(config-router)# area 1 authentication ipsec spi 256
 md5123456789ABCDEF0123456789ABCDEF0
4 <!--NeedCopy-->
```

## Configuring Graceful Restart for IPv6 OSPF

In a non-INC high availability (HA) setup in which a routing protocol is configured, after a failover, routing protocols are converged and routes between the new primary node and the adjacent neighbor routers are learned. Route learning take some time to complete. During this time, forwarding of packets is delayed, network performance might get disrupted, and packets might get dropped.

Graceful restart enables an HA setup during a failover to direct its adjacent routers to not remove the old primary node's learned routes from their routing databases. Using the old primary node's routing

information, the new primary node and the adjacent routers immediately start forwarding packets, without disrupting network performance.

**Note:**

Graceful restart is not supported for high availability setups in INC mode.

To configure graceful restart for IPv6 OSPF by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

Command	Example	Command Description
VTYSH	VTYSH	Enters VTYSH command prompt.
configure terminal	NS# configure terminal	Enters global configuration mode.
router-id id>	NS(config)#router-id 1.1.1.1	Sets a router identifier for the NetScaler appliance. This identifier is set for all the dynamic routing protocols. The same ID must be specified in the other node in a high availability set up for graceful restart to work properly in the HA set up.
IPv6ospf restart grace-period <1-1800>	NS(config)# IPv6ospf restart grace-period 170	Specifies the grace period, in seconds, for which the routes are to be preserved in the helper devices. Default value: 120 seconds.
IPv6 ospf restart helper max-grace-period <1-1800>	NS(config)# IPv6 ospf restart helper max-grace-period 180	This is an optional command to limit the maximum grace period for which the NetScaler appliance will be in the helper mode. If the NetScaler appliance receives an opaque LSA with grace-period greater than the set helper max-grace-period, the LSA is discarded and the NetScaler is not placed in helper mode.

Command	Example	Command Description
interface	NS(config)#interface vlan3	Enters VLAN configuration mode.
ipv6 router ospf area tag	NS(config-if)#ipv6 router ospf area 0 tag 1	Starts IPv6 OSPF routing process on a VLAN.
exit	NS(config-if)#exit	Exits VLAN configuration mode.
router ipv6 ospf	NS(config)# router ipv6 ospf 1	Starts IPv6 OSPF routing process and enters configuration mode for the routing process.
capability restart graceful	NS(config-router)#capability restart graceful	Enables graceful restart on the IPv6 OSPF routing process.
redistribute kernel	NS(config-router)# redistribute kernel	Redistributes kernel routes.

---

## Configuring ISIS

May 2, 2023

The NetScaler appliance supports the Intermediate System-to-Intermediate System (IS-IS or ISIS) dynamic routing protocol. This protocol supports IPv4 as well as IPv6 route exchanges. IS-IS is a link state protocol and is therefore less prone to routing loops. With the advantages of faster convergence and the ability to support larger networks, ISIS can be very useful in Internet Service Provider (ISP) networks.

### Prerequisites for configuring ISIS

Before you begin configuring ISIS, do the following:

- Make sure that you understand the ISIS protocol.
- For IPV6 routes, enable:
  - IPv6 protocol translation feature.
  - IPv6 Dynamic Routing option on the VLANs on which you want to run ISIS protocol.

## Enabling ISIS

Use either of the following procedures to enable the ISIS routing feature on the NetScaler appliance.

To enable ISIS routing by using the CLI:

At the command prompt, type:

```
enable ns feature ISIS
```

To enable ISIS routing by using the GUI:

1. Navigate to System > Settings, in Modes and Features group, click Change advanced features.
2. Select or clear the ISIS Routing option.

## Creating an ISIS Routing Process and Starting It on a VLAN

To create an ISIS routing process, you must use the VTYSH command line.

At the command prompt, type the following commands, in the order shown:

Command	Description
VTYSH	Displays VTYSH command prompt.
configure terminal	Enters the global configuration mode.
router ISIS [tag]	Creates an ISIS routing process and configuration mode for the routing process.
net XX...XXXX.YYYY.YYYY.YYYY.00	Specifies a NET value for the routing process, where: <b>XX.. .XXXX</b> is the Area Address (can be 1-13 bytes), <b>YYYY.YYYY.YYYY</b> is the System ID (6 bytes), <b>00</b> is the N-selector (1 byte).
is-type (level-1 level-1-2 level-2-only)	Sets the ISIS routing process to the specified level of routing. Default: level-1-2.
ns IPv6-routing	Starts the IPv6 dynamic routing daemon.
interface	Enters the VLAN configuration mode.
ip router ISIS	Enables the ISIS routing process on the VLAN for IPv4 route exchanges.
ipv6 router ISIS	Enables the ISIS routing process on the VLAN for IPv6 route exchanges.

### Example:

```

1 > VTYSH
2 NS# configure terminal
3 NS(config)# router isis 11
4 NS(config-router)# net 15.aabb.ccdd.0097.00
5 NS(config-router)# is-type level-1
6 NS(config-router)# exit
7 NS(config)# ns IPv6-routing
8 NS(config)# interface vlan0
9 NS(config-if)# ip router isis 11
10 NS(config-if)# ipv6 router isis 11
11 <!--NeedCopy-->

```

## Advertising Routes

Route advertisement enables an upstream router to track network entities located behind the NetScaler appliance.

To configure ISIS to advertise routes by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Description
VTYSH	Displays the VTYSH command prompt.
configure terminal	Enters the global configuration mode.
router ISIS [tag]	Starts the ISIS routing instance and enter configuration mode for the routing process.
redistribute connected (level-1 or level-1-2 or level-2)	Redistributes connected routes, where: <b>level-1:</b> Redistribute connected routes into Level-1, <b>level-1-2:</b> Redistribute connected routes into Level-1 and Level-2, <b>level-2:</b> Redistribute connected routes into Level-2.
redistribute kernel (level-1 or level-1-2 or level-2)	Redistributes kernel routes, where: <b>level-1:</b> Redistribute kernel routes into Level-1, <b>level-1-2:</b> Redistribute kernel routes into Level-1 and Level-2, <b>level-2:</b> Redistribute kernel routes into Level-2.

### Example:

```

1 >VTYSH
2 NS# configure terminal
3 NS(config)# router isis 11

```

```
4 NS(config-router)# redistribute connected level-1
5 NS(config-router)# redistribute kernel level-1
6 <!--NeedCopy-->
```

## Limiting ISIS Propagations

If you need to troubleshoot your configuration, you can configure the listen-only mode on any given VLAN.

To limit ISIS propagation by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

---

Command	Description
VTYSH	Displays the VTYSH command prompt.
configure terminal	Enters the global configuration mode.
router isis [tag]	Enters the configuration mode for the routing process.
passive-interface	Suppresses routing updates on interfaces bound to the specified VLAN.

---

### Example:

```
1 >VTYSH
2 NS# configure terminal
3 NS(config)# router isis 11
4 NS(config-router)# passive-interface VLAN0
5 <!--NeedCopy-->
```

## Verifying the ISIS Configuration

You can use VTYSH to display the ISIS routing table and ISIS information for a specified VLAN.

To view the ISIS settings by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

---

Commands	Description
VTYSH	Displays the VTYSH command prompt.
show ip isis route	Displays updated IPv4 ISIS routing table.

---

Commands	Description
show ipv6 isis route	Displays updated IPv6 ISIS routing table.
sh isis interface	Displays IPv6 ISIS information for the specified VLAN.

**Example:**

```

1 NS# VTYSH
2 NS# show ip isis route
3 NS# show ipv6 isis route
4 NS# sh isis interface VLAN0
5 <!--NeedCopy-->

```

**Install Routes to the NetScaler Routing Table**

May 2, 2023

The NetScaler appliance can use routes learned by various routing protocols after you install the routes in the appliance's routing table.

To install various routes to the internal routing table by using the VTYSH command line:

At the CLI, type the following commands as appropriate for the routes that you want to install:

Commands	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
ns route-install Default	Install IPv4 default routes to the internal routing table.
ns route-install RIP	Install IPv4 RIP specific routes to the internal routing table.
ns route-install BGP	Install IPv4 BGP specific routes to the internal routing table.
ns route-install OSPF	Install IPv4 OSPF specific routes to the internal routing table.
ns route-install IPv6 Default	Install IPv6 default routes to the internal routing table.

Commands	Specifies
ns route-install IPv6 RIP	Install IPv6 RIP specific routes to the internal routing table.
ns route-install IPv6 BGP	Install IPv6 BGP specific routes to the internal routing table.
ns route-install IPv6 OSPF	Install IPv6 OSPF specific routes to the internal routing table.

---

**Example:**

```
1 >VTYSH
2 NS# configure terminal
3 NS# ns route-install Default
4 NS(config)# ns route-install RIP
5 NS(config)# ns route-install BGP
6 NS(config)# ns route-install OSPF
7 NS# ns route-install IPv6 Default
8 NS(config)# ns route-install IPv6 RIP
9 NS(config)# ns route-install IPv6 BGP
10 NS(config)# ns route-install IPv6 OSPF
11 <!--NeedCopy-->
```

**Maximum number of ECMP routes supported in a NetScaler appliance**

In a NetScaler appliance up to 32 ECMP (Equal Cost Multiple Path) routes are supported. The route selection is based on five tuples. For more information, see [Route selection based on five tuples](#).

**Advertisement of SNIP and VIP Routes to Selective Areas**

September 21, 2020

To advertise some SNIP addresses to selective areas, enabling DRADV mode or redistribute connect ZebOS operations cannot be used. This is because these operations send all the connected routes to ZebOS. Also, adding dummy static routes in ZebOS for the required subnets, or adding ACLs in ZebOS to filter unwanted connected routes, is a cumbersome and tedious task.

The Network Route and the Tag options address this issue. You can enable the Network Route option for only one SNIP address per subnet. The connected route for that SNIP address is sent as a kernel route to ZebOS.

For VIP and SNIP addresses, Tag, can be assigned an integer from 1 to 4294967295. This parameter can be set only when Host Route or Network Route is enabled for VIP or SNIP addresses. The tag value associated with VIP and SNIP addresses are also sent along with their routes to ZebOS. Tags with different values can be set for VIP and SNIP routes. These tag values can then be matched in route maps in ZebOS and advertised to selective areas.

## Advertise SNIP Routes to Selective Areas

To configure the network route and tag parameters of a SNIP address by using the CLI:

At the command prompt, type:

- If adding a new SNIP address:
  - **add ns ip** <IPAddress>@ <netmask> -**type SNIP** -**networkroute** ( **ENABLED** | **DISABLED** ) -**tag** <positive\_integer>
  - **show ns ip** <IPAddress>
- If reconfiguring an existing SNIP address:
  - **set ns ip** <IPAddress>@ <netmask> -**type SNIP** - **networkroute** ( **ENABLED** | **DISABLED** ) -**tag** <positive\_integer>
  - **show ns ip** <IPAddress>

To configure the network route and tag parameters of a SNIP address by using GUI:

1. Navigate to **System > Network > IPs > IPV4s**.
2. Set the **Network Route** and **Tag** parameters while adding a Subnet IP (SNIP) address or modifying an existing Subnet IP address.

## Advertise VIP Routes to Selective Areas

To configure the host route and tag parameters of a VIP address by using the CLI:

At the command prompt, type one of the following sets of commands.

- If adding a new VIP address:
  - **add ns ip** <IPAddress>@ <netmask> -**type VIP** -**hostRoute** ( **ENABLED** | **DISABLED** ) -**tag** <positive\_integer>
  - **show ns ip** <IPAddress>
- If reconfiguring an existing VIP address:

- **set ns ip** <IPAddress>@ <netmask> -**type VIP** -**hostRoute** ( **ENABLED** | **DISABLED** ) -**tag** <positive\_integer>
- **show ns ip** <IPAddress>

To configure the network route and tag parameters of a VIP address by using the GUI:

1. Navigate to **System > Network > IPs > IPV4s**.
2. Set the **Host Route** and **Tag** parameters while adding a VIP address or modifying an existing VIP address.

## Configuring Bidirectional Forwarding Detection

May 2, 2023

Bidirectional Forwarding Detection (BFD) protocol is a mechanism for fast detection of failures of forwarding paths. BFD detects path failures in the order of milliseconds. BFD is used with dynamic routing protocols.

In BFD operation, routing peers exchange BFD packets at a negotiated interval. If a packet is not received from a peer within the negotiated interval plus grace interval, the peer is considered to be dead and a notification will be sent to the set of registered routing protocols. In turn, the routing protocols recalculate the best path and reprogram the routing table. BFD supports smaller time interval, when compared to the timers provided by the routing protocols, thus resulting in faster detection of failures.

The NetScaler appliance supports BFD for the following routing protocols: BGP (IPv4 and IPv6), OSPFv2 (IPv4), and OSPFv3 (IPv6). BFD support in the NetScaler appliance is compliant with RFCs 5880, 5881, and 5883.

### Points to Consider for Configuring Bidirectional Forwarding Detection

Before you start configuring BFD, consider the following points:

- Make sure that you understand the different components of BFD, described in RFCs 5880, 5881, and 5883.
- BFD on a NetScaler appliance is supported for the following routing protocols:
  - BGP (IPv4 and IPv6)
  - OSPFv2 (IPv4)
  - OSPFv3 (IPv6)
- BFD on a NetScaler appliance is not supported for the following routing protocols:

- ISIS
- RIP (IPv4)
- RIPng (IPv6)
- The following BFD features are not supported on a NetScaler appliance:
  - BFD Echo mode
  - BFD Authentication
  - BFD Demand asynchronous mode
- The minimum values for BFD interval and BFD Rx timers are 100 milliseconds.
- When BFD is used in a topology with shared IP addresses (for example, Layer 2 high availability setup with SNIP addresses or a cluster setup with striped IP addresses), BFD brings down the active sessions during a failover because the BFD failure detection time (order of milliseconds) is lesser than the HA failover detection interval (3–4 seconds). Therefore, Citrix recommends usage of Graceful restart in layer-2 HA topologies as the routes are retained during the failover process.

## Configuration Steps

Configuring BFD on a NetScaler appliance consists of the following tasks:

- Configure BFD Parameters
- Configure BFD Support for Dynamic Routing Protocols

### Configure BFD Parameters

The NetScaler appliance provides separate BFD session parameters for single hop sessions, IPv4 multiple hop sessions, and IPv6 multiple hop sessions. If you do not configure BFD parameters for a type of session, the default values are applied for that session.

The default value of each BFD parameter is same for single hop sessions, IPv4 multiple hop sessions, and IPv6 multiple hop sessions. The following table displays the default value of each BFD parameter.

BFD Parameter Name	Default Value
Interval	750 milliseconds
Minimum Rx	500 milliseconds
Multiplier	3

**IMPORTANT:**

Mellanox NICs in a NetScaler ADC appliance take around 1500 ms to initialize. You must set the BFD timers to more than 1500 ms for a NetScaler appliance with Mellanox NICs. Citrix recommends setting the BFD timers to 3000 ms:

- Interval Tx = 600 ms
- Minimum Rx = 600 ms
- Multiplier = 5

**Configuring BFD Parameters for a Single Hop Session**

To configure BFD parameters for a single hop session by using the **VTYSH** command line, at the command prompt, type the following commands, in the order shown:

Command	Specifies
<code>vtys</code>	Display <b>VTYSH</b> command prompt.
<code>configure terminal</code>	Enter global configuration mode.
<code>interface vlan ID&gt;</code>	Enter the interface configuration mode.
<code>bfd singlehop-peer interval &lt;num&gt; minrx &lt;num&gt; multiplier &lt;num&gt;</code>	Configure the BFD parameters on the specified interface.

**Sample configuration:**

```

1 > vtysh
2
3 ns# configure terminal
4
5 ns(config)# interface vlan3
6
7 ns(config-if)# bfd singlehop-peer interval 200 minrx 200 multiplier 5
8
9 ns(config-if)# exit
10 <!--NeedCopy-->

```

**Configuring BFD Parameters for IPv4 Multiple Hop Sessions**

To configure BFD parameters for IPv4 multiple hop sessions by using the **VTYSH** command line, at the command prompt, type the following commands, in the order shown:

Command	Specifies
<code>vttysh</code>	Display <code>VTYSH</code> command prompt.
<code>configure terminal</code>	Enter global configuration mode.
<code>bfd multihop-peer &lt;ipv4addr&gt; interval &lt;num&gt; minrx &lt;num&gt; multiplier &lt;num&gt;</code>	Configure the BFD parameters for IPv4 multiple hops sessions.

**Sample configuration:**

```

1 > vtysh
2
3 ns# configure terminal
4
5 ns(config)# bfd multihop-peer 20.20.20.138 interval 300 minrx 300
6 multiplier 5
7 ns(config)# exit
8 <!--NeedCopy-->
```

**Configuring BFD Parameters for IPv6 Multiple Hop Sessions**

To configure BFD parameters for IPv6 multiple hop sessions by using the `VTYSH` command line, at the command prompt, type the following commands, in the order shown:

Command	Specifies
<code>vttysh</code>	Display <code>VTYSH</code> command prompt.
<code>configure terminal</code>	Enter global configuration mode.
<code>bfd multihop-peer ipv6 &lt;ipv6addr&gt; interval &lt;num&gt; minrx &lt;num&gt; multiplier &lt;num&gt;</code>	Configure the BFD parameters for IPv6 multiple hops sessions.

**Sample configuration:**

```

1 > vtysh
2
3 ns(config)# bfd multihop-peer ipv6 20fe:125::138 interval 500 minrx
4 500 multiplier 5
5 ns(config)# exit
6 <!--NeedCopy-->
```

## Configure BFD Support for Dynamic Routing Protocols

You can enable BFD for a dynamic routing protocol for a type of session with a peer. For example, single hop and multiple hops. The NetScaler appliance applies the relevant BFD parameter settings to the session.

### Configuring BFD for an IPv4 BGP Single Hop Session

To configure BFD for an IPv4 BGP single hop session by using the **VTYSH** command line, at the command prompt, type the following commands, in the order shown:

Command	Specifies
<code>vtys</code>	Display <b>VTYSH</b> command prompt.
<code>configure terminal</code>	Enter global configuration mode.
<code>router bgp &lt;asnumber&gt;</code>	BGP autonomous system. <code>asnumber</code> is a required parameter.
<code>neighbor &lt;ipv4addr&gt; remote-as &lt;num&gt;</code>	Update the IPv4 BGP table with the IPv4 address of the neighbor in the specified autonomous system.
<code>neighbor &lt;ipv4addr&gt; fall-over bfd</code>	Enable BFD for the specified neighbor.

### Sample configuration:

```

1 > vtysh
2
3 ns# configure terminal
4
5 ns(config)#router bgp 1
6
7 ns(config-router)#neighbor 20.20.20.138 remote-as 1
8
9 ns(config-router)#neighbor 20.20.20.138 fall-over bfd
10
11 ns(config-router)#redistribute kernel
12
13 ns(config-router)#exit
14 <!--NeedCopy-->
```

### Configuring BFD for an IPv4 BGP Multiple Hop Session

To configure BFD for an IPv4 BGP multiple hop session by using the **VTYSH** command line, at the command prompt, type the following commands, in the order shown:

Command	Specifies
<code>vtys</code>	Display <b>VTYSH</b> command prompt.
<code>configure terminal</code>	Enter global configuration mode.
<code>router bgp &lt;asnumber&gt;</code>	BGP autonomous system. <code>asnumber</code> is a required parameter.
<code>neighbor &lt;ipv4addr&gt; remote-as &lt;num&gt;</code>	Update the IPv4 BGP table with the IPv4 address of the neighbor in the specified autonomous system.
<code>neighbor &lt;ipv4addr&gt; fall-over bfd multihop</code>	Enable BFD for the specified neighbor.

**Sample configuration:**

```

1 > vtys
2
3 ns# configure terminal
4
5 ns(config)#router bgp 1
6
7 ns(config-router)#neighbor 20.20.20.138 remote-as 1
8
9 ns(config-router)#neighbor 20.20.20.138 fall-over bfd multihop
10
11 ns(config-router)#redistribute kernel
12
13 ns(config-router)#exit
14 <!--NeedCopy-->
```

**Configuring BFD for an IPv6 BGP Single Hop Session**

To configure BFD for an IPv6 BGP single hop session by using the **VTYSH** command line, at the command prompt, type the following commands, in the order shown:

Command	Specifies
<code>vtys</code>	Display <b>VTYSH</b> command prompt.
<code>configure terminal</code>	Enter global configuration mode.
<code>router bgp &lt;asnumber&gt;</code>	BGP autonomous system. <code>asnumber</code> is a required parameter.

Command	Specifies
<code>neighbor &lt;ipv6addr&gt; remote-as &lt;num&gt;</code>	Update the IPv6 BGP table with the link local IPv6 address of the neighbor in the specified autonomous system.
<code>neighbor &lt;ipv6addr&gt; fall-over bfd</code>	Enable BFD for the specified neighbor.
<code>address-family ipv6</code>	Enter address family configuration mode.
<code>neighbor &lt;ipv6addr&gt; activate</code>	Exchange prefixes for the IPv6 router family between the peer and the local node by using the link local address.

**Sample configuration:**

```

1 > vtysh
2
3 ns# configure terminal ns(config)#router bgp 1
4
5 ns(config-router)#neighbor 30fe:123::124 remote-as 1
6
7 ns(config-router)#neighbor 30fe:123::124 fall-over bfd
8
9 ns(config-router)#address-family ipv6
10
11 ns(config-router-af)#neighbor 30fe:123::124 activate
12
13 ns(config-router-af)#redistribute kernel
14
15 ns(config-router-af)#exit
16
17 <!--NeedCopy-->

```

**Configuring BFD for an IPv6 BGP Multiple Hop Session**

To configure BFD for an IPv6 BGP multiple hop session by using the **VTYSH** command line, at the command prompt, type the following commands, in the order shown:

Command	Specifies
<code>vtys</code>	Display <b>VTYSH</b> command prompt.
<code>configure terminal</code>	Enter global configuration mode.
<code>router bgp &lt;asnumber&gt;</code>	BGP autonomous system. <code>asnumber</code> is a required parameter.

Command	Specifies
<code>neighbor &lt;ipv6addr&gt; remote-as &lt;num&gt;</code>	Update the IPv6 BGP table with the link local IPv6 address of the neighbor in the specified autonomous system.
<code>neighbor &lt;ipv6addr&gt; fall-over bfd multihop</code>	Enable BFD for the specified neighbor.
<code>address-family ipv6</code>	Enter address family configuration mode.
<code>neighbor &lt;ipv6addr&gt; activate</code>	Exchange prefixes for the IPv6 router family between the peer and the local node by using the link-local address.

**Sample configuration:**

```

1 > vtysh
2
3 ns# configure terminal
4
5 ns(config)# bfd multihop-peer ipv6 20fe:125::138 interval 500 minrx 500
 multiplier 5
6
7 ns(config)#router bgp 1
8
9 ns(config-router)#neighbor 20fe:125::138 remote-as 1
10
11 ns(config-router)#neighbor 20fe:125::138 fall-over bfd multihop
12
13 ns(config-router)#address-family ipv6
14
15 ns(config-router-af)#neighbor 20fe:125::138 activate
16
17 ns(config-router-af)#redistribute kernel
18
19 ns(config-router-af)#end
20
21 <!--NeedCopy-->

```

**Configuring BFD for OSPFv2 (IPv4) on Interfaces**

You can enable BFD on all or on a specific interface that uses the OSPFv2 protocol.

**To configure BFD for OSPFv2 on all interfaces by using the VTYSH command line:**

At the command prompt, type the following commands, in the order shown:

Command	Specifies
<code>vtys</code>	Display <b>VTYSH</b> command prompt.
<code>configure terminal</code>	Enter global configuration mode.
<code>router ospf &lt;process tag&gt;</code>	Enter OSPFv2 configuration mode.
<code>bfd all-interfaces</code>	Enable BFD on all interfaces that use OSPFv2.

**Sample configuration:**

```

1 > vtysh
2
3 ns# configure terminal
4
5 ns(config)#router ospf 1
6
7 ns(config-router)#bfd all-interfaces
8
9 ns(config-router)#redistribute kernel
10
11 ns(config-router)#exit
12 <!--NeedCopy-->
```

**To configure BFD for OSPFv2 on a specific interface by using the VTYSH command line:**

At the command prompt, type the following commands, in the order shown:

Command	Specifies
<code>vtys</code>	Display <b>VTYSH</b> command prompt.
<code>configure terminal</code>	Enter global configuration mode.
<b>interface</b> <vlan ID>	Enter the interface configuration mode.
<code>ip ospf bfd</code>	Enable BFD on the specified interface that uses OSPFv2.

**Sample configuration:**

```

1 > vtysh
2
3 ns# configure terminal
4
5 ns(config)# interface vlan5
6
7 ns(config-if)# ip ospf bfd
8
```

```

9 ns(config-if)# exit
10 <!--NeedCopy-->

```

### Configuring BFD for OSPFv3 (IPv6) on Interfaces

You can enable BFD on all or on a specific interface that uses the OSPFv3 protocol.

#### To configure BFD for OSPFv3 on all interfaces by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
<code>vtys</code>	Display VTYSH command prompt.
<code>configure terminal</code>	Enter global configuration mode.
<code>router ipv6 ospf &lt;process tag&gt;</code>	Enter OSPFv3 configuration mode.
<code>bfd all-interfaces</code>	Enable BFD on all interfaces that use OSPFv3.

#### Sample configuration:

```

1 > vtys
2
3 ns# configure terminal
4
5 ns(config)#router ipv6 ospf 10
6
7 ns(config-router)#bfd all-interfaces
8
9 ns(config-router)#redistribute kernel
10
11 ns(config-router)#exit
12 <!--NeedCopy-->

```

#### To configure BFD for OSPFv3 on a specific interface by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
<code>vtys</code>	Display VTYSH command prompt.
<code>configure terminal</code>	Enter global configuration mode.
<code>interface &lt;vlan ID&gt;</code>	Enter the interface configuration mode.

Command	Specifies
<code>ipv6 ospf bfd</code>	Enable BFD on the specified interface that uses OSPFv3.

---

**Sample configuration:**

```
1 > vtysh
2
3 ns# configure terminal
4
5 ns(config)# interface vlan15
6
7 ns(config-if)# ipv6 ospf bfd
8
9 ns(config-if)# exit
10 <!--NeedCopy-->
```

## Configuring Static Routes

May 2, 2023

Static routes are manually created to improve the performance of your network. You can monitor static routes to avoid service disruptions. Also, you can assign weights to ECMP routes, and you can create null routes to prevent routing loops.

**Monitored Static Routes.** If a manually created (static) route goes down, a backup route is not automatically activated. You must manually delete the inactive primary static route. However, if you configure the static route as a monitored route, the NetScaler appliance can automatically activate a backup route.

Static route monitoring can also be based on the accessibility of the subnet. A subnet is usually connected to a single interface, but it can be logically accessed through other interfaces. Subnets bound to a VLAN are accessible only if the VLAN is up. VLANs are logical interfaces through which packets are transmitted and received by the NetScaler. A static route is marked as DOWN if the next hop resides on a subnet that is unreachable.

**Note:** In a high availability (HA) setup, the default value for monitored state routes (MSRs) on the secondary node is UP. The value is set to avoid a state transition gap upon failover, which could result in dropping packets on those routes.

Consider the following simple topology, in which a NetScaler is load balancing traffic to a site across multiple servers.

Router R1 moves traffic between the client and the NetScaler appliance. The appliance can reach servers S1 and S2 through routers R2 or R3. It has two static routes through which to reach the servers'

subnet, one with R2 as the gateway and another with R3 as the gateway. Both these routes have monitoring enabled. The administrative distance of the static route with gateway R2 is lower than that of the static route with gateway R3. Therefore, R2 is preferred over R3 to forward traffic to the servers. Also, the default route on the NetScaler points to R1 so that all Internet traffic exits properly.

If R2 fails while monitoring is enabled on the static route, which uses R2 as the gateway, the NetScaler marks it as DOWN. The NetScaler now uses the static route with R3 as the gateway and forwards the traffic to the servers through R3.

The NetScaler supports monitoring of IPv4 and IPv6 static routes. You can configure the NetScaler to monitor an IPv4 static route either by creating a new ARP or PING monitor or by using existing ARP or PING monitors. You can configure the NetScaler to monitor an IPv6 static route either by creating a new Neighbor discovery for IPv6 (ND6) or PING monitor or by using the existing ND6 or PING monitors.

**Weighted Static Routes.** When the NetScaler appliance makes routing decisions involving routes with equal distance and cost, that is, Equal Cost Multi-Path (ECMP) routes, it balances the load between them by using a hashing mechanism based on the source and destination IP addresses. For an ECMP route, however, you can configure a weight value. The NetScaler then uses both the weight and the hashed value for balancing the load.

**Null Routes.** If the route chosen in a routing decision is inactive, the NetScaler appliance chooses a backup route. If all the backup routes become inaccessible, the appliance might reroute the packet to the sender, which could result in a routing loop leading to network congestion. To prevent this situation, you can create a null route, which adds a null interface as a gateway. The null route is never the preferred route, because it has a higher administrative distance than the other static routes. But it is selected if the other static routes become inaccessible. In that case, the appliance drops the packet and prevents a routing loop.

### Configuring IPv4 Static Routes

You can add a simple static route or a null route by setting a few parameters, or you can set additional parameters to configure a monitored or monitored and weighted static route. You can change the parameters of a static route. For example, you might want to assign a weight to an unweighted route, or you might want to disable monitoring on a monitored route.

#### CLI procedures

To create a static route by using the CLI:

At the command prompt, type:

- add route <network> <netmask> <gateway>[-cost <positive\_integer>] [-advertise ( DISABLED | ENABLED )]
- show route [<network> <netmask> [<gateway>]] [<routeType>] [-detail]

**Example:**

```
1 > add route 10.102.29.0 255.255.255.0 10.102.29.2 -cost 2 -advertise
 ENABLED
2 Done
3 <!--NeedCopy-->
```

To create a monitored static route by using the CLI:

At the command prompt, type the following commands to create a monitored static route and verify the configuration:

- add route <network> <netmask> <gateway> [-distance <positive\_integer>] [-weight <positive\_integer>][-msr ( ENABLED | DISABLED ) [-monitor <string>]]
- show route [<network> <netmask> [<gateway>]] [<routeType>] [-detail]

**Example:**

```
1 > add route 10.102.29.0 255.255.255.0 10.102.29.3 -distance 5 -weight 6
 -msr ENABLED -monitor PING
2 Done
3 <!--NeedCopy-->
```

To create a null route by using the CLI:

At the command prompt type:

- add route <network> <netmask> null
- show route <network> <netmask>

**Example:**

```
1 > add route 10.102.29.0 255.255.255.0 null
2 Done
3 <!--NeedCopy-->
```

To remove a static route by using the CLI:

At the command prompt, type:

rm route <network> <netmask> <gateway>

**Example:**

```
1 > rm route 10.102.29.0 255.255.255.0 10.102.29.3
2 Done
3 <!--NeedCopy-->
```

## GUI procedures

To configure a static route by using the GUI:

Navigate to System > Network > Routes and, on the Basic tab, add a new static route, or edit an existing static route.

To remove a route by using the GUI:

Navigate to System > Network > Routes and, on the Basic tab, delete the static route.

## Configuring IPv6 Static Routes

You can configure a maximum of six default IPv6 static routes. IPv6 routes are selected on the basis of whether the MAC address of the destination device is reachable. This can be determined by using the IPv6 Neighbor Discovery feature. Routes are load balanced and only source/destination-based hash mechanisms are used. Therefore, route selection mechanisms such as round robin are not supported. The next hop address in the default route need not belong to the NSIP subnet.

## CLI procedures

To create an IPv6 route by using the CLI:

At the command prompt, type the following commands to create an IPv6 route and verify the configuration:

- `add route6 <network> <gateway> [-vlan <positive_integer>]`
- `show route6 [<network> [<gateway>]`

### Example:

```
1 > add route6 ::/0 FE80::67 -vlan 5
2 Done
3 <!--NeedCopy-->
```

To create a monitored IPv6 static route by using the CLI:

At the command prompt, type the following commands to create a monitored IPv6 static route and verify the configuration:

- `add route6 <network> <gateway> [-msr ( ENABLED | DISABLED ) [-monitor <string>]`
- `show route6 [<network> [<gateway>]`

### Example:

```
1 > add route6 ::/0 2004::1 -msr ENABLED -monitor PING
2 Done
3 <!--NeedCopy-->
```

To remove an IPv6 route by using the CLI:

At the command prompt, type:

```
rm route6 <network> <gateway>
```

**Example:**

```
1 > rm route6 ::/0 FE80::67
2 Done
3 <!--NeedCopy-->
```

**GUI procedures**

To configure an IPv6 route by using the GUI:

Navigate to System > Network > Routes and, on the IPV6 tab, add a new IPv6 route, or edit an existing IPv6 route.

To remove an IPv6 route by using the GUI:

Navigate to System > Network > Routes and, on the IPV6 tab, delete the IPv6 route.

## Route Health Injection Based on Virtual Server Settings

May 2, 2023

The following option and parameter are introduced for controlling the Route Health Injection (RHI) functionality of the NetScaler appliance for advertising the route of a VIP address.

- **VSVR\_CNTRLD.** It is an option for the (Vserver RHI Level) parameter of a VIP address. When this option is set to the Vserver RHI Level parameter, the RHI behavior for advertising the route of the VIP address depends on the RHI STATE parameter setting on all the associated virtual servers of the VIP address along with their states.
- **RHI STATE.** It is a parameter of virtual server. You can set the RHI STATE parameter to either PASSIVE or ACTIVE. By default, the RHI STATE parameter is set to PASSIVE.

For a VIP address, when RHI (Vserver RHI Level) parameter is set to VSVR\_CNTRLD, the following are different RHI behaviours for the VIP address on the basis of RHI STATE settings on the virtual servers associated with the VIP address:

- If you set RHI STATE to PASSIVE on all virtual servers, the NetScaler always advertises the route for the VIP address.
- If you set RHI STATE to ACTIVE on all virtual servers, the NetScaler advertises the route for the VIP address if at least one of the associated virtual servers is in UP state.
- If you set RHI STATE to ACTIVE on some and PASSIVE on others, the NetScaler advertises the route for the VIP address if at least one of the associated virtual servers, whose RHI STATE set to ACTIVE, is in UP state.

Following table displays the sample RHI behaviour for a VIP address on the basis of RHI STATE settings on the virtual servers associated with the VIP address. The NetScaler appliance has two virtual servers V1 and V2 associated with the VIP address:

Associated virtual servers for a VIP	State 1	State 2	State 3	State 4
<b>RHI State set to PASSIVE on all virtual servers</b>				
V1	UP	UP	DOWN	DOWN
V2	UP	DOWN	UP	DOWN
Advertise the route for this VIP address?	Yes	Yes	Yes	Yes
<b>RHI State set to ACTIVE on all virtual servers</b>				
V1	UP	UP	DOWN	DOWN
V2	UP	DOWN	UP	DOWN
Advertise the route for this VIP address?	Yes	Yes	Yes	No
<b>RHI State set to ACTIVE on one virtual server and PASSIVE on the other</b>				
V1 (RHI State = ACTIVE)	UP	UP	DOWN	DOWN
V2 (RHI State = PASSIVE)	UP	DOWN	UP	DOWN
Advertise the route for this VIP address?	Yes	Yes	No	No

To configure RHI for a VIP address, to be based on the RHI (RHI State) parameter setting of the associated virtual servers, perform the following steps:

- Set the RHI (Vserver RHI Level) parameter to VSVR\_CNTRLD for the VIP address.

- Set the RHI State parameter for each virtual server associated with the VIP address.

To set the vServer RHI Level for a VIP address by using the CLI:

At the command prompt, type:

- **set ns ip** <IPAddress> [-**vserverRHILevel** <vserverRHILevel>]

To set the RHI State parameter of a virtual server by using the CLI:

At the command prompt, type:

- **set lb vserver** <name> [-**RHIstate** ( **PASSIVE** | **ACTIVE** )]

To set the vServer RHI Level for a VIP address by using GUI

1. Navigate to **System > Network > IPs**.
2. Select a VIP address, and then click **Edit**.
3. Set the **Vserver RHI Level** parameter to **VSVR\_CNTRLD**, and then click **OK**.

To set the RHI State parameter of a virtual server by using GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Select a load balancing virtual server, and then click **Edit**.
3. Set the **RHI State** parameter, and then click **OK**.

## Configuring Policy-Based Routes

May 2, 2023

Policy-based routing bases routing decisions on criteria that you specify. A policy-based route (PBR) specifies criteria for selecting packets and, typically, a next hop to which to send the selected packets. For example, you can configure the NetScaler appliance to route outgoing packets from a specific IP address or range to a particular next hop router. Each packet is matched against each configured PBR, in the order determined by the specified priorities, until a match is found. If no match is found, or if the matching PBR specifies a DENY action, the NetScaler applies the routing table for normal destination-based routing.

A PBR bases routing decisions for the data packets on parameters such as source IP address, source port, destination IP address, destination port, protocol, and source MAC address. A PBR defines the conditions that a packet must satisfy for the NetScaler to route the packet. These actions are known as “processing modes.” The processing modes are:

- **ALLOW**. The appliance sends the packet to the designated next-hop router.

- **DENY.** The NetScaler applies the routing table for normal destination-based routing.

You can create PBRs for outgoing IPv4 and IPv6 traffic.

Many users begin by creating PBRs and then modifying them. To activate a new PBR, you must apply it. To deactivate a PBR, you can either remove or disable it. You can change the priority number of a PBR to give it a higher or lower precedence.

## Policy-Based Routes (PBR) for IPv4 Traffic

May 2, 2023

Configuring PBRs involves the following tasks:

- Create a PBR.
- Apply PBRs.
- (Optional) Disable or enable a PBR.
- (Optional) Renumber the priority of the PBR.

### Creating or Modifying a PBR

You cannot create two PBRs with the same parameters. If you attempt to create a duplicate, an error message appears.

You can configure the priority of a PBR. The priority (an integer value) defines the order in which the NetScaler appliance evaluates PBRs. When you create a PBR without specifying a priority, the NetScaler automatically assigns a priority that is a multiple of 10.

If a packet matches the condition defined by the PBR, the NetScaler performs an action. If the packet does not match the condition defined by the PBR, the NetScaler compares the packet against the PBR with the next highest priority.

Instead of sending the selected packets to a next hop router, you can configure the PBR to send them to a link load balancing virtual server to which you have bound multiple next hops. This configuration can provide a backup if a next hop link fails.

Consider the following example. Two PBRs, p1 and p2, are configured on the NetScaler and automatically assigned priorities 20 and 30. You need to add a third PBR, p3, to be evaluated immediately after the first PBR, p1. The new PBR, p3, must have a priority between 20 and 30. In this case, you can specify the priority as 25.

## CLI procedures

To create a PBR by using the CLI:

At the command prompt, type:

- `add ns pbr <name> <action> [-srcIP [<operator>] <srcIPVal>] [-srcPort [<operator>] <srcPortVal>] [-destIP [<operator>] <destIPVal>] [-destPort [<operator>] <destPortVal>] [-nextHop <nextHopVal>] [-srcMac <mac_addr>] [-protocol <protocol> | -protocolNumber <positive_integer>] [-vlan <positive_integer>] [-interface <interface_name>] [-priority <positive_integer>] [-msr ( ENABLED | DISABLED )] [-monitor <string>]] [-state ( ENABLED | DISABLED )]`
- `show ns pbr`

### Example:

```
1 > add ns pbr pbr1 allow -srcip 10.102.37.252 -destip 10.10.10.2 -
 nexthop 10.102.29.77
2 Done
3 <!--NeedCopy-->
```

To modify the priority of a PBR by using the CLI:

At the command prompt, type the following commands to modify the priority and verify the configuration:

- `set ns pbr <name> [-action ( ALLOW | DENY )] [-srcIP [<operator>] <srcIPVal>] [-srcPort [<operator>] <srcPortVal>] [-destIP [<operator>] <destIPVal>] [-destPort [<operator>] <destPortVal>] [-nextHop <nextHopVal>] [-srcMac <mac_addr>] [-protocol <protocol> | -protocolNumber <positive_integer>] [-vlan <positive_integer>] [-interface <interface_name>] [-priority <positive_integer>] [-msr ( ENABLED | DISABLED )] [-monitor <string>]] [-state ( ENABLED | DISABLED )]`
- `show ns pbr [<name>]`

### Example:

```
1 > set ns pbr pbr1 -priority 23
2 Done
3 <!--NeedCopy-->
```

To remove one or all PBRs by using the CLI:

At the command prompt, type one of the following commands:

- `rm ns pbr <name>`
- `clear ns pbrs`

### Example:

```
1 > rm ns pbr pbr1
2 Done
3
4 > clear ns PBRs
5 Done
6 <!--NeedCopy-->
```

## GUI procedures

To create a PBR by using the GUI:

Navigate to System > Network > PBRs, on the PBRs tab, add a new PBR, or edit an existing PBR.

To remove one or all PBRs by using the GUI:

Navigate to System > Network > PBRs, on the PBRs tab, delete the PBR.

## Applying a PBR

You must apply a PBR to activate it. The following procedure reapplies all PBRs that you have not disabled. The PBRs constitute a memory tree (lookup table). For example, if you create 10 PBRs (p1 - p10), and then you create another PBR (p11) and apply it, all of the PBRs (p1 - p11) are freshly applied and a new lookup table is created. If a session has a DENY PBR related to it, the session is destroyed.

You must apply this procedure after every modification you make to any PBR. For example, you must follow this procedure after disabling a PBR.

**Note:** PBRs created on the NetScaler appliance do not work until they are applied.

To apply a PBR by using the CLI:

At the command prompt, type:

```
apply ns PBRs
```

To apply a PBR by using the GUI:

1. Navigate to System > Network > PBRs.
2. On the PBRs tab, select the PBR, in the Action list, select Apply.

## Enabling or Disabling PBRs

By default, the PBRs are enabled. This means that when PBRs are applied, the NetScaler appliance automatically compares incoming packets against the configured PBRs. If a PBR is not required in the lookup table, but it needs to be retained in the configuration, it must be disabled before the PBRs

are applied. After the PBRs are applied, the NetScaler does not compare incoming packets against disabled PBRs.

To enable or disable a PBR by using the CLI:

At the command prompt, type one of the following commands:

- `enable ns pbr <name>`
- `disable ns pbr <name>`

**Example:**

```
1 > enable ns PBR pbr1
2 Done
3 > show ns PBR pbr1
4 1) Name: pbr1
5 Action: ALLOW Hits: 0
6 srcIP = 10.102.37.252
7 destIP = 10.10.10.2
8 srcMac: Protocol:
9 Vlan: Interface:
10 Active Status: ENABLED Applied Status: APPLIED
11 Priority: 10
12 NextHop: 10.102.29.77
13
14 Done
15
16 > disable ns PBR pbr1
17 Warning: PBR modified, use 'apply pbrs' to commit this operation
18
19 > apply pbrs
20 Done
21
22 > show ns PBR pbr1
23 1) Name: pbr1
24 Action: ALLOW Hits: 0
25 srcIP = 10.102.37.252
26 destIP = 10.10.10.2
27 srcMac: Protocol:
28 Vlan: Interface:
29 Active Status: DISABLED Applied Status:
30 NOTAPPLIED
31 Priority: 10
32 NextHop: 10.102.29.77
33 Done
34 <!--NeedCopy-->
```

To enable or disable a PBR by using the GUI:

1. Navigate to System > Network > PBRs.
2. On the PBRs tab, select the PBR, in the Action list, select Enable or Disable.

## Renumbering PBRs

You can automatically renumber the PBRs to set their priorities to multiples of 10.

To renumber PBRs by using the CLI:

At the command prompt, type:

- `renumber ns pbrs`

To renumber PBRs by using the GUI:

Navigate to System > Network > PBRs, on the PBRs tab, in the Action list, select Renumber Priority (s).

## Use Case - PBR with Multiple Hops

Consider a scenario in which two PBRs, PBR1 and PBR2, are configured on NetScaler appliance NS1. PBR1 routes all the outgoing packets, with source IP address as 10.102.29.30, to next hop router R1. PBR2 routes all the outgoing packets, with source IP address as 10.102.29.90, to next hop router R2. R3 is another next hop router connected to NS1.

If router R1 fails, all the outgoing packets that matched against PBR1 are dropped. To avoid this situation, you can specify a link load balancing (LLB) virtual server in the next hop field while creating or modifying a PBR. Multiple next hops are bound to the LLB virtual server as services (for example R1, R2, and R3). Now, if R1 fails, all the packets that matched against PBR1 are routed to R2 or R3 as determined by the LB method configured on the LLB virtual server.

The NetScaler appliance throws an error if you attempt to create a PBR with an LLB virtual server as the next hop in the following cases:

- Adding another PBR with the same LLB virtual server.
- Specifying a nonexistent LLB virtual server.
- Specifying an LLB virtual server for which the bound services are not next hops.
- Specifying an LLB virtual server for which the LB method is not set to one of the following:
  - ROUNDROBIN
  - DESTINATIONIPHASH
  - SOURCEIPHASH
  - SRCIPDESTIPHASH
  - LEASTPACKETS
  - LEASTBANDWIDTH
  - LTRM
  - CALLIDHASH
  - CUSTOM LOAD

- Specifying an LLB virtual server for which the LB persistence type is not set to one of the following:
  - DESTIP
  - SOURCEIP
  - SRCDSTIP

The following table lists the names and values of the entities configured on the NetScaler appliance:

Entity Type	Name	IP Address
Link load balancing virtual server	LLB1	NA
Services (next hops)	Router1	1.1.1.254
	Router2	2.2.2.254
	Router3	3.3.3.254
PBRs	PBR1	NA
	PBR2	NA

Table 1. Sample Values for Creating Entities

To implement the configuration described above, you need to:

1. Create services Router1, Router2, and Router3 that represent next hop routers R1, R2, and R3.
2. Create link load balancing virtual server LLB1 and bind services Router1, Router2, and Router3 to it.
3. Create PBRs PBR1 and PBR2, with next hop fields set as LLB1 and 2.2.2.254 (IP address of the router R2), respectively.

To create a service by using the CLI:

At the command prompt, type:

- add service <name> <IP> <serviceType> <port>
- show service <name>

**Example:**

```

1 > add service Router1 1.1.1.254 ANY *
2 Done
3 > add service Router2 2.2.2.254 ANY *
4 Done
5 > add service Router3 3.3.3.254 ANY *
6 Done
7 <!--NeedCopy-->
```

To create a service by using the GUI:

Navigate to Traffic Management > Load Balancing > Services, and create a service.

To create a link load balancing virtual server and bind a service by using the CLI:

At the command prompt, type:

- add lb vserver <name> <serviceType>
- bind lb vserver < name> <serviceName>
- show lb vserver < name>

**Example:**

```
1 > add lb vserver LLB1 ANY
2 Done
3 > bind lb vserver LLB1 Router1 Router2 Router3
4 Done
5 <!--NeedCopy-->
```

To create a link load balancing virtual server and bind a service by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and create a virtual server for link load balancing. Specify **ANY** in the **Protocol** field.

Note: Make sure that

**Directly Addressable** is unchecked.

2. Under the **Services** tab, in the **Active** column, select the check box for the service that you want to bind to the virtual server.

To create a PBR by using the CLI:

At the command prompt, type:

- add ns pbr <name> <action> [-srcIP [<operator>] <srcIPVal>] [-nextHop <nextHopVal>]
- show ns pbr

**Example:**

```
1 > add pbr PBR1 ALLOW -srcIP 10.102.29.30 -nextHop LLB1
2 Done
3 > add pbr PBR2 ALLOW -srcIP 10.102.29.90 -nextHop 2.2.2.254
4 Done
5 <!--NeedCopy-->
```

To create a PBR by using the GUI:

Navigate to System > Network > PBRs, on the PBRs tab, add a new PBR.

## Policy-Based Routes (PBR6) for IPv6 Traffic

May 2, 2023

Configuring PBR6s involves the following tasks:

- Create a PBR6.
- Apply PBR6s.
- (Optional) Disable or enable a PBR6.
- (Optional) Renumber the priority of the PBR6.

### Creating or Modifying a PBR6

You cannot create two PBR6s with the same parameters. If you attempt to create a duplicate, an error message appears.

You can configure the priority of a PBR6. The priority (an integer value) defines the order in which the NetScaler appliance evaluates PBR6s. When you create a PBR6 without specifying a priority, the NetScaler automatically assigns a priority that is a multiple of 10.

If a packet matches the condition defined by the PBR6, the NetScaler performs an action. If the packet does not match the condition defined by the PBR6, the NetScaler compares the packet against the PBR6 with the next highest priority.

### CLI procedures

To create a PBR6 by using the CLI:

At the command prompt, type:

- **\*\*add ns pbr6\*\*** <name> <action> [-srcIPv6 [<operator>] <srcIPv6Val>] [-srcPort [<operator>] <srcPortVal>] [-destIPv6 [<operator>] <destIPv6Val>] [-destPort [<operator>] <destPortVal>] [-srcMac <mac\_addr>] [-protocol <protocol> | -protocolNumber <positive\_integer>] [-vlan <positive\_integer>] [-interface <interface\_name>] [-priority <positive\_integer>] [-state ( ENABLED | DISABLED )] [-msr ( ENABLED | DISABLED )] [-monitor <string>]] [-nextHop <nextHopVal>] [-nextHopVlan <positive\_integer>]
- **show ns pbr**

To modify or remove a PBR6 by using the CLI:

To modify a PBR6, type the **set pbr6** <name> command and the parameters to be changed, with their new values.

To remove one or all PBR6s by using the CLI:

At the command prompt, type one of the following commands:

- **rm ns pbr6** <name>
- **clear ns pbr6**

### GUI procedures

To create or modify a PBR6 by using the GUI:

Navigate to System > Network > PBRs and, on the PBR6s tab, add a new PBR6, or edit an existing PBR6.

To remove one or all PBR6s by using the GUI:

Navigate to System > Network > PBRs and, on the PBR6s tab, delete the PBR6.

### Applying PBR6s

You must apply a PBR6 to activate it. The following procedure reapplies all PBR6s that you have not disabled. The PBR6s constitute a memory tree (lookup table). For example, if you create 10 PBR6s (p6\_1 - p6\_10), and then you create another PBR6 (p6\_11) and apply it, all of the PBR6s (p6\_1 - p6\_11) are freshly applied and a new lookup table is created. If a session has a DENY PBR6 related to it, the session is destroyed.

You must apply this procedure after every modification you make to any PBR6. For example, you must follow this procedure after disabling a PBR6.

**Note:** PBR6s created on the NetScaler appliance do not work until they are applied.

To apply PBR6s by using the CLI:

At the command prompt, type:

- **apply ns PBR6**

To apply PBR6s by using the GUI:

1. Navigate to System > Network > PBRs.
2. On the PBR6s tab, select the PBR6, in the Action list, select Apply.

### Enabling or Disabling a PBR6

By default, the PBR6s are enabled. This means that when PBR6s are applied, the NetScaler appliance automatically compares outgoing IPv6 packets against the configured PBR6s. If a PBR6 is not required

in the lookup table, but it needs to be retained in the configuration, it must be disabled before the PBR6s are applied. After the PBR6s are applied, the NetScaler does not compare incoming packets against disabled PBR6s.

To enable or disable a PBR6 by using the CLI:

At the command prompt, type one of the following commands:

- **enable ns pbr** <name>
- **disable ns pbr** <name>

To enable or disable a PBR6 by using the GUI:

1. Navigate to System > Network > PBRs.
2. On the PBR6s tab, select the PBR6, in the Action list, select Enable or Disable.

## Renumbering PBR6s

You can automatically renumber the PBR6s to set their priorities to multiples of 10.

To renumber PBR6s by using the CLI:

At the command prompt, type:

- **renumber ns pbr6**

To renumber PBR6s by using the GUI:

Navigate to System > Network > PBRs, on the PBR6s tab, in the Action list, select Renumber Priority (s).

## MAC Address Wildcard Mask for PBRs

September 21, 2020

A wildcard mask parameter has been introduced for extended PBRs and PBR6s and is used with the source MAC address parameter to define a range of MAC addresses to be match against the source MAC address of outgoing packets.

Wild card masks specify which hexadecimal digits of the MAC address are used and which hexadecimal digits are ignored. The wildcard mask parameter specifies a series of ones and zeroes and has a length of 12 digits. Each digit is a mask for the corresponding hexadecimal digit of the MAC address. A zero digit in the wildcard mask indicates that the corresponding hexadecimal digit of the MAC address must be considered and a one digit indicates that the corresponding hexadecimal digit to be ignored.

The wildcard mask should meet the following conditions:

- Has only one series of zeroes
- Has only one series of ones
- Start with a series of zeroes

The following are some of the examples of valid wildcard masks:

- 000000111111
- 000000011111
- 000011111111

The following are some of the examples of invalid wildcard masks:

- 000000111100
- 111110000000
- 010101010101

For an PBR rule, a wildcard mask of 000000111111 for MAC address 96:fa:95:1d:67:4a defines the MAC address range 96:FA:95:00:00:00 - 96:FA:95:FF:FF:FF. This MAC address range is matched against the source MAC address of the outgoing packets.

To specify a range of source MAC addresses in a PBR rule by using the CLI:

At the command prompt, type:

- **add ns pbr** <name> <action> **-srcMac** <mac\_addr> **-srcMacMask** <string>
- **show ns pbr** <pbrname>

**Example:**

```
1 > add ns pbr PBR-1 ALLOW -srcip 192.0.2.34 -srcMac 96:fa:95:1d:67:4a
 - srcMacMask 000000111111 -nextHop 198.51.100.1
2
3 Done
```

To specify a range of source MAC addresses in an PBR6 rule by using the CLI:

At the command prompt, type:

- **add ns pbr6** <name> <action> **-srcMac** <mac\_addr> **-srcMacMask** <string>
- **show pbr6** <pbr6name>

**Example:**

```
1 > add ns pbr6 PBR6-1 ALLOW -srcipV6 2001:db8:0::7 -srcMac 96:fa:95:1d
 :67:4a - srcMacMask 000000001111 -nextHop 2001:db8:0::1
2 Done
```

## Using NULL Policy Based Routes to Drop Outgoing Packets

May 2, 2023

Some situations might demand that the NetScaler appliance drops specific outgoing packets instead of routing them, for example, in testing cases and during deployment migration.

NULL policy based routes can be used to drop specific outgoing packets. A NULL PBR is a type of PBR that has the nexthop parameter set to NULL. The NetScaler appliance drops outgoing packets that match a NULL PBR.

### Configuring NULL PBRs for IPv4 Packets

To create a NULL PBR by using the CLI:

At the command prompt, type:

- `add ns pbr <name> ALLOW [-td <positive_integer>] [-srcIP [<operator>] <srcIPVal>] [-srcPort [<operator>] <srcPortVal>] [-destIP [<operator>] <destIPVal>] [-destPort [<operator>] <destPortVal>] (-nextHop NULL) [-srcMac <mac_addr> [-srcMacMask <string>]] [-protocol <protocol> | -protocolNumber <positive_integer>] [-vlan <positive_integer> | -vxlan <positive_integer>] [-interface <interface_name>] [-priority <positive_integer>] [-msr ( ENABLED | DISABLED )] [-monitor <string>]] [-state ( ENABLED | DISABLED )][-ownerGroup <string>]`
- **apply ns pbrs**
- **show ns pbr**<id>

To configure a NULL PBR by using the GUI:

Navigate to **System > Network > PBRs**, on the **PBRs** tab, add a **new NULL PBR**, or edit an existing NULL PBR.

### Sample configuration

In the following sample configuration, NULL PBR6 PBR6-NULL-EXAMPLE-1 is configured for dropping any outgoing IPv6 packets from interface 1/5.

```

1 > add ns pbr PBR6-NULL-EXAMPLE-1 ALLOW - nextHop NULL -interface 1/5
2 Done
3
4 > apply ns pbr6
5 Done

```

## Traffic distribution in multiple routes based on five tuples information

May 2, 2023

In a load balancing setup, a NetScaler appliance can have multiple routes to send a packet to its destination. For example: to a server, and to a client.

A NetScaler appliance uses a hashing algorithm to select a route for sending the packet to its destination.

The hashing algorithm uses the following two tuples of a packet to calculate a hash, based on which the NetScaler appliance selects a route for the packet.

- Source IP address
- Destination IP address

The selection of routes based on two tuples information can cause an uneven distribution of traffic on the available routes. This uneven distribution of traffic leads to overloading of traffic in some routes.

To resolve this issue, from build 13.0 71.x, the NetScaler appliance uses the following five tuples information of a packet in the hashing algorithm to select a route for the packet:

- Source IP address (Client IP)
- Source Port (Client Port)
- Destination IP address (Service IP)
- Destination Port (Service Port)
- Protocol number

The selection of routes based on five tuples information ensures even distribution of traffic on the available routes. This even distribution of traffic prevents overloading of traffic in a route.

Consider an example of a load balancing setup where a client sends a request to the VIP address. The NetScaler appliance uses the following five tuples information to select a route to send the request packet to the load balanced server:

- Source IP address (Client IP address)
- Source Port (Client port)
- Destination IP address (Service IP address)
- Destination Port (Service port number)
- Protocol Number

If use source IP (USIP) mode is enabled, then all five tuples are considered as the input of hash to select a route. If use subnet IP (USNIP) mode is enabled, both SNIP and Source Port are not considered as the input because they are selected after route selection. For information on how to configure USIP and USNIP mode, see [Enable Use Source IP Mode](#) and [Configuring Subnet IP Addresses \(SNIPs\)](#).

**Note:**

From build 13.1 30.x, the NetScaler appliance uses the five tuples hashing algorithm instead of the two tuples hashing algorithm to select a route for load balancing monitor probes.

## **Precedence regarding other route selection based NetScaler features**

This section talks about the precedence of the route selection based on five tuples feature and other route selection related features in a NetScaler appliance.

- **Policy Based Routes (PBR).** PBR rules always take precedence over route selection based on five tuples.
- **Mac Based Forwarding (MBF).** In a load balancing configuration, MBF or route selection based on five tuples takes precedence in the following cases:
  - For a client initiated traffic to the VIP address of the load balancing configuration in the NetScaler appliance:
    - \* Request traffic destined to a load balanced server. Route selection based on five tuples takes preference over MBF.
    - \* Response Traffic destined to the client. MBF takes preference over route selection based on five tuples.
  - For a server initiated traffic to the SNIP address in the NetScaler appliance:
    - \* Response Traffic destined to the client. Route selection based on five tuples takes preference over MBF.
    - \* Request traffic destined to a load balanced server. MBF takes preference over route selection based on five tuples.

## **Troubleshooting Routing Issues**

May 2, 2023

To make your troubleshooting process as efficient as possible, begin by gathering information about your network. You need to obtain the following information about the NetScaler appliance and other systems in the Network:

- Complete Topology diagram, including interface connectivity and intermediate switch details.
- Running Configuration. You can use the show running command to get the running configuration for ns.conf and ZebOS.conf.

- Output of the History command, to determine whether any configuration changes were made when the issue arose.
- Output of the Top and ps -ax commands, to determine whether any routing daemon is over utilizing the CPU or is misbehaving.
- Any routing related core files in /var/core - nsm, bgpd, ospfd, or ripd. Check the time stamp to see if they are relevant.
- dr\_error.log and dr\_info.log files from /var/log.
- Output of the date command and time details for all relevant systems. Print dates across all devices one after another, so that the times on the log messages can be correlated with various events.
- Relevant ns.log, newslog files.
- Configuration files, log files and command history details from upstream and downstream routers.

## Generic Routing FAQs

September 21, 2020

Users typically have the following questions about how to troubleshoot generic routing issues:

- How do I save the config files?

The write command from VTYSH saves only ZebOS.conf. Run the save ns config command from CLI to save both ns.conf and ZebOS.conf files.

- If I have configured both a static default route and a dynamically learned default route, which is the preferred default route?

The dynamically learned route is the preferred default route. This behavior is unique to default routes. However, in case of the Network Services Module (NSM), unless the administrative distances are modified, a statically configured route in the RIB is preferred over a dynamic route. The route that is downloaded to the NSM FIB is the static route.

- How do I block the advertisement of default routes?

The default route is not injected into ZebOS.

- How do I view the debug output of networking daemons?

You can write debugging output from networking daemons to a file by entering the following log file command from the global configuration view in VTYSH:

```
1 ns(config)# log file /var/ZebOS.log
2 <!--NeedCopy-->
```

You can direct debug output to the console by entering the terminal monitor command from VTYS user view:

```
1 ns# terminal monitor
2 <!--NeedCopy-->
```

- How do I collect cores of running daemons?

You can use the `gcore` utility to collect cores of running daemons for processing by `gdb`. This might be helpful in debugging misbehaving daemons without bringing the whole routing operation to a standstill.

```
1 gcore [-s] [-c core] [executable] pid
2 <!--NeedCopy-->
```

The `-s` option temporarily stops the daemon while gathering the core image. This is a recommended option, because it guarantees that the resulting image shows the core in a consistent state.

```
1 root@ns#gcore -s -c nsm.core /netscaler/nsm 342
2 <!--NeedCopy-->
```

- How do I run a batch of ZebOS commands?

You can run a batch of ZebOS commands from a file by entering the VTYS `-f <file-name>` command. This does not replace the running configuration, but appends to it. However, by including commands to delete the existing configuration in the batch file and then add those for the new, desired configuration, you can use this mechanism to replace a specific configuration:

```
1 !
2 router bgp 234
3 network 1.1.1.1 255.255.255.0
4 !
5 route-map bgp-out2 permit 10
6 set metric 9900
7 set community 8602:300
8 !
9 <!--NeedCopy-->
```

## Troubleshooting OSPF-Specific Issues

May 2, 2023

Before you start debugging any OSPF specific issue, you must collect information from the NetScaler appliance and all systems in the affected LAN, including upstream and downstream routers. To begin, enter the following commands:

1. show interface from both nscli and VTYSH
2. show ip ospf interface
3. show ip ospf neighbor detail
4. show ip route
5. show ip ospf route
6. show ip ospf database summary
  - If there are only few LSAs in the database, then enter show ip ospf database router, show ip ospf database A. network, show ip ospf database external, and other commands to get the full details of LSAs.
  - If there are a large number of LSAs in the database, enter the show ip ospf database self-originated command.
7. show ip ospf
8. show ns ip. This ensures that the details of all VIPs of interest are included.
9. Get the logs from peering devices and run the following command:

```
1 gcore -s -c xyz.core /netscaler/ospfd <pid>
```

**Note:** The gcore command is non-disruptive.

Collect additional information from the NetScaler as follows:

1. Enable logging of error messages by entering the following command from the global configuration view in VTYSH:

```
1 ns(config)# log file /var/ospf.log
2 <!--NeedCopy-->
```

2. Enable debugging ospf events and log them by using the following command:

```
1 ns(config) #log file /var/ospf.log
2 <!--NeedCopy-->
```

Enable debug ospf lsa packet only if the number of LSAs in the database is relatively small (< 500).

## Internet Protocol version 6 (IPv6)

May 2, 2023

A NetScaler appliance supports both server-side and client-side IPv6 and can therefore function as an IPv6 node. It can accept connections from IPv6 nodes (both hosts and routers) and from IPv4 nodes, and can perform Protocol Translation (RFC 2765) before sending traffic to the services.

The following table lists some of the IPv6 features that the NetScaler appliance supports.

Table 1. Some Supported IPv6 Features

---

#### IPv6 features

---

IPv6 addresses for SNIPs (NSIP6, VIP6, and SNIP6)

Neighbor Discovery (Address Resolution, Duplicated Address Detection, Neighbor Unreachability Detection, Router Discovery)

Management Applications (ping6, telnet6, ssh6)

Static Routing and Dynamic routing (OSPF, BGP, RIPng, and ISIS)

Port Based VLANs

Access Control Lists for IPv6 addresses (ACL6)

IPv6 Protocols (TCP6, UDP6, ICMP6)

Server Side Support (IPv6 addresses for vservers, services)

USIP (Use source IP) and DSR (Direct Server Return) for IPv6

SNMP and CVPN for IPv6

HA with native IPv6 node address

IPv6 addresses for MIPs

Path-MTU discovery for IPv6

---

## Implementing IPv6 Support

You must enable IPv6 feature on a NetScaler appliance before you can use or configure it. If IPv6 is disabled, the NetScaler does not process IPv6 packets. It displays the following warning when you run an unsupported command:

```
1 "Warning: Feature(s) not enabled [IPv6PT]"
2 <!--NeedCopy-->
```

Use either of the following procedures to enable or disable IPv6.

## CLI procedures

To enable or disable IPv6 by using the CLI:

At the command prompt, type one of the following commands:

- enable ns feature ipv6pt
- disable ns feature ipv6pt

## GUI procedures

To enable or disable IPv6 by using the GUI:

1. Navigate to **System > Settings**, in the **Modes and Features** group, click **Configure Advanced Features**.
2. Select or clear the **IPv6 Protocol Translation** option.

## VLAN Support

If you need to send broadcast or multicast packets without identifying the VLAN (for example, during DAD for NSIP, or ND6 for the next hop of the route), you can configure the NetScaler appliance to send the packet on all the interfaces with appropriate tagging. The VLAN is identified by ND6, and a data packet is sent only on the VLAN. For more information about ND6 and VLANs, see [Configuring Neighbor Discovery](#).

Port-based VLANs are common for IPv4 and IPv6. Prefix-based VLANs are supported for IPv6.

## Simple Deployment Scenario

Following is an example of a simple load balancing set-up consisting of an IPv6 vserver and IPv4 services, as illustrated in the following topology diagram.

Figure 1. IPv6 Sample Topology

The following table summarizes the names and values of the entities that must be configured on the NetScaler.

Table 2. Sample Values for Creating Entities

Entity type	Name	Value
LB Vserver	VS1_IPv6	2002::9
Services	SVC1	10.102.29.1
	SVC2	10.102.29.2

The following figure shows the entities and values of the parameters to be configured on the NetScaler.

Figure 2. IPv6 Entity Diagram

To configure this deployment scenario, you need to do the following:

1. Create an IPv6 service.
2. Create an IPv6 LB vserver.
3. Bind the services to the vserver.

### **CLI procedures**

To create IPv4 services by using the CLI:

At the command prompt, type:

- **add service** <Name> <IPAddress> <Protocol> <Port>
- **sh service** <Name>

**Example:**

```
1 > add service SVC1 10.102.29.1 HTTP 80
2 Done
3
4 >add service SVC2 10.102.29.2 HTTP 80
5 Done
6 <!--NeedCopy-->
```

To create IPv6 vserver by using the CLI:

At the command prompt, type:

- **add lb vserver** <Name> <IPAddress> <Protocol> <Port>
- **sh lb vserver** <Name>

**Example:**

```
1 > add lb vserver VS1_IPv6 2002:::9 HTTP 80
2 Done
3 <!--NeedCopy-->
```

To bind a service to an LB vserver by using the CLI:

At the command prompt, type:

- **bind lb vserver** <name> <service>
- **sh lb vserver** <name>

**Example:**

```
1 > bind lb vserver VS1_IPv6 SVC1
2 Done
3 <!--NeedCopy-->
```

## GUI procedures

To create IPv4 services by using the GUI:

Navigate to **Traffic Management > Load Balancing > Services**, click **Add**, and then set the following parameters:

- Service Name
- IP Address
- Protocol
- Port

To create IPv6 vserver by using the GUI:

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, click **Add**, and select the **IPv6** check box.
2. Set the following parameters:
  - Name
  - Protocol
  - IP Address Type
  - IP Address
  - Port

To bind a service to an LB vserver by using the GUI:

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the **Load Balancing Virtual Servers** page, select the vserver for which you want to bind the service (for example, VS1\_IPv6).
3. Click **Open**.
4. In the **Configure Virtual Server (Load Balancing)** dialog box, on the **Services** tab, select the **Active** check box corresponding to the service that you want to bind to the vserver (for example, SVC1).
5. Click **OK**.
6. Repeat steps 1-4 to bind the service (for example, SVC2 to the vserver).

## Host Header Modification

When an HTTP request has an IPv6 address in the host header, and the server does not understand the IPv6 address, you must map the IPv6 address to an IPv4 address. The IPv4 address is then used in the host header of the HTTP request sent to the vserver.

## CLI procedures

To change the IPv6 address in the host header to an IPv4 address by using the CLI:

At the command prompt, type:

- **set ns ip6** <IPv6Address> **-map** <IPAddress>
- **sh ns ip6** <IPv6Address>

### Example:

```
1 > set ns ip6 2002::9 -map 200.200.200.200
2 Done
3 <!--NeedCopy-->
```

## GUI procedures

To change the IPv6 address in the host header to an IPv4 address by using the GUI:

1. Navigate to **System > Network > IPs** and, on the **IPv6s** tab, select the IP address for which you want to configure a mapped IP address, for example, 2002:0:0:0:0:0:9, and click Edit.
2. In the **Mapped IP** text box, type the mapped IP address that you want to configure, for example, 200.200.200.200.

## VIP Insertion

If an IPv6 address is sent to an IPv4-based server, the server may not understand the IP address in the HTTP header, and may generate an error. To avoid this, you can map an IPv4 address to the IPv6 VIP. Then, you can enable VIP insertion to enable insertion of the IPv4 VIP address and port number in the HTTP requests sent to the servers.

## CLI procedures

To configure a map IPv6 address by using the CLI:

At the command prompt, type:

```
set ns ip6 <IPv6Address> -map <IPAddress>
```

### Example:

```
1 > set ns ip6 2002::9 -map 200.200.200.200
2 Done
3 <!--NeedCopy-->
```

To enable VIP insertion by using the CLI:

At the command prompt, type:

- **set lb vsrver** <name> **-insertVserverIPPort** <Value>
- **sh lb vsrver** <name>

### Example:

```
1 > set lb vsrver VS1_IPv6 -insertVserverIPPort ON
2 Done
3
4 <!--NeedCopy-->
```

## GUI procedures

To configure a map IPv6 address by using the GUI:

1. Navigate to **System > Network > IPs**, on the **IPV6s** tab, select the IP address for which you want to configure a map IP address, for example, 2002:0:0:0:0:0:9, and click **Edit**.
2. In the **Mapped IP** text box, type the map IP address that you want to configure, for example, 200.200.200.200.

To enable VIP insertion by using the GUI:

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, select the virtual server that you want to enable port insertion, and click **Edit**.
2. In the **Advanced** tab, under **Traffic Settings**, in the **Vserver IP Port Insertion** drop-down list box, select **VIPADDR**.
3. In the **Vserver IP Port Insertion** text box, type the vip header.

## Traffic Domains

May 2, 2023

### Warning

Citrix recommends you to use Admin Partitions instead of using Traffic Domains. For more information, see [Admin Partitioning](#) page.

Traffic domains are a way to segment network traffic for different applications. You can use traffic domains to create multiple isolated environments within a NetScaler appliance. An application belonging to a specific traffic domain communicates with entities and processes traffic within that domain. The traffic belonging to one traffic domain cannot cross the boundary of another traffic domain.

## Benefits of using Traffic Domains

The main benefits of using traffic domains on a NetScaler appliance are the following:

- **Use of duplicate IP addresses in a Network.** Traffic domains allow you to use duplicate IP address on the network. You can assign the same IP address or network address to multiple devices on a network, or multiple entities on a NetScaler appliance, as long as each of the duplicate address belongs to a different traffic domain.

- **Use of Duplicate entities on the NetScaler appliance.** Traffic domains also allow you to use duplicate NetScaler feature entities on the appliance. You can create entities with the same settings as long as each entity is assigned to a separate traffic domain.

Note: Duplicate entities with same name are not supported.

- **Multitenancy.** Using traffic domains, you can provide hosting services for multiple customers by isolating each customer's type of application traffic within a defined address space on the network.

A traffic domain is uniquely identified by an identifier, which is an integer value. Each traffic domain needs a VLAN or a set of VLANs. The isolation functionality of the traffic domain depends on the VLANs bound to the traffic domain. More than one VLAN can be bound to a traffic domain, but the same VLAN cannot be a part of multiple traffic domains. Therefore, the maximum number of traffic domains that can be created depends on the number of VLANS configured on the appliance.

## Default Traffic Domain

A NetScaler appliance has a preconfigured traffic domain, called the *default traffic domain*, which has an ID of 0. All factory settings and configurations are part of the default traffic domain. You can create other traffic domains and then segment traffic between the default traffic domain and each of the other traffic domains. You cannot remove the default traffic domain from the NetScaler appliance. Any feature entity that you create without setting the traffic domain ID is automatically associated with the default traffic domain.

**Note:** Some features and configurations are supported only in the default traffic domain. They do not work in nondefault traffic domains. For a list of the features supported in all traffic domains, see Supported NetScaler Features in Traffic Domains.

## How Traffic Domains Work

As an illustration of traffic domains, consider an example in which two traffic domains, with IDs 1 and 2, are configured on NetScaler appliance NS1.

In traffic domain 1, load balancing virtual server LBVS-TD1 is configured to load balance traffic across servers S1 and S2. On the NetScaler appliance, servers S1 and S2 are represented by services SVC1-TD1 and SVC2-TD1, respectively. Servers S1 and S2 are connected to NS1 through L2 switch SW2-TD1. Client CL-TD1 is on a private network connected to NS1 through L2 switch SW1-TD1. SW1-TD1 and SW2-TD1 are connected to VLAN 2 of NS1. VLAN 2 is bound to traffic domain 1, which means that client CL-TD1 and servers S1 and S2 are part of traffic domain 1.

Similarly in traffic domain 2, load balancing virtual server LBVS-TD2 is configured to load balance traffic across S3 and S4. On the NetScaler appliance, servers S3 and S4 are represented by services

SVC3-TD2 and SVC4-TD2, respectively. Servers S3 and S4 are connected to NS1 through L2 switch SW2-TD2. Client CL-TD2 is on a private network connected to NS1 through L2 switch SW1-TD2. SW1-TD2 and SW2-TD2 are connected to VLAN 3 of NS1. VLAN 3 is bound to traffic domain 2, which means that client CL-TD2 and servers S3 and S4 are part of traffic domain 2.

On the NetScaler appliance, entities LBVS-TD1 and LBVS-TD2 share the same settings, including the IP address. The same is true for SVC1-TD1 and SVC3-TD2, and for SVC2-TD1 and SVC4-TD2. This is possible because these entities are in different traffic domains.

Similarly, servers S1 and S3, S2 and S4 share the same IP address, and clients CL-TD1 and CL-TD2 each have the same IP address.

Figure 1. How traffic domains work

The following table lists the settings used in the example.

Entity	Name	Details
<b>Settings in traffic domain 1</b>		
VLANs bound to traffic domain 1	VLAN 2	VLAN Id: 2 Interfaces bound: 1/1, 1/2
Client connected to TD1	CL-TD1 (for reference purposes only)	IP address: 192.0.2.3
Load balancing virtual server in TD1	LBVS-TD1	IP address: 192.0.2.27

Entity	Name	Details
Service bound to virtual server LBVS-TD1	SVC1-TD1	IP address: 192.0.2.36
Service bound to virtual server LBVS-TD1	SVC2-TD1	IP address: 192.0.2.37
SNIP	SNIP-TD1 (for reference purposes only)	IP address: 192.0.2.27
<b>Settings in traffic domain 2</b>		
VLAN bound to traffic domain 2	VLAN 3	VLAN Id: 3 Interfaces bound: 1/3, 1/4
Client connected to TD2	CL-TD2 (for reference purposes only)	IP address: 192.0.2.3
Load balancing virtual server in TD2	LBVS-TD2	IP address: 192.0.2.27
Service bound to virtual server LBVS-TD2	SVC3-TD2	IP address: 192.0.2.36
Service bound to virtual server LBVS-TD2	SVC4-TD2	IP address: 192.0.2.37
SNIP in TD2	SNIP-TD2 (for reference purposes only)	IP address: 192.0.2.29

Following is the traffic flow in traffic domain 1:

1. Client CL-TD1 broadcasts an ARP request for the IP address of 192.0.2.27 through L2 switch SW1-TD1.
2. The ARP request reaches NS1 on interface 1/1, which is bound to VLAN 2. Because VLAN 2 is bound to traffic domain 1, NS1 updates the ARP table of traffic domain 1 for the IP address of client CL-TD1.
3. Because the ARP request is received on traffic domain 1, NS1 looks for an entity configured on traffic domain 1 that has an IP address of 192.0.2.27. NS1 finds that a load balancing virtual server LBVS-TD1 is configured on traffic domain 1 and has the IP address 192.0.2.27.
4. NS1 sends an ARP response with the MAC address of interface 1/1.
5. The ARP reply reaches CL-TD1. CL-TD1 updates its ARP table for the IP address of LBVS-TD1 with the MAC address of interface 1/1 of NS1.
6. Client CL-TD1 sends a request to 192.0.2.27. The request is received by LBVS-TD1 on port 1/1 of NS1.
7. LBVS-TD1's load balancing algorithm selects server S2, and NS1 opens a connection between a SNIP in traffic domain 1 (192.0.2.27) and S2.
8. S2 replies to SNIP 192.0.2.27 on NS1.

9. NS1 sends S2's reply to client CL-TD1.

Following is the traffic flow in traffic domain 2:

1. Client CL-TD2 broadcasts an ARP request for the IP address of 192.0.2.27 through L2 switch SW1-TD2.
2. The ARP request reaches NS1 on interface 1/3, which is bound to VLAN 3. Because VLAN 3 is bound to traffic domain 2, NS1 updates traffic-domain 2's ARP-table entry for the IP address of client CL-TD2, even though an ARP entry for the same IP address (CL-TD1) is already present in the ARP table of traffic domain 1.
3. Because the ARP request is received in traffic domain 2, NS1 searches traffic domain 2 for an entity that has an IP address of 192.0.2.27. NS1 finds that load balancing virtual server LBVS-TD2 is configured in traffic domain 2 and has the IP address 192.0.2.27. NS1 ignores LBVS-TD1 in traffic domain 1, even though it has the same IP address as LBVS-TD2.
4. NS1 sends an ARP response with the MAC address of interface 1/3.
5. The ARP reply reaches CL-TD2. CL-TD2 updates its ARP table entry for the IP address of LBVS-TD2 with the MAC address of interface 1/3 of NS1.
6. Client CL-TD2 sends a request to 192.0.2.27. The request is received by LBVS-TD2 on interface 1/3 of NS1.
7. LBVS-TD2's load balancing algorithm selects server S3, and NS1 opens a connection between a SNIP in traffic domain 2 (192.0.2.29) and S3.
8. S2 replies to SNIP 192.0.2.29 on NS1.
9. NS1 sends S2's reply to client CL-TD2.

## Supported NetScaler Features in Traffic Domains

The NetScaler features in the following list are supported in all traffic domains.

### Important

Any NetScaler feature not listed below is supported only in the default traffic domain.

- ARP table
- ND6 table
- Bridge table
- All types of IPv4 and IPv6 addresses
- IPv4 and IPv6 routes
- ACL and ACL6
- PBR & PBR6
- INAT
- RNAT
- RNAT6

- MSR
- MSR6
- Net profiles
- SNMP MIBs
- Fragmentation
- Monitors (Scriptable monitors are not supported)
- Content Switching
- Cache Redirection
- Persistency (Persistency groups are not supported)
- Service (Domain based services are not supported)
- Service group (Domain based service groups are not supported)
- Policies (\*)
- PING
- TRACEROUTE
- PMTU
- High Availability (connection mirroring is not supported)
- Cluster (Supported on L2 clusters. Not supported on L3 clusters)
- Cookie Persistency
- MSS
- Logging (Syslog is not supported)
- Surge Protection
- Load balancing (The following types are not supported:)
  - TFTP
  - RTSP
  - Diameter
  - SIP
  - SMPP
- NAT46
- NAT64
- DNS64
- Forwarding Session Rules
- SNMP

**Note**

- \* Policies do not have global binding points for traffic domains. However, policies can be bound to a specific load balancing virtual server of a traffic domain.
- Global Server Loading Balancing (GSLB) and ADNS features in NetScaler are not aware of Traffic Domains. If the GSLB configuration needs to be shared across all traffic domains then

GSLB methods Static Proximity and Round Trip Time (RTT) do not work. As a workaround in this scenario you can use GSLB methods other than RTT and Static Proximity. For more information, see <http://support.citrix.com/article/CTX202277>.

## Configuring Traffic Domains

Configuring a traffic domain on the NetScaler appliance consists of the following tasks:

- **Add VLANs.** Create VLANs and bind specified interfaces to them.
- **Create a traffic domain entity and bind VLANs to it.** This involves the following two tasks:
  - Create a traffic domain entity uniquely identified by an ID, which is an integer value.
  - Bind the specified VLANs to the traffic domain entity. All the interfaces that are bound to the specified VLANs are associated with the traffic domain. More than one VLAN can be bound to a traffic domain, but a VLAN cannot be a part of multiple traffic domains.
- **Create feature entities on the traffic domain.** Create the required feature entities in the traffic domain. The CLI commands and configuration dialog boxes of all the supported features in a nondefault traffic domain include a parameter called a *traffic domain identifier* (td). When configuring a feature entity, if you want the entity to be associated with a particular traffic domain, you must specify the td. Any feature entity that you create without setting the td is automatically associated with the default traffic domain.

To give you an idea of how feature entities are associated with a traffic domain, this topic covers the procedures for configuring all the entities mentioned in the figure titled How Traffic Domains Work.

The CLI has two commands for these two tasks, but the GUI combines them in a single dialog box.

### CLI procedures

To create a VLAN and bind interfaces to it by using the CLI:

At the command prompt, type:

- **add vlan** <id>
- **bind vlan** <id> -ifnum <slot/port>
- **show vlan** <id>

To create a traffic domain entity and bind VLANs to it by using the CLI:

At the command prompt, type:

- **add ns trafficdomain** <td>
- **bind ns trafficdomain** <td> -vlan <id>

- **show ns trafficdomain** <td>

To create a service by using the CLI:

At the command prompt, type:

- **add service** <name> <IP> <serviceType> <port> **-td** <id>
- **show service** <name>

To create a load balancing virtual server and bind services to it by using the CLI:

At the command prompt, type:

- **add lb vserver** <name> <serviceType> <IPAddress> <port> **-td** <id>
- **bind lb vserver** <name> <serviceName>
- **show lb vserver** <name>

## GUI procedures

To create a VLAN by using the GUI:

Navigate to **System > Network > VLANs**, click **Add**, and set the parameters.

To create a traffic domain entity by using the GUI:

Navigate to **System > Network > Traffic Domains**, click **Add**, and in the **Create Traffic Domain** dialog box, set the parameters.

To create a service by using the GUI:

Navigate to **Traffic Management > Load Balancing > Services**, click **Add**, and set the parameters.

To create a load balancing virtual server by using the GUI:

Navigate to **Traffic Management > Load Balancing > Virtual Servers**, click **Add**, and set the parameters.

## Inter Traffic Domain Entity Bindings

May 2, 2023

You can bind services in one traffic domain to a virtual server in another traffic domain. All the services to be bound to a virtual server in a different traffic domain must reside in the same traffic domain.

You configure this support by using the existing bind lb vserver command or the related GUI procedure.

This capability can facilitate interaction between different traffic domains. In an enterprise, servers can be grouped in different traffic domains. Virtual servers are created in a traffic domain that faces the internet. A virtual server from this traffic domain can be configured to load balance servers in another traffic domain. This virtual server receives connection requests from the Internet to be forwarded to the bound servers.

When a NetScaler is used in a cloud infrastructure, each tenant can be assigned a separate traffic domain, and all the resources (including servers) for a tenant can be grouped together in the tenant's traffic domain. For each tenant, a virtual server is created for load balancing servers in its traffic domain. All of these virtual servers are grouped together in a single traffic domain that faces the Internet.

Consider an example of in which cloud service provider Example-Cloud-A has three traffic domains, with IDs 10, 20, and 30, configured on NetScaler appliance NS1.

Example-Org-A and Example-Org-B are tenants of Example-Cloud-A. Tenant A is assigned traffic domain 20, and tenant B is assigned domain 30. Servers S1 and S2 reside in traffic domain 20 and servers S3 and S4 reside in traffic domain 30.

Traffic domain 10 faces the internet. Virtual servers LBVS-1 and LBVS-2 are created in traffic domain 10. LBVS-1, in traffic domain 10, is configured to load balance servers S1 and S2, which are in traffic domain 20. LBVS-2, in traffic domain 10, is configured to load balance servers S3 and S4, which are in traffic domain 30.

Therefore, these virtual servers accept Internet connection requests for servers that are in a different traffic domain than that of the virtual servers.

## virtual MAC Based Traffic Domains

May 2, 2023

You can associate a traffic domain with a virtual MAC address instead of with VLANs. The NetScaler then sends the traffic domain's virtual MAC address in all responses to ARP queries for network entities in that domain. As a result, the ADC can segregate subsequent incoming traffic for different traffic domains on the basis of the destination MAC address, because the destination MAC address is the virtual MAC address of a traffic domain. After creating entities on a traffic domain, you can easily manage and monitor them by performing traffic domain level operations.

Consider an example in which two traffic domains, with IDs 1 and 2, are configured on NetScaler appliance NS1. The NetScaler creates a virtual MAC address virtual MAC1 and associates it with traffic domain 1. Similarly, the NetScaler created another virtual MAC address virtual MAC2 and associates with traffic domain 2.

In traffic domain 1, load balancing virtual server LBVS-TD1 is configured to load balance traffic across servers S1 and S2. On the NetScaler appliance, servers S1 and S2 are represented by services SVC1-TD1 and SVC2-TD1, respectively. A subnet IP address (SNIP) SNIP1 is configured for enabling the NetScaler to communicate with S1 and S2. Because virtual MAC1 is associated with traffic domain 1, the appliance sends virtual MAC1 as the MAC address in all ARP announcements and ARP responses for LBVS-TD1 and SNIP1.

Similarly in traffic domain 2, load balancing virtual server LBVS-TD2 is configured to load balance traffic across S3 and S4. On the NetScaler appliance, servers S3 and S4 are represented by services SVC3-TD2 and SVC4-TD2, respectively. A SNIP address SNIP2 is configured for enabling the NetScaler to communicate with S3 and S4. Because virtual MAC2 is associated with traffic domain 2, the appliance sends virtual MAC2 as the MAC address in all ARP announcements and ARP responses for LBVS-TD2 and SNIP2.

The NetScaler segregate subsequent incoming traffic for traffic domains 1 or 2 on the basis of the destination MAC address, if the destination MAC address is virtual MAC1 or virtual MAC2.

The following table lists the settings used in the example: [Virtual MAC based traffic domain example settings](#).

## Before you Begin

Following are points to consider before you configure virtual MAC based traffic domain:

1. virtual MAC based traffic domains are easiest way to achieve network traffic segregation.
2. Because virtual MAC based traffic domains segregate network traffic based on virtual MAC addresses and not VLANS, you cannot create duplicate IP addresses on different virtual MAC based traffic domains on a NetScaler.

3. virtual MAC based traffic domains do not work when the NetScaler is deployed only in L2 Mode.
4. Both VLAN and virtual MAC based traffic domains can coexist on a NetScaler. virtual MAC based traffic domains actually runs on all VLANs that are not bound to any VLAN based traffic domain.

## Configuration Steps

Configuring a virtual MAC based traffic domain on a NetScaler appliance consists of the following tasks:

- Create a traffic domain entity and enable the virtual MAC option. Create a traffic domain entity uniquely identified by an ID, which is an integer value, and then enable the virtual MAC option. After creating the traffic domain entity, the NetScaler creates a virtual MAC address and then associates it to the traffic domain entity.
- Create feature entities on the traffic domain. Create the required feature entities in the traffic domain by specifying the traffic domain identifier (td) when configuring these feature entities. NetScaler owned network entities created in a virtual MAC based traffic domain are associated with the virtual MAC address, which is associated with the traffic domain. The NetScaler then sends the traffic domain's virtual MAC address in ARP announcements and ARP responses for these network entities.

## CLI procedures

To create a virtual MAC based traffic domain by using the CLI:

At the command prompt, type:

---

```
add ns trafficDomain <td> [-vmac (ENABLED DISABLED)]
```

---

- 
- show ns trafficdomain <td>

To configure a SNIP address by using the CLI:

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type SNIP -td <id>
- show ns ip <IPAddress> -td <id>

To create a service by using the CLI:

At the command prompt, type:

- add service <name> <IP> <serviceType> <port> -td <id>
- show service <name> -td <id>

To create a load balancing virtual server and bind services to it by using the CLI:

At the command prompt, type:

- add lb vserver <name> <serviceType> <IPAddress> <port> -td <id>
- bind lb vserver <name> <serviceName>
- show lb vserver <name> -td <id>

**Example:**

```
1 > add ns trafficDomain 1 -vmac ENABLED
2 Done
3 > add ns trafficDomain 2 -vmac ENABLED
4 Done
5
6 > add ns ip 192.0.2.5 255.255.255.0 -type -SNIP -td 1
7 Done
8 > add service SVC-S1-TD1 192.0.2.10 HTTP 80 -td 1
9 Done
10 > add service SVC-S2-TD1 192.0.2.20 HTTP 80 -td 1
11 Done
12 > add lb vserver LBVS-TD1 HTTP 203.0.113.15 80 -td 1
13 Done
14 > bind lb vserver LBVS-TD1 SVC-S1-TD1
15 Done
16 > bind lb vserver LBVS-TD1 SVC-S2-TD1
17 Done
18
19 > add ns ip 192.0.2.6 255.255.255.0 -type -SNIP -td 2
20 Done
21 > add service SVC-S3-TD2 192.0.2.30 HTTP 80 -td 2
22 Done
23 > add service SVC-S4-TD2 192.0.2.40 HTTP 80 -td 2
24 Done
25 > add lb vserver LBVS-TD1 HTTP 203.0.113.16 80 -td 1
26 Done
27 > bind lb vserver LBVS-TD2 SVC-S3-TD2
28 Done
29 > bind lb vserver LBVS-TD2 SVC-S3-TD2
30 Done
31 <!--NeedCopy-->
```

**GUI procedures**

To create a virtual MAC based traffic domain by using the GUI:

1. Navigate to System > Network > Interfaces.

2. In the details pane, click Add.
3. On the Create Traffic Domain page, set the following parameters:
  - Traffic Domain ID\*
  - Enable Mac
4. Click Create.

To configure a SNIP address by using the GUI:

1. Navigate to System > Network > IPs > IPv4
2. Navigate to Network > IPs > IPv4
3. In the details pane, click Add
4. In the Create IP page, set the following parameters. For a description of a parameter, hover the mouse cursor over the corresponding field.
  - IP Address
  - Netmask
  - IP Type
  - Traffic Domain ID
5. Click Create.

To create a service by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Basic Settings Page, set the following parameters. For a description of a parameter, hover the mouse cursor over the corresponding field.
  - Service Name
  - Server
  - Protocol
  - Port
  - Traffic Domain ID
4. Click Continue, and click Done.
5. Repeat steps 2-4 to create another service.
6. Click Close.

To create a load balancing virtual server and bind services to it by using the GUI:

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the Load Balancing Virtual Servers pane, click Add.
3. In the Create Virtual Servers (Load Balancing) dialog box, set the following parameters. For a description of a parameter, hover the mouse cursor over the corresponding field.

- Name
  - IP Address
  - Protocol
  - Port
  - Traffic Domain ID
4. Click Continue, on the Service Pane, click >.
  5. On the Service page, click Insert, and then select the check box for the services that you want to bind to the virtual server.
  6. Click Continue, and click Done.
  7. Repeat steps 2-5 to create another virtual server

## VXLAN

May 2, 2023

NetScaler appliances support Virtual eXtensible Local Area Networks (VXLANs). A VXLAN overlays Layer 2 networks onto a layer 3 infrastructure by encapsulating Layer-2 frames in UDP packets. Each overlay network is known as a VXLAN Segment and is identified by a unique 24-bit identifier called the VXLAN Network Identifier (VNI). Only network devices within the same VXLAN can communicate with each other.

VXLANs provide the same Ethernet Layer 2 network services that VLANs do, but with greater extensibility and flexibility. The two main benefits of using VXLANs are the following:

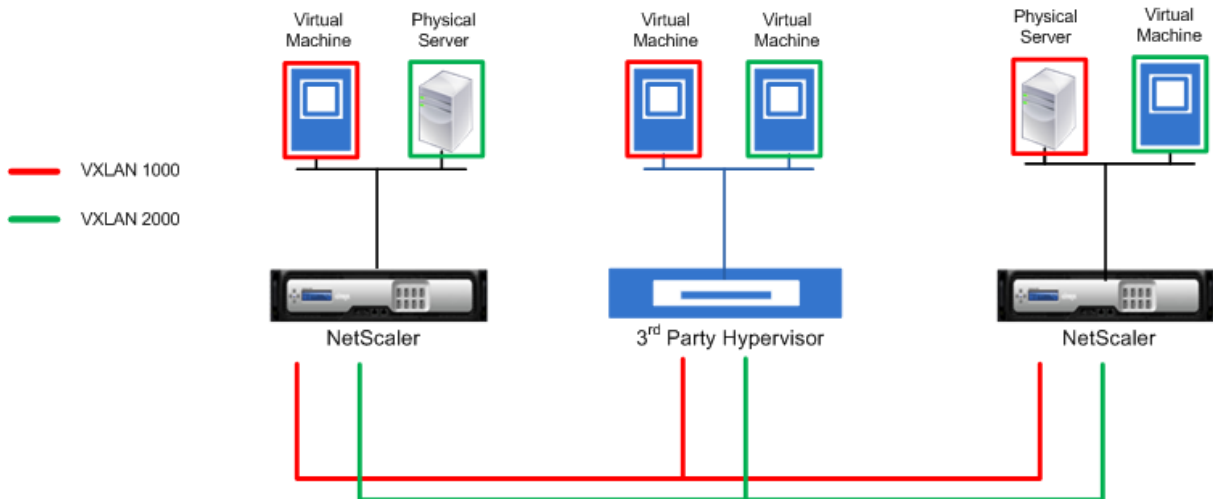

- **Higher scalability.** Server virtualization and cloud computing architectures have dramatically increased the demand for isolated Layer 2 networks in a datacenter. The VLAN specification uses a 12-bit VLAN ID to identify a Layer 2 network, so you cannot scale beyond 4094 VLANs. That number can be inadequate when the requirement is for thousands of isolated Layer 2 networks. The 24-bit VNI accommodates up to 16 million VXLAN segments in the same administrative domain.
- **Higher flexibility.** Because VXLAN carries Layer 2 data frames over Layer 3 packets, VXLANs extend L2 networks across different parts of a datacenter and across geographically separated datacenters. Applications that are hosted in different parts of a datacenter and in different datacenters but are part of the same VXLAN appear as one contiguous network.

### How VXLANs Work

VXLAN Segments are created between VXLAN Tunnel End Points (VTEPs). VTEPs support the VXLAN protocol and perform VXLAN encapsulation and decapsulation. You can think of a VXLAN segment as

a tunnel between two VTEPs, where one VTEP encapsulates a Layer2 frame with a UDP header and an IP header and sends it through the tunnel. The other VTEP receives and decapsulates the packet to get the Layer 2 frame. A NetScaler is one example of a VTEP. Other examples are third-party hypervisors, VXLAN aware virtual machines, and VXLAN capable switches.

The following illustration displays virtual machines and physical servers connected through VXLAN tunnels.

The following illustration displays the format of a VXLAN packet.

VXLANs on a NetScaler use a Layer 2 mechanism for sending broadcast, multicast, and unknown unicast frames. A VXLAN supports the following modes for sending these L2 frames.

- **Unicast mode:** In this mode, you specify the IP addresses of VTEPs while configuring a VXLAN on a NetScaler. The NetScaler sends broadcast, multicast, and unknown unicast frames over Layer 3 to all VTEPs of this VXLAN.
- **Multicast mode:** In this mode, you specify a multicast group IP address while configuring a VXLAN on a NetScaler. NetScalers do not support Internet Group Management Protocol (IGMP) protocol. NetScalers rely on the upstream router to join a multicast group, which shares a common multicast group IP address. The NetScaler sends broadcast, multicast, and unknown unicast frames over Layer 3 to the multicast group IP address of this VXLAN.

Similar to a Layer 2 bridge table, NetScalers maintain VXLAN mapping tables based on the inner and outer header of the received VXLAN packets. This table maps of remote host MAC addresses to VTEP

IP addresses for a particular VXLAN. The NetScaler uses the VXLAN mapping table to look up the destination MAC address of a Layer 2 frame. If an entry for this MAC address is present in the VXLAN table, the NetScaler sends the Layer 2 frame over Layer 3, using the VXLAN protocol, to the mapped VTEP IP address specified in the mapping entry for a VXLAN.

Because VXLANs function similarly to VLANs, most of the NetScaler features that support VLAN as a classification parameter support VXLAN. These features include an optional VXLAN parameter setting, which specifies the VXLAN VNI.

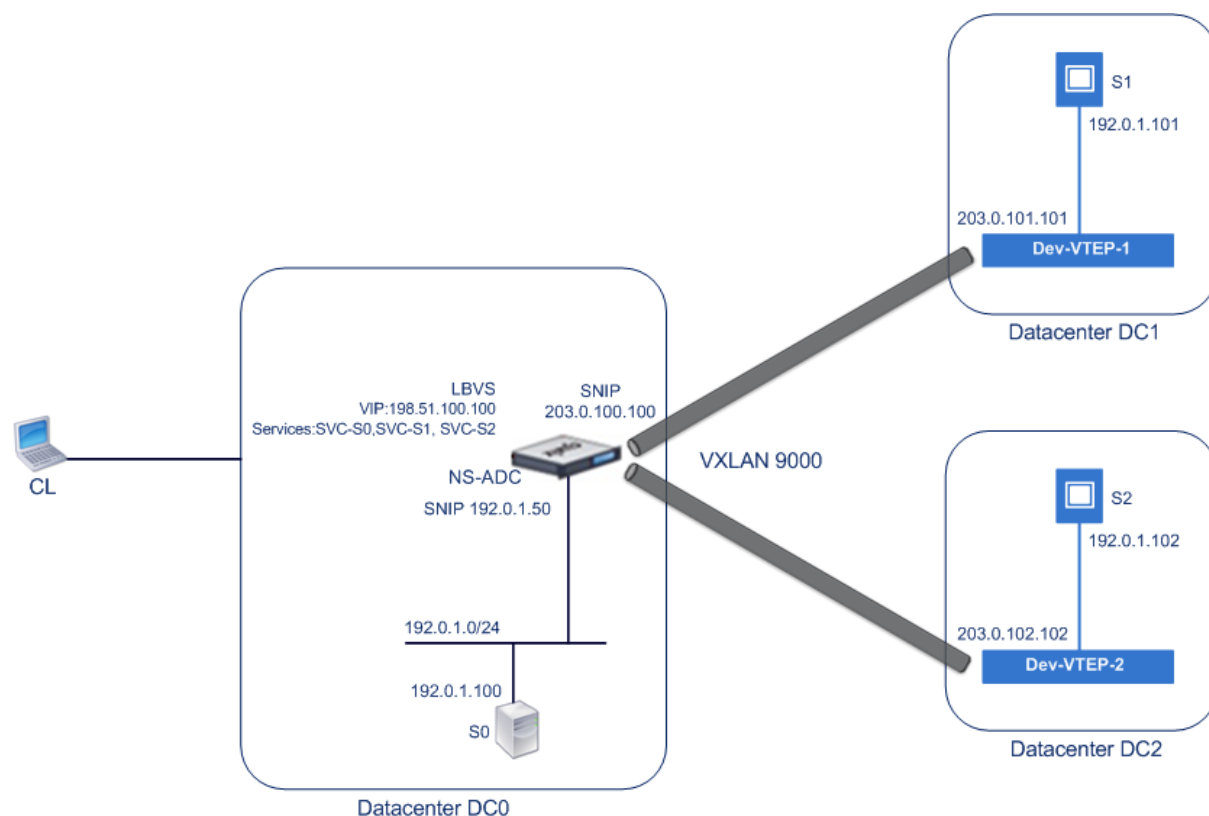

In a high availability (HA) configuration, the VXLAN configuration is propagated or synchronized to the secondary node.

### **VXLAN Use Case: Load Balancing across Datacenters**

To understand the VXLAN functionality of a NetScaler, consider an example in which Example Corp hosts a site at [www.example.com](http://www.example.com). To ensure application availability, the site is hosted on three servers, S0, S1, and S2. A load balancing virtual server, LBVS, on NetScaler NS-ADC is used to load balance these servers. S0, S1, and S2 reside in datacenters DC0, DC1, and DC2, respectively. In DC0, server S0 is connected to NS-ADC.

S0 is a physical server, and S1 and S2 are virtual machines (VMs). S1 runs on virtualization host device Dev-VTEP-1 in datacenter DC1, and S2 runs on host device Dev-VTEP-2 in DC2. NS-ADC, Dev-VTEP-1, and Dev-VTEP-2 support the VXLAN protocol.

S0, S1, and S2 are part of the same private subnet, 192.0.1.0/24. S0, S1, and S2 be part of a common broadcast domain, VXLAN 9000 is configured on NS-ADC, Dev-VTEP-1, and Dev-VTEP-2. Servers S1 and S2 are made part of VXLAN9000 on Dev-VTEP-1 and Dev-VTEP-2, respectively.

The following table lists the settings used in this example:

#### VXLAN settings.

Services SVC-S0, SVC-S1, and SVC-S2 on NS-ADC represent S0, S1, and S2. As soon as these services are configured, NS-ADC broadcasts ARP requests for S0, S1, and S2 to resolve IP-to-MAC mapping. These ARP requests are also sent over VXLAN 9000 to Dev-VTEP-1 and Dev-VTEP-2.

Following is the traffic flow for resolving the ARP request for S2:

1. NS-ADC broadcasts an ARP request for S2 to resolve IP-to-MAC mapping. This packet has:
  - Sourced IP address = Subnet IP address SNIP-for-Servers (192.0.1.50)
  - Source MAC address = MAC address of the NS-ADC's interface from which the packet is sent out = NS-MAC-1
2. NS-ADC prepares the ARP packet to be sent over the VXLAN 9000 by encapsulating the packet with following headers:
  - VXLAN header with an ID (VNI) of 9000
  - Standard UDP header, UDP checksum set to 0x0000, and destination port set to 4789.
3. NS-ADC sends the resulting encapsulated packet to Dev-VTEP-1 and Dev-VTEP-2 on VXLAN-9000. The encapsulated packet has:
  - Source IP address = SNIP-VTEP-0 (203.0.100.100).

4. Dev-VTEP-2 receives the UDP packet and decapsulates the UDP header, from which Dev-VTEP-2 learns that the packet is a VXLAN related packet. Dev-VTEP-2 then decapsulates the VXLAN header and learns the VXLAN ID of the packet. The resulting packet is the ARP request packet for S2, which is same as in step 1.
5. From the inner and outer header of the VXLAN packet, Dev-VTEP-2 makes an entry in its VXLAN mapping table that shows the mapping of MAC address (NS-MAC-1) and SNIP-VTEP-0 (203.0.100.100) for VXLAN9000.
6. Dev-VTEP-2 sends the ARP packet to S2. S2's response packet reaches Dev-VTEP-2. Dev-VTEP-2 performs a lookup in its VXLAN mapping table and gets a match for the destination MAC address NS-MAC-1. The Dev-VTEP-2 now knows that NS-MAC-1 is reachable through SNIP-VTEP-0 (203.0.100.100) over VXLAN 9000.
7. S2 responds with its MAC address (MAC-S2). The ARP response packet has:
  - Destination IP address = Subnet IP address SNIP-for-Servers (192.0.1.50)
  - Destination MAC address = NS-MAC-1
8. S2's response packet reaches Dev-VTEP-2. Dev-VTEP-2 performs a lookup in its VXLAN mapping table and gets a match for the destination MAC address NS-MAC-1. The Dev-VTEP-2 now knows that NS-MAC-1 is reachable through SNIP-VTEP-0 (203.0.100.100) over VXLAN 9000. Dev-VTEP-2 encapsulates the ARP response with VXLAN and UDP headers, and sends the resultant packet to SNIP-VTEP-0 (203.0.100.100) of NS-ADC.
9. NS-ADC on receiving the packet, decapsulates the packet by removing the VXLAN and UDP headers. The resultant packet is S2's ARP response. NS-ADC updates its VXLAN mapping table for S2's MAC address (MAC-S2) with Dev-VTEP-2's IP address (203.0.102.102) for VXLAN 9000. NS-ADC also updates its ARP table for S2's IP address (192.0.1.102) with S2's MAC address (MAC-S2).

Following is the traffic flow for load balancing virtual server LBVS in this example:

1. Client CL sends a request packet to LBVS of NS-ADC. The request packet has:
  - Source IP address = IP address of client CL (198.51.100.90)
  - Destination IP address = IP address (VIP) of LBVS = 198.51.110.100
2. LBVS of NS-ADC receives the request packet, and its load balancing algorithm selects server S2 of datacenter DC2.
3. NS-ADC processes the request packet, changing its destination IP address to the IP address of S2 and its source IP address to one of the Subnet IP (SNIP) addresses configured on NS-ADC. The request packet has:
  - Source IP address = Subnet IP address on NS-ADC= SNIP-for-Servers (192.0.1.50)
  - Destination IP address = IP address of S2 (192.0.1.102)
4. NS-ADC finds a VXLAN mapping entry for S2 in its bridge table. This entry indicates that S2 is reachable through Dev-VTEP-2 over VXLAN 9000.

5. NS-ADC prepares the packet to be sent over the VXLAN 9000 by encapsulating the packet with following headers:
  - VXLAN header with an ID (VNI) of 9000
  - Standard UDP header, UDP checksum set to 0x0000, and destination port set to 4789.
6. NS-ADC sends the resulting encapsulated packet to Dev-VTEP-2. The request packet has:
  - Source IP address = SNIP address = SNIP-VTEP-0 (203.0.100.100)
  - Destination IP address = IP address of Dev-VTEP-2 (203.0.102.102)
7. Dev-VTEP-2 receives the UDP packet and decapsulates the UDP header, from which Dev-VTEP-2 learns that the packet is a VXLAN related packet. Dev-VTEP-2 then decapsulates the VXLAN header and learns the VXLAN ID of the packet. The resulting packet is the same packet as in step 3.
8. Dev-VTEP-2 then forwards the packet to S2.
9. S2 processes the request packet and sends the response to the SNIP address of NS-ADC. The response packet has:
  - Source IP address = IP address of S2 (192.0.1.102)
  - Destination IP address = Subnet IP address on NS-ADC= SNIP-for-Servers (192.0.1.50)
10. Dev-VTEP-2 encapsulates the response packet in the same way that NS-ADC encapsulated the request packet in steps 4 and 5. Dev-VTEP-2 then sends the encapsulated UDP packet to SNIP address SNIP-for-Servers (192.0.1.50) of NS-ADC.
11. NS-ADC, upon receiving the encapsulated UDP packet, decapsulates the packet by removing the UDP and VXLAN headers in the same way that Dev-VTEP-2 decapsulated the packet in step 7. The resultant packet is the same response packet as in step 9.
12. NS-ADC then uses the session table for load balancing virtual server LBVS, and forwards the response packet to client CL. The response packet has:
  - Source IP address = IP address of client CL (198.51.100.90)
  - Destination IP address = IP address (VIP) of LBVS (198.51.110.100)

### **Points to Consider for Configuring VXLANs**

Consider the following points before configuring VXLANs on a NetScaler:

- A maximum of 2048 VXLANs can be configured on a NetScaler.
- VXLANs are not supported in a cluster.
- Link-local IPv6 addresses cannot be configured for each VXLAN.
- NetScalers do not support Internet Group Management Protocol (IGMP) protocol to form a multicast group. NetScalers rely on the IGMP protocol of its upstream router to join a multicast

group, which share a common multicast group IP address. You can specify a multicast group IP address while creating VXLAN bridge table entries but the multicast group must be configured on the upstream router. The NetScaler sends broadcast, multicast, and unknown unicast frames over Layer 3 to the multicast group IP address of this VXLAN. The upstream router then forwards the packet to all the VTEPs that are part of the multicast group.

- VXLAN encapsulation adds an overhead of 50 bytes to each packet:

Outer Ethernet Header (14) + UDP header (8) + IP header (20) + VXLAN header (8) = 50 bytes

To avoid fragmentation and performance degradation, you must adjust the MTU settings of all network devices in a VXLAN pathway, including the VXLAN VTEP devices, to handle the 50 bytes of overhead in the VXLAN packets.

Important: Jumbo frames are not supported on the NetScaler VPX virtual appliances, NetScaler SDX appliances, and NetScaler MPX 15000/17000 appliances. These appliances support an MTU size of only 1500 bytes and cannot be adjusted to handle the 50 bytes overhead of VXLAN packets. VXLAN traffic might be fragmented or suffer performance degradation, if one of these appliances is in the VXLAN pathway or acts as a VXLAN VTEP device.

- On NetScaler SDX appliances, VLAN filtering does not work for VXLAN packets.
- You cannot set a MTU value on a VXLAN.
- You cannot bind interfaces to a VXLAN.

## Configuration Steps

Configuring a VXLAN on a NetScaler appliance consists of the following tasks.

- **Add a VXLAN entity.** Create a VXLAN entity uniquely identified by a positive integer, which is also called the VXLAN Network Identifier (VNI). In this step, you can also specify the destination UDP port of remote VTEP on which the VXLAN protocol is running. By default, the destination UDP port parameter is set to 4789 for the VXLAN entity. This UDP port setting must match the settings on all remote VTEPs for this VXLAN. You can also bind VLANs to this VXLAN. The traffic (which includes broadcasts, multicasts, unknown unicasts) of all bound VLANs are allowed over this VXLAN. If no VLANs are bound to the VXLAN, the NetScaler allows traffic of all VLANs, on this VXLAN, that are not part of any other VXLANs.
- **Bind the local VTEP IP address and to the VXLAN entity.** Bind one of the configured SNIP address to the VXLAN to source outgoing VXLAN packets.
- **Add a bridgetable entry.** Add a bridgetable entry specifying the VXLAN ID and the remote VTEP IP address for the VXLAN to be created.
- **(Optional) Bind different feature entities to the configured VXLAN.** VXLANs function similarly to VLANs, most of the NetScaler features that support VLAN as a classification parameter

also support VXLAN. These features include an optional VXLAN parameter setting, which specifies the VXLAN VNI.

- **(Optional) Display the VXLAN mapping table.** Display the VXLAN mapping table, which includes mapping entries for remote host MAC address to VTEP IP address for a particular VXLAN. In other words, a VXLAN mapping states that a host is reachable through the VTEP on a particular VXLAN. The NetScaler learns VXLAN mappings and updates its mapping table from the VXLAN packets it receives. The NetScaler uses the VXLAN mapping table to lookup for the destination MAC address of a Layer 2 frame. If an entry for this MAC address is present in the VXLAN table, the NetScaler sends the Layer 2 frame over Layer 3, using the VXLAN protocol, to the mapped VTEP IP address specified in the mapping entry for a VXLAN.

### CLI procedures

To add a VXLAN entity by using CLI:

At the command prompt, type

- **add vxlan** <id>
- **show vxlan** <id>

To bind the local VTEP IP address to the VXLAN by using CLI:

At the command prompt, type

- **bind vxlan** <id> -SrcIP <IPaddress>
- **show vxlan** <id>

To add a bridgetable by using CLI:

At the command prompt, type

- **add bridgetable -mac** <macaddress> -vxlan <ID> -vtep <IPaddress>
- **show bridgetable**

To display the VXLAN forwarding table by using the command line:

At the command prompt, type:

- **show bridgetable**

### GUI procedures

To add a VXLAN entity and bind a local VTEP IP address by using the GUI:

Navigate to **System > Network > VXLANs**, and add a new VXLAN entity or modify an existing VXLAN entity.

To add a bridgetable by using the GUI:

Navigate to **System > Network > Bridge Table**, set the following parameters while adding or modifying a VXLAN bridge table entry:

- MAC
- VTEP
- VXLAN ID

To display the VXLAN forwarding table by using the GUI:

Navigate to **System > Network > Bridge Table**.

```
1 Example
2 > add vxlan 9000
3 Done
4 > bind vxlan 9000 -srcIP 203.0.100.100
5
6 Done
7 > add bridgetable -mac 00:00:00:00:00:00 -vxlan 9000 -vtep
 203.0.101.101
8
9 Done
10 > add bridgetable -mac 00:00:00:00:00:00 -vxlan 9000 -vtep
 203.0.102.102
11
12 Done
```

## Support of IPv6 Dynamic Routing Protocols on VXLANs

The NetScaler appliance supports IPv6 dynamic routing protocols for VXLANs. You can configure various IPv6 Dynamic Routing protocols (for example, OSPFv3, RIPng, BGP) on VXLANs from the VTYSH command line. An option IPv6 Dynamic Routing Protocol has been added to VXLAN command set for enabling or disabling IPv6 dynamic routing protocols on a VXLAN. After enabling IPv6 dynamic routing protocols on a VXLAN, processes related to the IPv6 dynamic routing protocols are required to be started on the VXLAN by using the VTYSH command line.

To enable IPv6 Dynamic routing protocols on a VXLAN by using the CLI:

- **add vxlan** <ID> [-**ipv6DynamicRouting** ( **ENABLED** | **DISABLED** )]
- **show vxlan**

```
1 In the following sample configuration, VXLAN-9000 is created and has
 IPv6 dynamic routing protocols enabled on it. Then, using the VTYSH
 command line, process for the IPv6 OSPF protocol is started on the
 VXLAN.
2
3 > add vxlan 9000 -ipv6DynamicRouting ENABLED
```

```
4
5 Done
6 > bind vxlan 9000 -srcIP 203.0.100.100
7
8 Done
9 > add bridgetable -mac 00:00:00:00:00:00 -vxlan 9000 -vtep
 203.0.101.101
10
11 Done
12 > VTYSH
13 NS# configure terminal
14 NS(config)# ns IPv6-routing
15 NS(config)# interface VXLAN-9000
16 NS(config-if)# ipv6 router OSPF area 3
```

## Extending VLANs from Multiple Enterprises to a Cloud using VXLAN-VLAN Maps

CloudBridge Connector tunnels is used to extend an enterprise's VLAN to a cloud. VLANs extended from multiple enterprises can have overlapping VLAN IDs. You can isolate each enterprise's VLANs, by mapping them to a unique VXLAN in the cloud. On a NetScaler appliance, which is the CloudBridge connector endpoint in the cloud, you can configure a VXLAN-VLAN map that links an enterprise's VLANs to a unique VXLAN in the cloud. VXLANs support VLAN tagging for extending multiple VLANs of an enterprise from CloudBridge Connector to the same VXLAN.

Perform the following tasks for extending VLANs of multiple enterprises to a cloud:

1. Create a VXLAN-VLAN map.
2. Bind the VXLAN-VLAN map to a network bridge based or PBR based CloudBridge Connector tunnel configuration on the NetScaler appliance on cloud.
3. (Optional) Enable VLAN tagging in a VXLAN configuration.

### CLI procedures

To add a VXLAN-VLAN map by using the CLI:

- **add vxlanVlanMap** <name>
- **show vxlanVlanMap** <name>

To bind a VXLAN and VLANS to a VXLAN-VLAN map by using the CLI:

- **bind vxlanVlanMap** <name> [-vxlan <positive\_integer> -vlan <int[-int]> ...]
- **show vxlanVlanMap** <name>

To bind a VXLAN-VLAN map to a network bridge based CloudBridge Connector tunnel by using the CLI:

At the command prompt, type one of the following sets of commands.

if adding a new network bridge:

- **add netbridge** <name> [-vxlanVlanMap <string>]
- **show netbridge** <name>

if reconfiguring an existing network bridge:

- **set netbridge** <name> [-vxlanVlanMap <string>]
- **show netbridge** <name>

To bind a VXLAN-VLAN map to a PBR based CloudBridge Connector tunnel by using the CLI:

At the command prompt, type one of the following sets of commands.

if adding a new PBR:

- **add pbr** <name> **ALLOW** (-ipTunnel <ipTunnelName> [-vxlanVlanMap <name>])
- **show pbr** <name>

if reconfiguring an existing PBR:

- **set pbr** <name> **ALLOW** (-ipTunnel <ipTunnelName> [-vxlanVlanMap <name>])
- **show pbr** <name>

To include VLAN tags in packets related to a VXLAN by using the CLI:

At the command prompt, type one of the following sets of commands.

if adding a new VXLAN:

- **add vxlan** <vnid> -vlanTag (\*\*ENABLED\*\* | \*\*DISABLED\*\*)
- **show vxlan** <vnid>

if reconfiguring an existing VXLAN:

- **set vxlan** <vnid> -vlanTag (\*\*ENABLED\*\* | \*\*DISABLED\*\*)
- **show vxlan** <vnid>

## GUI procedures

To add a VXLAN-VLAN map by using the GUI:

Navigate to **System > Network > VXLAN VLAN Map**, add a VXLAN VLAN map.

To bind a VXLAN-VLAN map to a netbridge based CloudBridge Connector tunnel by using the GUI:

Navigate to **System > CloudBridge Connector > Network Bridge**, select a VXLAN-VLAN map from the **VXLAN VLAN** drop down list while adding a new network bridge, or reconfiguring an existing network bridge.

To bind a VXLAN-VLAN map to a PBR based CloudBridge Connector tunnel by using the GUI:

Navigate to **System > Network > PBRs**, on the Policy Based Routing (PBRs) tab, select a **VXLAN-VLAN** map from the **VXLAN VLAN** drop down list while adding a new PBR, or reconfiguring an existing PBR.

To include VLAN tags in packets related to a VXLAN by using the GUI:

Navigate to **System > Network > VXLANs**, enable **Inner VLAN Tagging** while adding a new VXLAN, or reconfiguring an existing VXLAN.

```
1 > add vxlanVlanMap VXLANVLAN-DC1
2
3 Done
4
5 > bind vxlanvlanmap VXLANVLAN-DC1 -vxlan 3000 -vlan 3
6
7 Done
8
9 > bind vxlanvlanmap VXLANVLAN-DC1 -vxlan 3500 -vlan 4
10
11 Done
12
13 >add vxlanVlanMap VXLANVLAN-DC2
14
15 Done
16
17 > bind vxlanvlanmap VXLANVLAN-DC1 -vxlan 8000 -vlan 3 4
18
19 Done
20
21 > set pbr PBR-CBC-DC-1-CLOUD ALLOW -ipTunnel CBC-DC-1-CLOUD -
 vxlanVlanMap VXLANVLAN-DC1
22
23 Done
24
25 > set pbr PBR-CBC-DC-2-CLOUD ALLOW -ipTunnel CBC-DC-2-CLOUD -
 vxlanVlanMap VXLANVLAN-DC2
26
27 Done
```

## Geneve tunnels

May 2, 2023

A NetScaler appliance supports the Generic Network Virtualization Encapsulation (Geneve) protocol as defined in RFC 8926.

Server virtualization and cloud computing architecture have increased the demand for isolated Layer-2 networks in a data center.

The VLAN limit of 4094 has proven to be inadequate and encapsulation protocols like VXLAN and NVGRE were introduced to overcome this limitation. These protocols differ mainly in the control plane implementation. Geneve protocol does not define specifications for the control plane. The protocol leaves to the implementation to define the control plane specifications.

Geneve protocol is an encapsulation technology that aims to create Layer-2 overlay networks over Layer-3 infrastructure by encapsulating Layer-2 frames in UDP packets.

A unique 24-bit identifier called the VNID identifies each VLAN. Only within the same segment ID (VNID) can communicate with each other. A NetScaler appliance supports the Geneve encapsulation on UDP port 6081.

There are two types of Geneve tunnel that can be created:

- Tunnels can extend an existing VLAN in L2 or L3 mode. In L2 mode, bridging happens between VLAN and tunnel and the entries are updated in the bridge table.

In L3 mode, proxy ARP comes into effect to learn the MAC address and the tunnel information of the client/server address. The ARP table includes the corresponding MAC and tunnel information.

- Geneve Tunnel can work with different VLANs in L3 mode by using policy-based routes (PBRs). When a packet must be sent to a host which is reachable on a Geneve Tunnel segment, the NetScaler appliance encapsulates the packet in a Geneve Tunnel header and sends it to the tunnel endpoint.

NetScaler can act as a tunnel endpoint as well. A tunnel endpoint originates and terminates Geneve tunnels. When Layer 2 mode is turned ON, the NetScaler appliance acts as a tunnel endpoint and bridges packets between VLANs and Geneve Tunnels. The NetScaler learns the VNID and tunnel endpoint on which a MAC address is reachable. Then it stores this information in the bridging table.

Geneve tunnel is supported in NetScaler admin partitions, NetScaler high availability setups, and NetScaler cluster setups.

In a high availability setup, a Geneve tunnel configuration is propagated or synchronized to the secondary node. In a cluster setup, the Geneve tunnel configuration (striped) is identical and present on all cluster nodes.

### **Configuring Geneve tunnels**

Configuring a Geneve tunnel on a NetScaler appliance consists of the following tasks:

- Add an IP tunnel with protocol
- Add a net bridge
- bind the geneve tunnel to the net bridge

#### To add an IP tunnel with Geneve protocol by using the CLI:

At the command prompt, type:

- **add iptunnel** <name> <remote> <remoteSubnetMask> <local> **protocol** <Geneve> **destPort** <port> **tosInherit** (\*\*ENABLED\*\* | \*\*DISABLED\*\*) **vlanTagging** (\*\*ENABLED\*\* | \*\*DISABLED\*\*) **vnid** <positive\_integer>
- **show iptunnel**

#### To add a net bridge by using the CLI:

At the command prompt, type:

- **add netbridge** <name>
- **show netbridge**

#### To bind the geneve tunnel to the netbridge by using the CLI:

At the command prompt, type:

- **bind netbridge** <name> **vlan** <Vlan ID> **tunnel** <tunnel name>
- **show netbridge**

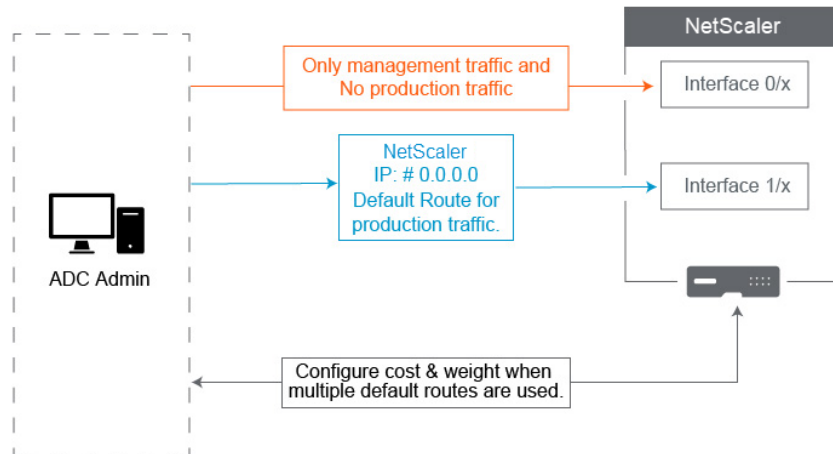

## Best practices for network configurations

May 2, 2023

The following sections talk about some best practices for configuring networking features on a NetScaler appliance.

### Routing and Default Routes

The following are some best practices for configuring Layer 3 features on a NetScaler appliance.

- **Interface 0/x on a NetScaler appliance or NetScaler SDX appliance must not be used for production traffic.** On an MPX or SDX, Interfaces named 0/x are referred to the Management Interfaces. This does not mean you must use these interfaces for Management. What it means is that these interfaces are NOT designed for Production traffic. They do not have the hardware buffers and optimization necessary to achieve sustained 1 Gbps throughput. Therefore, If your Default Route is in the same Subnet as your NSIP, you must either change the default route or use a 1/x interface for your Management network as the 1/x interfaces are fully optimized for production 1 Gbps traffic.

**Note:**

This does not apply to a NetScaler VPX appliance.

- **Option 1.** Do not connect to Interfaces 0/x –Disconnect the cable from interface 0/1. NetScaler listens for the NSIP on the other interfaces. (NOTE: This is not an option for SDX, as the SVM and XenServer can only speak to 0/x interfaces)
  - **Option 2.** change the default route to a different interface as detailed in the next section.
- **Default gateway (route 0.0.0.0) should be on a Production network, and not on any 0/x interface.** When first setting up a NetScaler, it asks you for the NSIP, Subnet Mask, and Gateway address. The problem this creates for Administrators is that they just configured their default route to be on their Management Network using Interface 0/1.
    - To check what your routes are, run in CLI `show route` and your default gateway is the IP in the line where the Network and Netmask are 0.0.0.0. Here’s an example where the Gateway is on Line 1:

```

1 > sh route
2 Network Netmask Gateway/OwnedIP
 State Traffic Domain Type

```

```

3 -----
4 1) 0.0.0.0 0.0.0.0 10.25.213.65 UP
 0 STATIC
5 2) 127.0.0.0 255.0.0.0 127.0.0.1 UP
 0 PERMANENT
6 3) 10.25.213.64 255.255.255.192 10.25.213.68 UP
 0 DIRECT
7 4) 172.16.0.0 255.255.255.0 172.16.0.1 UP
 0 DIRECT
8
9 <!--NeedCopy-->

```

- To check the Interface and VLAN used for your Default Gateway, check the ARP table using `sh arp` in CLI. You can also search for the specific IP using `show arp | grep 10.25.213.65`. Here's an example where you see the Gateway 10.25.213.65 is using Interface 1/1 and VLAN 1:

```

1 > sh arp
2 IP MAC Iface VLAN
3 Origin TTL Traffic Domain
4 -- --- -----
5 1) 127.0.0.1 02:00:18:a4:00:1e LO/1 1
 PERMANENT N/A 0
6 2) 10.25.213.70 02:00:0f:46:00:28 1/1 1
 DYNAMIC 967 0
7 3) 10.25.213.68 02:00:18:a4:00:1e LO/1 1
 PERMANENT N/A 0
8 4) 10.25.213.67 02:00:0f:46:00:28 1/1 1
 DYNAMIC 641 0
9 5) 10.25.213.65 00:08:e3:ff:fd:90 1/1 1
 DYNAMIC 483 0
10 <!--NeedCopy-->

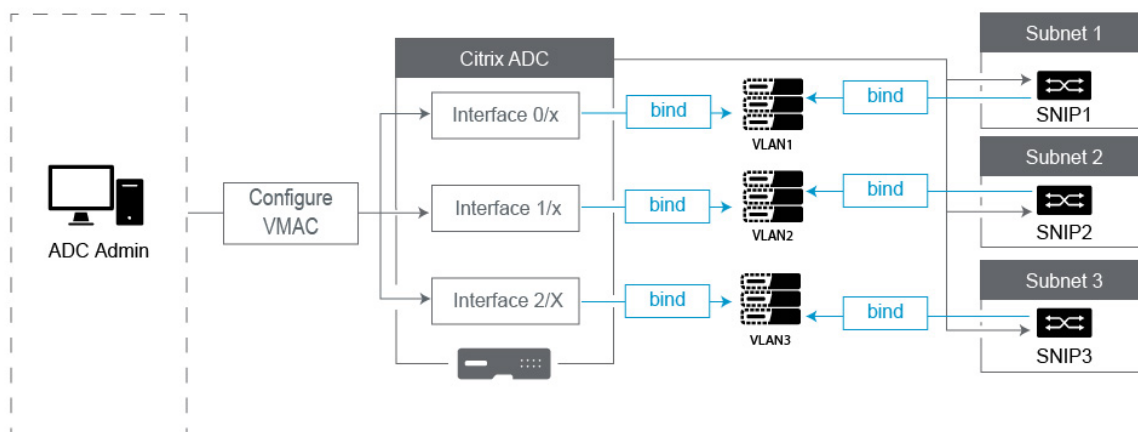

```

- Change the default route to use a Gateway on your Production Subnet and Interface. Assume your Management network is 10.0.0.0/24 with gateway 10.0.0.1, and Production network is 10.1.1.0/24 with gateway 10.1.1.1. Set up your config like this:
  - \* SNIP: (Management Access Disabled) 10.1.1.2
  - \* NSIP: (Management Access Enabled) 10.0.0.2
  - \* Default Route: 0.0.0.0 0.0.0.0 10.1.1.1 (System > Network > Routes). This uses a router on the SNIP network instead of the NSIP network.

**Note:**  
Changing the default gateway might break management traffic unless you configure static routes, a Policy Based Route, or enable MAC Based Forwarding.

## Interfaces, channels, and VLANs

The following are some best practices for configuring Layer 2 features on a NetScaler appliance.

- **Do not connect multiple interfaces/channels to the same VLAN, including VLAN 1:**

- If you do not properly configure your VLANs, it can cause some unexpected packet routing in your network and Layer 2 looping anytime there are more than one Active interface with the same VLAN (either Native or Tagged).
- By Default, all Interfaces and Channels are on Native VLAN 1. This creates two possible problems:
  - \* The NetScaler thinks all traffic received is on the same network, so it uses any interface to send the traffic out on. If you have a different Native VLAN on the interface it sent data out on, then the traffic will not be routed as you expect.
  - \* If the NetScaler receives broadcast packets on one port, it may retransmit on another port. If both switchports are on the same VLAN, you just created a Layer 2 loop.
- To remove an interface/channel from VLAN 1:
  - \* If you are not using Native VLANs on your switch interface/port channel. Change the Native VLAN on the NetScaler Interface/Channel to an unused VLAN number such as 999. You should not use the same unused VLAN number for multiple Channels or Interfaces, as it creates a layer 2 loop.
  - \* If you are using Native VLANs on your switch interface/port channel. Change the Native VLAN on the NetScaler Interface/Channel to match. However take care not to have multiple active Interfaces or Channels on the same VLAN as doing so creates Layer 2 loops.

- ★ You cannot remove the Native VLAN. Instead, you can change it or set TagAll for the interface or channel. If the switch port isn't configured with an untagged native VLAN, then enable tagall on the interface so High Availability heartbeat packets will be tagged.
- To view the Native VLAN on an interface, run `sh interface` in CLI. This will also inform you if the interface is using the TAGALL option.
- **Bind an Interface to your VLAN** - The NetScaler, by default, does not attach a new VLAN to an interface. This means the VLAN is not going to be used until you bind it to an interface. When the new VLAN is not bound to an Interface and that VLAN is Tagged, the NetScaler drops all inbound traffic from that VLAN. Also, do not bind the same VLAN to more than one interface.
  - Bind Subnets to your VLANs. The NetScaler does not work like a typical Router. Most Routers attach IPs to Interfaces. On a NetScaler, the IPs float on any Interface unless configured otherwise. Therefore, any Subnet you want to ensure the NetScaler sends over a specific VLAN, especially when the NetScaler is Initiating that traffic, then you must bind a SNIP within that subnet to the VLAN.
  - A common argument we hear against this is that it used to work fine and now it doesn't without binding the Subnet to the VLAN. This often occurs because the NetScaler learns which VLAN to send traffic out, but this can take time as it builds its ARP tables. After a reboot or firmware upgrade, as it starts building the ARP tables again, it may initially learn and therefore be using a different path than you desire, such as your default route. It's best to instruct it which path to take by Binding the SNIP to the VLAN. Once a SNIP is bound to a VLAN, the entire subnet for that SNIP will be bound to the VLAN.
  - Ensure every SNIP is bound to a VLAN (except in cases where you have more than 1 SNIP in a subnet, then you only must bind one), and that the VLAN, in turn, is bound to only one Interface or channel. It is also often best to have a SNIP in every Subnet, but that is not required as the most specific Route will be used for any destination Subnet that does not have a SNIP.
- To identify the VLAN and Interface used by a Subnet:
  1. Go to **System>Network > VLANs**.
  2. Edit each VLAN configured, in turn, until you find the correct IP address as explained in the next step.
  3. Click the IP Bindings tab to see which IP, and thus which Subnet is bound and thus is using this VLAN.
  4. Once you identify the VLAN that has an IP bound to it, where that IP is within the subnet of the Default Route, then click the Interface Bindings. Each Interface or Channel bound to this VLAN will be used.

### Example

Assume the Default route is 0.0.0.0 0.0.0.0 10.1.1.1.

Assume you have two SNIPs of 10.0.0.5 and 10.1.1.69. Since 10.1.1.69 is in the subnet of the default route, that is the one you want to look for. In the below screenshots, we are reviewing VLAN 1 and we see the IP 10.1.1.69 is bound to this VLAN, so we know we are looking at the correct VLAN.

Now Click Interface Bindings. In the VLAN Interface bindings we see that Interface 1 / 1 is used for this subnet, and therefore is used for the default route.

### ← Configure VLAN

VLAN ID: 1

Alias Name: [Empty]

Maximum Transmission Unit: [Empty]

Dynamic Routing

IPv6 Dynamic Routing

Partitions Sharing

Interface Bindings		IP Bindings	
<input type="checkbox"/>			Name
<input checked="" type="checkbox"/>			1/1
<input checked="" type="checkbox"/>			LO/1

**NOTE:**

If you do not have any IPs bound to your VLANs, then by default it will be sent out VLAN 1, so in that case look at which Interfaces are bound to VLAN 1. This also means the NetScaler will not use your Configured VLANs for traffic it Initiates unless you bind an IP to the new VLAN.

### Gratuitous ARP

If GARP does not work, use VMAC - By default, the NetScaler uses GARP to advertise its IP to MAC address bindings to other network devices. This typically works without issue, however, as you create more services in the NetScaler, you may begin to experience issues when failing over on an HA pair. The most common issue is that services remain down in the NetScaler you failed over to due to some network devices not having updated their ARP tables with the new MAC address. You can easily verify this by checking their ARP tables to see if the MAC addresses match those on the now-Primary NetScaler. When this occurs, it is highly likely that some of your network devices are limiting the number of GARP advertisements they honor. In this case it is necessary to configure VMAC on all

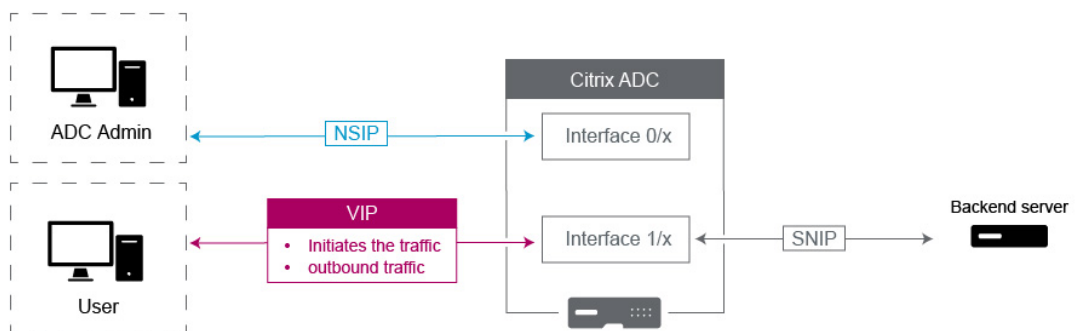

your active interfaces and/or channels. If you expect to have a large configuration on your NetScaler, it may be best to configure VMAC for all interfaces and channels during the initial deployment.

**NOTE:**

Do not forget to configure VMAC for the Interface or Channel used by your Default Route.

**NetScaler owned IP Addresses**

This section talks about the best practices for configuring NetScaler owned IP addresses:

- **NetScaler IP (NSIP):** Generally this IP used for Management because it is the only IP unique to an individual NetScaler in an HA or Cluster environment. Also important to note is that LDAP, RADIUS, and User scripted Monitor traffic (such as the LDAP monitor and StoreFront monitor) will Source from the NSIP and thus route over the VLAN and Interface the NSIP is bound to (Default Native VLAN 1). If you need the LDAP and RADIUS traffic to source from the SNIP, then create an LB virtual server for your back end servers.
- **Subnet IP (SNIP):** This IP address is used to initiate communication to back-end servers and is always going to initiate traffic. That said, it can be the destination for traffic in these cases:
  - It can be used as the Gateway address on other devices when doing Layer 3 routing on the NetScaler.
  - It can, when enabled, accept Management services, such as access to the GUI, SSH, and SNMP.
- **Virtual IP (VIP):** The VIP is unique in that it will never be used to initiate outbound traffic. It is intended to receive Traffic only. Once it receives traffic, it replies and sends traffic outbound back to the client. In other words, the VIP address does not initiate the outbound traffic.

Note this also means it is not used as the source for communicating with back-end servers used in, for example, an LB virtual server.

## Configure to source NetScaler FreeBSD data traffic from a SNIP address

May 2, 2023

Some NetScaler data features run on the underlying FreeBSD OS instead of on the NetScaler OS. Because of this reason, these features send traffic sourced from the NetScaler IP (NSIP) address instead of sourced from a SNIP address. Sourcing the data traffic from the NSIP address is not desirable if your setup has configurations to separate all management and data traffic.

The following NetScaler data features run on the underlying FreeBSD OS and send traffic sourced from the NetScaler IP (NSIP) address:

- Load balancing scriptable monitors
- GSLB autosync

To resolve this issue, you can use the global Layer-2 parameter: `useNetprofileBSDtraffic`. When you enable this parameter, the NetScaler features send traffic sourced from one of the SNIP addresses in a net profile associated with the feature.

### Before you begin

Before configuring the NetScaler appliance to source NetScaler features related traffic from a SNIP address, note the following points:

- Currently, the global Layer-2 parameter `useNetprofileBSDtraffic` is supported only for load balancing scriptable monitors.

For configuring the NetScaler appliance to source GSLB autosync traffic from a SNIP address, you can use extended ACL rules and RNAT rules as a workaround.

- The `useNetprofileBSDtraffic` support for load balancing scriptable monitors is applicable only for net profiles bound to the related services. The `useNetprofileBSDtraffic` support is not applicable for net profiles bound to the related service groups.

In other words, the NetScaler appliance does not use any SNIP address from the net profiles bound to the service groups for sourcing load balancing scriptable monitors traffic.

- The `useNetprofileBSDtraffic` support is not applicable for SSL services.

In other words, the NetScaler appliance does not use any SNIP address from the net profiles bound to the SSL services for sourcing load balancing scriptable monitors traffic.

## Configure the NetScaler appliance to source scriptable monitors traffic from a SNIP address

Configuring the NetScaler appliance to source scriptable monitors traffic from a SNIP address consists of the following tasks:

- Enable the global Layer-2 parameter `useNetprofileBSDtraffic`.
- Create a net profile and bind at least one SNIP address to it.
- Bind the net profile to the load balancing services that are using scriptable monitors.

### To enable the Layer-2 parameter `useNetprofileBSDtraffic` by using the CLI:

At the command prompt, type:

- **set l2param -useNetprofileBSDtraffic (ENABLED / DISABLED)**
- **show l2param**

### To Create a net profile and bind SNIP addresses to it by using the CLI:

At the command prompt, type:

- **add netProfile <name> -srcIP <string>**
- **show netProfile**

### To bind a net profile to a load balancing service by using the CLI:

At the command prompt, type:

- **set service <name> -netProfile <string>**
- **show service <name>**

## Sample configuration

The following sample configuration enables a NetScaler appliance to source scriptable monitors traffic from a SNIP address. A net profile NETPROFILE-1 is configured with SNIP address 198.51.100.20 bound to it. A user/scriptable monitor USER-MONITOR-1 is created and is bound to a load balancing service SERVICE-1. NETPROFILE-1 is bound to SERVICE-1. The NetScaler appliance sources all scriptable monitors packets of USER-MONITOR-1 from SNIP address 198.51.100.20.

```
1 set l2param -useNetprofileBSDtraffic ENABLED
2
3 set netprofile NETPROFILE-1 -srcip 198.51.100.20
4
5 add lb monitor USER-MONITOR-1 USER -scriptName nsftp.pl -scriptArgs "
 file=Index.png;user=nsroot;password=nsroot" -dispatcherIP 127.0.0.1
 -dispatcherPort 3013 -destIP 203.0.113.90 -destPort 21
6
```

```
7 bind service SERVICE-1 -monitorName USER-MONITOR-1
8
9 set service SERVICE-1 -netProfile NETPROFILE-1
10
11 <!--NeedCopy-->
```

## Configure the NetScaler appliance to source GSLB autosync traffic from a SNIP address

Configuring the NetScaler appliance to source GSLB autosync traffic from a SNIP address consists of the following workaround tasks:

- **Create an extended ACL rule.** An extended ACL rule identifies the GSLB autosync packets. This identification is based on the source IP and destination IP addresses.
- **Apply ACLs.** Applying ACLs activates the newly created ACL rule.
- **Create an ACL based RNAT rule.** An RNAT rule changes the source IP address of these packets from the NSIP address to a SNIP address.

### Note:

In a high availability or cluster setup, you must add ACL and RNAT rules for all the NSIP addresses of the setup.

### To create an extended ACL by using the CLI:

At the command prompt, type:

- **add acl** <aclname> **ALLOW** -**srcIP** = <NSIP address> -**destIP** = <destination IP address of the packets>
- **show acl** <aclName>

### To apply extended ACLs by using the CLI:

At the command prompt, type:

- **apply acls**

### To create an ACL based RNAT rule by using the CLI:

At the command prompt, type:

- **add rnat** <name> <aclname>
- **bind rnat** <name> -**natIP** <SNIP address - source IP address for the packets>
- **show rnat** <name>

## Sample configuration

The following sample configuration enables a NetScaler appliance to source GSLB autosync traffic from a SNIP address. ACL-2 identifies GSLB autosync packets, which are sourced from NSIP address 192.0.1.20 and destined to GSLB site IP address 203.0.113.20. RNAT-2 changes the source IP address to SNIP address 198.51.100.20 for these identified packets.

```
1 add acl ACL-2 ALLOW -srcIP = 192.0.1.20 -destIP = 203.0.113.20
2
3 apply acls
4
5 add rnat RNAT-2 ACL-2
6
7 bind rnat RNAT-2 -natIP 198.51.100.20
8 <!--NeedCopy-->
```

## Observability

June 26, 2023

Due to the increasing complexity of modern applications, monitoring and troubleshooting applications is becoming more challenging for IT teams. Also, gaining visibility into the behavior of infrastructure and applications are more critical for software development teams. Observability bridges this gap by providing deeper insights into the entire infrastructure. Observability tools can collect application or system performance telemetry continuously by integrating with various IT infrastructure components and provides holistic visibility into your IT infrastructure.

Some of the benefits of observability can be summarized as:

- **Faster troubleshooting:** Detailed data insights obtained from observability tools help you to diagnose and troubleshoot system issues faster.
- **Enhanced application performance:** Monitoring key metrics and identifying issues helps developers to make data-driven decisions to improve application performance.
- **Improved reliability and better user experience:** Observability data allows developers to proactively resolve system failures that may disrupt user experience.

### What is observability

Observability is the ability to understand the internal state of a system by analyzing the data it produces, such as logs, metrics, traces, and events. Observability enables you to understand and answer specific questions about the behavior of your system when failures occur. With a deep understanding

of your systems you can be better prepared for the unknowns.

For example, you can track how slow or fast, what is broken, and what should be done to enhance system performance.

Metrics, logs, and traces are the key pillars of observability.

- **Metrics:** Metrics are a numeric representation of data that are measured over a certain period of time. Metric data is useful to track the health of a system over time. These numerical measurements include CPU usage, memory usage, and error rates.
- **Logs:** Logs are messages or records that describe events that happened at a particular point in time. Usually, these messages or records are generated by an application or system.
- **Traces:** Traces represent the journey of a request as it moves through the different parts of a distributed system. Traces document how a request is processed and how long it takes to complete. This data can help identify bottlenecks and other latency issues.

## **Monitoring vs Observability**

Monitoring is a set of tools or solutions to inform you when something is wrong. With observability you can identify what is happening and quickly pinpoint the root of the issues to know why it happened. It integrates the facts and data generated by monitoring to offer you a thorough view of your system performance and health. Using observability, you can automatically analyze your data and improve user experiences based on a rapid, accurate input.

## **Observability with NetScaler**

When NetScaler is deployed as a proxy for application deployments, NetScaler inspects each user request or response for global routing and local data center routing. With the thousands of logs and counters provided by NetScaler you can have granular information about HTTP, TCP, SSL, and DNS packets. You can leverage such rich data and insights from NetScaler to troubleshoot and pinpoint issues. You can export the data from NetScaler to your preferred observability endpoints to create visualizations and get real-time, granular application insights.

NetScaler provides integrations with popular observability tools such as Prometheus, Splunk, Elastic-Serach, and Kafka.

Direct integration of NetScaler is available with Prometheus. With direct integration, there is no need to deploy any additional agent or node to export the data and build customized dashboards of your needs. Prometheus focuses on time series data monitoring which collects numeric metrics from all entities.

NetScaler Console has several built-in observability capabilities such as SSL insights, web transaction insights, and API insights.

NetScaler can provide three kinds of insights as part of observability:

- **Application and API insights:** Application health insights help with troubleshooting which application website has high latency or an elevated number of errors or subpar performance. It also includes monitoring errors, traffic, latency, and saturation metrics. Collectively these signals are known as the golden signals for monitoring the state of applications.
- **Application and API security insights:** Application security insights include WAF violations detected or prevented compared to the overall traffic, the top application affected by WAF or BOT violations, and CVEs, BOT classifications like good and bad bots, and provides information on attackers.
- **Network infrastructure insights:** NetScaler infrastructure insights include information about the NetScaler such as the CPU utilization, memory and disk usage, and network interface telemetry. You can also get specific feature level insights like SSL, GSLB, Multipath TCP (MPTCP) and insights for SSL TLS monitoring like certificate expiry details, protocol used, and cipher strength.

For detailed information on directly exporting metrics to Prometheus from NetScaler, see [Monitoring NetScaler, applications, and application security using Prometheus](#).

## Integration with Prometheus

April 1, 2024

NetScaler can be integrated with popular observability tools and Prometheus is one of them. NetScaler supports direct integration of NetScaler with Prometheus. With direct integration, there is no need to deploy any additional agent or node to export the data and build customized dashboards of your needs. NetScaler supports exporting metrics to Prometheus.

By integrating with Prometheus, you can perform the following actions:

- [Monitor NetScaler, applications, and application security using Prometheus](#)

## Monitor NetScaler, applications, and application security using Prometheus

May 9, 2024

Metrics are a numeric representation of data that are measured over a certain period of time. Metric data is useful to track the

health of a system over time. Prometheus is an open-source monitoring tool that collects metrics data and stores that data with a time stamp at which the data was recorded.

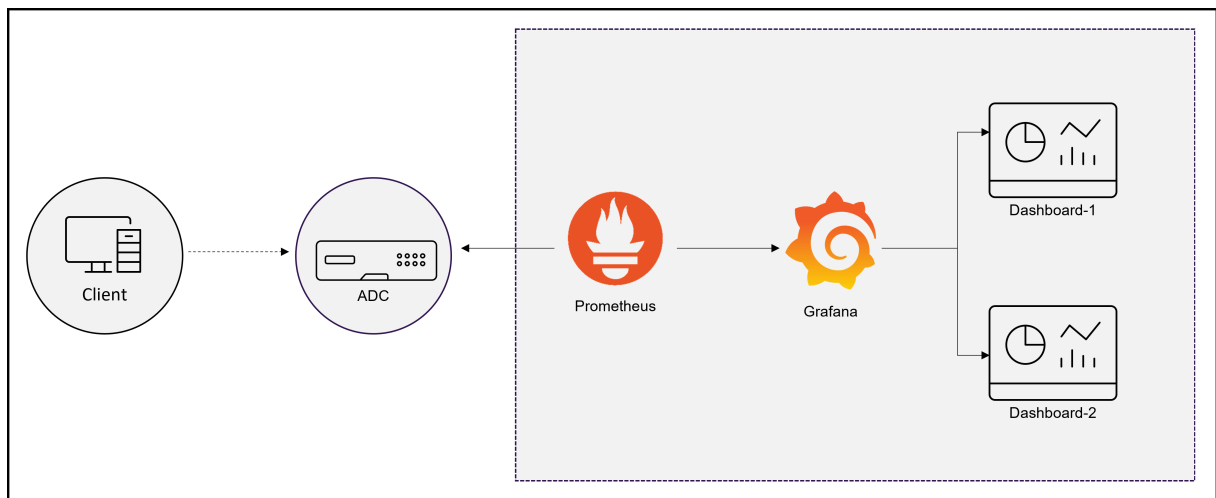

By monitoring and analyzing metrics, you can track the health of your applications, detect any anomalies, create alerts, and take necessary corrective actions to ensure robust software delivery.

NetScaler now supports directly exporting metrics to Prometheus. You can use the rich set of metrics provided by NetScaler ADC to monitor NetScaler health as well as application health. For example, you can gather metrics on CPU and memory usage to know the NetScaler health. Similarly, you can use metrics like the number of HTTP requests received per second or the number of active clients to monitor application health.

### Export of metrics from NetScaler to Prometheus

NetScaler supports the Prometheus pull mode as well as push mode. In the pull mode, you need to configure a time series profile that Prometheus queries at regular intervals and pulls the metrics data directly without an exporter resource in between. With pull mode, you can enable read-only access for a user without superuser privileges to export metrics to Prometheus. Using Grafana, you can visualize the NetScaler metrics exported to Prometheus for easier interpretation and understanding.

The following diagram shows a Prometheus and Grafana integration with NetScaler.

### Configure the export of metrics from NetScaler to Prometheus and visualization using Grafana

You must perform the following steps to configure the export of metrics from NetScaler to Prometheus and visualize it using Grafana.

1. Configure NetScaler with a time series analytics profile for exporting metrics to Prometheus.

2. Install prometheus and configure it with the NetScaler specific parameters.
3. Configure read-only Prometheus access for a non-super user.
4. Add Prometheus as a data source in Grafana.
5. Create visualization in Grafana.

### Configure a time series analytics profile on NetScaler to support the Prometheus pull mode

Do the following steps for configuring pull mode using the NetScaler CLI:

1. Create an analytics profile with type as time series. Specify the schema file with the required NetScaler metrics.

```
1 add analytics profile <timeseries_profile_name> -type timeseries
 -schemaFile <name_of_schema_file> -outputMode Prometheus -
 serveMode PULL -metrics ENABLED
2 <!--NeedCopy-->
```

In this command:

- `timeseries_profile_name`: Specify the time series profile name.
- `schemaFile`: Specify the name of the schema file with NetScaler counters. By default, a schema file `/var/metrics_conf/schema.json` with a list of counters is configured. A reference schema file `reference_schema.json` with all the supported counters is also available under the path `/var/metrics_conf/`. This schema file can be used as a reference to build a custom list of counters. When you specify the schema file, the path of the schema file `/var/metrics_conf/` is automatically added and you need to mention only the schema file name. For example, if you have created a schema file `schema1.json` with a custom list of counters at `/var/metrics_conf/`, you need to specify only the file name as `schema1.json`.

**Note:**

Do not configure the following string counters because they are not supported for Prometheus:

- `si_peer_ip_str`
- `cl_cur_vleader`
- `cl_cur_nodeip`
- `gslb_site_ip_str`
- `gslb_site_publicip_str`
- `vsvr_IPstr`
- `nic_cur_if_alias`
- `vsvr_DynamicProtocolStr`

```
- api_endpoint_apiname
```

- **outputMode**: Set the output mode as Prometheus.
- **serveMode**: Specify Prometheus pull mode.
- **metrics**: Enable collecting metrics from NetScaler.

**Note:**

You can configure an analytics profile with all the necessary parameters using the add command. If you need to make changes after creating the profile, you can use the set command to take the appropriate action such as disabling metrics and changing the server mode. You can configure read-only Prometheus access for a non-super user. For more information, see [configure read-only Prometheus access for a non-superuser](#).

### Install and configure Prometheus for metrics export from NetScaler

You can download Prometheus from repositories such as DockerHub or Quay or the official Prometheus repository.

To run Prometheus as a Docker container use the following command:

```
1 docker run -dp 39090:9090 -v /tmp/prometheus.yml:/etc/prometheus/
 prometheus.yml --name native_prom prom/prometheus:latest
2 <!--NeedCopy-->
```

**Note:**

Here, `/tmp/prometheus.yml` is used as the path to the `prometheus.yml` file. Instead of that, you can specify the path on your virtual machine.

You must edit the `prometheus.yml` with the NetScaler parameters.

To export metrics from NetScaler, you must specify the following NetScaler specific parameters in the **Prometheus YAML scrape configuration** section. The scrape configuration section specifies a set of targets and configuration parameters describing how to scrape them.

- **metrics\_path**: Specify the HTTP resource path in NetScaler to fetch metrics. This parameter is optional and the default path is `/metrics`. If there is no value defined, then Prometheus adds “/metrics” as the path.
- **username**: Specify the NetScaler user name.
- **password**: Specify the NetScaler password.
- **targets**: Specify the IP address of the NetScaler from which you need to export the metrics and the port you want to expose.

- `profilename` : Specify the name of the profile in place of `profilename`. The `profilename` parameter is optional and accepts a user-defined time series profile name. If `profile` name parameter is absent, then `ns_analytics_time_series_profile` is considered as the profile name.
- `follow_redirects`: Configure whether HTTP requests follow HTTP 3xx redirects. This parameter is optional and default value is set to `true` by Prometheus. If you are configuring this parameter, then you must set the value to `true`.

Following is the scrap configuration section of the Prometheus YAML to add the NetScaler IP address as a target on Prometheus to export metrics. Here, HTTP is used as the scheme. You can use either HTTP or HTTPS.

```

1 scrape_configs:
2 - job_name: 'vpx2_metrics_direct'
3 metrics_path: /metrics
4 params:
5 profilename:
6 - 'profile_name'
7 basic_auth:
8 username: 'prom_user'
9 password: 'user_password'
10 scheme: http
11 scrape_interval: 30s
12 follow_redirects: true
13 static_configs:
14 - targets: ['10.102.34.231:80']
15 <!--NeedCopy-->

```

### Configure read-only Prometheus access for a non-super user

Perform the following steps to configure read-only Prometheus access for a non-super user.

1. Add a new user to the NetScaler appliance.

```

1 add system user <ns_user_name> <ns_user's_password> -externalAuth
 enabled -promptString user-%u-at-%T logging enabled
2 <!--NeedCopy-->

```

Example :

```

1 add system user nspaul nspaul -externalAuth enabled -promptString
 user-%u-at-%T logging enabled
2 <!--NeedCopy-->

```

2. Create a command policy for a read-only user. This command policy allows read-only access from any file under the `/var/nslog/` directory.

```

1 add system cmdPolicy read-only-prometheus ALLOW "(^man.*)|(^show\\
s+(?!system)(?!configstatus)(?!ns ns\\.conf)(?!ns savedconfig)
(?!ns runningConfig)(?!gslb runningConfig)(?!audit messages)(?!
techsupport).*)|(^stat.*)|(show system file .* -filelocation
\"/var/nslog\")"
2 <!--NeedCopy-->

```

3. If metrics are only written to a certain file, you may even limit user access such that they can only get that specific file.

```

1 add system cmdPolicy read-only-prometheus ALLOW "(^man.*)|(^show\\
s+(?!system)(?!configstatus)(?!ns ns\\.conf)(?!ns savedconfig) (!ns
runningConfig)(?!gslb runningConfig)(?!audit messages)(?!
techsupport).*)|(^stat.*) |(show system file metrics_prom_<
name_of_timeseries_profile>.log -filelocation \"/var/nslog\")"
2 <!--NeedCopy-->

```

**Note:**

In the `show system file` command, specify the name of the time series profile you have configured in place of `name_of_timeseries_profile`.

4. Bind a user with the command policy.

```

1 bind system user <userName> ((<policyName> <priority>) | -
partitionName <string>)
2 <!--NeedCopy-->

```

For example :

```

1 bind system user user1 read-only-prometheus 0
2 <!--NeedCopy-->

```

To unbind and remove a user from the command policy use the following commands:

1. Unbind a configured user from the system command policy.

```

1 unbind system user <userName> (<policyName> | -partitionName <
string>)
2 <!--NeedCopy-->

```

For example:

```

1 unbind system user user1 read-only-prometheus
2 <!--NeedCopy-->

```

2. Remove the command policy from NetScaler.

```

1 rm system cmdPolicy read-only-prometheus
2 <!--NeedCopy-->

```

## Add Prometheus as a data source in Grafana

If you need visualization of metrics using Grafana dashboards, you need to add Prometheus as a data source in Grafana. For more information, see [add Prometheus as a data source in Grafana](#).

## Create the visualization of metrics in Grafana

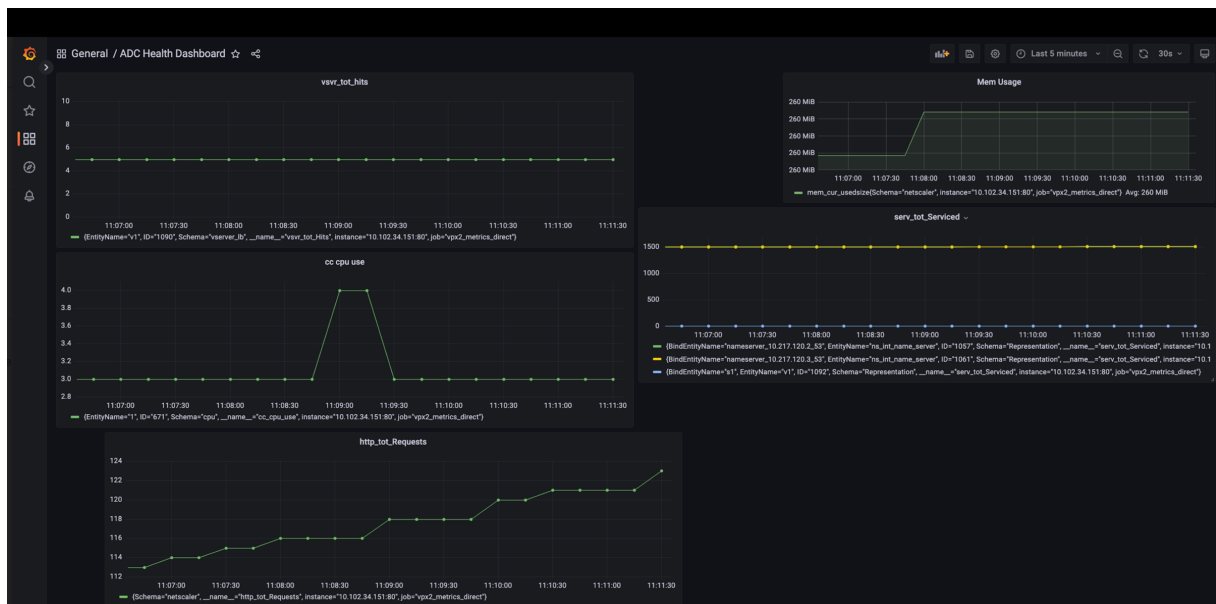

You can create a Grafana dashboard and select the key metrics and the appropriate visualization-type.

The following procedure shows adding a metric to the Grafana panel and creating a sample visualization dashboard.

1. Specify the Panel Title.
2. In the Query tab, for the query A, specify the required metric.
3. In the Settings tab, select the Visualization type.

You can modify the data and its representation in Grafana. For more information, see the [Grafana Documentation](#).

Following is a sample Grafana dashboard with a few NetScaler metrics:

In this dashboard, you can see graphs for different NetScaler metrics such as:

- **vsvr\_tot\_Hits**: Shows the number of requests received by the virtual server.
- **cc\_cpu\_use**: Shows the CPU utilization percentage.
- **http\_tot\_Requests**: Shows HTTP requests received.
- **serv\_tot\_serviced**: Shows the request being serviced.
- **mem\_cur\_used\_size**: Shows the currently used memory of the NetScaler appliance.

## Sample Prometheus graphs

Using the Prometheus expression browser, you can display the time series metrics collected by the Prometheus server. You can access the expression browser by pointing to `prometheus-server-ip-address/graph` in your browser. You can enter an expression and see the result either as a table or graph over time. Specify which exact metric that you want to display by typing in the metric name into the Expression field. You can specify multiple counters using different panels.

The following diagram shows Prometheus graphs for two NetScaler metrics `cpu_use` and `http_tot_requests`.

## Sample Grafana dashboard

NetScaler supports sample dashboards on Grafana. For complete list of sample dashboards supported on Grafana and their details, see [Sample dashboards for Grafana](#).

You can download the sample dashboards from [NetScaler downloads page](#).

## Additional information

### Schema with the required NetScaler counters to export

Metrics collector exports counters present in the configured schema file. The `/var/metrics_conf/schema.json` file is the default schema file configured in the analytics profile.

The schema file is a list of entity types and associated counters. In the schema, all global or system level counters are grouped under the entity type `netScaler`. Some of the global counters are CPU usage (`cpu_use`), management CPU usage (`mgmt_cpu_use`), and total number of HTTP requests received (`http_tot_Requests`). The counters specific to service groups, `lbvserver`, `csvserver`, and so on are listed under the respective entity types.

Following is a sample of counters in the `schema.json` file for the authentication virtual server (`vserver_authn`) entity.

```

1 "vserver_authn":
2 [
3 {
4 "name":"si_tot_Requests","rate":"True" }
5 ,
6 {
7 "name":"si_tot_Responses","rate":"True" }
8 ,
9 {
10 "name":"si_tot_RequestBytes","rate":"True" }
11 ,
12 {
13 "name":"si_cur_state","rate":"False" }
14 ,
15 {
16 "name":"si_tot_ResponseBytes","rate":"True" }
17 ,
18 {
19 "name":"si_peer_port","rate":"True" }
20 ,
21 {
22 "name":"svr_Protocol","rate":"False" }
23
24]
25 <!--NeedCopy-->
```

The following table explains the counters mentioned in this sample:

Counter name	Description
<code>si_tot_Requests</code>	Total number of requests received on this service or virtual server.
<code>si_tot_Responses</code>	Total number of responses received on this service or virtual server.
<code>si_tot_RequestBytes</code>	Total number of request bytes received on this service or virtual server.
<code>si_cur_state</code>	Current state of the virtual server.
<code>si_tot_ResponseBytes</code>	Total number of response bytes received on this service or virtual server.

---

Counter name	Description
<code>si_peer_port</code>	The port on which the service is running.
<code>vsvr_Protocol</code>	Protocol associated with the virtual server.

---

The `rate` field can be set as `True` if the rate value a counter needs to be exported. For example, the rate of `si_tot_Requests` is exported if the `rate` is set to `True` for `si_tot_Requests`.

Following is a sample of counters from the `netScaler` entity.

```
1 "netScaler":
2 [
3 {
4 "name":"cpu_use","rate":"False" }
5 ,
6 {
7 "name":"mgmt_cpu_use","rate":"False" }
8 ,
9 {
10 "name":"tcp_tot_rxpkts","rate":"True" }
11 ,
12 {
13 "name":"tcp_tot_rxbytes","rate":"True" }
14 ,
15 {
16 "name":"tcp_tot_txpkts","rate":"True" }
17 ,
18 {
19 "name":"tcp_tot_txbytes","rate":"True" }
20 ,
21 {
22 "name":"tcp_cur_ClientConnEst","rate":"False" }
23 ,
24 {
25 "name":"tcp_cur_ServerConnEst","rate":"False" }
26 ,
27 {
28 "name":"tcp_cur_ClientConn","rate":"False" }
29 ,
30 {
31 "name":"tcp_cur_ClientConnClosing","rate":"False" }
32 ,
33 {
34 "name":"tcp_tot_ClientOpen","rate":"True" }
35 ,
36 {
37 "name":"tcp_cur_ServerConn","rate":"False" }
38 ,
39 {
40 "name":"tcp_cur_ServerConnClosing","rate":"False" }
```

```

41 ,
42 {
43 "name": "http_tot_Requests", "rate": "True" }
44 ,
45 {
46 "name": "http_tot_Responses", "rate": "True" }
47 ,
48 {
49 "name": "http_tot_Gets", "rate": "True" }
50 ,
51 {
52 "name": "http_tot_Posts", "rate": "True" }
53 ,
54 {
55 "name": "http_tot_Others", "rate": "True" }
56 ,
57]
58 <!--NeedCopy-->

```

The following table explains the counters mentioned in this sample:

Counter name	Description
<code>cpu_use</code>	Tracks the CPU utilization percentage (CPU utilization percentage * 10).
<code>tcp_tot_rxpkts</code>	TCP packets received.
<code>tcp_tot_rxbytes</code>	Bytes of TCP data received.
<code>tcp_tot_txpkts</code>	TCP packets transmitted.
<code>tcp_tot_txbytes</code>	Bytes of TCP data transmitted.
<code>tcp_cur_ClientConnEst</code>	Current client connections in the Established state, which indicates that data transfer can occur between the NetScaler appliance and the client.
<code>tcp_cur_ServerConnEst</code>	Current server connections in the Established state, which indicates that data transfer can occur between the NetScaler appliance and the server.
<code>tcp_cur_ClientConn</code>	Client connections, including connections in the Opening, Established, and Closing state. Server connections, including connections in the Opening, Established, and Closing state.
<code>tcp_cur_ClientConnClosing</code>	Client connections in the Closing state, which indicates that the connection termination process has initiated but is not complete.

Counter name	Description
<code>tcp_cur_ServerConn</code>	Server connections, including connections in the Opening, Established, and Closing state.
<code>tcp_cur_ServerConnClosing</code>	Server connections in the Closing state, which indicates that the connection termination process has initiated but is not complete.
<code>http_tot_Requests</code>	This counter tracks HTTP requests received using the GET method.
<code>http_tot_Responses</code>	This counter tracks HTTP requests received using the POST method.
<code>http_tot_Gets</code>	This counter tracks HTTP requests received using the GET method.
<code>http_tot_Posts</code>	This counter tracks HTTP requests received.
<code>http_tot_Others</code>	This counter tracks HTTP requests received using methods other than GET and POST.

Following is a sample of counters from the `vserver_ssl` entity.

```

1 "vserver_ssl":
2 [
3 {
4 "name":"ssl_ctx_tot_session_hits","rate":"True" }
5 ,
6 {
7 "name":"ssl_ctx_tot_session_new","rate":"True" }
8 ,
9 {
10 "name":"ssl_ctx_tot_enc_bytes","rate":"True" }
11 ,
12 {
13 "name":"ssl_ctx_tot_dec_bytes","rate":"True" }
14 ,
15]
16 <!--NeedCopy-->

```

The following table explains the SSL counters mentioned in this sample:

Counter name	Description
<code>ssl_ctx_tot_session_hits</code>	This counter tracks the number of session hits.
<code>ssl_ctx_tot_session_new</code>	This counter tracks the number of new sessions created.

Counter name	Description
<code>ssl_ctx_tot_enc_bytes</code>	This counter tracks the number of encrypted bytes per SSL virtual server.
<code>ssl_ctx_tot_dec_bytes</code>	This counter tracks the number of bytes decrypted per SSL virtual server.

### Subscription of counters for multiple time series profiles

NetScaler supports creating multiple time series profiles and specifies different set of counters for each profile. Also, you can export only the counters based on your requirements.

You must create multiple `schema.json` files containing the necessary counters with unique names and the `.json` extension to configure multiple time series profiles. A reference schema file `reference_schema.json` is available under the path `/var/metrics_conf/` for your reference.

The configuration of the two new time series profiles is as follows:

```

1 add analytics profile ns_analytics_timeseries_profile_1 -type
 timeseries -schemaFile schema1.json
2
3 set analytics profile ns_analytics_timeseries_profile_1 -outputMode
 prometheus -serveMode PULL -metrics ENABLED
4
5 add analytics profile ns_analytics_timeseries_profile_2 -type
 timeseries -schemaFile schema2.json
6
7 set analytics profile ns_analytics_timeseries_profile_2 -outputMode
 prometheus -serveMode PULL -metrics ENABLED
8 <!--NeedCopy-->
```

In this example, `schema1.json` and `schema2.json` have different sets of counters.

### Prometheus configuration

Configuration of a sample `prometheus.yml` file is as follows:

```

1 scrape_configs:
2 - job_name: 'vpx2_metrics_direct'
3 metrics_path: /metrics
4 params:
5 - 'profile_name'
6 basic_auth:
7 username: 'prom_user'
8 password: 'user_password'
```

```
9 scheme: https
10 scrape_interval: 30s
11 follow_redirects: true
12 static_configs:
13 - targets: ['ADC1-ip:port', 'ADC2-ip:port']
14 <!--NeedCopy-->
```

## Integration with Splunk

April 22, 2024

NetScaler can be integrated with popular observability tools and Splunk is one of them. NetScaler supports direct integration of NetScaler with Splunk. With direct integration, there is no need to deploy any additional agent or node to export the data and build customized dashboards of your needs. NetScaler supports exporting data metrics, audit logs, management logs, transaction logs to Splunk.

By integrating with Splunk, you can perform the following actions:

- [Export metrics directly from NetScaler to Splunk](#)
- [Export transaction logs directly from NetScaler to Splunk](#)
- [Export management logs directly from NetScaler to Splunk](#)
- [Export audit logs and events directly from NetScaler to Splunk](#)

## Export metrics directly from NetScaler to Splunk

April 30, 2024

NetScaler now supports direct export of metrics to Splunk in the JSON format. NetScaler provides rich metrics to monitor your application health and application security health. By exporting the metrics provided by NetScaler to Splunk, you can visualize the metrics and get meaningful insights.

### Configure exporting metrics directly from NetScaler to Splunk

To configure the export of metrics you must perform the following steps:

1. Configure an HTTP event collector (HEC) on Splunk.
2. Create a service for Splunk on NetScaler.
3. Create a time series analytics profile for direct export of metrics to Splunk.

## Configure an HTTP event collector on Splunk

You can forward metrics to Splunk by configuring an HTTP event collector. Configuring the HTTP event collector involves creating an authentication token and associating a metric index with the token where metrics are sent, and setting the HTTP port number.

See the [Splunk documentation](#) for information on how to configure the HTTP event collector.

Once you have configured the HTTP event collector, copy the authentication token and save it for reference. You need to specify this token while configuring the analytics profile on NetScaler.

## Create a collector service for Splunk on NetScaler

You can create a collector service on NetScaler to collect and export metrics from NetScaler to Splunk. Do the following to create a collector service for Splunk.

```
1 add service <collector> <splunk-server-ip-address> <protocol> <port>
```

Example:

```
1 add service splunk_service 10.102.34.155 HTTP 8088
```

In this configuration:

- **ip-address**: Specify the Splunk server IP address.
- **collector-name**: Specify the collector.
- **protocol**: Specify the protocol as HTTP or HTTPS
- **port**: Specify the port number of the Splunk HTTP event collector.

## Configure a time series analytics profile on NetScaler

Do the following to create a time series analytic profile on NetScaler. While creating the time series profile, enable the option for metrics collection and specify details such as Splunk authentication token, name of the collector, output mode, and URL. By default, the time series analytics data is exported every 30 seconds but you can configure it in the range of 30–300 seconds using the metrics frequency parameter.

1. Create a time series analytics profile.

```
1 add analytics profile <profile-name> -type time series -metrics
 enabled -outputMode json -collectors <collector-name> -
 analyticsAuthToken <"auth-token"> -analyticsEndpointUrl <
 endpoint-url>
```

In this configuration, `auth_token` must be configured as “Splunk <auth token generated in Splunk HTTP event collector>”.

Example:

```
1 add analytics profile splunk_profile -type timeseries -metrics
 enabled -outputMode json -collectors splunk -
 analyticsAuthToken "Splunk 1234-5678-12345" -
 analyticsEndpointUrl /services/collector
```

In this configuration:

- `metrics`: Specify the value as `enabled` to enable metrics collection.
- `collectors`: Specify the collector service created for Splunk.
- `analyticsAuthToken`: Specify the authentication token to be included in the authorization header while sending metrics to Splunk. The format is “Splunk `auth-token`”. Here, `auth-token` is the authentication token created on the Splunk server while configuring the HTTP event collector.
- `analyticsEndpointUrl`: Configure this value as `/services/collector` to send metrics to the default index associated with the configured auth token. To redirect metrics to a specific index, specify the index name in the URL (`/services/collector?index=`).

**Note:**

You can modify the time series analytics profile parameters using the `set analytics profile` command.

2. Verify the analytics profile configuration using the `show analytics profile` command.

```
1 # show analytics profile splunk_profile
2
3 1) Name: splunk_profile
4 Collector: splunk
5 Profile-type: timeseries
6 Output Mode: json
7 Metrics: ENABLED
8 Schema File: schema.json
9 Metrics Export Frequency: 30
10 Events: DISABLED
11 Auditlog: DISABLED
12 Serve mode: Push
13 Authentication Token: <auth-token>
14 Endpoint URL: /services/collector
15 Endpoint Content-type:
16 Endpoint Metadata:
17 Reference Count: 0
```

Once the configuration is successful, metrics are sent as HTTP payloads to Splunk and you can view it on the Splunk application user interface.

## Export transaction logs directly from NetScaler to Splunk

April 30, 2024

You can now export transaction logs from NetScaler to industry-standard log aggregator platforms such as Splunk. The transaction log is the record of application traffic flow events on the NetScaler such as HTTP requests and responses, connection start and end. For more information on transaction logs, see [AppFlow](#).

You can export transaction logs in JSON format for different insights such as Web Insight, security, gateway, HDX insights. To export transaction logs to Splunk, you must configure Splunk as an HTTP server and use the HTTP event collector to send transaction logs over HTTP (or HTTPS) directly to the Splunk platform from your NetScaler. Using the visualization tools at Splunk, you can get meaningful insights about the exported data.

### Note:

The IP addresses that are exported as part of the transaction logs appear in the decimal format instead of the standard format. For example, if your NetScaler IP address is 10.102.154.153, the same in the transaction logs on Splunk is displayed as 174496409. You can use the inbuilt expressions available on Splunk to convert the IP address from decimal format to standard format.

## Export transaction logs from NetScaler to Splunk configured as an HTTP server

To configure the export of transaction logs you must perform the following steps:

1. Configure an HTTP event collector on Splunk.
2. Create a collector service and an analytics profile on NetScaler.

### Configure an HTTP event collector on Splunk

You can forward transaction logs to Splunk by configuring an HTTP event collector. Configuring the HTTP event collector involves creating an authentication token and associating an event index with the token where events are sent, and setting the HTTP port number. For information on how to configure the HTTP event collector, see the [Splunk documentation](#).

Once you have configured the HTTP event collector, copy the authentication token and save it for reference. You need to specify this token while configuring the analytics profile on NetScaler.

## Configure analytics profile on NetScaler

Do the following to export NetScaler transaction logs to Splunk.

1. Create a collector service for Splunk.

```
1 add service <collector> <splunk-server-ip-address> <protocol> <port>
```

Example:

```
1 add service splunk_service 10.102.34.155 HTTP 8088
```

In this configuration:

- ip-address: Splunk server IP address.
- collector-name: Name of the collector.
- protocol: Specify the protocol as HTTP or SSL.
- port: Port number.

2. Create an analytics profile.

```
1 add analytics profile `profile-name` -type <insight> -collectors `collector-name` -analyticsAuthToken `<auth-scheme> <authorization-parameters>` -analyticsEndpointContentType `application/json` -analyticsEndpointUrl `endpoint-url`
```

Example:

```
1 add analytics profile transaction-log-profile -type webinsight -collectors splunk_collector -analyticsAuthToken "Splunk 1234-5678-12345" -analyticsEndpointContentType "application/json" -analyticsEndpointUrl "/services/collector/event"
```

### Note:

The `-allHttpHeaders` option is not supported for Splunk transaction log export.

```
add analytics profile <profile-name> -type webinsight -allHttpHeaders
```

```
set analytics profile <profile-name> -type webinsight -allHttpHeaders
```

In this configuration:

- insight: Types of insights that you can export The following options are available:
  - botinsight
  - Clinsight

- Gatewayinsight
  - hdxinsight
  - lsninsight
  - securityinsight
  - tcpinsight
  - udpinsight
  - videoinsight
  - webinsight
- -analyticsAuthToke auth-scheme authorization-parameters: Specify the authentication token to be included in the authorization header with the auth-scheme “Splunk” while sending logs to Splunk. This token is the authentication token created on the Splunk server while configuring the HTTP event collector.
  - analyticsEndpointContentType: The Content-Type header. The hardcoded value is application/json.
  - analyticsEndpointUrl: The path to HEC on Splunk (/services/collector/event or /services/collector).

**NOTE:**

You can modify the analytics profile parameters using the `set analytics profile` command.

- dataFormatFile: The file that contains the details of what data in transaction log must be exported and in which format. Each endpoint expects JSON payload to be encoded in a specific format. If the format is not specified, then by default the `splunk_format.txt` is selected.

3. Verify the analytics profile configuration using the `show analytics profile` command.

```
1 > sh analytics profile
2
3 ns_analytics_default_http_profile
4 1) Name: ns_analytics_default_http_profile
5 Collector: splunk
6 Profile-type: webinsight
7 Page Tracking: DISABLED
8 Client Side Measurements: DISABLED
9 URL Logging: ENABLED
10 Host Header Logging: ENABLED
11 Method Logging: ENABLED
12 Cookie Header Logging: DISABLED
13 Referrer Header Logging: DISABLED
14 User Agent Logging: DISABLED
15 Content Type Logging: DISABLED
16 Authorization Header Logging: DISABLED
```

```

17 Via Header Logging: DISABLED
18 Location Header Logging: DISABLED
19 URL Category Logging: DISABLED
20 Log All HTTP Headers: DISABLED
21 X-Forwarded-For Header Logging: DISABLED
22 Set-Cookie Header Logging: DISABLED
23 Set-Cookie2 Header Logging: DISABLED
24 Domain Name Logging: DISABLED
25 URL-Query Logging: DISABLED
26 Integrated Cache Logging: DISABLED
27 gRPC Status Logging: DISABLED
28 API Spec Info Export Logging: DISABLED
29 Authentication Token:
30 Endpoint URL: /services/collector/event
31 Endpoint Content-type: text/json
32 Reference Count: 1
33 Managementlog: NONE

```

#### 4. Bind the analytics profile to the virtual server.

```

1 bind lb vserver <vserver-name> -analyticsProfile transaction-log-profile

```

Example:

```

1 bind lb vserver sample-virtualserver -analyticsProfile transaction-log-profile

```

After the configuration is successful, based on traffic, transactions will be logged and exported to HEC on Splunk.

### Field-based filtering of data records

By default, NetScaler exports hundreds of fields in transaction log even when the endpoints do not require all of the exported data. Also, each endpoint expects the JSON payload to be encoded in a specific format such as the start and end of a data record, the delimiter between data records, and buffer start and end.

Splunk expects the JSON payload coming from NetScaler to be encoded in the following format:

- Buffer start and end: No value required for `BUFFER-START` and `BUFFER-END`.
- Data record start and end: The data record must start with `{ "event": {` and end with `} }`. All the fields that get exported must be between `DATA-START` and `DATA-END`.

The data records must start with the following:

```

1 RECORD-START
2 {
3 "event": {

```

```

4
5 DATA_START

```

The data records must end with the following:

```

1 DATA-END
2 }
3 }
4
5 RECORD-END

```

- Delimiter between data records: No delimiter required.

By default, `splunk_format.txt` is available at `var/analytics_conf` folder that contains the JSON payload format that Splunk expects and also contains a few default fields for which the data gets exported. You can configure `splunk_format.txt` as the value for `-dataFormatFile` parameter in the `add analytics profile` command.

The following is a sample data format file for Splunk:

```

1 BUFFER-START
2 RECORD-START
3 {
4 "event":{
5
6 DATA-START
7 153 observationPointId
8 547 nsPartitionId
9 154 exportingProcessId
10 159 transactionId
11 801 httpReqUrl
12 685 httpReqMethod
13 683 httpReqHost
14 472 svrDstIpv4Address
15 579 srvSrcPort
16 580 srvDstPort
17 13 backendSvrIpv6Address
18 473 cltIpv4Address
19 474 cltDstIpv4Address
20 577 cltSrcPort
21 578 cltDstPort
22 14 transCltIpv6Address
23 15 transCltDstIpv6Address
24 DATA-END
25 }
26 }
27
28 RECORD-END
29 RECORD-DELIMITER
30
31 RECORD-DELIMITER-END
32 BUFFER-END

```

The `JSON_fields.txt` file under `var/analytics_conf` is a reference master file that contains the complete list of fields along with their identification numbers. The fields in the master file are categorized based on the insights. For example, if you want to know the fields associated with HDX insight, you can look at the HDX insights category of `JSON_fields.txt` file.

You can customize the `splunk_format.txt` file based on your requirement. For example, if you want to export HDX insights, you can look at the HDX insights category in `JSON_fields.txt` file and add the required fields in the `splunk_format.txt` file. Similarly, you can delete any fields that you do not wish to export.

After customizing the `splunk_format.txt` file, execute the following command to update the analytics profile:

```
1 update analytics profile <profile-name> -dataFormatFile <data-format-file-name>
```

Example:

```
1 update analytics profile ns _analytics_ default_http_profile -
 dataFormatFile splunk format.txt
```

You can also specify the value of data format file using the GUI. Navigate to **System > AppFlow > Analytics Profiles** and click **Add**. On the **Create Analytics Profile** page, if you select one of the following options for **Type**, then the **Data Format File** field appears where you can specify the file name:

- GLOBAL
- WEB INSIGHT
- TCP INSIGHT
- SECURITY INSIGHT
- VIDEO INSIGHT
- HDX INSIGHT
- GATEWAY INSIGHT
- LSN INSIGHT
- BOT INSIGHT
- TIME SERIES

## Sample outputs

This section contains sample outputs for different transaction logs.

### HTTP transaction log sample output

The following is a sample output for the HTTP transaction log.

```
1 {
2
3 appName: VS1
4 clientMss: 1460
5 clntFastRetxCount: 0
6 clntTcpJitter: 0
7 cintTcpPacketsRetransmitted: 0
8 clntTcpRtoCount: 0
9 clntTcpZeroWindowCount: 0
10 cltDstIpv4Address: 174496411
11 cltIpv4Address: 174496407
12 connEndTimeStamp: 0
13 connStartTimeStamp: 7329468222993076980
14 exportingProcessId: 0
15 httpRegHost: 10.102.154.155
16 httpReqMethod: GET
17 httpReqUrl: /big.html
18 httpRspLen: 114380
19 httpRspStatus: 200

## Sample dashboards for transaction logs

The following dashboards available on Splunk provide the data related to transaction logs:

- NetScaler HTTP Insight Dashboard
- NetScaler SSL Insight Dashboard
- NetScaler TCP Insight Dashboard

For more information, see [Sample dashboards on Splunk](#).

## Export management logs directly from NetScaler to Splunk

April 30, 2024

You can now export management logs (non-packet engine logs) on a category basis such as `shell`, `access`, and `nsmgmt` logs from NetScaler to industry standard log aggregator platforms such as Splunk. Using the visualization tools at Splunk, you can get meaningful insights about the exported data.

There are multiple ways to export management logs from NetScaler to Splunk. You can either configure Splunk as an HTTP server or a syslog server. In the HTTP server configuration, you can use the HTTP event collector to send management logs over HTTP (or HTTPS) directly to the Splunk platform from your NetScaler. In the syslog server configuration, management logs are sent as syslog payloads from NetScaler to Splunk.

## Export management logs to Splunk configured as an HTTP server

To configure the export of management logs you must perform the following steps:

1. Configure an HTTP event collector on Splunk.
2. Create a collector service and a time series analytics profile on NetScaler.

### Configure an HTTP event collector on Splunk

You can forward management logs to Splunk by configuring an HTTP event collector. Configuring the HTTP event collector involves creating an authentication token and associating an event index with the token where events are sent, and setting the HTTP port number.

For information on how to configure the HTTP event collector, see the [Splunk documentation](#).

Once you have configured the HTTP event collector, copy the authentication token and save it for reference. You need to specify this token while configuring the analytics profile on NetScaler.

### Configure a time series analytics profile on NetScaler using the CLI

Do the following to export NetScaler management logs to Splunk.

1. Create a collector service for Splunk.

```
1 add service <collector> <splunk-server-ip-address> <protocol> <
 port>
```

Example:

```
1 add service splunk_service 10.102.34.155 HTTP 8088
```

In this configuration:

- **ip-address**: Splunk server IP address.
- **collector-name**: Name of the collector.
- **protocol**: Specify the protocol as HTTP or HTTPS
- **port**: Port number.

2. Create a time series analytics profile.

```
1 add analytics profile `profile-name` -type time series -
 managementlog <management-log-type> -collectors `collector-name`
 -analyticsAuthToken `auth-token` -
 analyticsEndpointContentType `Application/json` -
 analyticsEndpointMetadata `meta-data-for-endpoint` -
 analyticsEndpointUrl `endpoint-url`
```

Example:

```

1 add analytics profile managementlogs_profile -type timeseries -
 managementlog ACCESS -collectors splunk -analyticsAuthToken "
 Splunk 1234-5678-12345" -analyticsEndpointContentType "
 application/json" -analyticsEndpointMetadata "{
2 \"sourcetype\": \"logs-and-events-directly-from-netscaler\", \"
 source\": \"test\", \"event\": }
3 \" -analyticsEndpointUrl \"/services/collector/event"

```

In this configuration:

- **managementlog**: Types of management logs that you must export. The following options are available:
  - ALL: Includes all categories of management and host logs.
  - SHELL: Includes `bash.log` and `sh.log`.
  - Access: Includes logs such as `auth.log`, `nsvpn.log`, `vpndebug.log`, `httpaccess.log`, `httperror.log`, `httpaccess-vpn.log`, and `httperror-vpn.log`.
  - NSMGMT: Includes `ns.log` and `notice.log`.
  - NONE: None of the logs are exported.
- **analyticsAuthToken**: Specify the authentication token to be included in the authorization header with the prefix “Splunk” while sending logs to Splunk. This token is the authentication token created on the Splunk server while configuring the HTTP event collector.
- **analyticsEndpointContentType**: Format of the logs.
- **analyticsEndpointMetadata**: Meta data that is endpoint specific.
- **analyticsEndpointUrl**: Location in the endpoint to export logs.

**Note:**

You can modify the time series analytics profile parameters using the `set analytics profile` command.

3. Verify the analytics profile configuration using the `show analytics profile` command.

```

1 # show analytics profile splunkexport
2 1) Name: audit_profile
3 Collector: splunk
4 Profile-type: timeseries
5 Output Mode: avro
6 Metrics: DISABLED
7 Schema File: schema.json
8 Metrics Export Frequency: 30

```

```
9 Events: DISABLED
10 Auditlog: DISABLED
11 Serve mode: Push
12 Authentication Token: <auth-token>
13 Endpoint URL: /services/collector/event
14 Endpoint Content-type: Application/json
15 Endpoint Metadata: Event:
16 Reference Count: 0
17 Managementlog: ACCESS
```

Once the configuration is successful, the management logs are sent as HTTP payloads to Splunk and you can view it on the Splunk application user interface.

### Configure a time series analytics profile on NetScaler using the GUI

Perform the following steps:

1. Create a collector service.
  - a) Navigate to **Traffic Management > Load Balancing > Services** and click **Add**.
  - b) On the **Load Balancing Service** page, enter the details in the required fields, click **OK** and then click **Done**.
2. Create a time series analytics profile.
  - a) Navigate to **System > Profiles > Analytics Profiles** and click **Add**.
  - b) On the **Create Analytics Profile** page, provide the following details:
    - i. Enter a name for the profile.
    - ii. From the **Collectors** list, select the service that you created.
    - iii. Select a **TIME SERIES** from the **Type** list.
    - iv. Enter the **Analytics Auth Token** that you received from Splunk with the prefix “Splunk”.
    - v. Enter the details for **Analytics Endpoint URL**, **Analytics Endpoint Content Type**, and **Analytics Endpoint Metadata**.
    - vi. Select the **Management Logs** that you want to export and also the **Output Mode** in which you want to export.
    - vii. Click **Create**.

### Export management logs to Splunk configured as a syslog server

To configure the export of management logs, you must perform the following steps:

1. Configure the syslog port on Splunk.

2. Create an audit syslog action on NetScaler with the management log option.
3. Create a syslog audit policy with the syslog action.
4. Bind the syslog audit policy with the system global entity to enable logging of all NetScaler system events.

### Configure Splunk as an external syslog server

You can forward management logs to Splunk by configuring an external syslog server on Splunk.

For information on how to configure the syslog port, see the [Splunk documentation](#). Once you have configured the syslog port, save it for reference. You need to specify this port while configuring the `audit syslogaction` on NetScaler.

### Configure syslog audit action

To configure syslog audit action on NetScaler using CLI, run the following command:

```
1 add audit syslogAction <name> \(<serverIP> \[-serverPort <port>] -
 logLevel <logLevel> ... \[-managementlog <managementlog> ...]
 ... \[-managementloglevel <managementloglevel> ...]\[-transport
 \(\ TCP | UDP))
```

Example:

```
1 add audit syslogAction test 10.106.186.102 -serverPort 514 -
 logLevel ALL -managementlog SHELL NSMGMT -managementloglevel ALL
 -transport TCP
```

In this configuration:

- `name`: Name of the syslog action
- `serverIP`: IP address of the syslog server.
- `serverPort`: Port on which the syslog server accepts connections.
- `logLevel`: Audit log level.
- `managementlog`: Types of management logs that you must export.
- `managementloglevel`: Management log levels that you want to set for export.
- `transport`: The transport type used to send audit logs to the syslog server.

#### Note:

When management logs is enabled, the `syslogAction` configuration supports only server IP address and port configuration. Domain Based Service (DBS) and load balancing virtual server name configurations are not supported.

For load balancing management logs exported across multiple external syslog servers (for exam-

ple, Splunk syslog servers or endpoints), you can use the following sample configuration:

```
add service syslog_server <server_ip> UDP <port>
add service syslog_server1 1.3.4.4 UDP 514
add service syslog_server2 1.3.4.5 UDP 514
add lb vserver lb1 UDP <lb_vip> <lb_port>
bind lb vserver lb1 syslog_server1
bind lb vserver lb1 syslog_server2
```

In syslogAction, configure the following:

```
add syslogAction sys1 <server_ip> -serverPort <server_port> -
transport UDP -loglevel <loglevel>

add syslogAction sys1 lb_vip -serverPort lb_port -transport UDP -
loglevel <loglevel>
```

To configure syslog audit action on NetScaler using the GUI, perform the following steps:

1. Navigate to **System > Auditing > Syslog > Server** tab and click **Add**.
2. On the **Create Auditing Server** page, provide the following details:
  - a) Enter a name for the Syslog server.
  - b) Select **Server IP** from the **Server Type** list and enter the syslog server IP address and port.
  - c) Choose the required log levels from the **Log Levels, Management Logs** and **Management Log Levels** sections.
3. Click **Create**.

### Configure syslog audit policy

To configure a syslog audit policy using CLI, run the following command:

```
1 add audit syslogPolicy <name> TRUE <syslogAction>
```

Example:

```
1 add audit syslogPolicy test-policy TRUE test
```

To configure a syslog audit policy using the GUI, perform the following steps:

1. Navigate to **System > Auditing > Syslog > Policies** tab and click **Add**.
2. On the **Create Auditing Syslog Policy** page, enter a name, select **Advanced Policy**, and then select the audit syslog server that you created from the **Server** list.

## Bind audit log policy

To bind the syslog audit log policy to the bind point `SYSTEM_GLOBAL` using CLI, run the following command:

```
1 bind audit syslogGlobal <policyname> -globalBindType SYSTEM_GLOBAL
```

Example:

```
1 bind audit syslogGlobal test-policy -globalBindType SYSTEM_GLOBAL
```

To bind the syslog audit log policy globally using the GUI, run the following command:

1. Navigate to **System > Auditing > Syslog > Policies** tab and select the syslog audit policy that you created.
2. Right-click on the selected syslog audit policy and click **Advanced Policy Global Bindings**.
3. Select the syslog audit policy that you created from the **Select Policy** list.
4. Enter the priority in the **Priority** field.
5. Select **SYSTEM\_GLOBAL** from the **Global Bind Type** field and click **Bind**.
6. On the **Syslog Auditing** page, select the syslog audit policy and click **Done**.

Once the configuration is successful, the management logs are sent as syslog payloads to Splunk and you can view it on the Splunk application user interface.

## Additional information

This section provides more information on the three types of logs specified in this topic:

- `shell` logs: Includes `bash.log` and `sh.log`.
- `access` logs: Includes `httpaccess.log`, `httperror.log`, `httpaccess-vpn.log`, `httperror-vpn.log`, `vpndebug.log`, `nsvpn.log`, and `auth.log`.
- `nsmgmt` logs: Includes `notice.log`, and `ns.log` (only includes non-packet engine logs).

## Export audit logs and events directly from NetScaler to Splunk

April 30, 2024

Audit logging enables you to log the NetScaler states and status information collected by various modules in NetScaler. By reviewing the logs, you can troubleshoot problems or errors and fix them.

You can now export audit logs and events from NetScaler to industry standard log aggregator platforms such as Splunk and get meaningful insights.

There are multiple ways to export audit logs from NetScaler to Splunk. You can either configure Splunk as a syslog server or as an HTTP server. This topic provides information on configuring Splunk as an HTTP server using the Splunk HTTP event collector. Using the HTTP event collector you can send audit logs over HTTP (or HTTPS) directly to the Splunk platform from your NetScaler.

## Configure exporting audit logs from NetScaler to Splunk

To configure the export of audit logs you must perform the following steps:

1. Configure the HTTP event collector on Splunk.
2. Create a collector service and time series analytics profile on NetScaler.

### Configure HTTP event collector on Splunk

You can forward audit logs to Splunk by configuring an HTTP event collector. Configuring the HTTP event collector involves creating an authentication token and associating an event index with the token where events are sent, and setting the HTTP port number.

See the [Splunk documentation](#) for information on how to configure the HTTP event collector.

Once you have configured the HTTP event collector, copy the authentication token and save it for reference. You need to specify this token while configuring the analytics profile on NetScaler.

### Configure time series analytics profile on NetScaler

Do the following to export NetScaler audit logs to Splunk.

1. Create a collector service for Splunk.

```
1 add service <collector> <splunk-server-ip-address> <protocol> <port>
```

Example:

```
1 add service splunk_service 10.102.34.155 HTTP 8088
```

In this configuration:

- **ip-address**: Specify the Splunk server IP address.
  - **collector-name**: Specify the collector.
  - **protocol**: Specify the protocol as HTTP or HTTPS
  - **port**: Specify the port number.
2. Create a time series analytics profile.

```

1 add analytics profile <profile-name> -type time series -
 auditlog enabled -collectors <collector-name> -
 analyticsAuthToken <"auth-token">
2 -analyticsEndpointContentType <"application/json"> -
 analyticsEndpointMetadata <"meta-data-for-endpoint:"> -
 analyticsEndpointUrl <"endpoint-url">

```

**Example:**

```

1 add analytics profile audit_profile -type timeseries -auditlog
 enabled -collectors -analyticsAuthToken "Splunk
 1234-5678-12345" -analyticsEndpointContentType "application
 /json" -analyticsEndpointMetadata "{
2 \"event\":[" -analyticsEndpointUrl "/services/collector/event"

```

**In this configuration:**

- **auditlog:** Specify the value as `enabled` to enable audit logging.
- **analyticsAuthToken:** Specify the authentication token to be included in the authorization header while sending logs to Splunk. This token is the authentication token created on the Splunk server while configuring the HTTP event collector. The authentication token must be in the format “Splunk <token-copied-from-splunk>”. For example, “Splunk 3e52aa4b-1db7-45b2-9af9-173eedc8e1bc”.
- **analyticsEndpointContentType:** Specify the format of the logs.
- **analyticsEndpointMetadata:** Specify the meta data that Splunk expects at the start of the data, which is `{ \"event\":[`.
- **analyticsEndpointUrl:** Specify the URL to which you have configured Splunk HEC to get requests to. For example, `/services/collector/event`”.

**Note:**

You can modify the time series analytics profile parameters using the `set analytics profile` command.

**3. Verify the analytics profile configuration using the show analytics profile command.**

```

1 # show analytics profile audit_profile
2
3 1) Name: audit_profile
4 Collector: splunk
5 Profile-type: timeseries
6 Output Mode: avro
7 Metrics: DISABLED
8 Schema File: schema.json
9 Metrics Export Frequency: 30
10 Events: DISABLED

```

```

11 Auditlog: ENABLED
12 Serve mode: Push
13 Authentication Token: <auth-token>
14 Endpoint URL: /services/collector/event
15 Endpoint Content-type: application/json
16 Endpoint Metadata: {
17 "event":[
18 Reference Count: 0

```

Once the configuration is successful, the audit logs are sent as HTTP payloads to Splunk and you can view it on the Splunk application user interface.

## Configure exporting events from NetScaler to Splunk

To configure the export of events from NetScaler to Splunk, you must perform the following steps:

1. Configure the HTTP event collector on Splunk following the steps in [Configure HTTP event collector on Splunk](#).
2. Create a collector service on NetScaler by using the following command.

```

1 add service <collector> <splunk-server-ip-address> <protocol> <
 port>

```

Example:

```

1 add service splunk_service 10.102.34.155 HTTP 8088

```

In this configuration:

- `ip-address`: Specify the Splunk server IP address.
  - `collector-name`: Specify the collector.
  - `protocol`: Specify the protocol as HTTP or HTTPS.
  - `port`: Specify the port number.
3. Create a time series analytics profile on NetScaler using the `add analytics profile` command. You must specify the `-events enabled` option while creating the analytics profile to enable the export events.

Example:

```

1 add analytics profile event_profile -type timeseries -events
 enabled -collectors splunk -analyticsAuthToken "Splunk
 1234-5678-12345" -analyticsEndpointContentType "application/
 json" -analyticsEndpointMetadata "{
2 \"event\":[\" -analyticsEndpointUrl \"/services/collector/event"

```

4. Verify the analytics profile configuration using the `show analytics profile` command.

```
1 # show analytics profile event_profile
2
3 1) Name: event_profile
4 Collector: splunk
5 Profile-type: timeseries
6 Output Mode: avro
7 Metrics: DISABLED
8 Schema File: schema.json
9 Metrics Export Frequency: 30
10 Events: ENABLED
11 Auditlog: DISABLED
12 Serve mode: Push

## Integration with Elasticsearch

April 2, 2024

NetScaler can be integrated with popular observability tools and Elasticsearch is one of them. NetScaler supports direct integration of NetScaler with Elasticsearch. With direct integration, there is no need to deploy any additional agent or node to export the data and build customized dashboards of your needs.

By integrating with Elasticsearch, you can perform the following actions:

- [Export transaction logs directly from NetScaler to Elasticsearch](#)

## Export transaction logs directly from NetScaler to Elasticsearch

April 8, 2024

You can now export transaction logs from NetScaler to industry-standard log aggregator platforms such as Elasticsearch. The transaction log is the record of application traffic flow events on the NetScaler such as HTTP requests and responses, connection start and end. For more information on transaction logs, see [AppFlow](#).

You can export transaction logs in JSON format for various insights such as Web Insight, security, gateway, HDX insights. To export transaction logs to Elasticsearch, you must configure Elasticsearch as an

HTTP server and use the HTTP event collector to send transaction logs over HTTP (or HTTPS) directly to the Elasticsearch platform from your NetScaler. Using the visualization tools at Kibana, you can get meaningful insights about the exported data.

**Note:**

The IP addresses that are exported as part of the transaction logs appear in the decimal format instead of the standard format. For example, if your NetScaler IP address is 10.102.154.153, the same in the transaction logs on Elasticsearch is displayed as 174496409. You can use the inbuilt expressions available on Elasticsearch to convert the IP address from decimal format to standard format.

## Export transaction logs from NetScaler to Elasticsearch configured as an HTTP server

To configure the export of transaction logs you must perform the following steps:

1. Configure Elasticsearch to receive transaction logs.
2. Create a collector service and an analytics profile on NetScaler.

### Configure Elasticsearch to receive transaction logs

You can configure Elasticsearch to receive the transaction logs forwarded by NetScaler by following the configuration steps available in [Elasticsearch documentation](#).

Once you have configured, copy the authentication token and save it for reference. You need to specify this token while configuring the analytics profile on NetScaler.

### Configure analytics profile on NetScaler

Do the following to export NetScaler transaction logs to Elasticsearch.

1. Create a collector service for Elasticsearch.

```
1 add service <collector> <elasticsearch-server-ip-address> <
 protocol> <port>
```

Example:

```
1 add service elasticsearch_service 10.102.34.155 HTTP 8088
```

In this configuration:

- ip-address: Elasticsearch server IP address.
- collector-name: Name of the collector.

- protocol: Specify the protocol as HTTP or SSL.
- port: Port number.

## 2. Create an analytics profile.

```
1 add analytics profile `profile-name` -type <insight> -collectors `collector-name` -analyticsAuthToken `<auth-scheme> <authorization-parameters>` -analyticsEndpointContentType `application/json` -analyticsEndpointUrl `endpoint-url`
```

### Example:

```
1 add analytics profile transaction-log-profile -type webinsight -collectors elasticsearch_collector -analyticsAuthToken "ApiKey 1234-5678-12345" -analyticsEndpointContentType "application/json" -analyticsEndpointUrl "/_bulk"
```

### Note:

The `-allHttpHeaders` option is not supported for Elasticsearch transaction log export.

```
add analytics profile <profile-name> -type webinsight -allHttpHeaders
set analytics profile <profile-name> -type webinsight -allHttpHeaders
```

### In this configuration:

- insight: Types of insights that you can export The following options are available:
  - botinsight
  - Clinsight
  - Gatewayinsight
  - hdxinsight
  - lsninsight
  - securityinsight
  - tcpinsight
  - udpinsight
  - videoinsight
  - webinsight
- -analyticsAuthToke auth-scheme authorization-parameters: Specify the authentication token to be included in the authorization header with the auth-scheme “ApiKey” while sending logs to Elasticsearch. This token is the authentication token created on the Elasticsearch server while configuring the HTTP event collector.

- `analyticsEndpointContentType`: The Content-Type header. The hardcoded value is `application/json`.
- `analyticsEndpointUrl`: The path on Elasticsearch to which transactions need to be posted. For example, `/_bulk`.

**NOTE:**

You can modify the analytics profile parameters using the `set analytics profile` command.

3. Verify the analytics profile configuration using the `show analytics profile` command.

```
1 > sh analytics profile
```

4. Bind the analytics profile to the vserver.

```
1 bind lb vserver <vserver-name> -analyticsProfile transaction-log-profile
```

**Example**

```
1 bind lb vserver sample-log -analyticsProfile transaction-log-profile
```

After the configuration is completed, based on traffic, transactions will be logged and exported to Elasticsearch.

## Field-based filtering of data records

By default, NetScaler exports hundreds of fields in transaction log even when the endpoints do not require all of the exported data. Also, each endpoint expects the JSON payload to be encoded in a specific format such as the start and end of a data record, the delimiter between data records, and buffer start and end.

Elasticsearch expects the JSON payload from coming from NetScaler to be encoded in the following format:

- Buffer start and end: No value required for `BUFFER-START` and `BUFFER-END`. At the end of the buffer, you must add a blank line.
- Data record start and end: The data record must start with `{ "index": { "_index": "transactions" } }` and end with `}`. All the fields that get exported must be captured between `DATA-START` and `DATA-END`.

The data records must start with the following:

```
1 RECORD-START
2 {
3 "index": {
4 "_index": "transactions" }
5 }
6
7 {
8
9 DATA-START
```

The data records must end with the following:

```
1 DATA-START
2 }
3
4 RECORD-END
```

- Delimiter between data records: One blank line between the data records.

By default, `elastic_format.txt` is available at `var/analytcs_conf` folder that contains the the JSON payload format that Elasticsearch expects and also contains a few default fields for which the data gets exported. You can configure `elastic_format.txt` as the value for `-dataFormatFile` parameter in the add analytics profile command.

The following is a sample data format file for Elasticsearch:

```
1 BUFFER-START
2 RECORD-START
3 {
4 "index": {
5 "_index": "transactions" }
6 }
7
8 {
9
10 DATA-START
11 153 observationPointId
12 547 nsPartitionId
13 154 exportingProcessId
14 159 transactionId
15 801 httpReqUrl
16 685 httpReqMethod
17 683 httpReqHost
18 689 httpReqUserAgent
19 680 httpContentType
20 691 httpReqXForwardedFor
21 682 httpDomainName
22 803 appName
23 851 appNameVserverLs
24 484 httpRspStatus
25 53 httpRspLen
26 684 httpResLocation
```

```
27 687 httpResSetCookie
28 DATA-END
29 }
30
31 RECORD-END
32 RECORD-DELIMITER
33
34
35 RECORD-DELIMITER-END
36
37
38 BUFFER-END
```

The `JSON_fields.txt` file under `var/analytics_conf` is a reference master file that contains the complete list of fields along with their identification numbers. The fields in the master file are categorized based on the insights. For example, if you want to know the fields associated with HDX insight, you can look at the HDX insights category of `JSON_fields.txt` file to know the fields associated with HDX insights category.

You can customize the `elastic_format.txt` file based on your requirement. For example, if you want to export HDX insights, you can look at the HDX insights category in `JSON_fields.txt` file and add the required fields in the `elastic_format.txt` file. Similarly, you can delete fields that you do not wish to export.

After customizing the `elastic_format.txt` file, execute the following command to update the analytics profile:

```
1 update analytics profile <profile-name> -dataFormatFile <data-format-
 file-name>
```

Example:

```
1 update analytics profile ns _analytics_ default_http_profile -
 dataFormatFile elastic_format.txt
```

You can also specify the value of data format file using the GUI. Navigate to **System > AppFlow > Analytics Profiles** and click **Add**. On the **Create Analytics Profile** page, if you select one of the following options for Type, then the **Data Format File** field appears where you can specify the file name:

- GLOBAL
- WEB INSIGHT
- TCP INSIGHT
- SECURITY INSIGHT
- VIDEO INSIGHT
- HDX INSIGHT
- GATEWAY INSIGHT
- LSN INSIGHT

- BOT INSIGHT
- TIME SERIES

## Sample outputs

This section contains sample outputs for different transaction logs.

### HTTP transaction log sample output

The following is a sample output for the HTTP transaction log.

## NetScaler advanced analytics

April 24, 2024

NetScaler advanced analytics examines the data gathered by NetScaler and extracts valuable insights about its performance. By leveraging the power of advanced analytics, the administrators gain insights into the network's performance and can take proactive measures to enhance overall network reliability, performance, and security.

Analytics typically involves examining historical data to gain insights into past events and behavior. Advanced analytics uses more sophisticated techniques to gain insights into past events and also forecast future trends and potential outcomes.

## Advantages of NetScaler advanced analytics

NetScaler advanced analytics provide you the following benefits:

- Early identification of abnormal network behavior
- Improved security posture
- Optimized resource allocation
- Deeper understanding of application-level traffic patterns

## NetScaler advanced analytics on Splunk

NetScaler advanced analytics collects and analyzes network traffic data using third-party observation tools, such as Splunk. NetScaler advanced analytics aims at developing a robust system capable of continuously monitoring network traffic, analyzing transactions at the application layer, and flagging instances where transaction bytes surpass predefined thresholds (upload and download transaction bytes).

NetScaler adopts anomaly detection techniques that include statistical methods to identify any abnormal behavior. These techniques utilize the past 21 days' data to establish a reliable baseline for what is considered normal behavior. NetScaler keeps a close eye on incoming traffic, in real-time. It employs advanced algorithms to define thresholds for normal transactions. These thresholds are dynamic, which means they are adjusted continuously based on the historical data and domain knowledge. Whenever a transaction exceeds the predefined threshold, the system immediately flags it for further investigation.

When anomalies are detected, the NetScaler notifies administrators to investigate and take action. This notification ensures that any potentially fraudulent or suspicious activity is identified and dealt with promptly, allowing a safer and more secure environment for all users. You can notify using email or any of the notification options that Splunk supports. To know more about notification options, see [Configure alert actions](#).

## Configure NetScaler advanced analytics on Splunk

To configure NetScaler advanced analytics app on Splunk, perform the following steps:

### Prerequisites

- Ensure that NetScaler is exporting the metrics and transactions data to Splunk.
  - **Transaction data:** For information on how to configure exporting data from NetScaler to Splunk, see [Export transaction logs directly from NetScaler to Splunk](#). Along with this

configuration, you must enable the following arguments to export UserAgent and URL variables in the analytics profile:

```
1 -httpURL ENABLED -httpUserAgent ENABLED
2 <!--NeedCopy-->
```

Sample command

```
1 set analytics profile <http analytics profile name> -
 collectors <splunk hec endpoint service name> -type
 websight -httpURL ENABLED -httpUserAgent ENABLED -
 httpContentType ENABLED -analyticsAuthToken "Splunk <
 HEC_TOKEN HERE>" -analyticsEndpointUrl "/services/
 collector/event" -analyticsEndpointContentType "
 application/json"
2 <!--NeedCopy-->
```

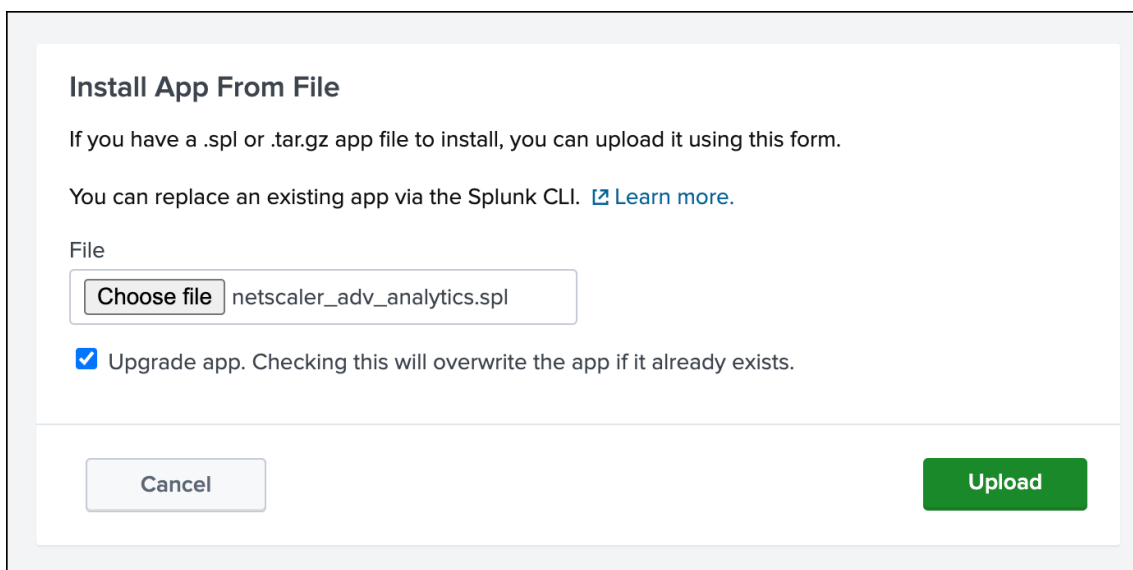

Enable export of Useragent and URL in existing analytics profile :

```
1 set analytics profile <http analytics profile name> --
 httpClientSideMeasurements ENABLED -httpURL ENABLED -
 httpUserAgent ENABLED
2 <!--NeedCopy-->
```

- **Metrics:** For information on how to export metrics directly from NetScaler to Splunk, see [Export metrics directly from NetScaler to Splunk](#).
- Ensure that the **Python for Scientific computing** app is installed on Splunk. To install this app, navigate to **Apps > Manage Apps**, click **Browse for more apps**, search for the **Python for Scientific computing** app and click **Install**.
- Download the `.spl` file from <https://www.citrix.com/downloads/citrix-adc/splunk-apps/list-of-apps.html>.
- Ensure that an index that can store 21 days of data exists on Splunk. You can use an existing index or create a new index of type **Events**. For information on how to create an index, see [Splunk documentation](#).

## Configuration

1. Log in to Splunk.
2. Navigate to **Apps > Manage Apps** and click **Install from file**.
3. Click **Choose file** and upload the `.spl` file.

**Install App From File**

If you have a .spl or .tar.gz app file to install, you can upload it using this form.

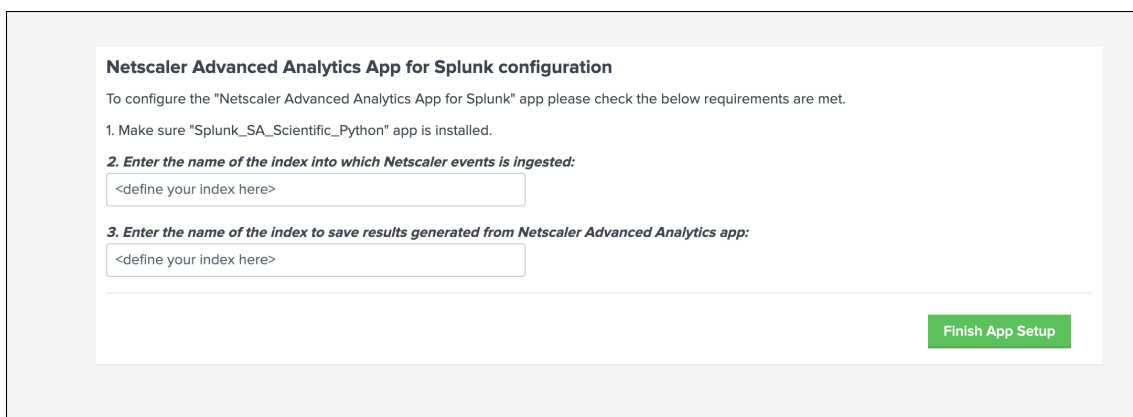

You can replace an existing app via the Splunk CLI. [Learn more.](#)

File

netscaler\_adv\_analytics.spl

Upgrade app. Checking this will overwrite the app if it already exists.

4. Click **Upload** and then click **Continue to App setup page**.
5. On the **NetScaler Advanced Analytics App for Splunk configuration** page, enter data in the following fields:
  - a) **Enter the name of the index into which NetScaler events are ingested:** The index where the data from NetScaler is stored.
  - b) **Enter the name of the index to save results generated from NetScaler Advanced Analytics app:** The index where the data generated from the Splunk app is saved. The index must store a minimum of 21 days of data.

**Netscaler Advanced Analytics App for Splunk configuration**

To configure the "Netscaler Advanced Analytics App for Splunk" app please check the below requirements are met.

1. Make sure "Splunk\_SA\_Scientific\_Python" app is installed.
2. **Enter the name of the index into which Netscaler events is ingested:**
3. **Enter the name of the index to save results generated from Netscaler Advanced Analytics app:**

6. Click **Finish App Setup**.
7. Once the upload is complete, navigate to **Apps** and click **NetScaler advanced analytics**.

**Note:**

It takes a minimum of 20 days for the apps to start forecasting the anomalies.

## NetScaler advanced analytics dashboards on Splunk

NetScaler advanced analytics insights consist of several dashboards that provide data on various use cases.

### Unusually large download transactions

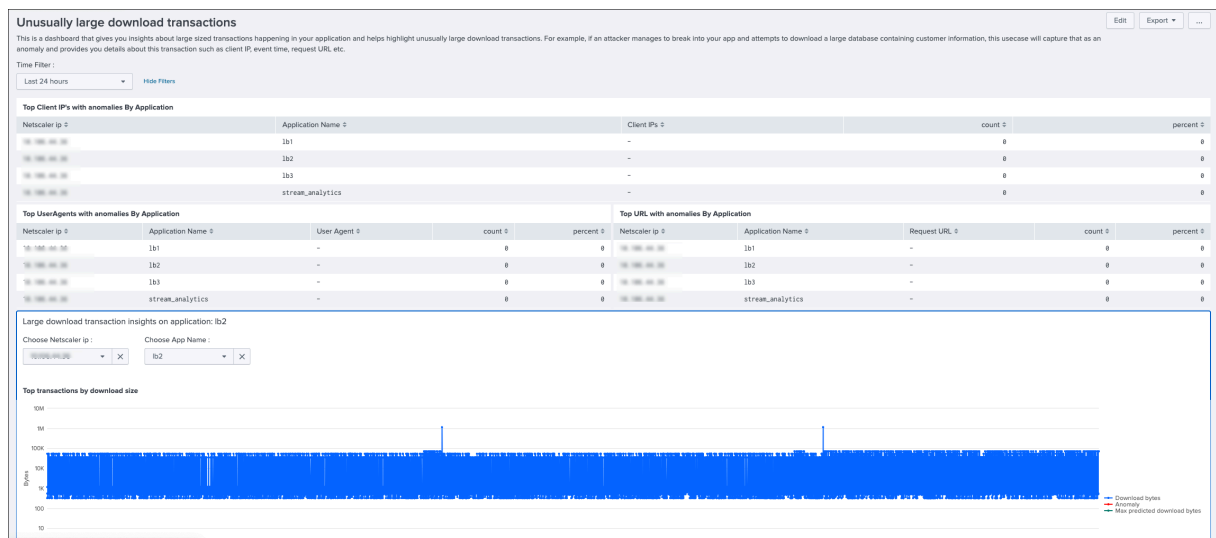

You can use the **Unusually large download transactions** dashboard to analyze the transactions that have unusually high data downloaded from the applications.

Example: If an attacker manages to break into an application and attempts to download a large database containing sensitive information, then this scenario is captured as an anomaly in the **Unusually large download transactions** dashboard. Using the dashboard you can get the details of the transaction, such as client IP address, event time, request URL, and user agent.

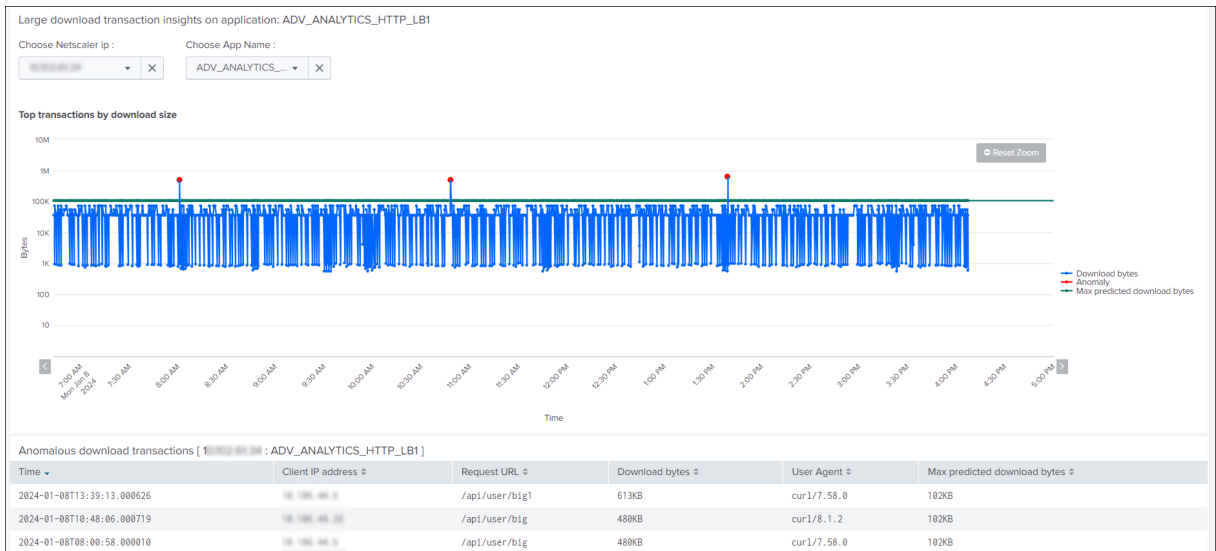

You can filter the data based on the following categories:

- Time
- NetScaler IP address
- Application name

For a selected time frame, the dashboard displays the top client IP addresses, top UserAgents, and the top URL with anomalies. You can drill down further on the anomaly by filtering the data based on the NetScaler IP address and application name.

For a selected NetScaler IP address and application name, a graph is displayed that shows all transactions including the ones with high download size. The graph contains the details of downloaded bytes, maximum predicted downloaded bytes, and the anomalies.

You can export the data to PDF, clone the dashboard, and set the dashboard as the home dashboard.

### Unusually large upload transactions

You can use the **Unusually large upload transactions** dashboard to analyze the transactions that have unusually high data upload to the application.

Example: If an attacker manages to break into an application and attempts to upload huge files hoping to exhaust storage, then this scenario is reported as an anomaly in the **Unusually large upload transactions** dashboard. Using this dashboard you can get the details of the anomalous transaction, such as client IP address, event time, request URL, and user agent.

You can filter the data based on the following categories:

- Time
- NetScaler IP address
- Application name

For a selected time frame, the dashboard displays the top client IP addresses, top User agents, and the top URL with anomalies. You can drill down further on the anomaly by filtering the data based on NetScaler IP address and application name.

For a selected NetScaler IP address and application name, a graph is displayed that shows all transactions including the ones with high upload size. The graph contains the details of uploaded bytes, maximum predicted uploaded bytes, and the anomalies.

You can export the data to PDF, clone the dashboard, and set the dashboard as the home dashboard.

### Traffic surge - download volume

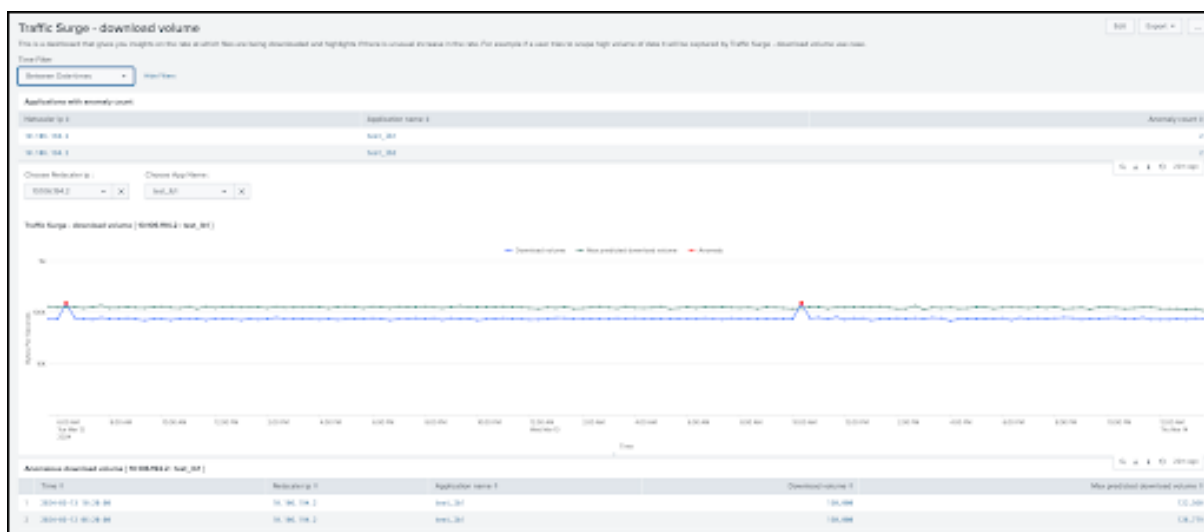

You can use the **Traffic surge - download volume** dashboard to analyze abnormal scenarios of data download from the application through bots. The dashboard highlights if there is an unusual increase in the download rate.

Example: If a user or a bot attempts to download a high volume of data quicker than the usual download rate, then this scenario is considered as a traffic surge and reported as an anomaly. Consider that the average download data per day is 500 MB and if a bot tries to download 2 GB data, then this scenario is considered as unusually high download data volume.

You can filter the data based on the following categories:

- Time
- NetScaler IP address
- Application name

For a selected time frame, the dashboard displays the list of NetScaler IP addresses and application names that have reported anomalies. You can drill down further on the anomaly by filtering the data based on the NetScaler IP address and application name.

For a selected NetScaler IP address and application name, a graph is displayed that shows the data download, maximum predicted data download, and the anomalies.

You can export the data to PDF, clone the dashboard, and set the dashboard as the home dashboard.

### Traffic surge - request rate

You can use the **Traffic surge - request rate** dashboard to analyze the unusual request rates received by an application. You can control the incoming and outgoing traffic from or to an application. A bot

attack can perform an unusual high request rate.

Example: If you configure an application to allow 100 requests per minute and if you observe 350 requests per minute, then this scenario is considered as a possible bot attack and reported as an anomaly.

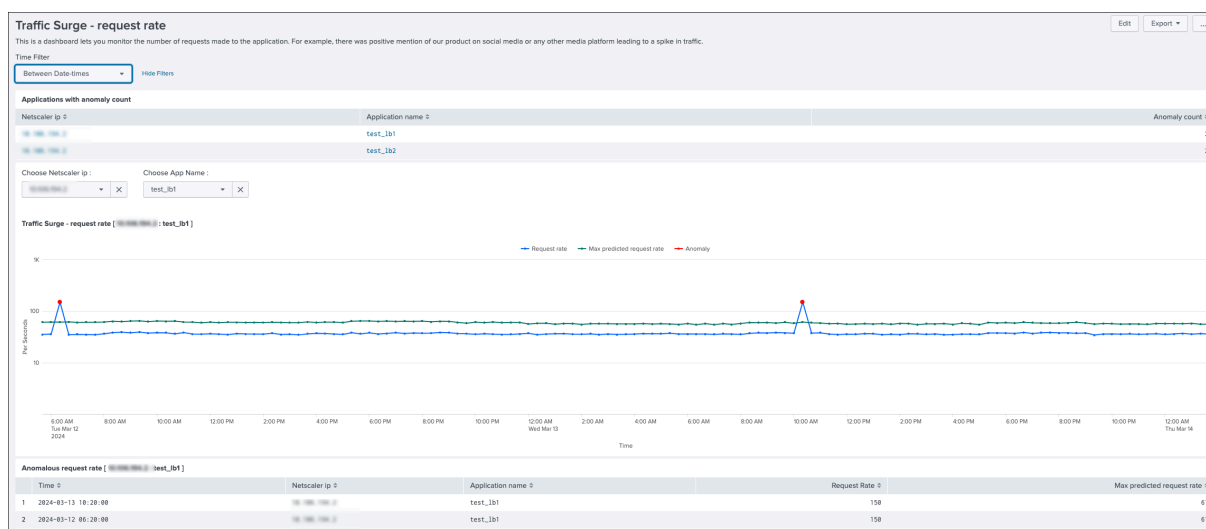

You can filter the data based on the following categories:

- Time
- NetScaler IP address
- Application name

You can drill down further on the anomaly by filtering the data based on the NetScaler IP address and application name.

For a selected NetScaler IP address and application name, a graph is displayed that shows the request rate, maximum predicted request rate, and the anomalies.

You can export the data to PDF, clone the dashboard, and set the dashboard as the home dashboard.

## Sample dashboards for endpoints

February 19, 2024

Consider a scenario where you want to view the overall health of NetScaler in your network. To know the overall health, you need to view the data such as the total number of requests received by the virtual server, CPU utilization, currently used memory of NetScaler and so on. The **Observability Sample Dashboard for NetScaler ADC** provides you the visualization of some key metrics that helps you

determine the health of NetScaler in less time. The **Observability Sample Dashboard for NetScaler ADC** is one of many dashboards that NetScaler supports.

A sample dashboard is a collection of metrics related to a particular use case/scenario that allows you to visualize the metrics and analyze the scenario in a meaningful way within a short duration. With the sample dashboards, you can avoid looking at multiple metrics in different locations or files to analyze a particular scenario.

NetScaler provides sample dashboards for the following endpoints:

- Grafana
- Splunk

The sample dashboards are available in the JSON format at the following location: <https://www.citrix.com/downloads/citrix-adc/sample-dashboards/endpoints-and-dashboards.html>

## List of sample dashboards

The following table lists all the sample dashboards that NetScaler supports:

Sample dashboard name	Details	Endpoint	JSON file name
Observability Sample Dashboard for NetScaler ADC	Provides various metrics of overall infrastructure at one place like NetScaler health, virtual server status, application health (HTTP and TCP apps), and application security (SSL apps). <a href="#">Read more</a>	Grafana	Netscaler_grafana_dashboard.json
Infra and Network Health Dashboard for NetScaler ADC	Provides all system metrics such as golden signals-latency, traffic, error, saturations, HA sync failures for all NetScalers on a central dashboard to ensure business continuity. <a href="#">Read more</a>	Splunk	netscaler_infra_and_network_health.json

---

Sample dashboard name	Details	Endpoint	JSON file name
App and API Health Dashboard	Provides metrics for the web applications and gain clients' insights to ensure high performing and seamless web experience for end users. <a href="#">Read more</a>	Splunk	netScaler_app_and_api_health_spl
NetScaler HTTP Insight Dashboard	Provides visibility into Web Insight. This dashboard is valid for both HTTP and HTTPS traffic, and includes commonly used data such as Response Time, Latency, NetScaler Processing Time at Layer 7, distributions such as Application Load, Response Length, Host, URL, Method, and some common HTTP headers. <a href="#">Read more</a>	Splunk	NetScalerHTTPInsightDashboard.xr
NetScaler SSL Insight Dashboard	Provides SSL insight. This dashboard includes TLS/SSL transactions or sessions related fields that are commonly looked for. For example, Ciphers and their strengths, TLS/SSL versions, certificate types. <a href="#">Read more</a>	Splunk	NetScalerSSLInsightDashboard.xml

Sample dashboard name	Details	Endpoint	JSON file name
NetScaler TCP Insight Dashboard	Provides TCP insight. This dashboard includes data such as, Throughput, Connection Length, Latency, Jitter at L4, and events such as Retransmissions, Resets, Zero Windows. <a href="#">Read more</a>	Splunk	NetScalerTCPInsightDashboard.xml
NetScaler Management Logs Dashboard (HEC)	Provides data on management logs exported to an HTTP Event Collector (HEC) input on Splunk. This dashboard includes data such as Logins, GUI Access, Shell access. <a href="#">Read more</a>	Splunk	NetScalerManagementLogsDashbo
NetScaler Management Logs Dashboard (Syslog)	Provides data on NetScaler management logs exported to a Syslog Input on Splunk this dashboard is a counterpart of NetScaler Management Logs Dashboard (HEC). This dashboard includes data such as Logins, GUI Access, Shell access. <a href="#">Read more</a>	Splunk	NetScalerManagementLogsDashbo

## Enable additional metrics

The schema file from where the data is fetched for the dashboards might not have all the metrics enabled. Due to this, you might see that some panels on the dashboard do not have data.

You can manually edit the schema file to include these metrics. The schema file is found on NetScaler at `/var/metrics_conf/schema.json`. After updating the schema file, you must disable and enable the metrics. Only after disabling and enabling the metrics, the panels display the data.

To disable and enable the metrics, run the following commands:

```
1 set analytics profile <splunk_new_profile> metrics DISABLED
2
3 set analytics profile splunk_new_profile metrics ENABLED
4 <!--NeedCopy-->
```

The following is the list of metrics that are not enabled by default in the schema file:

Infra and Network Health Dashboard for NetScaler ADC:

- cur\_syshealth\_disk0\_size
- cur\_syshealth\_disk0\_used
- cur\_syshealth\_disk1\_size
- cur\_syshealth\_disk1\_used
- cur\_syshealth\_ps1fail
- ssl\_cfg\_tot\_cards
- ssl\_num\_cards\_up
- nic\_err\_ifOutDiscards
- cur\_syshealth\_disk0\_errors
- cur\_syshealth\_disk1\_errors
- ha\_err\_sync\_failure
- ha\_cur\_system\_state
- ha\_err\_pkt\_rx\_ver
- ha\_err\_heartbeat
- cl\_cur\_enable
- clusterd\_tot\_cu\_timedout
- si\_tot\_pkt\_sent
- si\_tot\_pkt\_rcvd
- ssl\_tot\_enc\_bytes
- ssl\_tot\_dec\_bytes

App and API Health Dashboard:

- tcp\_err\_retransmit\_giveups
- tcp\_err\_retransmit

- tcp\_err\_stray\_packets
- tcp\_cur\_surgequeueulen

Observability Sample Dashboard for NetScaler ADC:

- as\_sig\_num\_viols

## Sample dashboards on Grafana

February 13, 2024

NetScaler provides sample dashboards on Grafana.

### View a sample dashboard on Grafana

To view a sample dashboard on Grafana, do the following:

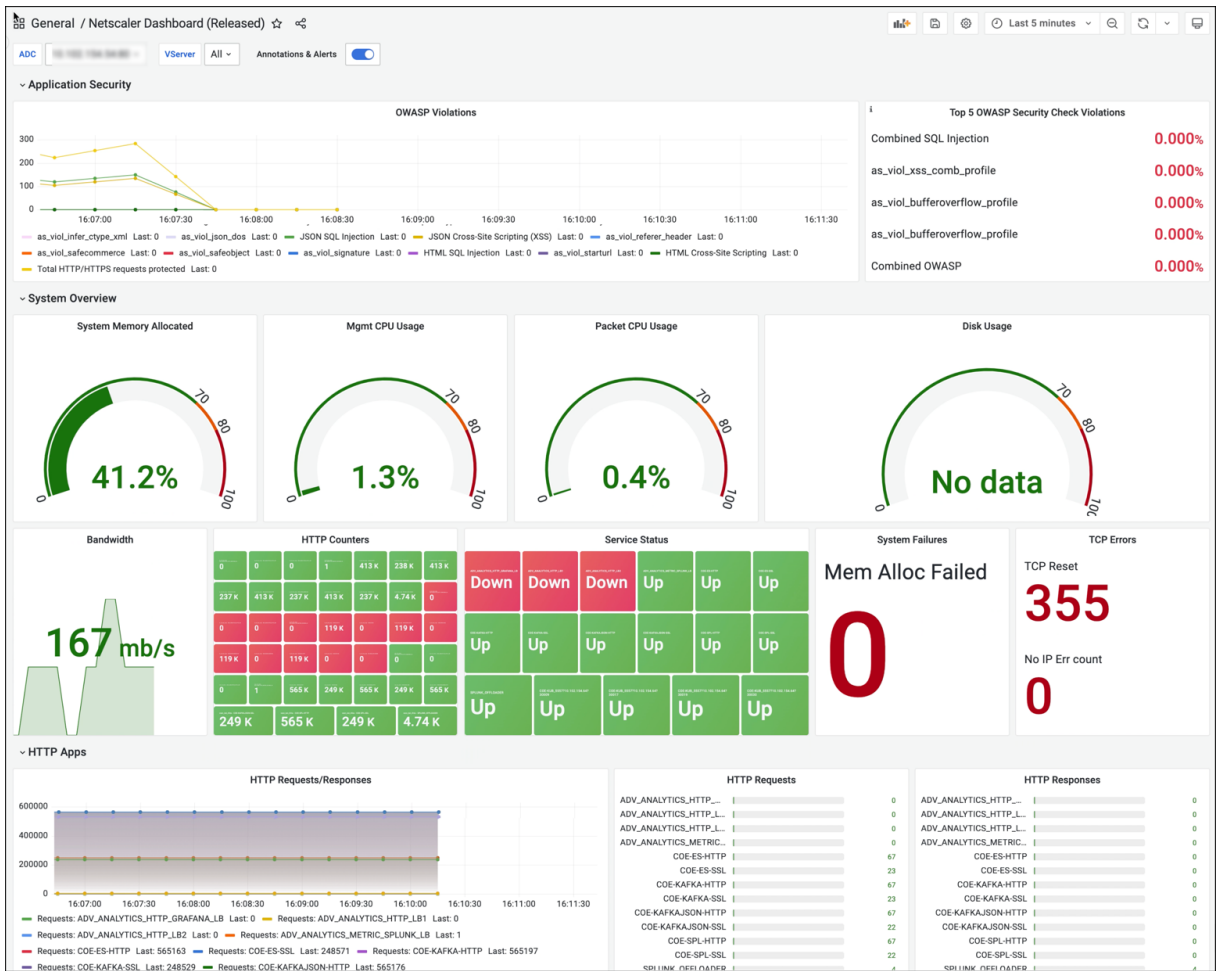

**Prerequisites:** Ensure that you have completed the required configurations on NetScaler and Prometheus. For more information, see [Configure the export of metrics from NetScaler to Prometheus and visualization using Grafana](#).

1. Launch Grafana and Prometheus.
2. Navigate to **Dashboards** and click **New dashboard**.
3. Click **Import dashboard**.
4. Provide a name for the dashboard.
5. Click **Upload** to select the JSON file corresponding to the required dashboard or copy the JSON file content and paste it into the **Source** page. For the list of dashboards supported and its corresponding JSON file name, see [List of sample dashboards](#).
6. Select the data source as **Prometheus**.
7. Click **Import**.
8. Select the **ADC, Vserver** and other details to view the required metrics.

### Observability Sample Dashboard for NetScaler ADC

You can use the **Observability Sample Dashboard for NetScaler ADC** to view the overall health of NetScaler in your network. The dashboard provides various metrics of overall infrastructure at one place like NetScaler health, virtual server status, application health (HTTP and TCP apps), and application security (SSL apps).

You can expand the corresponding section in the dashboard to view the detailed visualization of each section such as HTTP Apps, SSL Apps, TCP Apps, virtual server stats (vStats), and NetScaler stats.

## Sample dashboards on Splunk

April 11, 2024

NetScaler provides sample dashboards on Splunk.

### View a sample dashboard on Splunk

To view sample dashboards on Splunk, do the following:

**Prerequisite:** Ensure that you have completed the required configurations for export of metrics from NetScaler to Splunk. For more information, see [Exporting metrics directly from NetScaler to Splunk](#).

1. Launch Splunk and navigate to **Dashboards**.
2. Click **Create New Dashboard**.
3. Enter a name for the dashboard.

4. Select one of the following options and click **Create**:
  - a) **Dashboard Studio**: Select this option if you are importing a JSON file. Select **Absolute** layout.
  - b) **Classic Dashboard**: Select this option if you are importing an XML file.
5. Click the **Source** icon and remove the default entries (if any).
6. Copy the JSON or XML file content corresponding to the required dashboard and paste it on the **Source** page. For the list of dashboards supported and its corresponding JSON or XML file name, see [List of sample dashboards](#).
7. Perform one of the following actions based on your selection:
  - a) If you have pasted JSON file content, then click **Back** and then **Save**.
  - b) If you have pasted XML file content, then click **Save**.
8. Navigate to **Dashboards** and click the newly created dashboard. Select the required filters such as **Index, Time** to view the metrics.

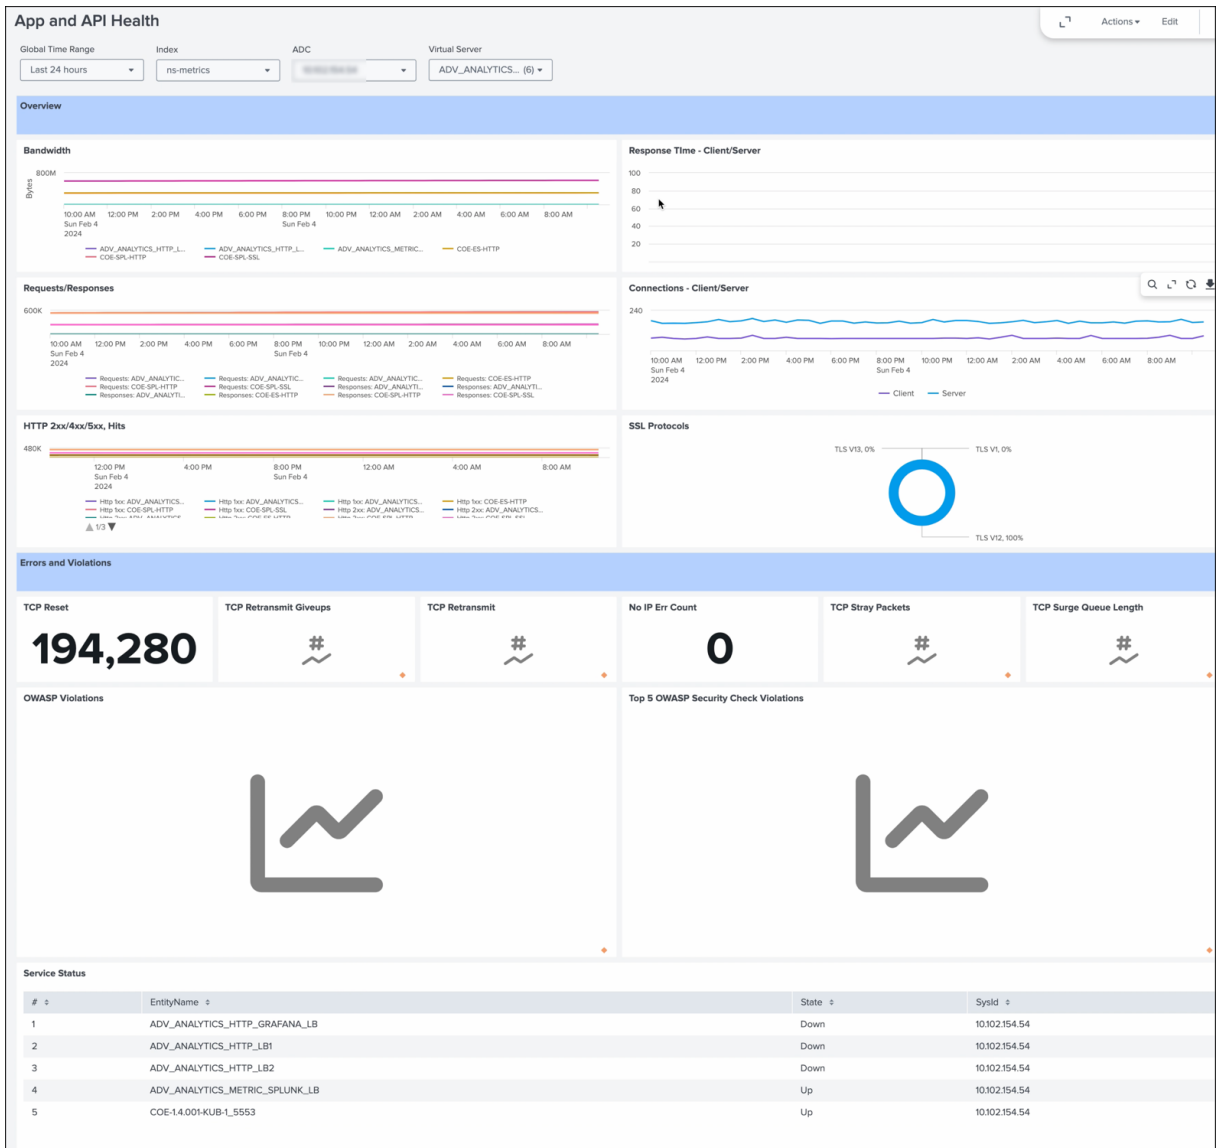

### **Infra and Network Health Dashboard for NetScaler ADC**

You can use the **Infra and Network Health Dashboard for NetScaler ADC dashboard** to monitor all the system metrics such as golden signals - latency, traffic, error, saturations, HA sync failures for all NetScalers on a central dashboard to ensure business continuity. The dashboard also helps you assess the health of NetScaler, identify any issues, correlate issues to find the root cause of an issue and probable remediations.

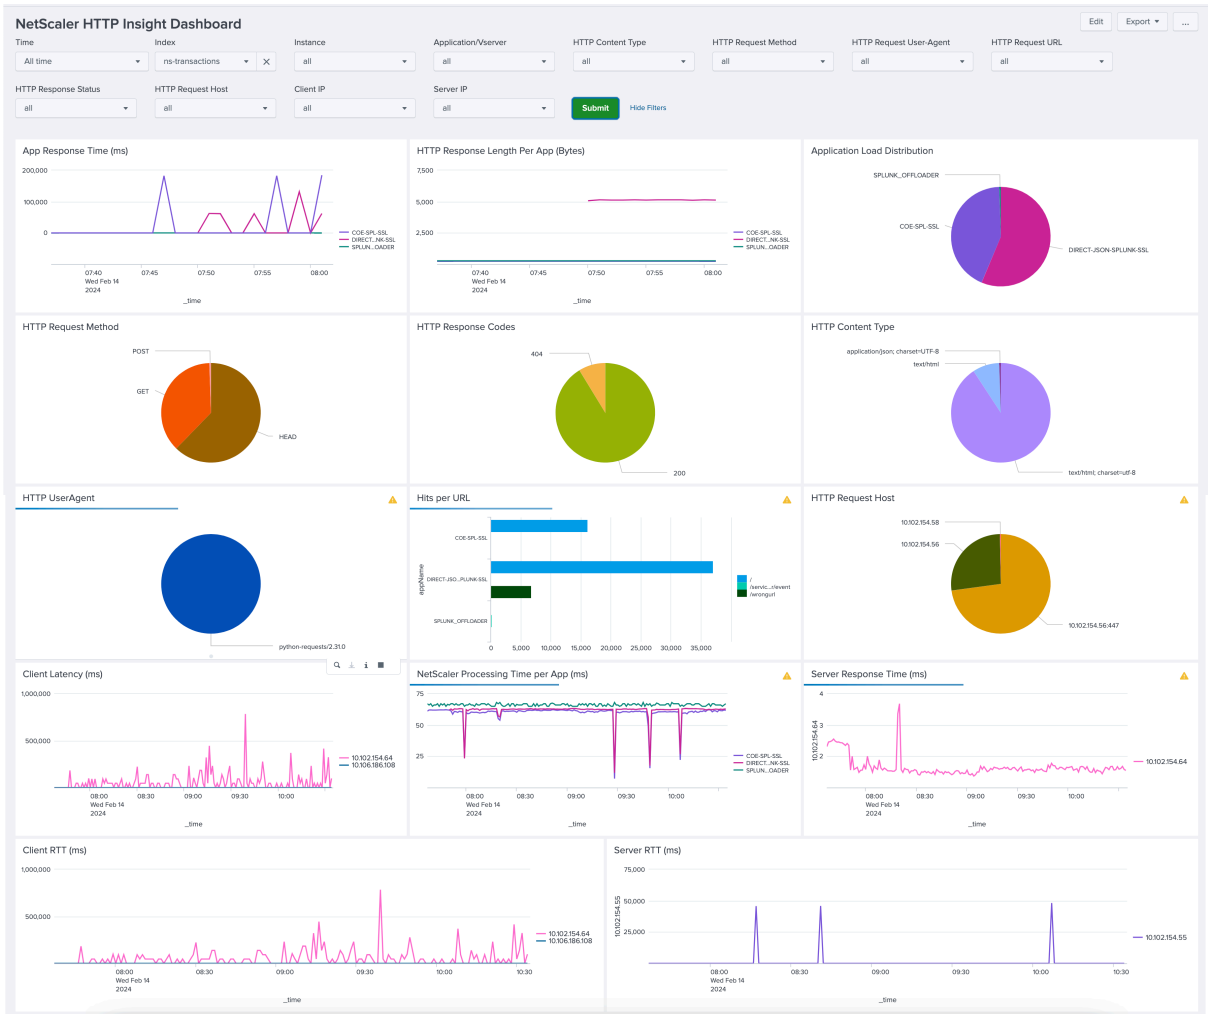

## App and API Health Dashboard

You can use the **App and API Health Dashboard** to monitor the metrics for the web applications and gain clients' insights to ensure a high performing and seamless web experience for end users. With this dashboard, you can understand the average latency for specific apps, major contributors of latency, and back end servers contributing to HTTP errors and so on and correlate these with metrics. Based on the insights, you can decide the actions needed for NetScaler or back-end applications.

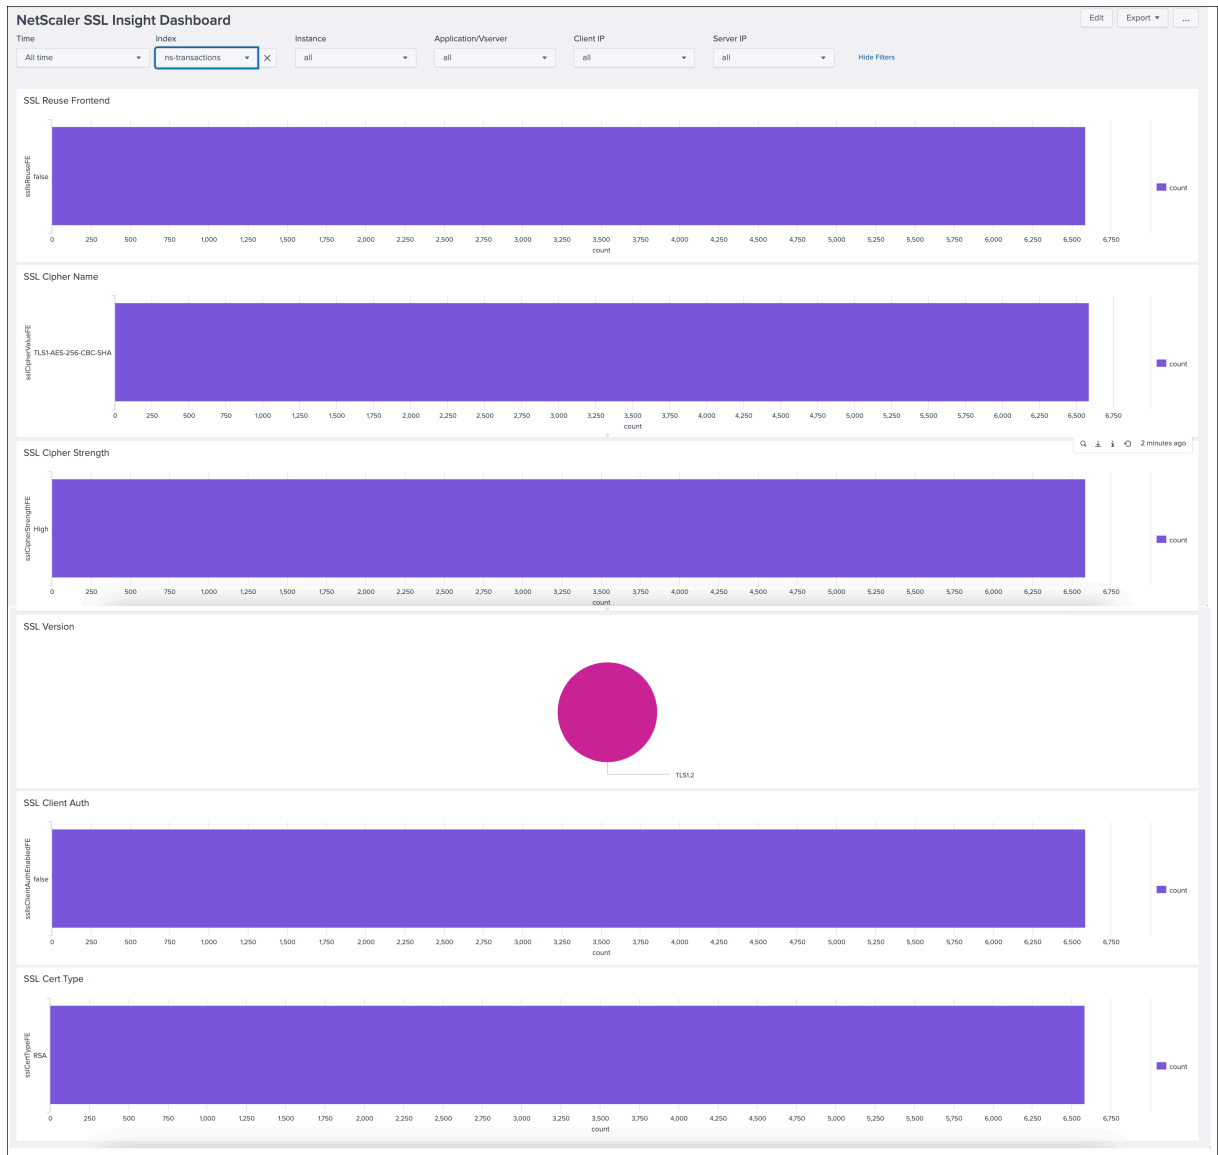

## NetScaler HTTP Insight Dashboard

You can use the **NetScaler HTTP Insight Dashboard** to monitor HTTP traffic. This dashboard is valid for both HTTP and HTTPS traffic, and includes data such as Response Time, Latency, NetScaler Processing Time at Layer 7, distributions such as Application Load, Response Length, Host, URL, Method, and some common HTTP headers.

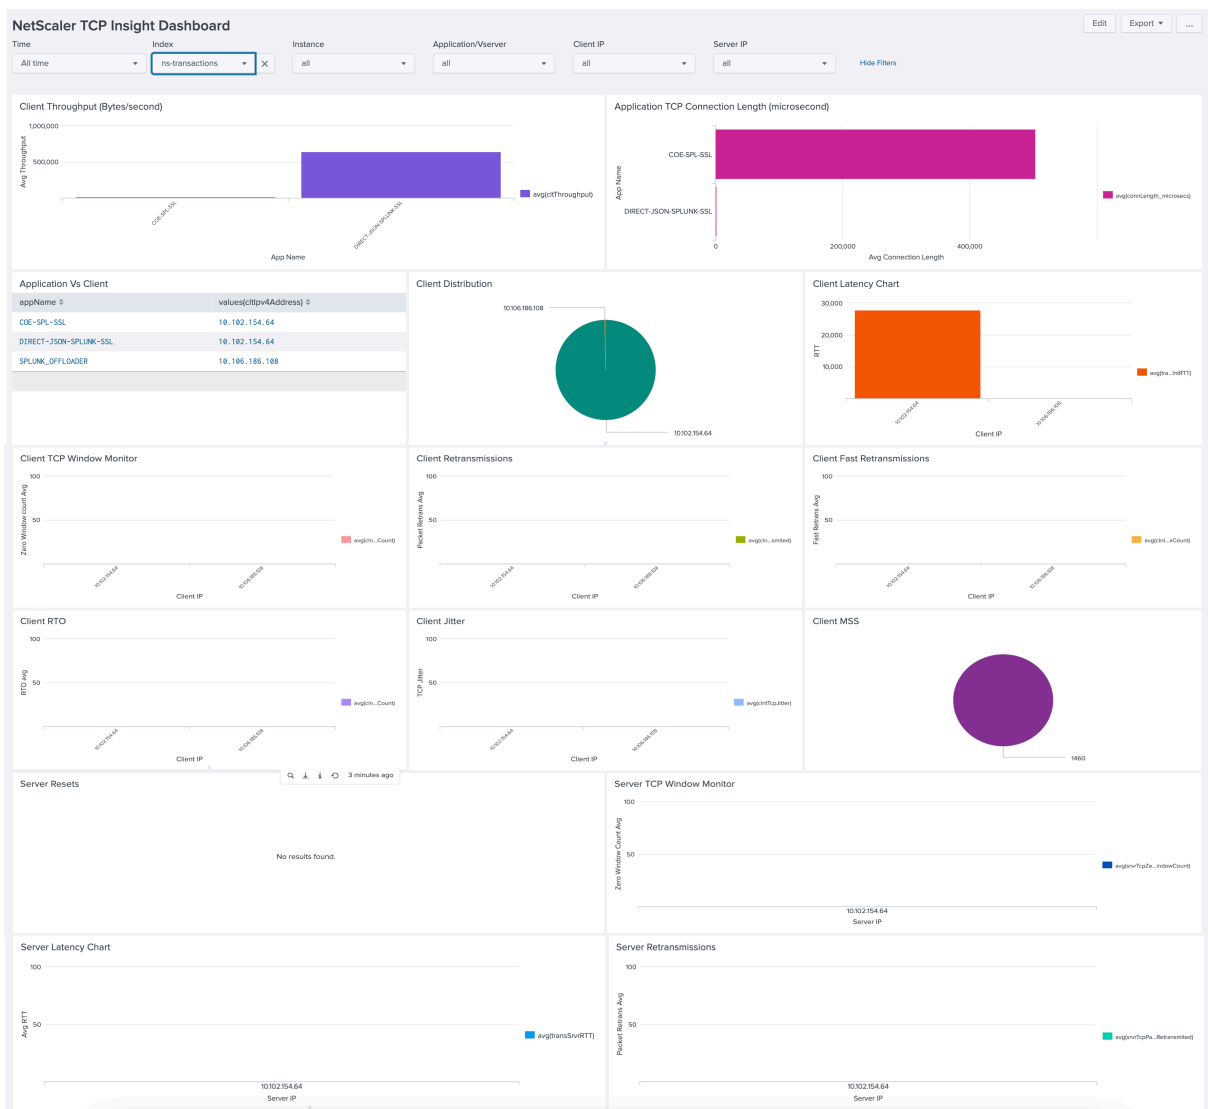

### NetScaler SSL Insight Dashboard

You can use the **NetScaler SSL Insight Dashboard** to monitor SSL traffic. This dashboard includes TLS/SSL transactions or sessions related fields that are commonly looked for such as ciphers and their strengths, TLS/SSL versions, certificate types. As HTTPS operates on TLS, you can correlate the data in this dashboard with the **NetScaler HTTP Insight Dashboard** to get holistic insights about the HTTPS traffic.

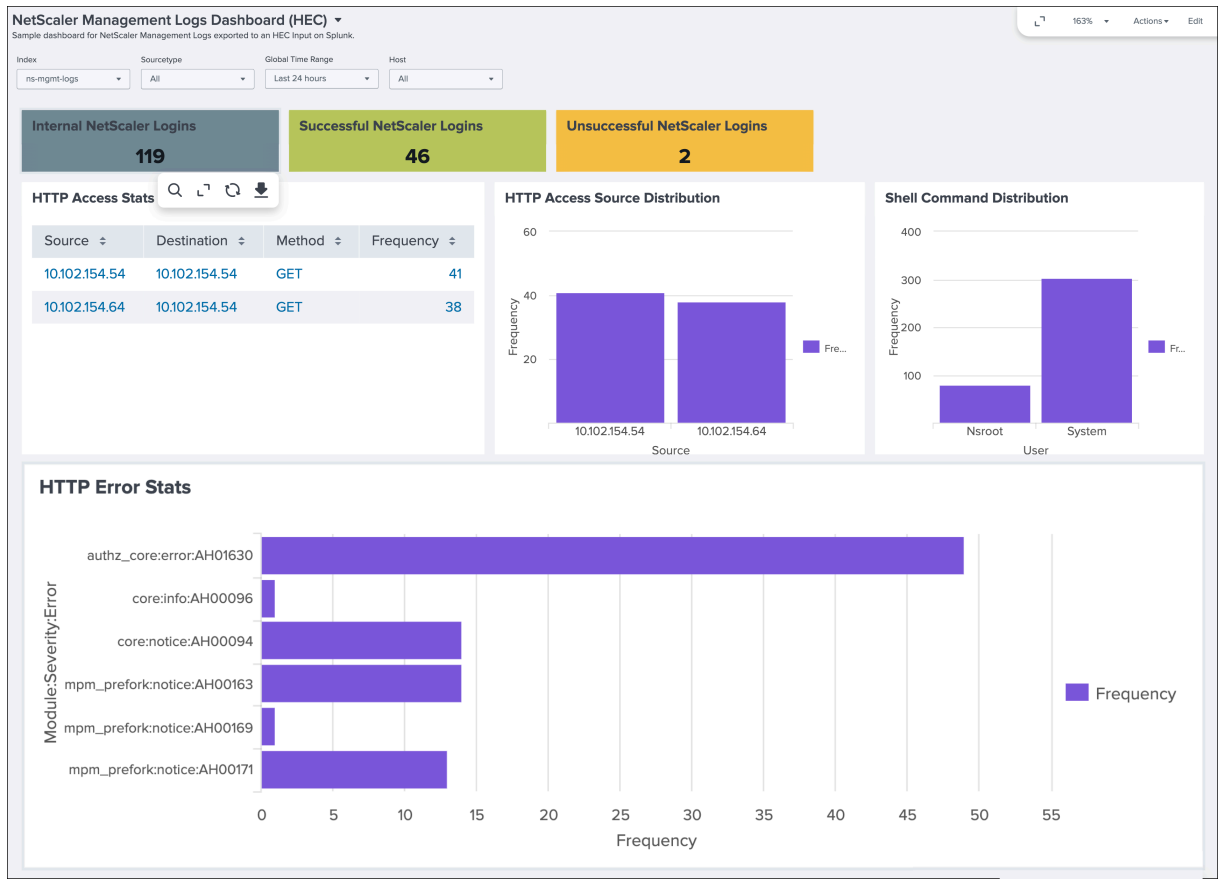

## NetScaler TCP Insight Dashboard

You can use the **NetScaler TCP Insight Dashboard** to monitor TCP traffic. This dashboard includes data such as Throughput, Connection Length, Latency, Jitter at Layer 4, and events such as Retransmissions, Resets, Zero Windows. As HTTP, HTTPS, SSL operate on TCP, you can correlate the data with the **NetScaler HTTP Insight Dashboard** and **NetScaler SSL Insight Dashboard** to get holistic insights about the traffic at Layer 4.

## NetScaler Management Logs Dashboard (HEC)

You can use the **NetScaler Management Logs Dashboard (HEC)** to view the management logs exported to an HTTP Event Collector (HEC) input on Splunk. This dashboard includes management events such as Logins, GUI Access, Shell access. You can also drill down to the finer details of these management events.

### NetScaler Management Logs Dashboard (Syslog)

You can use the **NetScaler Management Logs Dashboard (Syslog)** to view the management logs exported to a Syslog Input on Splunk. This dashboard includes management events such as Logins, GUI Access, Shell access.

## NetScaler metrics reference

November 6, 2023

This section provides information on the different metrics provided by NetScaler.

You can classify NetScaler metrics into three categories:

- **Application and API metrics:** Application health metrics help in troubleshooting which application website has high latency or an elevated number of errors or subpar performance. It also includes monitoring errors, traffic, latency, and saturation metrics.
- **Application security and API security metrics:** Application security metrics include the metrics such as WAF and BOT.
- **NetScaler system metrics:** NetScaler system metrics include information about the NetScaler such as the CPU utilization, memory, and disk usage. You can also get specific feature-level insights such as SSL, and GSLB. Also, insights for SSL TLS monitoring like certificate expiry details, protocol used, and cipher strength.

### Application and API metrics

This section describes a set of application health metrics available for NetScaler.

**HTTP metrics**

The following is a set of HTTP metrics and their description.

Metrics	Description
<code>http_tot_Gets</code>	This counter tracks HTTP requests received using the GET method.
<code>http_tot_Posts</code>	This counter tracks HTTP requests received using the POST method.
<code>http_tot_Others</code>	This counter tracks HTTP requests received using methods except GET and POST. Some of the well-defined HTTP methods are HEAD, PUT, DELETE, OPTIONS, and TRACE. User-defined methods are also allowed.
<code>http_tot_rxRequestBytes</code>	This counter tracks the bytes of HTTP data received.
<code>http_tot_rxResponseBytes</code>	This counter tracks the bytes received as response data.
<code>http_tot_txRequestBytes</code>	This counter tracks the bytes of HTTP data transmitted.
<code>http_tot_txResponseBytes</code>	This counter tracks the bytes transmitted as response data.
<code>http_tot_Requests</code>	This counter tracks HTTP requests received, including HTTP/1.0 and HTTP/1.1 requests.
<code>http_tot_Requests1_0</code>	This counter tracks HTTP/1.0 requests received.
<code>http_tot_Requests1_1</code>	This counter tracks HTTP/1.1 requests received.
<code>http_tot_Responses</code>	This counter tracks HTTP responses sent including HTTP/1.0 and HTTP/1.1 responses.
<code>http_tot_Responses1_0</code>	This counter tracks HTTP/1.0 responses sent.
<code>http_tot_Responses1_1</code>	This counter tracks HTTP/1.1 responses sent.
<code>http_tot_CLenResponses</code>	This counter tracks HTTP responses that are sent with the content-length field set to a value. The content field of the HTTP header specifies the length of the content, in bytes, in the associated HTTP body.

Metrics	Description
<a href="#">http_tot_ChunkedResponses</a>	This counter tracks the HTTP responses that are sent with the transfer-encoding field set as chunked. With this setting the server starts sending the HTTP response before knowing its total length. The server breaks the response into chunks and sends them in sequence, inserting the length of each chunk before the actual data. The message ends with a chunk of size zero.
<a href="#">http_tot_noClenChunkResponses</a>	This counter tracks the FIN-terminated responses sent. In FIN-terminated responses, the server finishes sending the data and closes the connection.
<a href="#">http_err_noreuse_multipart</a>	This counter tracks the HTTP multi-part responses sent. In multi-part responses, one or more entities are encapsulated within the body of a single message.
<a href="#">http_err_IncompleteRequests</a>	This counter tracks the HTTP requests received in which the header spans more than one packet.
<a href="#">http_err_IncompleteResponses</a>	This counter tracks the HTTP responses received in which the header spans more than one packet.
<a href="#">http_err_IncompleteHeaders</a>	This counter tracks the HTTP requests and responses received in which the HTTP header spans more than one packet.
<a href="#">http_err_server_busy</a>	This counter tracks the error responses received. Some of the error responses are: 500 Internal Server Error, 501 Not Implemented, 502 Bad Gateway, 503 Service Unavailable, 504 Gateway Timeout, and 505 HTTP Version Not supported
<a href="#">http_tot_ChunkedRequests</a>	This counter tracks the HTTP requests in which the transfer-encoding field of the HTTP header is set as chunked.
<a href="#">http_tot_CLenRequests</a>	This counter tracks the HTTP requests in which the content-length field of the HTTP header is set to a value. Content-length specifies the length of the content, in bytes, in the associated HTTP body.

Metrics	Description
<code>http_err_large_content</code>	This counter tracks the large or invalid requests and responses received.
<code>http_err_large_ctlen</code>	This counter tracks the large or invalid requests received, in which the content-length field of the HTTP header is set to a value. Content-length specifies the length of the content, in bytes, in the associated HTTP body.
<code>http_err_large_chunk</code>	This counter tracks the large or invalid requests received in which the Transfer-Encoding field of the HTTP header is set as chunked.

### TCP metrics

The following is a set of TCP metrics and their description.

Counter	Description
<code>tcp_tot_ServerOpen</code>	This counter tracks the server connections initiated by NetScaler after startup. This counter is reset when the appliance restarts.
<code>tcp_tot_ServerClosed</code>	This counter tracks the total number of server connections that are closed.
<code>tcp_tot_ClientOpen</code>	This counter tracks the client connections initiated on NetScaler after startup. This counter is reset when the appliance restarts.
<code>tcp_tot_ClientClosed</code>	This counter tracks the total number of client connections that are closed.
<code>tcp_tot_syn</code>	This counter tracks the <code>SYN</code> packets received.
<code>tcp_tot_syn_probe</code>	This counter tracks the probes from NetScaler to a server. The appliance sends a <code>SYN</code> packet to the server to check its availability and expects a <code>SYN_ACK</code> packet from the server before a specified response timeout.
<code>tcp_tot_fin_srvr</code>	This counter tracks the <code>FIN</code> packets received from the server.
<code>tcp_tot_fin_clnt</code>	This counter tracks the <code>FIN</code> packets received from the clients.

---

Counter	Description
<code>tcp_tot_timeWaitToSyn</code>	This counter tracks the <code>SYN</code> packets received on connections that are in the <code>TIME_WAIT</code> state. Packets cannot be transferred on a connection in this state.
<code>tcp_tot_timeWaitData</code>	This counter tracks the bytes of data received on connections that are in the <code>TIME_WAIT</code> state. Data cannot be transferred on a connection that is in this state.
<code>tcp_tot_clnt_flushed</code>	This counter tracks the client connections that are flushed because the client is idle for some time.
<code>tcp_tot_srvr_flushed</code>	This counter tracks the server connections that are flushed because there are no client requests in the queue for some time.
<code>tcp_tot_clnt_flushed_ho</code>	This counter tracks the half-opened client connections that are flushed because the three-way handshakes are not complete.
<code>tcp_tot_srvr_flushed_ho</code>	This counter tracks the half-opened server connections that are flushed because the three-way handshakes are not complete.
<code>tcp_tot_clnt_flushed_ahc</code>	This counter tracks the active half-closed client connections that are flushed because the client has closed the connection and there is no activity on the connection.
<code>tcp_tot_srvr_flushed_ahc</code>	This counter tracks the active half-closed server connections that are flushed because the server has closed the connection and there is no activity on the connection.
<code>tcp_tot_clnt_flushed_phc</code>	This counter tracks the passive half-closed client connections that are flushed because NetScaler has closed the connection and there is no activity on the connection.
<code>tcp_tot_srvr_flushed_phc</code>	This counter tracks the passive half-closed server connections that are flushed because NetScaler has closed the connection and there is no activity on the connection.

Counter	Description
<code>tcp_err_badchecksums</code>	This counter tracks the packets received with a TCP checksum error.
<code>tcp_err_syn_n_syn_rcvd</code>	This counter tracks the <code>SYN</code> packets received on a connection that is in the <code>SYN_RCVD</code> state. A connection goes into the <code>SYN_RCVD</code> state after receiving a <code>SYN</code> packet.
<code>tcp_err_syn_n_est</code>	This counter tracks the <code>SYN</code> packets received on a connection that is in the <code>ESTABLISHED</code> state. A <code>SYN</code> packet is not expected on an <code>ESTABLISHED</code> connection.
<code>tcp_err_syn_giveups</code>	This counter attempts to establish a connection on NetScaler that has timed out.
<code>tcp_err_syn_sentbadack</code>	This counter specifies the incorrect <code>ACK</code> packets received on a connection that is in the <code>SYN_SENT</code> state. An incorrect <code>ACK</code> packet is the third packet in the three-way handshake that has an incorrect sequence number.
<code>tcp_err_syn_retransmit</code>	This counter specifies the <code>SYN</code> packets resent to a server.
<code>tcp_err_fin_retransmit</code>	This counter specifies the <code>FIN</code> packets resent to a server or a client.
<code>tcp_err_fin_giveups</code>	This counter specifies the connections that were timed out by NetScaler because of not receiving the <code>ACK</code> packet after retransmitting the <code>FIN</code> packet four times.
<code>tcp_err_fin_dup</code>	This counter specifies the number of duplicate <code>FIN</code> packets received.
<code>tcp_err_rs</code>	This counter specifies the packets received from a client or a server.
<code>tcp_err_rst_not_est</code>	This counter specifies the reset packets received on a connection that is not in the <code>ESTABLISHED</code> state.
<code>tcp_err_rst_outof_wnd</code>	This counter specifies the reset packets received on a connection that is out of the current TCP window.

Counter	Description
<code>tcp_err_rst_inTimewaits</code>	This counter specifies the reset packets received on a connection that is in the <code>TIME_WAIT</code> state. Packets cannot be transferred on a connection that is in the <code>TIME_WAIT</code> state.
<code>tcp_err_srvr_retransmit</code>	This counter tracks the packets retransmitted by a server. Retransmission usually occurs because the acknowledgment from NetScaler has not reached the server.
<code>tcp_err_clnt_retransmit</code>	This counter tracks the packets retransmitted by a client. Retransmission usually occurs because the acknowledgment from NetScaler has not reached the client.
<code>tcp_err_full_retransmit</code>	This counter tracks the full packet retransmissions by the client or the server.
<code>tcp_err_partial_retransmit</code>	This counter tracks the partial packet retransmissions by a client or server because of congestion on the connection. This situation usually occurs because the window advertised by NetScaler is not large enough to hold the full packet.
<code>tcp_err_srvr_out_of_order</code>	This counter tracks the out of order TCP packets received from a server.
<code>tcp_err_clnt_out_of_order</code>	This counter tracks the out of order TCP packets received from a client.
<code>tcp_err_cookie_pkt_seq_reject</code>	This counter tracks the <code>SYN</code> cookie packets rejected because they contain an incorrect sequence number.
<code>tcp_err_cookie_signature_reject</code>	This counter tracks the <code>SYN</code> cookie packets rejected because they contain an incorrect signature.
<code>tcp_err_cookie_pkt_seq_drop</code>	This counter tracks the <code>SYN</code> cookie packets dropped because the sequence number specified in the packets is outside the current Window.
<code>tcp_err_cookie_mss</code>	This counter tracks the <code>SYN</code> cookie packets rejected because the maximum segment size (MSS) specified in the packets is incorrect.

---

Counter	Description
<code>tcp_err_retransmit</code>	This counter tracks the TCP packets retransmitted. NetScaler attempts to retransmit the packet up to seven times and then resets the other half of the TCP connection.
<code>tcp_err_retransmit_giveups</code>	This counter tracks the number of times NetScaler terminates a connection after retransmitting the packet seven times on that connection.
<code>tcp_max_Clients</code>	This counter tracks the maximum number of connections that can be made from the system to the Web servers attached to it. This value is applied globally to all attached servers.
<code>tcp_max_ReqPerConn</code>	This counter tracks the maximum number of requests that the system can pass to a particular connection between the system and a server attached to it. If the value is zero, then it allows an unlimited number of requests to be passed.
<code>tcp_err_cip_alloc</code>	This counter tracks the number of times TCP level client header insertion fails.
<code>tcp_tot_ClientOpen_Rate</code>	This counter tracks the rate at which connections are opened in the system.
<code>tcp_tot_acl_bridge</code>	This counter tracks the packets matching a bridge access control list (ACL), which in transparent mode bypasses service processing.
<code>tcp_tot_acl_drop</code>	This counter tracks the packets dropped because they match ACLs with processing mode set to <code>DENY</code> .
<code>tcp_tot_acl_allow</code>	This counter tracks the packets matching ACLs with the processing mode set to <code>ALLOW</code> . NetScaler appliance processes these packets.
<code>tcp_tot_acl_nat</code>	This counter tracks packets matching a NAT ACL, resulting in a NAT session.
<code>tcp_tot_acl_hits</code>	This counter tracks the packets matching an ACL.
<code>tcp_tot_acl_miss</code>	This counter tracks the packets not matching any ACL.

---

Counter	Description
<code>tcp_tot_sacl_bridge</code>	This counter tracks the packets that matched a simple ACL with processing mode set as <code>BRIDGE</code> and got bridged by NetScaler.
<code>tcp_tot_sacl_drop</code>	This counter tracks the packets dropped because they match the <code>Deny</code> action in a simple ACL.
<code>tcp_tot_sacl_allow</code>	This counter tracks the packets that matched a simple ACL with the <code>ALLOW</code> action and got consumed by NetScaler.
<code>tcp_tot_sacl_hits</code>	This counter tracks the packets matching a simple ACL.
<code>tcp_tot_sacl_miss</code>	This counter tracks the packets not matching any simple ACL.
<code>tcp_tot_sacl_count</code>	This counter tracks the number of simple ACLs configured.
<code>tcp_tot_sacl6_bridge</code>	This counter tracks the total packets that matched a simple ACL6 with action <code>BRIDGE</code> and got bridged by NetScaler.
<code>tcp_tot_sacl6_drop</code>	This counter tracks the packets dropped because they match the <code>Deny</code> action in a simple ACL6.
<code>tcp_tot_sacl6_allow</code>	This counter tracks the total packets that matched a simple ACL6 with the action <code>ALLOW</code> and got consumed by NetScaler.
<code>tcp_tot_sacl6_hits</code>	This counter tracks the packets matching a simple ACL6.
<code>tcp_tot_sacl6_miss</code>	This counter tracks the packets not matching any simple ACL6.
<code>tcp_tot_sacl6_count</code>	This counter tracks the number of simple ACL6s configured.
<code>tcp_tot_acl6_bridge</code>	This counter tracks the packets matching a bridge IPv6 ACL, which in transparent mode bypasses service processing.
<code>tcp_tot_acl6_drop</code>	This counter tracks the packets dropped because they match IPv6 ACLs with processing mode set to <code>DENY</code> .
<code>tcp_tot_acl6_allow</code>	This counter tracks the packets matching IPv6 ACLs with processing mode set to <code>ALLOW</code> . NetScaler processes these packets.

---

Counter	Description
<code>tcp_tot_acl6_nat</code>	This counter tracks the packets matching a NAT ACL6, resulting in a NAT session.
<code>tcp_tot_acl6_hits</code>	This counter tracks the packets matching an IPv6 ACL.
<code>tcp_tot_acl6_miss</code>	This counter tracks the packets not matching any IPv6 ACL.
<code>pbr_tot_allow</code>	This counter tracks the total packets that matched the policy-based routing (PBR) with the action <code>ALLOW</code> .
<code>pbr_tot_deny</code>	This counter tracks the total packets that matched PBR with the action <code>DENY</code> .
<code>pbr_tot_hits</code>	This counter tracks the total packets that matched any PBR.
<code>pbr_tot_miss</code>	This counter tracks the total packets that did not match any PBR.
<code>tcp_tot_rxpkts</code>	This counter tracks the TCP packets received.
<code>tcp_tot_rxbytes</code>	This counter tracks the bytes of TCP data received.
<code>tcp_tot_txpkts</code>	This counter tracks the TCP packets transmitted.
<code>tcp_tot_txbytes</code>	This counter tracks the bytes of TCP data transmitted.
<code>pcb_tot_zombie_called</code>	This counter tracks the number of times the Zombie cleanup function is called. Every time a connection is flushed, it is marked for cleanup. The Zombie cleanup function clears all these connections at predefined intervals.
<code>tcp_tot_synheld</code>	<code>SYN</code> packets held on NetScaler that are waiting for a server connection.
<code>tcp_tot_synheld_flushed</code>	<code>SYN</code> packets flushed on NetScaler because of no response from the server for three or more seconds.
<code>tcp_tot_fintimewaitconnclosedearly</code>	This counter tracks the connections closed on NetScaler because the number of connections in the <code>TIME_WAIT</code> state has exceeded the default value of 7000.

Counter	Description
<code>tcp_err_any_portalloc_failed</code>	This counter tracks the port allocations that have failed on a mapped IP address because the maximum limit of 65536 has exceeded or the mapped IP address is not configured.
<code>tcp_err_ip_portalloc_failed</code>	This counter tracks the port allocations that have failed on a subnet IP address or virtual server IP address because the maximum limit of 65536 has exceeded.
<code>tcp_err_stray_packets</code>	This counter tracks the packets received on a connection whose state is not maintained on NetScaler.
<code>tcp_err_send_rst</code>	This counter tracks the reset packets sent to a client or a server.
<code>tcp_err_bad_state_connections</code>	This counter tracks the connections that are not in a valid TCP state.
<code>tcp_tot_fast_retransmit</code>	This counter tracks the TCP packets on which NetScaler performs a fast retransmission in response to three duplicate acknowledgments or a partial acknowledgment. The appliance assumes that the packet is lost and retransmits the packet before its time-out.
<code>tcp_err_1st_retransmit</code>	This counter tracks the packets retransmitted once by NetScaler.
<code>tcp_err_2nd_retransmit</code>	This counter tracks the packets retransmitted twice by NetScaler.
<code>tcp_err_3rd_retransmit</code>	This counter tracks the packets retransmitted three times by NetScaler.
<code>tcp_err_4th_retransmit</code>	This counter tracks the packets retransmitted four times by NetScaler.
<code>tcp_err_5th_retransmit</code>	This counter tracks the packets retransmitted five times by NetScaler.
<code>tcp_err_6th_retransmit</code>	This counter tracks the packets retransmitted six times by NetScaler.
<code>tcp_err_7th_retransmit</code>	This counter tracks the packets retransmitted seven times by NetScaler. If this retransmission fails, the appliance terminates the connection.

---

Counter	Description
<code>tcp_err_data_after_fin</code>	This counter tracks the bytes received following a connection termination request. This error is usually caused by reordering packets during transmission.
<code>tcp_err_threshold</code>	This counter tracks the reset packets dropped because the default threshold of 100 resets per 10 milliseconds has exceeded. This is a configurable value using the <code>set ns ratecontrol</code> command.
<code>tcp_err_oowindow</code>	This counter tracks the packets received that are out of the current advertised window.
<code>tcp_err_in_congestion_syndropped</code>	This counter tracks the <code>SYN</code> packets dropped because of network congestion.
<code>tcp_tot_bdg_mac_moved</code>	This counter tracks the number of times bridging registered MAC is moved.
<code>tcp_tot_bdg_collisions</code>	This counter tracks the number of bridging table collisions.
<code>tcp_err_bdg_muted</code>	This counter tracks the number of bridging related interface mutes.
<code>bdg_tot_pkts</code>	This counter tracks the total amount of bridged traffic.
<code>bdg_tot_Mbits</code>	This counter tracks the total number of bridged Mb.
<code>tcp_cur_ServerConn</code>	This counter tracks the server connections, including connections in the <code>Opening</code> , <code>Established</code> , and <code>Closing</code> state.
<code>tcp_cur_ServerConnClosing</code>	This counter tracks the server connections in the <code>Closing</code> state, which indicates that the connection termination process has initiated but it is not complete.
<code>tcp_cur_ServerConnEst</code>	This counter tracks the server connections in the <code>Established</code> state, which indicates that data transfer can occur between NetScaler and the server.
<code>tcp_cur_ServerConnOpening</code>	This counter tracks the server connections in the <code>Opening</code> state, which indicates that the handshakes are not yet complete.

---

Counter	Description
<code>tcp_cur_ClientConn</code>	This counter tracks the client connections, including connections in the <code>Opening</code> , <code>Established</code> , and <code>Closing</code> state.
<code>tcp_cur_ClientConnClosing</code>	This counter tracks the client connections in the <code>Closing</code> state, which indicates that the connection termination process has initiated but is not complete.
<code>tcp_cur_ClientConnEst</code>	This counter tracks the current client connections in the <code>Established</code> state, which indicates that data transfer can occur between NetScaler and the client.
<code>tcp_cur_ClientConnOpening</code>	This counter tracks the client connections in the <code>Opening</code> state, which indicates that the handshakes are not yet complete.
<code>tcp_cur_surgequeueLen</code>	This counter tracks the connections in the surge queue. When NetScaler cannot open a connection to the server, for example when maximum connections are reached, the appliance queues these requests.
<code>tcp_cur_GlobalReusePool</code>	This counter tracks the spare connections available. The connection on the server is not closed after completing the request from the first client to save time and resources in establishing another connection for a new client. This connection is available for serving future requests.
<code>tcp_cur_active_server_conn</code>	This counter tracks connections to a server currently responding to requests.
<code>tcp_cur_nServers</code>	This counter tracks the number of physical servers that NetScaler has established connections.
<code>tcp_tot_reuse_hit</code>	This counter tracks the total number of client transactions found with the server connection in the reuse-pool.

---

## Application security and API security metrics

This section contains information about a set of counters related to application security.

### Bot metrics

The following table lists a set of metrics related to the bot profile.

counter name	Description
<code>bot_Requests_profile</code>	Specifies the number of HTTP or HTTPS requests sent to your protected web servers via the bot profile.
<code>bot_Responses_profile</code>	Specifies the number of HTTP or HTTPS responses sent by your protected web servers via the bot profile.
<code>bot_req_bytes_profile</code>	Specifies the number of bytes transferred for requests.
<code>bot_res_bytes_profile</code>	Specifies the number of bytes transferred for responses.
<code>bot_tot_drop_profile</code>	Specifies the total number of drops by the bot profile.
<code>bot_tot_log_profile</code>	Specifies the total number of logs by the bot profile.
<code>bot_tot_redirect_profile</code>	Specifies the total number of redirects by the bot profile.
<code>bot_tot_reset_profile</code>	Specifies the total number of resets by the bot profile.
<code>bot_viol_black_list_drop_profile</code>	Specifies the number of block list violations dropped by the bot profile.
<code>bot_viol_black_list_log_profile</code>	Specifies the number of block list violations logged by the bot profile.
<code>bot_viol_black_list_profile</code>	Specifies the number of block list violations seen by the bot profile.
<code>bot_viol_black_list_redirect_profile</code>	Specifies the number of block list violations redirected by the bot profile to a different webpage or web server.
<code>bot_viol_black_list_reset_profile</code>	Specifies the number of block list violations reset by the bot profile.

---

counter name	Description
bot_viol_captcha_drop_profile	Specifies the number of CAPTCHA challenge failures dropped by the bot profile.
bot_viol_captcha_log_profile	Specifies the number of CAPTCHA challenge failures logged by the bot profile.
bot_viol_captcha_profile	Specifies the number of CAPTCHA challenge failures seen by the bot profile.
bot_viol_captcha_redirect_profile	Specifies the number of CAPTCHA challenge failures redirected by the bot profile.
bot_viol_captcha_reset_profile	Specifies the number of CAPTCHA challenge failures reset by the bot profile.
bot_viol_device_fingerprint_captcha_profile	Specifies the number of device fingerprint violation requests for which a CAPTCHA challenge was sent due to the bot profile.
bot_viol_device_fingerprint_drop_profile	Specifies the number of device fingerprint violations dropped by the bot profile.
bot_viol_device_fingerprint_log_profile	Specifies the number of device fingerprint violations logged by the bot profile.
bot_viol_device_fingerprint_profile	Specifies the number of device fingerprint violations seen by the bot profile.
bot_viol_device_fingerprint_redirect_profile	Specifies the number of device fingerprint violations requests redirected by the bot profile to a different webpage or web server.
bot_viol_device_fingerprint_reset_profile	Specifies the number of device fingerprint violations reset by the bot profile.
bot_viol_iprep_captcha_profile	Specifies the number of IP reputation violation requests for which a CAPTCHA challenge was sent.
bot_viol_iprep_drop_profile	Specifies the number of IP reputation violations dropped by the bot profile.
bot_viol_iprep_log_profile	Specifies the number of IP reputation violations logged by the bot Profile.
bot_viol_iprep_profile	Specifies the number of IP reputation violations seen by the bot profile.
bot_viol_iprep_redirect_profile	Specifies the number of IP reputation violations requests redirected by the bot profile to a different webpage or web server.

---

counter name	Description
<code>bot_viol_iprep_reset_profile</code>	Specifies the number of IP reputation violations reset by the bot profile.
<code>bot_viol_rate_limit_drop_profile</code>	Specifies the number of rate limiting violations dropped by the bot profile.
<code>bot_viol_rate_limit_log_profile</code>	Specifies the number of rate limiting violations logged by the bot profile.
<code>bot_viol_rate_limit_profile</code>	Specifies the number of rate limiting violations seen by the bot profile.
<code>bot_viol_rate_limit_redirect_profile</code>	Specifies the number of rate limiting violations requests redirected by the bot profile to a different webpage or web server.
<code>bot_viol_rate_limit_reset_profile</code>	Specifies the number of rate-limiting violations reset by the bot profile.
<code>bot_viol_static_signature_drop_profile</code>	Specifies the number of static signature violations dropped by the bot profile.
<code>bot_viol_static_signature_log_profile</code>	Specifies the number of static signature violations logged by the bot profile.
<code>bot_viol_static_signature_profile</code>	Specifies the number of static signature violations seen by the bot profile.
<code>bot_viol_static_signature_redirect_profile</code>	Specifies the number of static signature violations redirected by the bot profile to a different webpage or web server.
<code>bot_viol_static_signature_reset_profile</code>	Specifies the number of static signature violations reset by the bot profile to a different webpage or web server.
<code>bot_viol_tps_captcha_profile</code>	Specifies the number of transactions per second (TPS) violation requests for which a CAPTCHA challenge was sent due to the bot profile.
<code>bot_viol_tps_drop_profile</code>	Specifies the number of TPS violations dropped by the bot profile.
<code>bot_viol_tps_log_profile</code>	Specifies the number of TPS violations logged by the bot profile.
<code>bot_viol_tps_profile</code>	Specifies the number of TPS violations observed by the bot profile.

counter name	Description
<code>bot_viol_tps_redirect_profile</code>	Specifies the number of TPS violations requests redirected by the bot profile to a different webpage or web server.
<code>bot_viol_tps_reset_profile</code>	Specifies the number of TPS violations reset by the bot profile.
<code>bot_viol_trap_drop_profile</code>	Specifies the number of bot trap violations dropped by the bot profile.
<code>bot_viol_trap_log_profile</code>	Specifies the number of bot trap violations logged by the bot profile.
<code>bot_viol_trap_profile</code>	Specifies the number of bot trap violations observed by the bot profile.
<code>bot_viol_trap_redirect_profile</code>	Specifies the number of bot trap violations requests redirected by the bot profile to a different webpage or web server.
<code>bot_viol_trap_reset_profile</code>	Specifies the number of bot trap violations reset by the bot profile.
<code>bot_viol_white_list_log_profile</code>	Specifies the number of allow list violations logged by the bot profile.
<code>bot_viol_white_list_profile</code>	Specifies the number of allow list violations observed by the bot profile.

## NetScaler system metrics

This section provides information about metrics related to NetScaler infrastructure.

### System metrics

System metrics are used for NetScaler system resource monitoring such as CPU, and memory. The following table lists a set of NetScaler system metrics and description.

Metrics name	Description
<code>allnic_tot_rx_mbit</code>	This counter tracks the amount of data (in MB) received by the NetScaler appliance.
<code>allnic_tot_tx_mbits</code>	This counter tracks the amount of data (in MB) transmitted by the NetScaler appliance.

---

Metrics name	Description
<code>cpu_speed_expected</code>	This counter tracks the CPU speed in MHz.
<code>cpu_usage</code>	This counter tracks the CPU utilization percentage.
<code>cpu_use</code>	This counter tracks the CPU utilization: percentage * 10.
<code>cur_moninfo</code>	This counter tracks the number of monitor bindings defined on this NetScaler appliance.
<code>cur_monitor</code>	This counter tracks the number of monitors defined on this NetScaler appliance.
<code>cur_server</code>	This counter tracks the number of servers defined on this NetScaler appliance.
<code>cur_service</code>	This counter tracks the number of services defined on this NetScaler appliance.
<code>cur_servinfo</code>	This counter tracks the number of virtual server bindings on this NetScaler appliance.
<code>cur_svcgroup</code>	This counter tracks the number of service groups defined on this NetScaler appliance.
<code>cur_svcgroup_svcitem</code>	This counter tracks the number of service group members defined on this NetScaler appliance.
<code>cur_svcgroup_vsrvitem</code>	This counter tracks the number of virtual server, service group bindings on this NetScaler appliance.
<code>cur_syshealth_disk0_avail</code>	This counter tracks the available space in the <code>/flash</code> partition of the hard disk.
<code>cur_syshealth_disk0_errors</code>	This counter tracks the disk ( <code>/flash</code> ) error counter.
<code>cur_syshealth_disk0_pusage</code>	This counter tracks the <code>cur_syshealth_disk0_errors</code> .
<code>cur_syshealth_disk0_size</code>	This counter tracks the size of the <code>/flash</code> partition of the hard disk.
<code>cur_syshealth_disk0_used</code>	This counter tracks the used space in the <code>/flash</code> partition of the hard disk.
<code>cur_syshealth_disk1_avail</code>	This counter tracks the available space in the <code>/var</code> partition of the hard disk.
<code>cur_syshealth_disk1_errors</code>	This counter tracks the number of errors on the <code>/var</code> partition of the hard disk.

Metrics name	Description
<code>cur_syshealth_disk1_pusage</code>	This counter tracks the used space in the <code>/var</code> partition of the disk, as a percentage. You can configure the used percentage with the <code>set snmp alarm DISK-USAGE-HIGH</code> command.
<code>cur_syshealth_disk1_size</code>	This counter tracks the size of the <code>/var</code> partition of the hard disk.
<code>cur_syshealth_disk1_used</code>	This counter tracks the used space in the <code>/var</code> partition of the hard disk.
<code>cur_syshealth_fan0</code>	This counter tracks the system fan speed and the acceptable range is 3000–6000 RPM. You can configure the system fan speed by using the <code>set snmp alarm FAN-SPEED-LOW</code> command to set the lower limit.
<code>cur_syshealth_fan1</code>	This counter tracks the speed of system fan 1.
<code>cur_syshealth_fan2</code>	This counter tracks the speed of system fan 2.
<code>cur_syshealth_fan3</code>	This counter tracks the speed of fan 0 if the associated pin is connected to the health monitoring chip.
<code>cur_syshealth_fan4</code>	This counter tracks the speed of fan 1 if the associated pin is connected to the health monitoring chip.
<code>cur_syshealth_fan5</code>	This counter tracks the speed of fan 2 if the associated pin is connected to the health monitoring chip.
<code>cur_syshealth_fan6</code>	This counter tracks the speed of fan 3 if the associated pin is connected to the health monitoring chip.
<code>cur_syshealth_fancpu0</code>	This counter tracks the CPU fan 0 speed. The acceptable range is 3000–6000 RPM. You can configure CPU fan 0 speed by using the <code>set snmp alarm FAN-SPEED-LOW</code> command to set the lower limit.

Metrics name	Description
<code>cur_syshealth_fancpu1</code>	This counter tracks the speed of CPU fan 1. The acceptable range is 3000–6000 RPM. You can configure CPU fan 1 speed by using the <code>set snmp alarm FAN-SPEED-LOW</code> command to set the lower limit.
<code>cur_syshealth_ps1fail</code>	This counter tracks the power supply 1 failure status.
<code>cur_syshealth_ps2fail</code>	This counter tracks the power supply 2 failure status.
<code>cur_syshealth_ps3fail1</code>	This counter tracks the power supply 3 failure status.
<code>cur_syshealth_ps4fail</code>	This counter tracks the power supply 4 failure status.
<code>cur_syshealth_tcpu0</code>	This counter tracks the CPU 0 temperature. You can configure CPU 0 temperature by using the <code>set snmp alarm TEMPERATURE-HIGH</code> command to set the upper limit.
<code>cur_syshealth_tcpu1</code>	This counter tracks the CPU 1 temperature. You can configure CPU 1 temperature by using the <code>set snmp alarm TEMPERATURE-HIGH</code> command to set the upper limit.
<code>cur_syshealth_temp0</code>	This counter tracks the temperature of a device connected to the health monitoring chip through pin 0.
<code>cur_syshealth_temp1</code>	This counter tracks the temperature of a device connected to the health monitoring chip through pin 1.
<code>cur_syshealth_temp2</code>	This counter tracks the temperature of a device connected to the health monitoring chip through pin 2.
<code>cur_syshealth_temp3</code>	This counter tracks the temperature of a device connected to the health monitoring chip through pin 3.
<code>cur_syshealth_tint</code>	This counter tracks the internal temperature of the health monitoring chip. You can configure the internal temperature by using the <code>set snmp alarm TEMPERATURE-HIGH</code> command to set the upper limit.

---

Metrics name	Description
<code>cur_syshealth_v12n</code>	This counter tracks the power supply -12 V output. The acceptable range is -13.20--10.80 volts.
<code>cur_syshealth_v12p</code>	This counter tracks the power supply +12 V output. The acceptable range is 10.80-13.20 volts.
<code>cur_syshealth_v33main</code>	You can configure the standby 3.3 V supply voltage by using the <code>set snmp alarm VOLTAGE-LOW</code> command to set the lower limit and the <code>set snmp alarm VOLTAGE-HIGH</code> command to set the upper limit.
<code>cur_syshealth_v33stby</code>	This counter tracks the output of standby power supply +3.3 V. The acceptable range is 2.970-3.630 volts.
<code>cur_syshealth_v50n</code>	This counter tracks the output of power supply -5 V. The acceptable range is -5.50--4.50 volts.
<code>cur_syshealth_v50p</code>	This counter tracks the output of power supply +5 V.
<code>cur_syshealth_v5sb</code>	This counter tracks the output of power supply 5 V standby.
<code>cur_syshealth_vbat</code>	This counter tracks the output of onboard battery power supply.
<code>cur_syshealth_vcc0</code>	This counter tracks the CPU core 0 voltage. The acceptable range is 1.080-1.650 volts.
<code>cur_syshealth_vcc1</code>	This counter tracks the CPU core 1 voltage. The acceptable range is 1.080-1.650 volts. If CPU 1 is not connected to the health monitoring chip, then display shows the voltage of CPU 0.
<code>cur_syshealth_volt0</code>	This counter tracks the voltage of a device connected to the health monitoring chip through pin 0.
<code>cur_syshealth_volt1</code>	This counter tracks the voltage of a device connected to the health monitoring chip through pin 1.

---

Metrics name	Description
<code>cur_syshealth_volt2</code>	This counter tracks the voltage of a device connected to the health monitoring chip through pin 2.
<code>cur_syshealth_volt3</code>	This counter tracks the voltage of a device connected to the health monitoring chip through pin 3.
<code>cur_syshealth_volt4</code>	This counter tracks the voltage of a device connected to the health monitoring chip through pin 4.
<code>cur_syshealth_volt5</code>	This counter tracks the voltage of a device connected to the health monitoring chip through pin 5.
<code>cur_syshealth_volt6</code>	This counter tracks the voltage of a device connected to the health monitoring chip through pin 6.
<code>cur_syshealth_volt7</code>	This counter tracks the voltage of a device connected to a health monitoring chip through pin 7.
<code>cur_syshealth_vsen2</code>	This counter tracks the voltage sensor 2 input.
<code>cur_syshealth_vtt</code>	This counter tracks the Intel CPU VTT power (volts).
<code>master_cpu_usage</code>	This counter tracks the CPU 0 (currently the main CPU) utilization, as a percentage of capacity.
<code>master_cpu_use</code>	This counter tracks the CPU0 utilization: percentage * 10.
<code>mem_cur_feature_allocpercen</code>	This counter tracks the percentage of NetScaler appliance memory used by the feature.
<code>mem_cur_feature_allocsize</code>	This counter tracks the total current NetScaler appliance memory available for use by the feature, in kilobytes.
<code>mem_err_feature_alloc_failed</code>	This counter tracks the memory allocation failure for a particular feature.
<code>mem_tot_allocated</code>	This counter tracks the currently allocated memory, in MB.
<code>mem_tot_allocated_pcmt</code>	This counter tracks the currently allocated memory in percent.

---

Metrics name	Description
<code>mem_tot_MB</code>	This counter tracks the total main memory available for use by the packet engine (PE), in MB.
<code>mem_tot_use_MB</code>	This counter tracks the total NetScaler memory in use, in MB.
<code>mem_usage_pcnt</code>	This counter tracks the percentage of memory utilization on NetScaler.
<code>mem_usage_percent</code>	This counter tracks the percentage of memory utilization on a NetScaler appliance.
<code>mem_use_MB</code>	This counter tracks the main memory currently in use, in MB.
<code>mgmt_cpu_usage_pcn</code>	This counter tracks the management CPU utilization percentage.
<code>mgmt_cpu_use</code>	This counter tracks the management CPU utilization: percentage * 10.
<code>ns_interval</code>	This counter tracks the interval in seconds between performance monitoring records taken on the NetScaler appliance.
<code>ns_time</code>	This counter tracks the current time set on the NetScaler appliance.
<code>shmem_cur_alloc_pcnt</code>	This counter tracks the shared memory in use in percentage.
<code>shmem_cur_alloctype</code>	This counter tracks the shared memory (MB) in use.
<code>shmem_max_allowed</code>	This counter tracks the total shared memory (MB) allowed for allocation.
<code>slave_cpu_usage</code>	This counter tracks the CPU 1 (currently the subordinate CPU) utilization, as a percentage of capacity. Not applicable for a single-CPU system.
<code>slave_cpu_use</code>	This counter tracks the CPU 1 utilization, percentage * 10.
<code>sys_cpus</code>	This counter tracks the number of CPUs on the NetScaler appliance.
<code>sys_cpus_1</code>	This counter tracks the number of CPUs on the NetScaler appliance.
<code>sys_cur_duration_sincestart</code>	This counter tracks the seconds after the NetScaler appliance started.

Metrics name	Description
<code>sys_memorysize_MB</code>	This counter tracks the total amount of system memory, in MB.
<code>sys_starttime</code>	This counter tracks the time when the NetScaler appliance was last started.
<code>sys_tot_config_changes</code>	This counter tracks the number of times a configuration change was made on the NetScaler appliance.
<code>sys_tot_save_configs</code>	This counter tracks the number of times the system configuration was saved on the NetScaler appliance.

### SSL metrics

The following table lists some of the SSL counters and description.

Metrics name	Description
<code>ssl_tot_sslInfo_TotalSessionCount</code>	Specifies the number of SSL sessions on the NetScaler appliance.
<code>ssl_tot_sslInfo_TotalTxCount</code>	Specifies the number of SSL transactions on the NetScaler.
<code>ssl_tot_sslInfo_SSLe2TxCount</code>	Specifies the number of SSLe2 transactions on the NetScaler.
<code>ssl_tot_sslInfo_SSLe3TxCount</code>	Specifies the number of SSLe3 transactions on the NetScaler.
<code>ssl_tot_sslInfo_TLSv1TxCount</code>	Specifies the number of TLSv1 transactions on the NetScaler.
<code>ssl_tot_sslInfo_TLSv11TxCount</code>	Specifies the number of TLS1.1 transactions on the NetScaler.
<code>ssl_tot_sslInfo_TLSv12TxCount</code>	Specifies the number of TLSv1.2 transactions on the NetScaler.
<code>ssl_tot_sslInfo_TLSv13TxCount</code>	Specifies the number of TLSv1.3 transactions on the NetScaler.
<code>ssl_tot_sslInfo_DTLSv1TxCount</code>	Specifies the number of DTLSv1 transactions on the NetScaler.
<code>ssl_tot_sslInfo_DTLSv12TxCount</code>	Specifies the number of DTLSv1.2 transactions on the NetScaler.

Metrics name	Description
<code>ssl_tot_sslInfo_SSLe2SessCount</code>	Specifies the number of SSLv2 sessions on the NetScaler.
<code>ssl_tot_sslInfo_SSLe3SessCount</code>	Specifies the number of SSLv3 sessions on the NetScaler.
<code>ssl_tot_sslInfo_TLSv1SessCount</code>	Specifies the number of TLSv1 sessions on the NetScaler.
<code>ssl_tot_sslInfo_TLSv11SessCount</code>	Specifies the number of TLSv1.1 sessions on the NetScaler.
<code>ssl_tot_sslInfo_TLSv12SessCount</code>	Specifies the number of TLSv1.2 sessions on the NetScaler.
<code>ssl_tot_sslInfo_TLSv13SessCount</code>	Specifies the number of TLSv1.3 sessions on the NetScaler.
<code>ssl_tot_sslInfo_DTLSv1SessCount</code>	Specifies the number of DTLSv1 sessions on the NetScaler.
<code>ssl_tot_sslInfo_DTLSv12SessCount</code>	Specifies the number of DTLSv1.2 sessions on the NetScaler.
<code>ssl_tot_sslInfo_SessionNew</code>	Specifies the number of new SSL sessions created on the NetScaler.
<code>ssl_tot_sslInfo_SessionMiss</code>	Specifies the number of SSL session reuse misses on the NetScaler.
<code>ssl_tot_sslInfo_SessionHits</code>	Specifies the number of SSL session reuse hits on the NetScaler.
<code>ssl_tot_sslInfo_Backend_TotalSessionCount</code>	Specifies the number of back-end SSL sessions on the NetScaler.
<code>ssl_tot_sslInfo_Backend_SSLe3SessCount</code>	Specifies the number of back-end SSLv3 sessions on the NetScaler.
<code>ssl_tot_sslInfo_Backend_TLSv1SessCount</code>	Specifies the number of back-end TLSv1 sessions on the NetScaler.
<code>ssl_tot_sslInfo_Backend_TLSv11SessCount</code>	Specifies the number of back-end TLSv1.1 sessions on the NetScaler.
<code>ssl_tot_sslInfo_Backend_TLSv12SessCount</code>	Specifies the number of back-end TLSv1.2 sessions on the NetScaler.
<code>ssl_tot_sslInfo_Backend_DTLSv1SessCount</code>	Specifies the number of back-end DTLSv1 sessions on the NetScaler.
<code>ssl_tot_sslInfo_Backend_TotalSessMultiplexAttempts</code>	Specifies the number of back-end SSL session multiplex attempts on the NetScaler.

Metrics name	Description
<code>ssl_tot_sslInfo_Backend_TotalSessM</code>	Specifies the number of back-end SSL session multiplex successes on the NetScaler.
<code>ssl_tot_sslInfo_Backend_TotalSessM</code>	Specifies the number of back-end SSL session multiplex failures on the NetScaler.
<code>ssl_tot_enc_bytes</code>	Specifies the number of bytes encrypted on the NetScaler.
<code>ssl_tot_dec_bytes</code>	Specifies the number of bytes decrypted on the NetScaler.
<code>ssl_tot_sslServerInRecords</code>	Specifies the number of SSL servers in record on the NetScaler.
<code>ssl_tot_sslInfo_SessionRenegotiate</code>	Specifies the number of SSL session renegotiations on the NetScaler.
<code>ssl_tot_sslInfo_SSLv3Renego</code>	Specifies the number of session renegotiations done on SSLv3.
<code>ssl_tot_sslInfo_TLSv1Renego</code>	Specifies the number of SSL session renegotiations done on TLSv1.
<code>ssl_tot_sslInfo_TLSv11Renego</code>	Specifies the number of SSL session renegotiations done on TLSv1.1.
<code>ssl_tot_sslInfo_TLSv12Renego</code>	Specifies the number of SSL session renegotiations done on TLSv1.2.
<code>ssl_tot_sslInfo_DTLSv1Renego</code>	Specifies the number of SSL session renegotiations done on DTLSv1.
<code>ssl_tot_sslInfo_DTLSv12Renego</code>	Specifies the number of SSL session renegotiations done on DTLSv1.2.
<code>ssl_tot_sslInfo_KeyEx_RSA_512</code>	Specifies the number of RSA 512-bit key exchanges on the NetScaler.
<code>ssl_tot_sslInfo_KeyEx_RSA_1024</code>	Specifies the number of RSA 1024-bit key exchanges on the NetScaler.
<code>ssl_tot_sslInfo_KeyEx_RSA_2048</code>	Specifies the number of RSA 2048-bit key exchanges on the NetScaler.
<code>ssl_tot_sslInfo_KeyEx_RSA_3072</code>	Specifies the number of RSA 3072-bit key exchanges on the NetScaler.
<code>ssl_tot_sslInfo_KeyEx_RSA_4096</code>	Specifies the number of RSA 4096-bit key exchanges on the NetScaler.
<code>ssl_tot_sslInfo_KeyEx_DH_512</code>	Specifies the number of Diffie-Hellman 512-bit key exchanges on the NetScaler.

---

Metrics name	Description
<code>ssl_tot_sslInfo_KeyEx_DH_1024</code>	Specifies the number of Diffie-Hellman 1024-bit key exchanges on the NetScaler.
<code>ssl_tot_sslInfo_KeyEx_DH_2048</code>	Specifies the number of Diffie-Hellman 2048-bit key exchanges on the NetScaler.
<code>ssl_tot_sslInfo_KeyEx_DH_4096</code>	Specifies the number of Diffie-Hellman 4096-bit key exchanges on the NetScaler.
<code>ssl_tot_sslInfo_KeyEx_ECDHE_curve_se</code>	Specifies the number of 521 Elliptical Curve Diffie-Hellman key exchanges on the NetScaler.
<code>ssl_tot_sslInfo_KeyEx_ECDHE_curve_384</code>	Specifies the number of 384 Elliptical Curve Diffie-Hellman key exchanges on the NetScaler.
<code>ssl_tot_sslInfo_KeyEx_ECDHE_curve_256</code>	Specifies the number of 256 Elliptical Curve Diffie-Hellman key exchanges on the NetScaler.
<code>ssl_tot_sslInfo_KeyEx_ECDHE_curve_224</code>	Specifies the number of 224 Elliptical Curve Diffie-Hellman key exchanges on the NetScaler.
<code>ssl_tot_sslInfo_ECDHE_Tx</code>	Specifies the total number of Elliptic Curve Diffie-Hellman Ephemeral (ECDHE) transactions on NetScaler.
<code>ssl_tot_sslInfo_Cipher_RC4_40</code>	Specifies the number of RC4 40-bit cipher encryptions on the NetScaler.
<code>ssl_tot_sslInfo_Cipher_RC4_56</code>	Specifies the number of RC4 56-bit cipher encryptions on the NetScaler.
<code>ssl_tot_sslInfo_Cipher_RC4_64</code>	Specifies the number of RC4 64-bit cipher encryptions on the NetScaler.
<code>ssl_tot_sslInfo_Cipher_RC4_128</code>	Specifies the number of RC4 128-bit cipher encryptions on the NetScaler.
<code>ssl_tot_sslInfo_Cipher_DES_40</code>	Specifies the number of DES 40-bit cipher encryptions on the NetScaler.
<code>ssl_tot_sslInfo_Cipher_DES_56</code>	Specifies the number of DES 56-bit cipher encryptions on the NetScaler.
<code>ssl_tot_sslInfo_Cipher_3DES_168</code>	Specifies the number of DES 168-bit cipher encryptions on the NetScaler.
<code>ssl_tot_sslInfo_Cipher_AES_128</code>	Specifies the number of AES 128-bit cipher encryptions on the NetScaler.
<code>ssl_tot_sslInfo_Cipher_AES_256</code>	Specifies the number of AES 256-bit cipher encryptions on the NetScaler.

---

Metrics name	Description
<code>ssl_tot_sslInfo_Cipher_RC2_40</code>	Specifies the number of RC2 40-bit cipher encryptions on the NetScaler.
<code>ssl_tot_sslInfo_Cipher_RC2_56</code>	Specifies the number of RC2 56-bit cipher encryptions on the NetScaler.
<code>ssl_tot_sslInfo_Cipher_RC2_128</code>	Specifies the number of RC2 128-bit cipher encryptions on the NetScaler.
<code>ssl_tot_sslInfo_Cipher_AESGCM_128</code>	Specifies the number of AEC-GCM 128-bit cipher encryptions on the NetScaler.
<code>ssl_tot_sslInfo_Cipher_AESGCM_256</code>	Specifies the number of AEC-GCM 256-bit cipher encryptions on the NetScaler.
<code>ssl_tot_sslInfo_Cipher_NULL</code>	Specifies the number of Null cipher encryptions on the NetScaler.
<code>ssl_tot_sslInfo_Hash_MD5</code>	Specifies the number of MD5 hashes on the NetScaler.
<code>ssl_tot_sslInfo_Hash_SHA</code>	Specifies the number of SHA hashes on the NetScaler.
<code>ssl_tot_sslInfo_Hash_SHA256</code>	Specifies the number of SHA256 hashes on the NetScaler.
<code>ssl_tot_sslInfo_Hash_SHA384</code>	Specifies the number of SHA384 hashes on the NetScaler.
<code>ssl_tot_sslInfo_SSLv2HandskCount</code>	Specifies the number of handshakes on SSLv2 on the NetScaler.
<code>ssl_tot_sslInfo_SSLv3HandskCount</code>	Specifies the number of handshakes on SSLv3 on the NetScaler.
<code>ssl_tot_sslInfo_TLSv1HandskCount</code>	Specifies the number of SSL handshakes on TLSv1 on the NetScaler.
<code>ssl_tot_sslInfo_TLSv11HandskCount</code>	Specifies the number of SSL handshakes on TLSv1.1 on the NetScaler.
<code>ssl_tot_sslInfo_TLSv12HandskCount</code>	Specifies the number of SSL handshakes on TLSv1.2 on the NetScaler.
<code>ssl_tot_sslInfo_TLSv13HandskCount</code>	Specifies the number of SSL handshakes on TLSv1.3 on the NetScaler.
<code>ssl_tot_sslInfo_DTLSv1HandskCount</code>	Specifies the number of SSL handshakes on DTLSv1 on the NetScaler.
<code>ssl_tot_sslInfo_DTLSv12HandskCount</code>	Specifies the number of SSL handshakes on DTLSv1.2 on the NetScaler.
<code>ssl_tot_sslEvent_SSLv2CA</code>	Specifies the number of client authentications done on SSLv2.

Metrics name	Description
<code>ssl_tot_sslEvent_SSLv3CA</code>	Specifies the number of client authentications done on SSLv3.
<code>ssl_tot_sslEvent_TLSv1CA</code>	Specifies the number of client authentications done on TLSv1.
<code>ssl_tot_sslEvent_TLSv11CA</code>	Specifies the number of client authentications done on TLSv1.1.
<code>ssl_tot_sslEvent_TLSv12CA</code>	Specifies the number of client authentications done on TLSv1.2.
<code>ssl_tot_sslEvent_TLSv13CA</code>	Specifies the number of client authentications done on TLSv1.3.
<code>ssl_tot_sslEvent_DTLSv1CA</code>	Specifies the number of client authentications done on DTLSv1.
<code>ssl_tot_sslEvent_DTLSv12CA</code>	Specifies the number of client authentications done on DTLSv1.2.
<code>ssl_tot_sslInfo_Auth_RSA</code>	Specifies the number of RSA authentications on the NetScaler.
<code>ssl_tot_sslInfo_Auth_DH</code>	Specifies the number of Diffie-Hellman authentications on the NetScaler.
<code>ssl_tot_sslInfo_Auth_DSS</code>	Total Specifies the number of times DSS authorization is used on the NetScaler.
<code>ssl_tot_sslInfo_Auth_ECDSA</code>	Total Specifies the number of times ECDSA authorization is used on the NetScaler.
<code>ssl_tot_sslInfo_Auth_NULL</code>	Specifies the number of Null authentications on the NetScaler.
<code>ssl_tot_sslInfo_Backend_SessionRenego</code>	Specifies the number of back-end SSL session renegotiations on the NetScaler.
<code>ssl_tot_sslInfo_Backend_SSLv3Renego</code>	Specifies the number of back-end SSLv3 session renegotiations on the NetScaler.
<code>ssl_tot_sslInfo_Backend_TLSv1Renego</code>	Specifies the number of back-end TLSv1 session renegotiations on the NetScaler.
<code>ssl_tot_sslInfo_Backend_TLSv11Renego</code>	Specifies the number of back-end TLSv1.1 session renegotiations on the NetScaler.
<code>ssl_tot_sslInfo_Backend_TLSv12Renego</code>	Specifies the number of back-end TLSv1.2 session renegotiations on the NetScaler.
<code>ssl_tot_sslInfo_Backend_DTLSv1Renego</code>	Specifies the number of back-end DTLSv1 session renegotiations on the NetScaler.

Metrics name	Description
<code>ssl_tot_sslInfo_Backend_KeyEx_RSA_512</code>	Specifies the number of back-end RSA 512-bit key exchanges on the NetScaler.
<code>ssl_tot_sslInfo_Backend_KeyEx_RSA_1024</code>	Specifies the number of back-end RSA 1024-bit key exchanges on the NetScaler.
<code>ssl_tot_sslInfo_Backend_KeyEx_RSA_2048</code>	Specifies the number of back-end RSA 2048-bit key exchanges on the NetScaler.
<code>ssl_tot_sslInfo_Backend_KeyEx_RSA_3072</code>	Specifies the number of back-end RSA 3072-bit key exchanges on the NetScaler.
<code>ssl_tot_sslInfo_Backend_KeyEx_RSA_4096</code>	Specifies the number of back-end RSA 4096-bit key exchanges on the NetScaler.
<code>ssl_tot_sslInfo_Backend_KeyEx_DH_512</code>	Specifies the number of back-end DH 512-bit key exchanges on the NetScaler.
<code>ssl_tot_sslInfo_Backend_KeyEx_DH_1024</code>	Specifies the number of back-end DH 1024-bit key exchanges on the NetScaler.
<code>ssl_tot_sslInfo_Backend_KeyEx_DH_2048</code>	Specifies the number of back-end DH 2048-bit key exchanges on the NetScaler.
<code>ssl_tot_sslInfo_Backend_KeyEx_DH_4096</code>	Specifies the number of back-end DH 4096-bit key exchanges on the NetScaler.
<code>ssl_tot_sslInfo_KeyEx_backend_ecdhe_521</code>	Specifies the number of back-end ECDHE 521 curve Key exchanges on the NetScaler.
<code>ssl_tot_sslInfo_KeyEx_backend_ecdhe_384</code>	Specifies the number of back-end ECDHE 384 curve Key exchanges on the NetScaler.
<code>ssl_tot_sslInfo_KeyEx_backend_ecdhe_256</code>	Specifies the number of back-end ECDHE 256 curve Key exchanges on the NetScaler.
<code>ssl_tot_sslInfo_KeyEx_backend_ecdhe_224</code>	Specifies the number of back-end ECDHE 224 curve Key exchanges on the NetScaler.
<code>ssl_tot_sslInfo_Backend_Cipher_RC4_40</code>	Specifies the number of back-end RC4 40-bit cipher encryptions on the NetScaler.
<code>ssl_tot_sslInfo_Backend_Cipher_RC4_56</code>	Specifies the number of back-end RC4 56-bit cipher encryptions on the NetScaler.
<code>ssl_tot_sslInfo_Backend_Cipher_RC4_64</code>	Specifies the number of back-end RC4 64-bit cipher encryptions on the NetScaler.

Metrics name	Description
<code>ssl_tot_sslInfo_Backend_Cipher_RC4_128</code>	Specifies the number of back-end RC4 128-bit cipher encryptions on the NetScaler.
<code>ssl_tot_sslInfo_Backend_Cipher_DES_40</code>	Specifies the number of back-end DES 40-bit cipher encryptions on the NetScaler.
<code>ssl_tot_sslInfo_Backend_Cipher_DES_56</code>	Specifies the number of back-end DES 56-bit cipher encryptions on the NetScaler.
<code>ssl_tot_sslInfo_Backend_Cipher_3DES_168</code>	Specifies the number of back-end 3DES 168-bit cipher encryptions on the NetScaler.
<code>ssl_tot_sslInfo_Backend_Cipher_AES_128</code>	Specifies the back-end AES 128-bit cipher encryptions on the NetScaler.
<code>ssl_tot_sslInfo_Backend_Cipher_AES_256</code>	Specifies the back-end AES 256-bit cipher encryptions on the NetScaler.
<code>ssl_tot_sslInfo_Backend_Cipher_RC2_40</code>	Specifies the number of back-end RC2 40-bit cipher encryptions on the NetScaler.
<code>ssl_tot_sslInfo_Backend_Cipher_RC2_56</code>	Specifies the number of back-end RC2 56-bit cipher encryptions on the NetScaler.
<code>ssl_tot_sslInfo_Backend_Cipher_RC2_128</code>	Specifies the number of back-end RC2 128-bit cipher encryptions on the NetScaler.
<code>ssl_tot_sslInfo_Backend_Cipher_AESGCM_128</code>	Specifies the number of back-end AES-GCM 128-bit cipher encryptions on the NetScaler.
<code>ssl_tot_sslInfo_Backend_Cipher_AESGCM_256</code>	Specifies the back-end AES-GCM 256-bit cipher encryptions on the NetScaler.
<code>ssl_tot_sslInfo_Backend_Cipher_NULL</code>	Specifies the number of back-end null cipher encryptions on the NetScaler.
<code>ssl_tot_sslInfo_Backend_Hash_MD5</code>	Specifies the number of back-end MD5 hashes on the NetScaler.
<code>ssl_tot_sslInfo_Backend_Hash_SHA</code>	Specifies the number of back-end SHA hashes on the NetScaler.
<code>ssl_tot_sslInfo_Backend_Hash_SHA256</code>	Specifies the number of back-end SHA256 hashes on the NetScaler.
<code>ssl_tot_sslInfo_Backend_Hash_SHA384</code>	Specifies the number of back-end SHA384 hashes on the NetScaler.

Metrics name	Description
<code>ssl_tot_sslInfo_Backend_SSLe3Handshakes</code>	Specifies the number of back-end SSLv3 handshakes on the NetScaler.
<code>ssl_tot_sslInfo_Backend_TLsv1Handshakes</code>	Specifies the number of back-end TLSv1 handshakes on the NetScaler.
<code>ssl_tot_sslInfo_Backend_TLsv11Handshakes</code>	Specifies the number of back-end TLSv1.1 handshakes on the NetScaler.
<code>ssl_tot_sslInfo_Backend_TLsv12Handshakes</code>	Specifies the number of back-end TLSv1.2 handshakes on the NetScaler.
<code>ssl_tot_sslInfo_Backend_DTLsv1Handshakes</code>	Specifies the number of back-end DTLSv1 handshakes on the NetScaler.
<code>ssl_tot_sslEvent_Backend_SSLe3CA</code>	Specifies the number of back-end SSLv3 client authentications on the NetScaler.
<code>ssl_tot_sslEvent_Backend_TLsv1CA</code>	Specifies the number of back-end TLSv1 client authentications on the NetScaler.
<code>ssl_tot_sslEvent_Backend_TLsv11CA</code>	Specifies the number of back-end TLSv1.1 client authentications on the NetScaler.
<code>ssl_tot_sslEvent_Backend_TLsv12CA</code>	Specifies the number of back-end TLSv1.2 client authentications on the NetScaler.
<code>ssl_tot_sslEvent_Backend_DTLsv1CA</code>	Specifies the number of back-end DTLSv1 client authentications on the NetScaler.
<code>ssl_tot_sslInfo_Backend_Auth_RSA</code>	Specifies the number of back-end RSA authentications on the NetScaler.
<code>ssl_tot_sslInfo_Backend_Auth_DH</code>	Specifies the number of back-end DH authentications on the NetScaler.
<code>ssl_tot_sslInfo_Backend_Auth_DSS</code>	Specifies the number of back-end DSS authentications on the NetScaler.
<code>ssl_tot_sslInfo_Backend_Auth_ECDSA</code>	Specifies the number of back-end ECDSA authentications on the NetScaler.
<code>ssl_tot_sslInfo_Backend_Auth_NULL</code>	Specifies the number of back-end null authentications on the NetScaler.
<code>ssl_tot_sslEvent_KeyExOff_RSA</code>	Specifies the number of RSA key exchanges offloaded to the cryptography card.
<code>ssl_tot_sslEvent_SignOff_RSA</code>	Specifies the number of RSA sign operations offloaded to the cryptography card.
<code>ssl_tot_sslEvent_KeyExOff_DH</code>	Specifies the number of DH key exchanges offloaded to the cryptography card.

---

Metrics name	Description
<code>ssl_tot_sslEvent_BulkOff_RC4</code>	Specifies the number of RC4 encryptions offloaded to the cryptography card.
<code>ssl_tot_sslEvent_BulkOff_DES</code>	Specifies the number of DES encryptions offloaded to the cryptography card.
<code>ssl_tot_sslEvent_BulkOff_AES</code>	Specifies the number of AES encryptions offloaded to the cryptography card.
<code>ssl_tot_sslEvent_BulkOff_AESGCM_128</code>	Specifies the number of AES-GCM 128-bit encryptions offloaded to the cryptography card.
<code>ssl_tot_sslEvent_BulkOff_AESGCM_256</code>	Specifies the number of AES-GCM 256-bit encryptions offloaded to the cryptography card.
<code>ssl_tot_hw_enc_bytes</code>	Specifies the number of bytes encrypted in hardware.
<code>ssl_tot_sw_enc_bytes</code>	Specifies the number of bytes encrypted in software.
<code>ssl_tot_enc_bytes_FE</code>	Specifies the number of bytes encrypted on the front-end.
<code>ssl_tot_hw_enc_bytes_FE</code>	Specifies the number of bytes encrypted in hardware on the front-end.
<code>ssl_tot_sw_enc_bytes_FE</code>	Specifies the number of bytes encrypted in software on the front-end.
<code>ssl_tot_enc_bytes_BE</code>	Specifies the number of bytes encrypted on the back-end.
<code>ssl_tot_hw_enc_bytes_BE</code>	Specifies the number of bytes encrypted in hardware on the back-end.
<code>ssl_tot_sw_enc_bytes_BE</code>	Specifies the number of bytes encrypted in software on the back-end.
<code>ssl_tot_hw_dec_bytes</code>	Specifies the number of bytes decrypted in hardware.
<code>ssl_tot_sw_dec_bytes</code>	Specifies the number of bytes decrypted in software.
<code>ssl_tot_dec_bytes_FE</code>	Specifies the number of bytes decrypted on the front-end.
<code>ssl_tot_hw_dec_bytes_FE</code>	Specifies the number of bytes decrypted in hardware on the front-end.
<code>ssl_tot_sw_dec_bytes_FE</code>	Specifies the number of bytes decrypted in software on the front-end.
<code>ssl_tot_dec_bytes_BE</code>	Specifies the number of bytes decrypted on the back-end.

---

Metrics name	Description
<code>ssl_tot_hw_dec_bytes_BE</code>	Specifies the number of bytes decrypted in hardware on the back-end.
<code>ssl_tot_sw_dec_bytes_BE</code>	Specifies the number of bytes decrypted in software on the back-end.
<code>ssl_cur_sslInfo_SPCBInUseCount</code>	Specifies the number of SPCB in use.
<code>ssl_cur_session_inuse</code>	Specifies the number of active SSL sessions on the NetScaler.
<code>ssl_cur_q_size</code>	Specifies the current queue size.
<code>ssl_cur_sslInfo_nsCardInQCount</code>	Specifies the number of current SSL card InQ counts.
<code>ssl_cur_sslInfo_cardinBlkQ</code>	Specifies the number of current SSL cards In BulkQ counts.
<code>ssl_cur_sslInfo_cardinKeyQ</code>	Specifies the number of current SSL cards In KeyQ counts.

---

## Priority Load Balancing

May 2, 2023

The priority load balancing feature enables you to assign a priority number for each of the services or service groups that are bound to a priority load balancing virtual server. A service or a service group with the lowest number has the highest priority. The application traffic is distributed only to this service or a service group as long as this service or the service group is UP. The service or the service group that is assigned the next priority number becomes operational only when all the services or members in the service group with the highest priority are DOWN. However, when any of the services or a member in the service group with the highest priority becomes available again, the traffic is redirected to that service or the service group.

For example, consider the service groups SVG1, SVG2, and SVG3 that is bound to a priority load balancing virtual server. The maximum number of priority groups is set to three. You assign the priority for each group as follows:

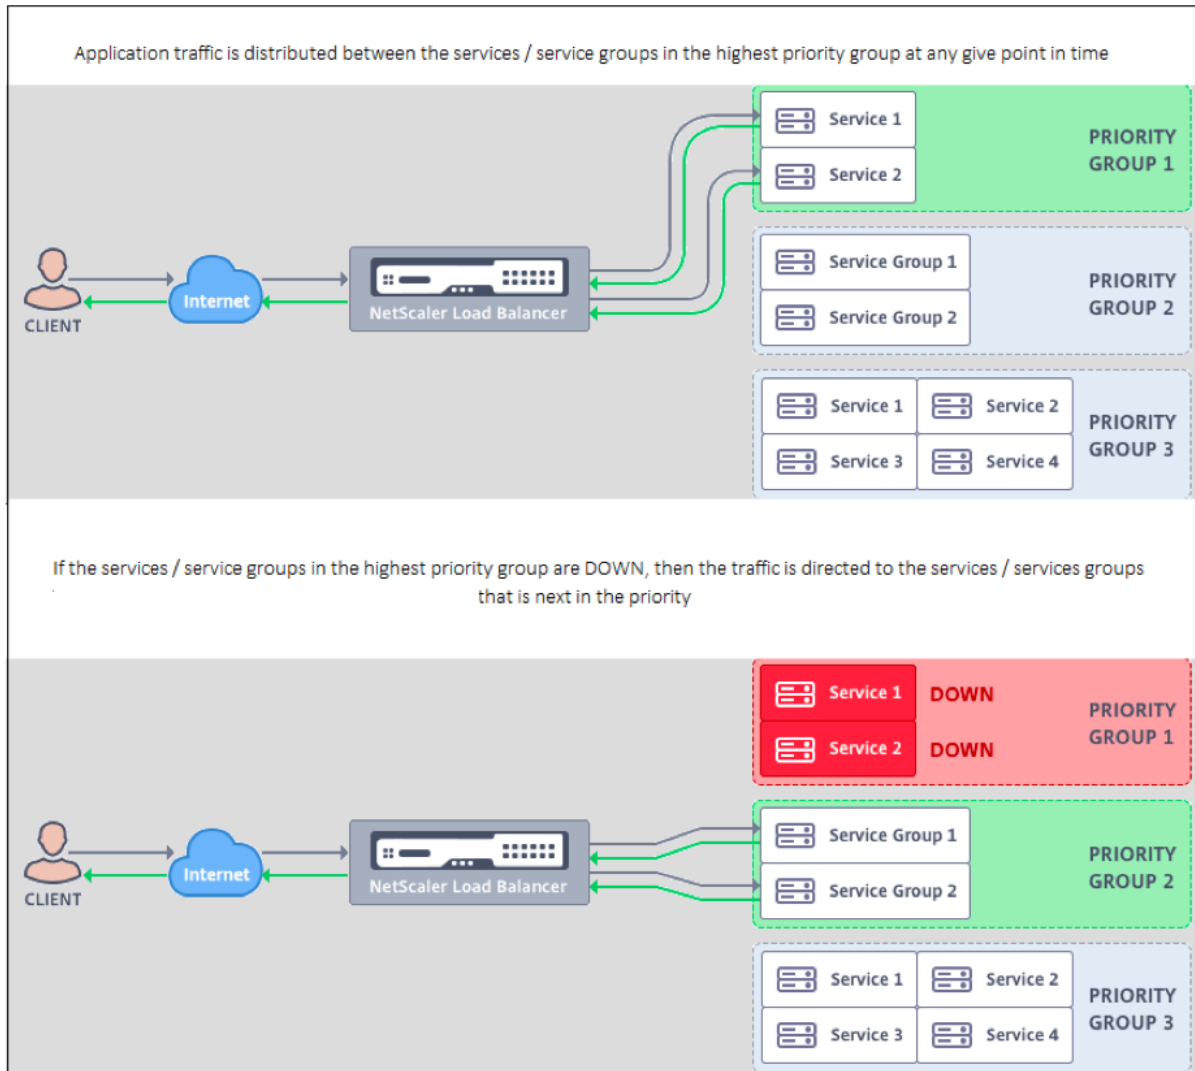

- SVG1 –priority 1
- SVG2 –priority 2
- SVG3 –priority 3

In this scenario, the application traffic is directed to service group SVG1 because this group is assigned the lowest priority number. If all the members in SVG1 are DOWN, the traffic is distributed to service group SVG2 as this group is assigned the next lower priority number. If all the members in SVG2 are also DOWN, the traffic is distributed to SVG3. However, when any of the members in SVG1 is UP, the traffic is redirected to SVG1 because SVG1 is assigned the lowest number and has the highest priority.

You can assign a priority to a service or a service group to upgrade the specific service or service group that has the highest priority, whenever required with minimal or no impact to the production traffic.

Also, if the upgrade is not successful, you can safely switch to the service or the service group that is next in the priority, with minimal or no impact to the production traffic.

The following figure illustrates the priority load balancing feature.

## Configure priority load balancing

### Note

The NetScaler priority load balancing configuration is supported only through the GUI. You cannot configure priority load balancing by using the CLI.

1. Navigate to **Traffic Management > Priority Load Balancing > Virtual \*Servers** and specify the protocol for the virtual server, the IP address, and the port number of the virtual server.
2. In the **Maximum Priority Groups** box, enter the number of priority services or the service groups that can be bound to this virtual server. Default value is 2, and the maximum priority that can be set is 10. This parameter is noneditable after it is configured.

### Note:

After you specify the maximum number of priority groups and click **OK**, a content switching virtual server and “n” number of backup load balancing virtual servers are created. The alphabet “n” represents the maximum number of priority groups.

For example, if you have entered the virtual server name as vs1, and have set the maximum priority group as 5, then a content switching virtual server with the name `_Pri.LB#vs1#MaxPri=5` and the following 5 load balancing virtual servers are created.

- `_Pri.LB#vs1#MaxPri=5_LB1`
- `_Pri.LB#vs1#MaxPri=5_LB2`
- `_Pri.LB#vs1#MaxPri=5_LB3`
- `_Pri.LB#vs1#MaxPri=5_LB4`
- `_Pri.LB#vs1#MaxPri=5_LB5`

3. After you specify the maximum number of priority groups and click **OK**, you are prompted to choose the services or service groups that must be bound to this content switching virtual server.
  - To bind services to the virtual server, click **Insert** in the Services section. Next, either select an existing service or create a service and set the priority for this service. Also, set the priority number at which this service must be bound.
  - To bind service groups to the virtual server, click **Insert** in the Service Groups section. Next, either select an existing service group or create a service group and set the priority for this service group. Also, set the priority number at which this service group must be bound.

Repeat step 3, depending on the maximum number of priority groups that you have entered.

### Note:

- The service or the service group with the highest priority is bound to the load balancing virtual server that represents the highest priority.

For example, if you have assigned priority 1 and 2 to service groups `SG_App1` and `SG_App2` respectively, then `SG_App1` is bound to `virtual server _Pri.LB#vs1#MaxPri=5_LB1` and `SG_App2` is bound to `virtual server _Pri.LB#vs1#MaxPri=5_LB2` created in step 2.

- To change the priority of the service group or service, click the edit icon in the Priority Load Balancing Virtual Server page and change the priority as required.
  - You cannot set the load balancing methods and persistence for each virtual server explicitly, because the configuration of all load balancing virtual servers is identical.
4. From the Advanced Setting sections, complete the other configuration that meets your requirement.

**Important:**

The entities created during the priority load balancing configuration must not be modified from other tabs in the GUI and also from the CLI. It is recommended that you modify the priority load balancing entities from the Priority Load Balancing tab only.

## NetScaler Extensions

May 2, 2023

NetScaler extensions can be used to customize a NetScaler appliance by writing extension code. Presently, policy extensions and protocol extensions are supported. Policy extensions can be used to extend the policy language. Protocol extensions can be used to add support for custom protocols on a NetScaler appliance.

NetScaler extensions are also supported on NetScaler CPX.

This document includes the following information:

- [NetScaler Extensions - Language Overview](#)
- [NetScaler Extensions - Library Reference](#)
- [NetScaler Extensions API Reference](#)
- [Protocol Extensions](#)
- [Policy Extensions](#)

## NetScaler extensions - language overview

May 2, 2023

The extension language is based on the Lua 5.2 programming language. Lua provides a compact execution engine with good performance that is designed for embedding in C programs, like NetScaler software.

The extension language is dynamically typed, which means each object carries its own type information. Any variable can hold any type at any time during execution, so variable types are not declared.

The language is also free form, where white space between tokens is ignored. Statements may be separated by semicolons, but that is not required and usually not done. Blocks of statements are typically terminated by end. There are no brackets around blocks like the { and } in C or Java.

Identifiers are sequences of letters (a through z and A through Z), digits (0 through 9), and underscores (\_), not starting in a digit. Identifiers are case-sensitive, so var, VAR, and Var are all different identifiers.

Comments are started by `--`. Everything after `--` is ignored to the end of the line. Example:

```
-- This is a comment.
```

## Simple types

May 2, 2023

The language allows values of the following simple types:

- Numbers
- Strings
- Boolean
- Nil
- Other Types

### Numbers

All numbers (even integers) are represented by IEEE 754 floating point values. Integers up to  $2^{54}$  have exact representations. Numeric values can be represented by:

- Signed and unsigned decimal integers (examples: 10, -5)
- Real numbers with decimal points (10.5, 3.14159)
- Real numbers with exponents (1.0e+10)
- Hexadecimals (0xffff0000)

NetScaler policy expressions have three numeric types:

- 32-bit integers (`num_at`)
- 64-bit integers (`unsigned_long_at`)
- 64-bit floating point (`double_at`)

All of these are converted into the number type when passed into an extension function, and numbers are converted to the expected policy numeric type when returned.

## Strings

Strings are byte sequences of any length. They correspond to the policy **text\_at** type. Strings can contain null (0x00) bytes. Arbitrary binary data can be held in strings, including any character code representation (e.g. UTF-8 and full Unicode). However, string functions **likestring.upper()** assume 8-bit ASCII.

Strings are automatically allocated when used. There is no need (or even way) to explicitly allocate buffers for strings. Strings are also automatically deallocated by garbage collection when no longer in use. There is no need (or even way) to explicitly free strings. This automatic allocation and deallocation avoids some common problems in languages like C, such as memory leaks and dangling pointers.

String literals are character strings enclosed in double or single quotes. There is no difference between the two types of quotes: “a string literal” is the same as ‘a string literal’. The usual backslash escaping is available: `\s` (bell), `\b` (backspace), `\f` (form feed), `\n` (newline/line feed), `\t` (horizontal tab), `\\` (backslash), `\“` (double quote), and `\`` (single quote). Decimal byte values can be entered by a backslash and one to three digits (`\d`, `\dd`, `\ddd`). Hexadecimal byte values can be entered by a backslash, an `x`, and two hex digits (`\xhh`)

A special syntax call the long bracket notation can be used for long, multi-line string literals. This notation encloses the string in double square brackets with zero or more equal signs between the brackets –the idea is to come up with a combination of brackets and equals that is not in the string. No escape sequences are honored in the string. Some examples:

```
[[This is a multi-line string using long bracket notation.]]
```

```
[=[This is a multi-line string using long notation with [[and]] and and an unescaped in it.]=]
```

Long bracket notation can be used to make a multi-line comment. Example:

```
-[[
This is a multi-line comment.
-]]
```

## Boolean

The usual true and false boolean values are provided. Note that boolean values are different than number values, in contrast to C where zero is assumed to be false and any non-zero value is true.

## Nil

nil is a special value that means “no value”. It is its own type and is not equivalent to any other value, in contrast to C where NULL is defined to be zero.

## Other types

There are two other types, userdata and threads. These are advanced topics and are not covered here.

## Variables

September 21, 2020

Variables hold values that may change during extension execution. Because of dynamic typing, any variable may hold values of any type. There are no type declarations for variables. Instead, a variable's type is determined at run time. In fact, the type of a variable's value may change during execution, although this is not a recommended practice. A variable initially has the value nil.

Variable names are identifiers, so are strings of letters, digits, and underscores not beginning in a digit. Examples: headers, combined\_headers.

## Global variables

In Lua, variables that are not otherwise declared are global within the program. However, global variables are not allowed in policy extension functions, because there are multiple Packet Engines in which a function can be executed, and each Packet Engine has its own memory.

If you use a global variable in your extension, you will get a runtime error: attempt to update or create a global reported in **/var/log/ns.log**.

Typos in variable names are a potential problem, because the variable with the typo will be interpreted as another, global variable, and will not cause a syntax error as in language like C or Java. As noted above, you will get a runtime error instead.

## Local variables

A variable may be declared to be local to a block of statements, such as a function. This is done by local variable-name. The variable will be scoped to the block, that is, it will only exist within the block. The local declaration may optionally assign a value to the variable.

### Examples:

```
local headers = {}
```

```
local combined_headers = {}
```

## Expressions

September 21, 2020

Expressions compute values from variable and literal values.

- Arithmetic Operations
- Relational Operations
- Logical Operations
- Concatenation
- Length
- Precedence

## Arithmetic operations

Arithmetic operations are performed on number values. If a string value is used in an arithmetic operation, it is converted to a number –if that fails, an error is returned.

---

---

$a + b$	add a and b
$a - b$	subtract b from a
$a * b$	multiply a and b
$a / b$	divide a by b
$a \% b$	modulo = $a - \text{math.floor}(a/b)*b$
$a ^ b$	raise a to the b power; b can be any number
$-a$	negate a

---

## Relational operations

Relational operations compare two values and return true if the relation is satisfied and false if it is not. Relational operations can be performed between values of any type. If the values are not the same type, false is returned. Numbers are compared in the usual way. Strings are compared using the collating sequence for the current locale.

---

---

<code>a == b</code>	a is equal to b
<code>a ~= b</code>	a is not equal to b
<code>a &lt; b</code>	a is less than b
<code>a &gt; b</code>	a is greater than b
<code>a &lt;= b</code>	a is less than or equal to b
<code>a &gt;= b</code>	a is greater than or equal to b

---

## Logical operations

Logical operations are traditionally performed on Boolean values, but in this language they can be performed on any two values. nil and false is considered false and any other value is considered true. Logical operations use short-cut evaluation, where if the first value determines the result of the operation, the second value is not evaluated.

---

---

<code>a and b</code>	if a is false or nil then return a else return b
<code>a or b</code>	if a is not false and not nil then return a else return b
<code>not a</code>	if a is not false or nil return false else return true

---

The and and or operations can be used for conditional evaluation within an expression:

---

---

<code>a or b</code>	can be used to provide a default value b if a is uninitialized (nil). This is useful for optional parameters in functions.
---------------------	----------------------------------------------------------------------------------------------------------------------------

a and b or c

can be used to chose non-nil b or c based on the condition a. If a is true, then a and b returns b, and b or c returns b. If a is false, then a and b returns false and false or c returns c. This is equivalent to a ? b : c in the C programming language.

---

## Concatenation

String concatenation is `s1 .. s2`. This creates a new string large enough to hold the contents of `s1` and `s2` and copies the contents to the new string. An error results if `s1` or `s2` are not strings. Note that repeated concatenation may have considerable copying overhead. If you build a string of `n` bytes by concatenating one byte at a time, this will copy  $n*(n+1)/2$  bytes. For better performance, you can put pieces of a string to be concatenated into a table (discussed later) and then use the `table.concat()` function. An example of this is shown in the `COMBINE_HEADERS()` example.

## Length

The length of a string `s` is returned by `#s`. The `#` operator is also used with array tables, as discussed later.

## Precedence

Operator precedence determines the order in which operations are performed in an expression, with higher precedence operations done before those with lower precedence. Precedence order can as usual be overridden by parentheses. For example, in `a + b \* c`, `*` has higher precedence than `+`, so the expression is evaluated as `a + (b \* c)`.

---

highest

- not # - (unary)
- • / %
- ..
- = ~= < > <= >=

-	and
lowest	or

---

Operations with the same precedence are performed left to right (left associative), except `^` and `..` that are performed right to left (right associative). So `a^b^c` is evaluated as `a^(b^c)`.

## Assignment

September 21, 2020

The assignment statement evaluates an expression and assigns the resulting value to a variable.

```
variable = expression
```

As noted earlier, values of any type can be assigned to any variable, so the following is allowed:

```
local v1 = "a string literal"
v1 = 10
```

An assignment statement can actually set multiple variables, using the form

```
variable1, variable2, ... = expression1, expression2, ...
```

If there are more variables than expressions, the extra variables are assigned `nil`. If there are more expressions than variables, the extra expression values are discarded. The expressions are all evaluated before the assignments, so this can be used to succinctly exchange the values of two variables:

```
v1, v2 = v2, v1
```

is equivalent to

```
tmp = v1
v2 = v1
v1 = tmp
```

## Tables

September 21, 2020

Tables are collections of entries with keys and values. They are the only aggregate data structure provided. All other data structures (arrays, lists, sets, and so on) are built from tables. Table keys and values can be any type, including other tables. Keys and values within the same table can mix types.

- Table Constructors
- Table Usage
- Tables as Arrays
- Tables as Records

## Table constructors

Table constructors allow you to specify a table with keys and associated values. The syntax is:

```
{[key1] = value1, [key2] = value2, ...}
```

where the keys and values are expressions. If the keys are strings that are not reserved words, the brackets and quotes around the keys can be omitted. Example:

```
{key1 = "value1", key2 = "value2", key3 = "value3"}
```

An empty table is specified simply by {}.

A table constructor may be used in an assignment to set a variable to refer to a table. Examples:

```
local t1 = {} –set t1 to an empty table
```

```
local t2 = {key1 = "value1", key2 = "value2", key3 = "value3"}
```

Note that tables themselves are anonymous. More than one variable may refer to the same table. Continuing the above example:

```
local t3 = t2 –both t2 and t3 refer to the same table
```

## Table usage

As you would expect, you can use keys to find values in a table. The syntax is `table[key]`, where `table` is a table reference (typically a variable assigned a table), and `key` is an expression providing the key. If this is used in an expression and the key exists in the table, this returns the value associated with the key. If the key is not in the table, this returns `nil`. If this is used as the variable in an assignment, and the key does not exist in the table, it creates a new entry for the key and value. If the key already exists in the table, it replaces the key's value with the new value. Examples:

```
local t = {} –sets t to an empty table
```

```
t["k1"] = "v1" –creates an entry for key "k1" and value "v1"
```

```
v1 = t["k1"] –sets v1 to the value for key "k1" = "v1"
```

```
t["k1"] = "new_v1" –sets the value for key "k1" to "new_v1"
```

## Table as arrays

The traditional array can be implemented using a table with integer keys as indices. An array can have any indices, including negative ones, but the convention is to start arrays at index 1 (not 0 as is the case with languages like C and Java). There is a special purpose table constructor for such arrays:

```
{value1, value2, value3, ...}
```

Array references are then `array[index]`.

The length operator `#` returns the number of elements in an array with consecutive indices starting at 1. Example:

```
local a = {"value1", "value2", "value3"}
local length = #a –sets length to the length of array a = 3
```

Arrays can be sparse, where only the defined elements are allocated. But `#` cannot be used on a sparse array with non-consecutive indices. Example:

```
local sparse_array = {} –set up an empty array
sparse_array[1] = "value1" –add an element at index 1
sparse_array[99] = "value99" –add an element at index 99
```

Multidimensional arrays can be set up as tables of tables. For example, a 3x3 matrix could be set up by:

```
local m = {{1, 2, 3}, {4, 5, 6}, {7, 8, 9}}
local v22 = m[2][2] –sets v22 to 5
```

## Tables as records

Records with fields can be implemented as tables with field name keys. The reference form `table.field` can be used for `table["field"]`. Examples:

```
local person = {name = "John Smith", phone = "777-777-7777"}
local name = person.name –sets name to "John Smith"
```

An array of tables can be used for a sequence of records. Example:

```
local people = {
{name = "John Smith", phone = "777-777-7777"},
{name = "Jane Doe", phone = "888-888-8888"}
...
}
name = people[2].name –sets name to "Jane Doe"
```

## Control structures

May 2, 2023

The extension function language provides the usual statements to control program execution.

- If Then Else
- While Do and Repeat Until
- Numeric For
- Break
- Goto

### If Then Else

If statements select blocks of statements to execute based on one or more conditions. There are three forms:

#### If then Form

```
1 if expression then
2 statements to execute if expression is not false or nil
3 end
4 <!--NeedCopy-->
```

#### If then else Form

```
1 if expression then
2 statements to execute if expression is not false or nil
3 else
4 statements to execute if expression is false or nil
5 end
6 <!--NeedCopy-->
```

#### If then elseif else Form

```
1 if expression1 then
2 statements to execute if expression1 is not false or nil
3 elseif expression2 then
4 statements to execute if expression2 is not false or nil
5 . . .
6 else
7 statements to execute if all expressions are false or nil
```

```
8 end
9 <!--NeedCopy-->
```

**Example:**

```
1 if headers[name] then
2
3 local next_value_index = #(headers[name]) + 1
4 headers[name][next_value_index] = value
5
6 else
7
8 headers[name] = {
9 name .. ":" .. value }
10
11
12 end
13 <!--NeedCopy-->
```

**Note:**

- The expression is not enclosed in parentheses as is the case in C and Java.
- There is no equivalent to the C/Java switch statement. You have to use a series of if elseif statements to do the equivalent.

**While Do and Repeat Until**

The **while** and **repeat** statements provide loops controlled by an expression.

```
1 while expression do
2 statements to execute while expression is not false or nil
3 end
4
5 repeat
6
7 statements to execute until expression is not false or nil
8
9 until expression
10 <!--NeedCopy-->
```

**Example for while:**

```
1 local a = {
2 1, 2, 3, 4 }
3
4 local sum, i = 0, 1 -- multiple assignment initializing sum and i
5 while i <= #a do -- check if at the end of the array
6 sum = sum + a[i] -- add array element with index i to sum
7 i = i + 1 -- move to the next element
8 end
9 <!--NeedCopy-->
```

**Example for repeat:**

```

1 sum, i = 0, 1 -- multiple assignment initializing sum and i
2 repeat
3 sum = sum + a[i] -- add array element with index i to sum
4 i = i + 1 -- move to the next element
5 until i > #a -- check if past the end of the array
6 <!--NeedCopy-->

```

Of course it is possible to write a loop that does not terminate, for example, if you omit the `i = i + 1` statement in either of these examples. When such a function is executed, NetScaler will detect that the function did not complete in a reasonable time and will kill it with a runtime error:

```
Cpu limit reached. Terminating extension execution in [[string "
function extension function..."]]: line line-number.
```

will be reported in `/var/log/ns.log`.

**Numeric For**

There are two types of for loops. The first is the numeric for, which is similar to the usual use of the for statement in C and Java. The numeric for statement initializes a variable, tests if the variable has passed a final value, and if not executes a block of statements, increments the variable, and repeats. The syntax for the numerical for loop is:

```

1 for variable = initial, final, increment do
2
3 statements in the loop body
4
5 end
6 <!--NeedCopy-->

```

where `initial`, `final`, and `increment` are all expressions that yield (or can be converted to) numbers. `variable` is considered to be local to the for loop statement block; it cannot be used outside of the loop. `increment` can be omitted; the default is 1. The expressions are evaluated once at the beginning of the loop. The terminating condition is `variable > final` if the increment is positive and `variable < final` if the increment is negative. The loop terminates immediately if the increment is 0.

Example (equivalent to the while and repeat loops in the preceding section):

```

1 sum = 0
2 for i = 1, #a do -- increment defaults to 1
3 sum = sum + a[i]
4 end
5 <!--NeedCopy-->

```

The second type of for loop is the generic for, which can be used for more flexible types of loops. It involves the use of functions, so will be discussed later after functions have been introduced.

## Break

The break statement is used inside a while, repeat, or for loop. It will terminate the loop and resume execution at the first statement after the loop. Example (also equivalent to the preceding while, repeat, and for loops):

```
1 sum, i = 0, 1
2 while true do
3 if i > #a then
4 break
5 end
6 sum = sum + a[i]
7 i = i + 1
8 end
9 <!--NeedCopy-->
```

## Goto

The goto statement can be used to jump forward or backward to a label. The label is an identifier, and its syntax is ::label::. The goto statement is goto label. Example (once again equivalent to the preceding loops):

```
1 sum, i = 0, 1
2 ::start_loop::
3 if i > #a then
4 goto end_loop -- forward jump
5 end
6 sum = sum + a[i]
7 i = i + 1
8 goto start_loop -- backwards jump
9 ::end_loop::
10 . . .
11 <!--NeedCopy-->
```

There has been a long running controversy over using gotos in programming. In general, you should try to use the other control structures to make your functions more readable and reliable. But occasional judicious use of gotos may lead to better programs. In particular, gotos may be useful in handling errors.

## Functions

May 2, 2023

Functions are a basic building block of programming –they are a convenient and powerful way to group statements that perform a task. They are the interface between the NetScaler appliance and

extension code. For policies, you define policy extension functions. For protocols, you implement callback functions for the protocol behaviors. Functions consist of function definitions that specify what values are passed into and out of the function and what statements are run for the function, and function calls, which run functions with specific input data and get results from the function.

### Protocol behavior callback functions

The TCP client behavior consists of a callback function (`on_data`) that processes TCP client data stream events. To implement Message Based Load Balancing (MLB) for a TCP based protocol, you can add code for this callback function to process the TCP data stream from the client and parse the byte stream into protocol messages.

The callback functions in a behavior are called with a context, which is the processing module state. The context is the instance of the processing module. For example, the TCP client behavior callbacks are called with different contexts for different client TCP connections.

In addition to the context, the behavior callbacks can have other arguments. Usually the rest of the arguments are passed as payload, which is the collection of all the arguments. So, the programmable processing module instances can be seen as a combination of instance state plus event callback functions, that is, the context plus behavior. And the traffic flows through the pipeline as event payload.

#### Prototype of TCP client callback function:

```
1
2 Function client on_data (ctxt, payload)
3
4 //.code
5
6 end
7
8
9 <!--NeedCopy-->
```

Where,

- `ctxt` - TCP client processing context
- `payload` –event payload
  - `payload.data` - TCP data received, available as a stream of bytes

### Policy extension functions

Since the NetScaler policy expression language is typed, the definition of an extension function must specify the types of its inputs and its return value. The **Lua function** definition has been extended to include these types:

```
1 function self-type: function-name(parameter1: parameter1-type, and so
 on): return-type
2 statements
3 end
4
5 <!--NeedCopy-->
```

Where,

The types are NSTEXT, NSNUM, NSBOOL, or NSDOUBLE.

Self-type is the type of the implicit self-parameter that is passed into the function. When the extension function is used in a NetScaler policy expression, this is the value generated by the expression to the left of the function. Another way to view this is that the function extends that type in the NetScaler policy language.

The parameter-types are the types of each parameter specified in the extension function call in the policy expression. An extension function can have zero or more parameters.

Return-type is the type of the value returned by the extension function call. It is the input to the part of the policy expression, if any, to the right of the function, or else is the value of the expression result.

**Example:**

```
function NSTEXT:COMBINE_HEADERS(): NSTEXT
```

Use of the extension function in a policy expression:

```
HTTP.REQ.FULL_HEADER.AFTER_STR("HTTP/1.1\r\n").COMBINE_HEADERS()
```

Here the self-parameter is the result of `HTTP.REQ.FULL_HEADER.AFTER_STR("HTTP/1.1\r\n")`, which is a text value. The result of the `COMBINE_HEADERS()` call is text, and since there is nothing to the right of this call, the result of the entire expression is text.

### Local function definition

Besides extension functions, no global functions can be defined in an extension file. But local functions can be defined within extension functions using the normal Lua function statement. This declares the name of the function and the names of its parameters (also known as arguments), and like all declarations in Lua, does not specify any types. The syntax for this is:

```
1 local function function-name(parameter1-name, parameter2-name, and so
 on)
2 statements
3 end
4
5 <!--NeedCopy-->
```

The function and parameter names are all identifiers. (The function name is actually a variable and the function statement is shorthand for local function-name = function(parameter1, and so on), but you don't have to understand this subtlety to use functions.)

Note that and so on is used here for continuation of the pattern of parameter names instead of the usual .... This is because ...itself actually means a variable parameter list, which will not be discussed here.

### Function body and return

The block of statements between the function and end statements is the function body. In the function body, the function parameters act like local variables, with values supplied by the function calls, as described previously.

The return statement supplies values to be returned to the caller of the function. It must appear at the end of a block (in a function, if then, for loop, and so on. It can be in its own block do return ...end). It specifies no, one, or more than one return values:

```
1 return -- returns nil
2 return expression -- one return value
3 return expression1, expression2, ... -- multiple return values
4
5 <!--NeedCopy-->
```

### Examples:

```
1 local function fsum(a)
2 local sum = 0
3 for i = 1, #a do
4 sum = sum + a[i]
5 end
6 return sum
7 end
8
9 Local function fsum_and_average(a)
10 local sum = 0
11 for i = 1, #a do
12 sum = sum + a[i]
13 end
14 return sum, sum/#a
15 end
16
17 <!--NeedCopy-->
```

## Function calls

A function call runs the body of a function, supplying values for its parameters, and receiving results. The syntax for a function call is `function-name(expression1, expression2, and so on)`, where the function parameters are set to the corresponding expressions. The number of expressions and parameters need not be the same. If there are fewer expressions than parameters, the remaining parameters are set to `nil`. So you can make one or more parameters at the end of the call optional, and your function can check if they are specified by checking if they are not `nil`. A common way to do this is with the OR operation:

```
1 function f(p1, p2) -- p2 is optional
2 p2 = p2 or 0 -- if p2 is nil, set to a default of 0
3 . . .
4 end
5
6 <!--NeedCopy-->
```

If there are more expressions than parameters, the remaining expression values are ignored.

As noted previously, functions can return multiple values. These returns can be used in a multiple assignment statement. Example:

```
1 local my_array = {
2 1, 2, 3, 4 }
3
4 local my_sum, my_ave = sum_and_average(my_array)
5
6 <!--NeedCopy-->
```

## Iterator functions and generic for loops

Now that we have introduced functions, we can talk about generic for loops. The syntax for the generic for loop (with one variable) is:

```
1 for variable in iterator(parameter1, parameter2, and so on) do
2 statements in the for loop body
3 end
4
5 <!--NeedCopy-->
```

Where `iterator()` is a function with zero or more parameters that provide a value for a variable on each iteration of the loop body. The iterator function keeps track of where it is in the iteration using a technique called closure, which you don't have to worry about here. It signals the end of the iteration by returning `nil`. Iterator functions can return more than one value, for use in a multiple assignment.

Writing an iterator function is beyond the scope of this paper, but there are few useful built-in iterators that illustrate the concept. One is the `pairs()` iterator, which iterates through the entries in a table and

returns two values, the key and the value of the next entry.

**Example:**

```
1 local t = {
2 k1 = "v1", k2 = "v2", k3 = "v3" }
3
4 local a = {
5 }
6 -- array to accumulate key-value pairs
7 local n = 0 -- number of key-value pairs
8 for key, value in pairs(t) do
9 n = n + 1
10 a[n] = key.. " = ".. Value -- add key-value pair to the array
11 end
12 local s = table.concat(a, ";") -- concatenate all key-value pairs into
 one string
13
14 <!--NeedCopy-->
```

Another useful iterator is the `string.gmatch()` function, which is used in the following `COMBINE_HEADERS()` example.

## NetScaler extensions - library reference

May 2, 2023

The list of libraries supported in policy extensions.

- Basic library
- String library
- Regular Expression Patterns - Character Classes
- Regular Expression Patterns - Pattern Items
- Table library
- Math library
- Bitwise library
- Operating System library
- NetScaler library

### Basic library

---

<code>assert(v[,message])</code>	Issues an error, with an optional message, when <code>v</code> is false.
<code>error(message)</code>	Terminates a function and reports the error message.
<code>ipairs(a)</code>	Iterator for an array <code>a</code> . Returns an index and value for each iteration.
<code>pairs(t)</code>	Iterator for a table <code>t</code> . Returns a key and value for each iteration.
<code>tonumber(e[,base])</code>	Converts <code>e</code> to a number, with an optional base.
<code>tostring(v)</code>	Converts <code>v</code> to a string
<code>type(v)</code>	Returns the type of <code>v</code> : number, string, boolean, table, etc.
<code>getmetatable (object)</code>	Returns nil if the object does not have a metatable. Otherwise, if the object's metatable has a " <code>__metatable</code> " field, returns the associated value. Otherwise, returns the metatable of the given object.
<code>setmetatable (table, metatable)</code>	Sets the metatable for the given table. (You cannot change the metatable of other types from Lua, only from C.) If metatable is nil, removes the metatable of the given table. If the original metatable has a " <code>__metatable</code> " field, raises an error.
<code>select (index, -)</code>	Returns all arguments after argument number <code>index</code> . If <code>index</code> is string " <code>#</code> ", then it returns the total number of extra arguments it received.
<code>pcall (f [, arg1, -])</code>	Calls function <code>f</code> with the given arguments in protected mode. It returns status code as first result which tells whether call succeeded or not. If call succeeded, then along with status code it also returns all results from the call, otherwise returns error message.
<code>xpcall (f, msgch [, arg1, -])</code>	This function is similar to <code>pcall</code> , except that it also takes an argument for error handling.
<code>_VERSION</code>	Returns the current interpreter version.

---

## String library

---

<code>string.byte(s[,i[,j]])</code>	Returns the byte values for <code>s[i]</code> to <code>s[j]</code> . Default <code>i = 1</code> and <code>j = i</code>
<code>string.char(...)</code>	Returns a string constructed of the integer parameters.
<code>string.find(s,pattern[,init[,plain]])</code>	Looks for the first match of a regular expression pattern in <code>s</code> . Return the first and last indices of match or <code>nil</code> . <code>init</code> is index to start, default <code>1</code> . <code>plain = true</code> means pattern is not a regex.
<code>string.format(form,...)</code>	Returns a formatted version of the parameters.
<code>string.gmatch(s,pattern)</code>	Iterator for searching <code>s</code> with the regex pattern. Returns matching values.
<code>string.gsub(s,pattern,repl[,n])</code>	Returns a copy of <code>s</code> in which all (or <code>n</code> ) occurrences of the pattern have been replaced by <code>repl</code> .
<code>string.len(s)</code>	Returns the string length.
<code>string.lower(s)</code>	Returns a copy of the string converted to lowercase.
<code>string.match(s,pattern[,init])</code>	Looks for the first match of the regex pattern in <code>s</code> and returns the captures or the whole pattern. <code>init</code> is the index to start, default <code>1</code> .
<code>string.rep(s,n[,sep])</code>	Returns a string that is <code>n</code> copies of <code>s</code> , with separator <code>sep</code> , default no separator
<code>string.reverse(s)</code>	Returns a string that is <code>s</code> reversed.
<code>string.sub(s,i[,j])</code>	Returns the substring of <code>s</code> from <code>s[i]</code> to <code>s[j]</code> , default <code>j</code> is the end of the string.
<code>string.upper(s)</code>	Returns a copy of the string converted to uppercase.
<code>string.dump (function)</code>	Returns a string containing a binary representation of the given function.

---

## Regular expression patterns - character classes

x	the character x, except for magic characters ^\$()%.[\]*+~?)
.	any character
%a	any letter
%c	any control character
%d	any digit
%g	any printable character except space
%l	any lowercase letter
%p	any punctuation character
%s	any white space character
%u	any uppercase letter
%w	any alphanumeric letter
%x	an escaped magic character x (for example %%)
[set]	a set of characters: sequence of individual characters, ranges x-y, and % classes
[^set]	characters not in the set.

---

### Regular expression patterns - pattern items

---

X	a character class
X*	0 or more longest repetitions of characters in X
X+	1 or more repetitions of characters in X
X-	0 or more shortest repetitions of characters in X
X?	0 or 1 character in X
%n	n=1 to 9; matches nth captured string
%bxy	matches substring between two balanced characters x and y. Example %b() matches substring between two balanced parentheses.

---

<code>%f[set]</code>	matches an empty string at any position such that the next character belongs to set and the previous character does not belong to set.
----------------------	----------------------------------------------------------------------------------------------------------------------------------------

---

A pattern is a sequence of pattern items. `^pattern` matches the beginning of a string and `pattern$` matches the end of the string.

Matched substrings can be captured using `(pattern)`. Parentheses with no pattern `()` capture the current string position (a number).

## Table library

---

---

<code>table.concat(list[,sep[,i[,j]])</code>	Returns a string <code>list[i] .. sep .. list[i+1] .. sep . . . list[j]</code> . Default <code>sep</code> is the empty string. Default <code>i</code> is 1, <code>j</code> is <code>#list</code> .
<code>table.insert(list,[pos,]value)</code>	Inserts <code>value</code> into <code>list</code> at index <code>pos</code> . Default for <code>pos</code> is <code>#list</code> (end of the list).
<code>table.pack(...)</code>	Returns an array containing the parameters starting at index 1, and a key <code>n</code> with the total number of parameters.
<code>table.remove(list[,pos])</code>	Removes from <code>list</code> the element at position <code>pos</code> , shifting elements to fill the position. Returns the removed element. Default for <code>pos</code> is <code>#list</code> (end of the list.)
<code>table.sort(list[,comp])</code>	Sort the elements of <code>list</code> in place. <code>comp</code> is the comparison function to use. Default for <code>comp</code> is <code>&lt;</code> .
<code>table.unpack(list[,i[,j]])</code>	Returns <code>list[i]</code> through <code>list[j]</code> . Default for <code>i</code> is 1 and <code>j</code> is <code>#list</code> .

---

## Math library

Various trigonometric and logarithmic functions not shown.

<code>math.abs(x)</code>	Returns the absolute value of $x$ .
<code>math.ceil(x)</code>	Returns the smallest integer $\geq x$ .
<code>math.floor(x)</code>	Returns the largest integer $\leq x$ .
<code>math.fmod(x,y)</code>	Returns the remainder of $x/y$ rounding the quotient towards zero.
<code>math.huge</code>	A value $\geq$ any other number.
<code>math.max(x,...)</code>	Returns the maximum argument.
<code>math.min(x,...)</code>	Returns the minimum argument.
<code>math.modf(x)</code>	Returns the integral and fractional parts of $x$ .
<code>math.random()</code>	Returns a pseudo-random number between 0 and 1.
<code>math.random(m)</code>	Returns a pseudo-random integer between 1 and $m$ .
<code>math.random(m, n)</code>	Returns a pseudo-random integer between $m$ and $n$ .
<code>math.randomseed(x)</code>	Sets the pseudo-random number generator set to $x$ .
<code>math.sqrt(x)</code>	Returns the square root of $x$ ( $x^{0.5}$ )
<code>math.acos(x)</code>	Returns the arc cosine of $x$ (in radians).
<code>math.asin(x)</code>	Returns the arc sine of $x$ (in radians).
<code>math.atan(x)</code>	Returns the arc tangent of $x$ (in radians).
<code>math.atan2(y, x)</code>	Returns the arc tangent of $y/x$ (in radians).
<code>math.cos(x)</code>	Returns the cosine of $x$ .
<code>math.cosh(x)</code>	Returns the hyperbolic cosine of $x$ .
<code>math.sin(x)</code>	Returns the sine of $x$ .
<code>math.sinh(x)</code>	Returns the hyperbolic sine of $x$ .
<code>math.tan(x)</code>	Returns the tangent of $x$ .
<code>math.tanh(x)</code>	Returns the hyperbolic tangent of $x$ .
<code>math.deg(x)</code>	Returns the angle $x$ (given in radians) in degrees.
<code>math.exp(x)</code>	Returns the value $e^x$ .

---

<code>math.frexp(x)</code>	Returns $m$ and $e$ such that $x = m2^e$ , $e$ is an integer and the absolute value of $m$ is in the range $[0.5, 1)$ .
<code>math.ldexp(m, e)</code>	Returns $m2^e$ ( $e$ should be an integer).
<code>math.log(x[, base])</code>	Returns the logarithm of $x$ in the given base. The default for base is $e$ .
<code>math.pow(x, y)</code>	Returns $x^y$ .
<code>math.rad(x)</code>	Returns the angle $x$ (given in degrees) in radians.
<code>math.pi</code>	The value of $\pi$ .

---

## Bitwise library

Unless otherwise stated:

- All functions accept numeric arguments in the range  $(-2^{51}, 2^{51})$ .
  - Each argument is normalized to the remainder of its division by  $2^{32}$  and truncated to an integer (in some unspecified way), so that its final value falls in the range  $[0, 2^{32} - 1]$ .
  - All results are in the range  $[0, 2^{32} - 1]$ .
- 

---

<code>bit32.arshift(x, disp)</code>	Returns $x$ arithmetically shifted $disp$ bits to the right ( $+disp$ ) or left ( $-disp$ ).
<code>bit32.band(...)</code>	Returns the bitwise and of the arguments.
<code>bit32.bnot(x)</code>	Returns the bitwise negation of $x$ .
<code>bit32.bor(...)</code>	Returns the bitwise or of the arguments.
<code>bit32.btest(...)</code>	Returns true if the bitwise and of the arguments is not zero.
<code>bit32.bxor(...)</code>	Returns the bitwise exclusive or of the arguments.
<code>bit32.extract(n, field[, width])</code>	Returns the bits in $n$ from $field$ to $field + width - 1$ (bits number from most to least significant). Default for $width$ is 1.
<code>bit32.replace(n, v, field[, width])</code>	Returns a copy of $n$ with bits from $field$ to $field + width - 1$ replaced by $v$ . Default $width$ is 1.

---

<code>bit32.lrotate(x,disp)</code>	Returns x rotated disp bits to the left (+disp) or right (-disp).
<code>bit32.lshift(x,disp)</code>	Returns x shifted disp bits to the left (+disp) or right (-disp).
<code>bit32.rrotate(x,disp)</code>	Returns x rotated disp bits to the right (+disp) or left (-disp).
<code>bit32.rshift(x,disp)</code>	Returns x shifted disp bits to the right (+disp) or left (-disp).

---

## Operating system library

---

<code>os.clock ()</code>	Returns an approximation of the amount in seconds of CPU time.
<code>os.date ([format [, time]])</code>	Returns a string or a table containing date and time, formatted according to the given string format.
<code>os.time ([table])</code>	Returns the current time when called without arguments, or a time representing the date and time specified by the given table.
<code>os.difftime (t2, t1)</code>	Returns the number of seconds from time t1 to time t2.

---

## NetScaler library

---

<code>ns.logger:level(message)</code>	To log messages where level is emergency, alert, critical, error, warning, notice, info, or debug. The parameters are the same as the C <code>printf()</code> function: a format string, and a variable number of arguments to supply values for the % specifiers in the format string.

## NetScaler extensions API reference

May 2, 2023

Behaviors are a formalization of common programmable patterns that are available on a NetScaler appliance. For example, a TCP virtual server supports a TCP client behavior and a TCP server behavior. A behavior is a pre-defined set of callback functions. You can implement behaviors by providing callback functions. For example, a TCP client behavior can consist of the `on_data` function, which processes the TCP data stream.

### TCP client behavior

**on\_data** - function callback for TCP client data events. The callback takes two arguments:

- **ctxt** - TCP client processing context
- **payload** –event payload
  - **payload.data** - TCP data received, available as a stream of bytes

### TCP server behavior

**on\_data** - function callback for TCP server data events, the callback takes two arguments:

- **ctxt** - TCP server processing context
- **payload** –event payload
  - **payload.data** - tcp data received, available as a stream of bytes

### TCP client context

The context that is passed to the TCP client event callbacks:

- **ctxt.output** - The next processing context in the pipeline. Extension call back handlers can send `ns.tcp.stream` type data to `ctxt.output` using the events `DATA`, which means partial message or `EOM` which means end of protocol message. The `EOM` event may or may not have TCP data with it. An `EOM` event with TCP data can be sent without a preceding `DATA` event to send a whole protocol message data and mark the end of message. The load balancing decision is made, downstream by the load balancing virtual server, on the first data received. A new load balancing decision is made after the receipt of the `EOM` message. So, to stream protocol message data, send multiple `DATA` events with the last event as `EOM`. All the contiguous `DATA` events and the

following EOM events are sent to the same server connection selected by the load balancing decision on the first DATA event in the sequence.

- **ctxt.input** - The previous processing context in the pipeline where the TCP stream data is coming from.
- **ctxt:hold(data)** - Function to store the data for future processing. On calling hold with data, the data is stored in the context. Later, when more data is received on the same context, newly received data is appended to the previously stored data and the combined data stream is then passed to the on\_data callback function. After calling a hold, the data reference is no longer usable and gives error on any usage.
- **ctxt.vserver** - The virtual server context.
- **ctxt.client** –Client connection processing context. This processing context can be used to send data to the client, and to fetch some connection related information like IP address, source and destination ports.
- **ctxt:close()** –Close the client connection by sending FIN to the client. After calling this API, the client processing context is no longer usable and gives error on any usage.

## TCP server context

The context that is passed to the TCP server event callbacks:

- **ctxt.output** –The next processing context in the pipeline. Extension call back handlers can send ns.tcp.stream type data to ctxt.output using the events DATA, which means partial message or EOM which means end of protocol message.
- **ctxt.input** - The previous processing context in the pipeline where the TCP stream data is coming from.
- **ctxt:hold(data)** - Function to store the data for future processing. On calling hold with data, the data is stored in the context. Later, when more data is received on the same context, newly received data is appended to the previously stored data and the combined data stream is then passed to the on\_data callback function. After calling a hold, the data reference is no longer usable and gives error on any usage.
- **ctxt.vserver** - The virtual server context.
- **ctxt.server** - Server connection processing context. This processing context can be used to send data to the server, and to fetch some connection related information like IP address, source and destination ports.
- **ctxt:reuse\_server\_connection ()** - This API is used to allow the server connection to be reused for other client connections in the server context only. This API can be used only if an EOM event

is used (in `ns.send()` API) to send the data in the client context. Otherwise, the ADC appliance throws an error.

To allow a server connection to be reused by other clients, this API must be called at the end of each response message. After calling this API, if more data is received on this server connection, this is treated as an error and the server connection is closed. If this API is not used, then the server connection can be used only for that client for which it was opened. Also, if the same server is selected for another load balancing decision for that client, then the same server connection is used to send the client data. After using this API, server connection stops being tied to the client connection for which it was opened, and can be reused for a new load balancing decision for any other client connection. After calling this API, the server context is no longer usable and throws an error on any usage.

**Note:** This API is available in NetScaler 12.1 build 49.xx and later.

- **ctxt:close()** –Close the server connection by sending FIN to the server. After calling this API, the client processing context is no longer usable and displays an error on any usage.

**Note:** This API is available in NetScaler 12.1 build 50.xx and later.

## Vserver context

The user virtual server context available through the contexts passed to callbacks:

- **vserver:counter\_increment(counter\_name)** - Increments the value of a virtual server counter passed as argument. Currently the following built-in counters are supported.
  - - **invalid\_messages** –Number of invalid requests/responses on this virtual server.
  - - **invalid\_messages\_dropped** –Number of invalid requests/responses dropped by this virtual server.
- **vserver.params** - The configured parameters for the user virtual server. Parameters provide configurability of extensions. The extension code can access parameters that are specified in the CLI to add a user virtual server.

## Client connection context

Client connection processing context to get connection related information.

- **client.ssl** –SSL context
- **client.tcp** –TCP context
- **client.is\_ssl** –True if client connection is SSL-based

## Server connection context

Server connection processing context to get connection related information.

- **server.ssl** –SSL context
- **server.tcp** –TCP context
- **server.is\_ssl** –True if server connection is SSL-based

## TCP context

TCP context operates on TCP protocol.

- **tcp.srcport** –Source port as a number
- **tcp.dstport** - Destination port as a number

## IP context

IP context works on IP or IPv6 protocol data.

- **ip.src** - Source IP address context.
- **ip.dst** - Destination IP address context.

**Note:** This API is available in NetScaler 12.1 build 51.xx and later.

## IP address context

IP address context works on IP or IPv6 address data.

- **<address>.to\_s** - The address string in the appropriate ASCII notation.
- **<address>.to\_n** - The address' numeric value as a string of bytes in network order (4 bytes for IPv4 and 16 bytes for IPv6).
- **<address>.version** - Returns 4 for IPv4 and 6 for IPv6.
- **<address>:subnet(<prefix value>)** - Returns the subnet address string after applying the prefix number.
  - For IPv4 address, value must be between 0 and 32
  - For IPv6 address, value must be between 0 and 128.
- **<address>:apply\_mask(<mask string>)** - Returns the address string after applying mask string. API validates the version of argument and does appropriate error checking.
- **<address>:eq(<address string>)** - Returns true or false based on whether the argument is equivalent to the address object. API validates the version of the arguments.

**Note:** This API is available in NetScaler 12.1 build 51.xx and later.

## SSL context

The SSL context provides information related to frontend SSL connection.

- **ssl.cert** –SSL certificate context. For the client connection, it provides client certificate context and for the server connection, it provides server certificate context.
- **ssl.version** - A number that represents the SSL protocol version of the current transaction, as follows:
  - - 0: The transaction is not SSL-based
  - - 0x002: The transaction is SSLv2
  - - 0x300: The transaction is SSLv3
  - - 0x301: The transaction is TLSv1
  - - 0x302: The transaction is TLSv1.1
  - - 0x303: The transaction is TLSv1.2
- **ssl.cipher\_name** - SSL Cipher name as string if invoked from an SSL connection, otherwise gives NULL string.
- **ssl.cipher\_bits** –Number of bits in cryptographic key.

## SSL certificate context

- **Cert.version** –Version number of the certificate. If the connection is not SSL based, returns 0.
- **Cert.valid\_not\_before** –Date in string format before which certificate is not valid.
- **Cert.valid\_not\_after** –Date in string format after which certificate is no longer valid.
- **Cert.days\_to\_expire** –Number of days before which certificate is valid. Returns -1 for expired certificate.
- **Cert.to\_pem** –Certificate in binary format.
- **cert.issuer** - Distinguished Name (DN) of the Issuer in the certificate as a name-value list. An equals sign (“=”) is the delimiter for the name and the value, and the slash (“/”) is the delimiter that separates the name-value pairs.

Following is an example of the returned DN:

```
/C=US/O=myCompany/OU=www.mycompany.com/CN=www.mycompany.com/emailAddress=myuserid@mycompany.com
```

- **cert.auth\_keyid** –Context of Authority Key Identifier extension of the X.509 V3 certificate.
  - **auth\_keyid.exists** - TRUE if the certificate contains an Authority Key Identifier extension.
  - **auth\_keyid.issuer\_name** - Issuer Distinguished Name in the certificate as a name-value list.

An equals sign (“=”) is the delimiter for the name and the value, and the slash (“/”) is the delimiter that separates the name-value pairs.

Following is an example:

```
/C=US/O=myCompany/OU=www.mycompany.com/CN=www.mycompany.com/emailAddress=myuserid@n
```

- **auth\_keyid.keyid** - KeyIdentifier field of the Authority Key Identifier as a blob
- **auth\_keyid.cert\_serialnumber** - SerialNumber field of the Authority Key Identifier as a blob.
- **cert.pk\_algorithm** - Name of the public key algorithm used by the certificate.
- **cert.pk\_size** - Size of the public key used in the certificate.
- **cert.serialnumber** - Serial number of the client certificate. If this is a non-SSL transaction or there is an error in the certificate, this gives an empty string.
- **cert.signature\_algorithm** - Name of the cryptographic algorithm used by the CA to sign this certificate.
- **cert.subject\_keyid** - Subject KeyID of the client certificate. If there is no Subject KeyID, this gives a zero-length text object.
- **cert.subject** - Distinguished Name of the Subject as a name-value. An equals sign (“=”) separates names and values and a slash (“/”) delimits name-value pairs.

Following is an example:

```
/C=US/O=myCompany/OU=www.mycompany.com/CN=www.mycompany.com/emailAddress=myuserid@mycom
```

## NetScaler libraries

- **ns.tcp.stream** - String like library for handling TCP data as a stream of bytes. The maximum size of TCP stream data on which these APIs can work is 128 KB. The ns.tcp.stream library functions can also be called in the usual extension object oriented style of calling. For example, data:len() is the same as ns.tcp.stream.len(data)
  - **ns.tcp.stream.len(data)** - Returns length of data in bytes, similar to Lua’s string.len
  - **ns.tcp.stream.find(data, pattern [, init])** - Function similar to Lua’s string.find. In addition, it also does partial matching at the end of data. Upon partial match, the start index is returned and the end index becomes nil.
  - **ns.tcp.stream.split(data, length)** - Splits the data into two chunks, the first chunk is of the specified length. After a successful split the original data is no longer usable as a TCP data stream. Any attempt to use it that way causes an error.
  - **ns.tcp.stream.byte(data, i [, j])** - Function similar to Lua’s string.byte. Returns the internal numerical codes of the characters data[i], data[i+1], ..., data[j].

- **ns.tcp.stream.sub(data, i [, j])** - Function similar to Lua's string.sub. Returns the substring of s that starts at i and continues until j.
- **ns.tcp.stream.match(data, pattern, [, init])** - Function similar to Lua's string.match. Looks for the first *match* of pattern in string s.
- **ns.send(processing\_ctxt, event\_name, event\_data)** - Generic function to send events to a processing context. Event data is a Lua table that can have any content. The contents depend on the event. After the ns.send() API is called, the data reference is no longer usable. Any attempt to use it causes an error.
- **ns.pipe(src\_ctxt, dest\_ctxt)** - Using a call to pipe() API, extension code can connect source context to a destination context. After a call to pipe, all the events that are sent from source context to the next module in the pipeline go directly to the destination context. This API is typically used by the module that makes the pipe() call, to remove itself from the pipeline.
- **ns.inet** –Library for internet addresses.
  - **ns.inet.apply\_mask(address\_str, mask\_str)** - returns the address string after applying mask string.
  - **ns.inet.aton(address\_str)** - Returns address' numeric value as a string of bytes in network order (4 bytes for IPv4 and 16 for IPv6).
  - **ns.inet.ntoa(byte\_str)** - Converts numeric byte value as a string of bytes to address string.
  - **ns.inet.ntohs(number)** - Convert the given network byte order to host byte order. If the input is greater than  $2^{16} - 1$ , then throws an error.
  - **ns.inet.htons(number)** - Converts the given host byte order to network byte order. If the input is greater than  $2^{16} - 1$ , then throws an error.
  - **ns.inet.ntohl(number)** - Converts the given network byte order to host byte order. If the input is greater than  $2^{32} - 1$ , then throws an error.
  - **ns.inet.htonl(number)** - Converts the given host byte order to network byte order. If the input is greater than  $2^{32} - 1$ , then throws an error.
  - **ns.inet.subnet(address\_str, subnet\_value)** –Returns the subnet address string after applying given subnet.

## Protocol extensions

May 2, 2023

The NetScaler appliances have native support for protocols such as HTTP. In addition to this, you can use protocol extensions to add support for custom protocols. Presently only TCP-based custom protocols are supported, for example, Message Queuing Telemetry Transport (MQTT) protocol. For secure transactions, TCP over SSL is also supported.

The protocol extensions on the NetScaler appliance are part of the high-level scripting infrastructure available on the NetScaler appliance. The scripting language is based on the Lua 5.2 programming language. To add a custom protocol to a NetScaler appliance, the user has to write extension code to implement the applicable behaviors. For example, the `ns.tcp.client` and `ns.tcp.server` behaviors are applicable to TCP based protocols. To implement a behavior, implement only the callbacks that you want to customize. If callback is not implemented, its default takes effect. For more information about the scripting language, see [NetScaler Extensions - Language Overview](#). For details on behaviors, see [NetScaler Extensions API Reference](#).

The NetScaler protocol extensions can be used for the following:

- Add new protocol support on the NetScaler appliance programmatically, using extensions.
- Parse protocol traffic and do protocol-specific message based load balancing (MLB).
- Configure user defined load balancing persistence.

## Protocol extensions - architecture

May 2, 2023

To achieve traffic-level extensibility, the traffic processing on a NetScaler appliance is exposed as a pipeline of separate processing modules. Traffic flows through them as it processes it from ingress to egress. These modules in the pipeline follow a shared nothing model. Message passing is used to send the traffic data from one module in the pipeline to the next module.

Certain points in the traffic processing pipeline are made extensible, so that you can add code to customize the NetScaler behavior.

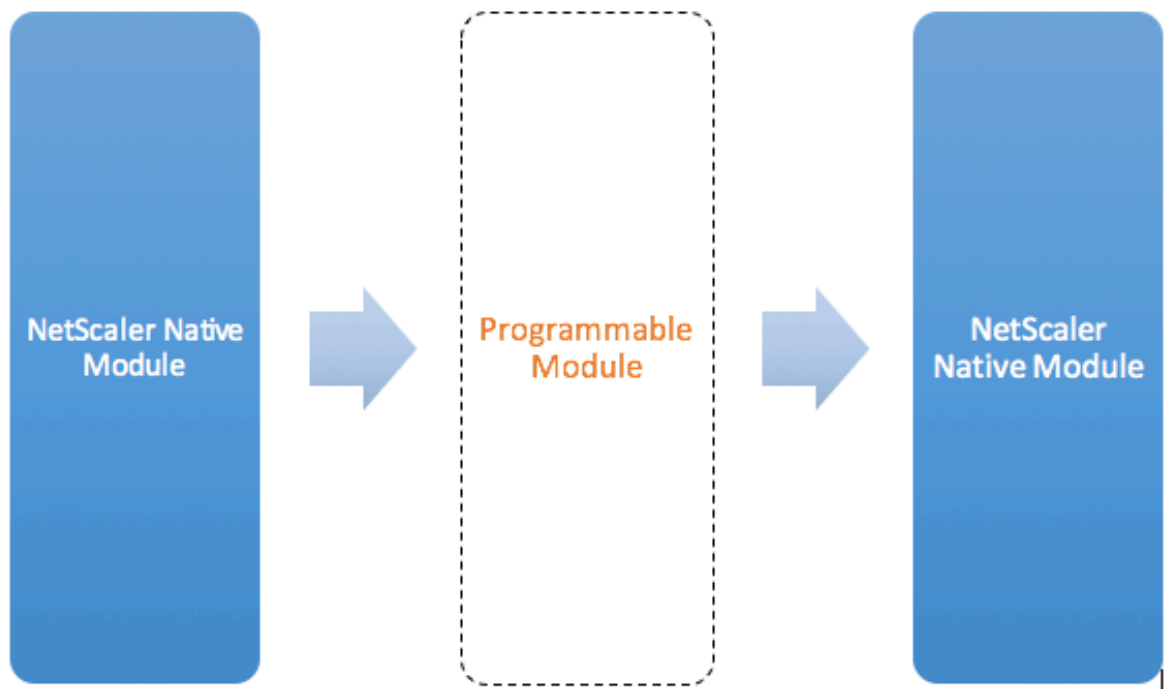

Figure: A Programmable Module In the Traffic Pipeline

By default, the traffic bypasses a programmable module to which you do not add any code.

Figure: User Defined Traffic Module

## Behaviors

The programmable interfaces for customizing the traffic handling are called behaviors. Behaviors are basically a formalization of common programmable patterns that are available on a NetScaler appliance. The behaviors consist of a pre-defined set of event callback functions. You can implement a behavior by providing callback functions conforming to the behavior.

For example, the TCP client behavior consists of a callback function (`on_data`) that processes TCP client data stream events. To implement Message Based Load Balancing (MBLB) for a TCP based protocol, you can add code for this callback function to process the TCP data stream from the client and parse the byte stream into protocol messages.

### Context:

The callback functions in a behavior are called with a context, which is the processing module state. The context is the instance of the processing module. For example, the TCP client behavior callbacks are called with different contexts for different client TCP connections.

### Payload:

In addition to the context, the behavior callbacks can have other arguments. Usually the rest of the arguments are passed as payload, which is the collection of all the arguments.

So, the programmable processing module instances can be seen as a combination of instance state plus event callback functions, that is, the context plus behavior. And the traffic flows through the pipeline as event payload.

For NetScaler API extensions, see [NetScaler extension API reference](#).

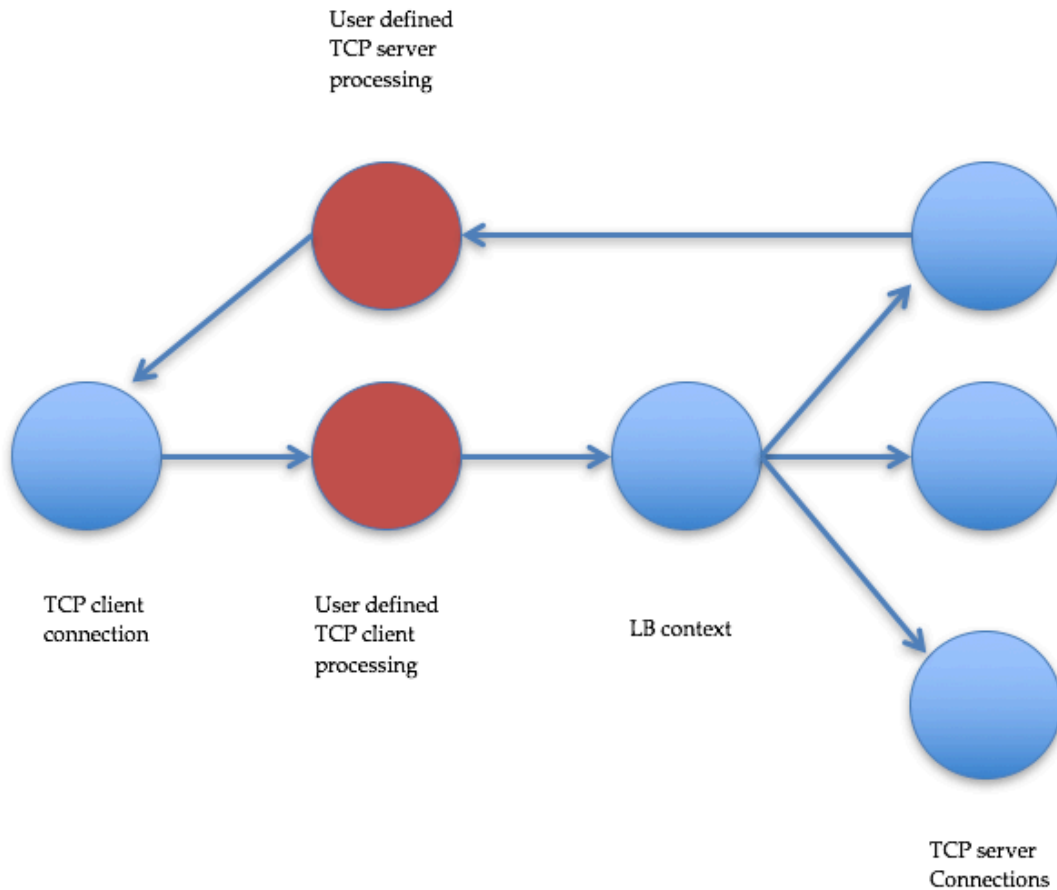

The following code snippet shows a user defined function to handle TCP client data stream events. The context and payload are passed to the function by NetScaler code. This code simply forwards the TCP data received in every call to the next processing module context in the pipeline. In this case, the next module is the load balancing (LB) context, which is a NetScaler native module.

```
1 function client.on_data(ctxt, payload)
2 ns.send(ctxt.output, "DATA", {
3 data = payload.data }
4)
5 end
6 <!--NeedCopy-->
```

## Protocol extensions - traffic pipeline for user defined TCP client and server behaviors

May 2, 2023

The following figure illustrates the sample protocol extension - traffic pipeline for user defined TCP client and server behaviors

**Traffic Pipeline For User Defined TCP Client And Server Behaviors**

### Add a custom protocol by using protocol extensions

The command line interface (CLI) commands for custom protocol use the keyword “user” to signify the user defined nature of the underlying configuration entities. With the help of extension code, you can add a new user protocol to the system and add user virtual servers for user-defined protocols. The user virtual servers are in turn configurable by setting parameters. Configured values for virtual server parameters are available in the extension code.

The following example illustrates the user flow for adding support for a new protocol. The example adds MQTT protocol support to the system. MQTT is a machine-to-machine “Internet of Things” connectivity protocol. It is a lightweight publish/subscribe messaging transport. Useful for connections with remote locations, this protocol uses client and broker tools to publish messages to subscribers.

1. Import the MQTT protocol extension implementation file to NetScaler system. The code listing for mqtt.lua is given below. The example below imports the MQTT extension file hosted on a webserver.

```
import extension http://10.217.24.48/extensions/mqtt.lua mqtt_code
```

2. Add a new user TCP based protocol to the system using the extension.

```
add user protocol MQTT -transport TCP -extension mqtt_code
```

3. Add a user load balancing vserver and bind backend services to it.

```
1 add service mqtt_svr1 10.217.24.48 USER_TCP 1501
2 add service mqtt_svr2 10.217.24.48 USER_TCP 1502
3 add lb vserver mqtt_lb USER_TCP -lbmethod USER_TOKEN
4 bind lb vserver mqtt_lb mqtt_svr1
5 bind lb vserver mqtt_lb mqtt_svr2
6 <!--NeedCopy-->
```

4. Add a user vserver for the newly added protocol. Set the defaultlb to the LB vserver configured above.

```
add user vserver mqtt_vs MQTT 10.217.24.28 8765 -defaultLb
mqtt_lb
```

5. Optionally, enable MQTT session persistence based on ClientID, set the persistence type to USERSESSION.

```
set lb vserver mqtt_lb -persistenceType USERSESSION
```

## Protocol extensions - use cases

May 2, 2023

Protocol extensions can be used for the following use cases.

- Message based load balancing (MLB)
- Streaming
- Token based load balancing
- Load balancing persistence
- TCP connection based load balancing
- Content based load balancing
- SSL
- Modify traffic

- Originate traffic to client or server
- Process data on the connection establishment

## Message based load balancing

Protocol extensions support Message Based Load Balancing (MBLB), which can parse any protocol on a NetScaler appliance and load balance the protocol messages arriving on one client connection, that is, distribute the messages over multiple server connections. MBLB is achieved by user code that parses the client TCP data stream.

The TCP data stream is passed to the `on_data` callbacks for client and server behaviors. The TCP data stream is available to the extension functions through a Lua string like interface. You can use an API similar to the Lua string API to parse the TCP data stream.

Useful APIs include:

`data:len()`

`data:find()`

`data:byte()`

`data:sub()`

`data:split()`

Once the TCP data stream has been parsed into a protocol message, the user code achieves load balancing by just sending the protocol message to the next context available from the context passed to the `on_data` callback for the client.

The `ns.send()` API is used to send messages to other processing modules. In addition to the destination context, the send API takes the event name and optional payload as arguments. There is one-to-one correspondence between the event name and the callback function names for the behaviors. The callbacks for events are called `on_<event_name>`. The callback names use only lowercase.

For example, the TCP client and server `on_data` callbacks are user-defined handlers for events named "DATA." For sending the whole protocol message in one send call, the EOM event is used. EOM, which stands for end of message, signifies the end of protocol message to the LB context down stream, so a new load balancing decision is made for data that follows this message.

The extension code might sometimes not receive the whole protocol message in the `on_data` event. In such a case, the data can be held by using the `ctxt:hold()` API. The hold API is available for both TCP-client and server-callback contexts. When "hold with data" is called, the data is stored in the context. When more data is received in the same context, the newly received data is appended to the previously stored data and the `on_data` callback function is called again with the combined data.

**Note:** The load balancing method used depends on the configuration of the load balancing virtual server corresponding to the load balancing context.

The following code snippet shows the use of the send API to send the parsed protocol message.

**Example:**

```
1 function client.on_data(ctxt, payload)
2 --
3 -- code to parse payload.data into protocol message comes here
4 --
5 -- sending the message to lb
6 ns.send(ctxt.output, "EOM", {
7 data = message }
8)
9 end -- client.on_data
10
11 function server.on_data(ctxt, payload)
12 --
13 -- code to parse payload.data into protocol message comes here
14 --
15 -- sending the message to client
16 ns.send(ctxt.output, "EOM", {
17 data = message }
18)
19
20 end -- server.on_data
21 <!--NeedCopy-->
```

## Streaming

In some scenarios, holding the TCP data stream until the whole protocol message is collected might not be necessary. In fact, it is not advised unless it is required. Holding the data increases memory usage on NetScaler appliance and can make the appliance susceptible to DDoS attacks by exhausting the memory on NetScaler appliance with incomplete protocol messages on many connections.

Users can achieve streaming of TCP data in the extension callback handlers by using the send API. Instead of holding the data until the whole message is collected, data can be sent in chunks. Sending data to ctxt.output by using the DATA event sends a partial protocol message. It can be followed by more DATA events. An EOM event must be sent to mark the end of the protocol message. The load balancing context downstream makes the load balancing decision on the first data received. A new load balancing decision is made after the receipt of the EOM message.

To stream protocol message data, send multiple DATA events followed by an EOM event. The contiguous DATA events and the following EOM event are sent to the same server connection selected by load balancing decision for the first DATA event in the sequence.

For a send to client context, EOM and DATA events are effectively the same, because there is no special

handling by the client context downstream for EOM events.

### Token based load balancing

For natively supported protocols, a NetScaler appliance supports a token based load balancing method that uses PI expressions to create the token. For extensions, the protocol is not known in advance, so PI expressions cannot be used. For token based load balancing, you have to set the default load balancing virtual server to use the USER\_TOKEN load balancing method, and provide the token value from the extension code by calling the send API with a user\_token field. If the token value is sent from the send API and the USER\_TOKEN load balancing method is configured on the default load balancing virtual server, the load balancing decision is made by calculating a hash based on the token value. The maximum length of token value is 64 bytes.

```
add lb vserver v_mqttlb USER_TCP -lbMethod USER_TOKEN
```

The code snippet in the following example uses a send API to send an LB token value.

#### Example:

```
1 -- send the message to lb
2
3
4
5
6 -- user_token is set to do LB based on clientID
7
8
9
10
11 ns.send(ctxt.output, "EOM", {
12 data = message,
13
14 user_token = token_info }
15)
16 <!--NeedCopy-->
```

### Load balancing persistence

Load balancing persistence is closely related to token based load balancing. Users have to be able to programmatically calculate the persistence session value and use it for load balancing persistence. The send API is used to send persistence parameters. To use load balancing persistence, you have to set the USERSESSION persistence type on the default load balancing virtual server and provide a persistence parameter from the extension code by calling the send API with a user\_session field. The maximum length of the persistence parameter value is 64 bytes.

If you need multiple types of persistence for a custom protocol, you have to define user persistence types and configure them. The names of the parameters used to configure the virtual servers are decided by the protocol implementer. A parameter's configured value is also available to the extension code.

The following CLI and code snippet shows the use of a send API to support load balancing persistence. The code listing in the section [Code Listing for mqtt.lua](#) also illustrates the use of the `user_session` field.

For persistency, you have to specify the `USERSESSION` persistency type on the load balancing virtual server and pass the `user_session` value from the `ns.send` API.

```
add lb vserver v\ _mqttlb USER\ _TCP -persistencetype USERSESSION
```

Send the MQTT message to the load balancer, with the `user_session` field set to `clientID` in the payload.

**Example:**

```
1 -- send the data so far to lb
2
3 -- user_session is set to clientID as well (it will be used to persist
 session)
4
5 ns.send(ctxt.output, " DATA " , {
6 data = data, user_session = clientID }
7)
8 <!--NeedCopy-->
```

## TCP connection based load balancing

For some protocols, MBLB might not be needed. Instead, you might need TCP connection based load balancing. For example, the MQTT protocol must parse the initial part of the TCP stream to determine the token for load balancing. And, all the MQTT messages on the same TCP connection must be sent to the same server connection.

TCP connection based load balancing can be achieved by using the send API with only DATA events and not sending any EOM. That way the downstream load balancing context bases the load balancing decision on the data received first, and sends all the subsequent data to the same server connection selected by the load balancing decision.

Also, some use cases might require the ability to bypass extension handling after the load balancing decision has been made. Bypassing the extension calls results in better performance, because the traffic is processed purely by native code. Bypass can be done by using the `ns.pipe()` API. A call to the `pipe()` API extension code can connect input context to an output context. After the call to `pipe()`, all the events coming from input context directly go to the output context. Effectively, the module from which the `pipe()` call is made is removed from the pipeline.

The following code snippet shows streaming and the use of the pipe() API to bypass a module. The code listing in the section [Code Listing for mqtt.lua](#) also illustrates how to do streaming and the use of pipe() API to bypass the module for rest of the traffic on the connection.

**Example:**

```
1 -- send the data so far to lb
2 ns.send(ctxt.output, "DATA", {
3 data = data,
4 user_token = clientID }
5)
6 -- pipe the subsequent traffic to the lb - to bypass the client
7 ns.pipe(ctxt.input, ctxt.output)
8 <!--NeedCopy-->
```

## Content based load balancing

For native protocols, content switching like feature for protocol extensions is supported. With this feature, instead of sending the data to the default load balance, you can send the data to the selected load balancer.

Content switching feature for protocol extensions is achieved by using the ctxt:lb\_connect(<lbname >) API. This API is available to the TCP client context. Using this API, the extension code can obtain a load balancing context corresponding to an already configured load balancing virtual server. You can then use the send API with the load balancing context thus obtained.

The lb context can be NULL sometimes:

- Virtual server does not exist
- Virtual server is not of user protocol type
- Virtual server's state is not UP
- Virtual server is user virtual server, not load balancing virtual server

If you remove the target load balancing virtual server when it is in use, then all connections associated with that load balancing virtual server is reset.

The following code snippet shows the use of lb\_connect() API. The code maps the client ID to load balancing virtual server names (lbname) using the Lua table lb\_map and then gets the LB context for lbname using lb\_connect(). And finally sends to the LB context using send API.

```
1 local lb_map = {
2

4 ["client2*"] = "lb_2",
5 ["client3*"] = "lb_3",
6 ["client4*"] = "lb_4"
```

```
7 }
8
9
10 -- map the clientID to the corresponding LB vserver and connect to
 it
11 for client_pattern, lbname in pairs(lb_map) do
12 local match_idx = string.find(clientID, client_pattern)
13 if (match_idx == 1) then
14 lb_ctxt = ctxt:lb_connect(lbname)
15 if (lb_ctxt == nil) then
16 error("Failed to connect to LB vserver: " .. lbname)
17 end
18 break
19 end
20 end
21 if (lb_ctxt == nil) then
22 -- If lb context is NULL, the user can raise an error or send data
 to default LB
23 error("Failed to map LB vserver for client: " .. clientID)
24 end
25 -- send the data so far to lb
26 ns.send(lb_ctxt, "DATA", {
27 data = data }
28
29 <!--NeedCopy-->
```

## SSL

SSL for protocols using extensions is supported in ways similar to how SSL for native protocols is supported. Using the same parsing code for creating custom protocols, you can create a protocol instance over TCP or over SSL which can then be used to configure the virtual servers. Similarly, you can add user services over TCP or SSL.

For more information, see [Configuring SSL Offloading for MQTT](#) and [Configuring SSL Offloading for MQTT With End-To-End Encryption](#).

## Server connection multiplexing

Sometimes, the client sends one request at a time and sends the next request only after the response for the first request is received from the server. In such a case, server connection can be reused for other client connections, and for the next message on the same connection, after the response has been sent to the client. To allow reuse of server connection by other client connections, you must use the `ctxt: reuse_server_connection()` API on the server side context.

**Note:** This API is available in NetScaler 12.1 build 49.xx and later.

## Modify traffic

To modify data in the request or response, you must use the native rewrite feature that uses an advanced policy PI expression. Because you cannot use PI expressions in extensions, you can use the following APIs to modify a TCP stream data.

```
1 data:replace(offset, length, new_string)
2 data:insert(offset, new_string)
3 data:delete(offset, length)
4 data:gsub(pattern, replace [,n]))
```

The following code snippet shows the use of replace() API.

```
1 -- Get the offset of the pattern, we want to replace
2 local old_pattern = " pattern to repalace "
3 local old_pattern_length = old_pattern:len()
4 local pat_off, pat_end = data:find(old_pattern)
5 -- pattern is not present
6 if (not pat_off) then
7 goto send_data
8 end
9 -- If the data we want to modify is not completely present, then
10 -- wait for more data
11 if (not pat_end) then
12 ctxt:hold(data)
13 data = nil
14 goto done
15 end
16 data:replace(pat_off, old_pattern_length, " new pattern ")
17 ::send_data::
18 ns.send(ctxt.output, " EOM " , {
19 data = data }
20)
21 ::done::
```

The following code snippet shows the use of insert() API.

```
1 data:insert(5, " pattern to insert ")
```

The following code snippet shows the use of insert() API, when we want to insert after or before some pattern:

```
1 -- Get the offset of the pattern, after or before which we want to
 insert
2 local pattern = " pattern after/before which we need to insert "
3 local pattern_length = pattern:len()
4 local pat_off, pat_end = data:find(pattern)
5 -- pattern is not present
6 if (not pat_off) then
7 goto send_data
8 end
9 -- If the pattern after which we want to insert is not
```

```

10 -- completely present, then wait for more data
11 if (not pat_end) then
12 ctxt:hold(data)
13 data = nil
14 goto done
15 end
16 -- Insert after the pattern
17 data:insert(pat_end + 1, " pattern to insert ")
18 -- Insert before the pattern
19 data:insert(pat_off, " pattern to insert ")
20 ::send_data::
21 ns.send(ctxt.output, " EOM " , {
22 data = data }
23)
24 ::done::

```

The following code snippet shows the use of delete() API.

```

1 -- Get the offset of the pattern, we want to delete
2 local delete_pattern = " pattern to delete "
3 local delete_pattern_length = delete_pattern:len()
4 local pat_off, pat_end = data:find(old_pattern)
5 -- pattern is not present
6 if (not pat_off) then
7 goto send_data
8 end
9 -- If the data we want to delete is not completely present,
10 -- then wait for more data
11 if (not pat_end) then
12 ctxt:hold(data)
13 data = nil
14 goto done
15 end
16 data:delete(pat_off, delete_pattern_length)
17 ::send_data::
18 ns.send(ctxt.output, " EOM " , {
19 data = data }
20)
21 ::done::

```

The following code snippet shows the use of gsub() API.

```

1 -- Replace all the instances of the pattern with the new string
2 data:gsub(" old pattern " , " new string ")
3 -- Replace only 2 instances of " old pattern "
4 data:gsub(" old pattern " , " new string " , 2)
5 -- Insert new_string before all instances of " http "
6 data:gsub(" input data " , " (http)" , " new_string%1 ")
7 -- Insert new_string after all instances of " http "
8 data:gsub(" input data " , " (http)" , " %1new_string ")
9 -- Insert new_string before only 2 instances of " http "
10 data:gsub(" input data " , " (http)" , " new_string%1 " , 2)

```

**Note:** This API is available in NetScaler 12.1 build 50.xx and later.

### Originate traffic to client or server

You can use the `ns.send()` API to send data that originates from the extension code to a client and a back-end server. To send or receive response directly with a client, from client context, you must use `ctxt.client` as the target. To send or receive response directly with a back-end server from server context, you must use `ctxt.server` as the target. The data in the payload can be a TCP stream data or a Lua string.

To stop traffic processing on a connection, you can use `ctxt:close()` API from either the client or the server context. This API closes the client-side connection or any server connections linked to it.

When you call the `ctxt:close()` API, extension code sends TCP FIN packet to the client and server connections and if more data is received from the client or server on this connection, then the appliance resets the connection.

The following code snippet shows the use of `ctxt.client` and `ctxt:close()` APIs.

```

1 -- If the input packet is not MQTT CONNECT type, then
2 -- send some error response to the client.
3 function client.on_data(ctxt, payload)
4 local data = payload.data
5 local offset = 1
6 local msg_type = 0
7 local error_response = "Missing MQTT Connect packet."
8 byte = data:byte(offset)
9 msg_type = bit32.rshift(byte, 4)
10 if (msg_type ~= 1) then
11 -- Send the error response
12 ns.send(ctxt.client, "DATA", {
13 data = error_response }
14)
15 -- Since error response has been sent, so now close the connection
16 ctxt:close()
17 end

```

The following code snippet shows the example when user can inject the data in the normal traffic flow.

```

1 -- After sending request, send some log message to the server.
2 function client.on_data(ctxt, payload)
3 local data = payload.data
4 local log_message = "client id : "..data:sub(3, 7).. " user name : "
5 data:sub(9, 15)
6 -- Send the request we get from the client to backend server
7 ns.send(ctxt.output, "DATA", {
8 data = data }
9)

```

```
9 After sending the request, also send the log message
10 ns.send(ctxt.output, "DATA", {
11 data = log_message " }
12)
13 end
```

The following code snippet shows the use of `ctxt.to_server` API.

```
1 -- If the HTTP response status message is "Not Found",
2 -- then send another request to the server.
3 function server.on_data(ctxt, payload)
4 local data = payload.data
5 local request "GET /default.html HTTP/1.1\r\n\r\n" ss
6 local start, end = data:find("Not Found")
7 if (start) then
8 -- Send the another request to server
9 ns.send(ctxt.server, "DATA", {
10 data = request }
11)
12 end
```

**Note:** This API is available in NetScaler 12.1 build 50.xx and later.

### Data processing on the connection establishment

There might be a use case where you want to send some data at the connection establishment (when the final ACK is received). For example, in proxy protocol, you might want to send client's source and destination IP addresses and ports to the back-end server at the connection establishment. In this case, you can use `client.init()` callback handler to send the data on connection establishment.

The following code snippet shows the use of `client.init()` callback:

```
1 -- Send a request to the next processing context
2 -- on the connection establishment.
3 function client.init(ctxt)
4 local request "PROXY TCP4 " + ctxt.client.ip.src.to_s + " " +
5 ctxt.client.ip.dst.to_s + " " + ctxt.client.tcp.srcport + " "
6 + ctxt.client.tcp.dstport
7 -- Send the another request to server
8 ns.send(ctxt.output, "DATA", {
9 data = request }
10)
11 end
```

**Note:** This API is available in NetScaler 13.0 build xx.xx and later.

## Tutorial –Add MQTT protocol to the NetScaler appliance by using protocol extensions

May 2, 2023

The command line interface (CLI) commands for custom protocol use the keyword “user” to signify the user defined nature of the underlying configuration entities. With the help of extension code, you can add a new user protocol to the system and add user virtual servers for user-defined protocols. The user virtual servers are in turn configurable by setting parameters. Configured values for virtual server parameters are available in the extension code.

MQTT protocol is used for illustration purposes.

The following diagram illustrates a NetScaler appliance and MQTT client and broker tools.

### Code listing for mqtt.lua

May 2, 2023

The code listing below, `mqtt.lua`, gives the code to implement the MQTT protocol on NetScaler using protocol extensions. The code only has the TCP client data callback function defined - `client.on_data()`. For server data, it does not add a callback function and the server to client takes the fast native path. For client data, the code parses the CONNECT MQTT protocol message and extracts the ClientID. It then uses the ClientID for `user_token` value, which is used to load balance all the client traffic for the connection based on the ClientID by setting LB method for the LB vserver as `USER_TOKEN`. It uses the ClientID also for `user_session` value, which can be used for LB persistence by setting persistence type

for the LB vserver as USERSESSION. The code uses the ns.send() to do LB and send the initial data. It uses the ns.pipe() API to send the rest of the client traffic directly to server connection, bypassing calls to extension callback handler.

```
1 --[[
2
3 MQTT event handler for TCP client data
4
5 ctxt - TCP client side App processing context.
6
7 data - TCP Data stream received.
8
9 - parse the client ID from the connect message - the first message
 should be connect
10
11 - send the data to LB with ClientID as user token and session
12
13 - pipe the subsequent data to LB directly. This way the subsequent
 MQTT traffic will
14
15 bypass the tcp client on_data handler
16
17 - if a parse error is seen, throw an error so the connection is
 reset
18
19 --]]
20
21 function client.on_data(ctxt, payload)
22
23 local data = payload.data
24
25 local data_len = data:len()
26
27 local offset = 1

## Configure MQTT by using protocol extensions

May 2, 2023

The following steps add a MQTT protocol to the NetScaler appliance.

Import the extension file to the NetScaler appliance, from either a web server (using HTTP) or your local workstation. For details about importing the extension file, see [Import extensions](#).

```
import ns extension local:mqtt_generic_fs.lua mqtt_code
```

Add a new user TCP based protocol to the system by using the extension.

```
add user protocol MQTT -transport TCP -extension mqtt_code
```

Add a service of type USER\_TCP to indicate that this is a user-defined protocol.

```
add service s1 10.102.90.112 USER_TCP 80
```

Add a user load balancing vserver and bind backend services to it.

```
add lb vs mysv USER_TCP
```

```
bind lb vs mysv s1
```

Add a user virtual server for the newly added protocol and make the load balancing virtual server configured in the previous step the default load balancer.

```
add user vs v_mqtt MQTT 10.217.24.28 80 -defaultlb mysv
```

Optionally, enable MQTT session persistence based on ClientID, set the persistence type to USERSESSION.

```
set lb vserver mqtt_lb -persistenceType USERSESSION
```

## Configuring SSL offloading for MQTT

May 2, 2023

You can implement SSL offloading for user protocols by adding an SSL instance for the protocol. The example below shows how to do SSL offloading for a user protocol. The traffic to backend services is unencrypted with this configuration.

Note: This example does not provide details related to adding or updating a certificate-key pair and binding it to a virtual server. For those details, see [SSL certificates](#).

The following commands add the MQTT\_SSL protocol by including mqtt.lua with transport value “SSL.”

```
1 import extension http://10.217.24.48/extensions/mqtt.lua mqtt_code
2 add user protocol MQTT_SSL -transport SSL -extension mqtt_code
3 <!--NeedCopy-->
```

The following commands add a user load balancing virtual server and bind backend services to it.

```
1 add service mqtt_svr1 10.217.24.48 USER_TCP 1501
2 add service mqtt_svr2 10.217.24.48 USER_TCP 1502
3 add lb vserver mqtt_lb USER_TCP -lbMethod ROUNDROBIN
4 bind lb vserver mqtt_lb mqtt_svr1
```

```
5 bind lb vserver mqtt_lb mqtt_svr2
6 <!--NeedCopy-->
```

The following command adds a user virtual server for the newly added protocol MQTT\_SSL. Using MQTT\_SSL means the NetScaler appliance will do SSL offloading, because MQTT\_SSL was configured with SSL transport. The command also sets the defaultlb to the load balancing virtual server configured in the previous step.

```
add user vserver mqtt_vs MQTT_SSL 10.217.24.28 8765 -defaultlb
mqtt_lb
```

For SSL offloading, you also need to enable the SSL feature and bind a certkey to the user virtual server. For more information, see the following topics:

[Add or update a certificate-key pair](#)

[Bind the certificate-key pair to the SSL virtual server](#)

**Example:**

```
1 enable ns feature SSL
2
3 add SSL certKey mqtt_svr_cert_key -cert server1.cert -key server1.key
4
5 bind ssl vserver mqtt_vs -certkeyName mqtt_svr_cert_key
6 <!--NeedCopy-->
```

## Configuring SSL offloading with end-to-end encryption for MQTT

May 2, 2023

The following example shows how to do SSL offloading for MQTT with end-to-end encryption.

**Note:** This example does not provide details related to adding or updating a certificate-key pair and binding it to a virtual server. For those details, see [SSL certificates](#).

The following commands import the extension file and add the MQTT\_SSL protocol with SSL transport.

```
1 import extension http://10.217.24.48/extensions/mqtt.lua mqtt_code
2 add user protocol MQTT_SSL -transport SSL -extension mqtt_code
3 <!--NeedCopy-->
```

The following commands add a user load balancing virtual server and bind backend services to it. Both the load balancing virtual server and the services are configured for the service type USER\_SSL\_TCP.

```
1 add service mqtt_svr1 10.217.24.48 USER_SSL_TCP 1501
2 add service mqtt_svr2 10.217.24.48 USER_SSL_TCP 1502
3 add lb vserver mqtt_lb USER_SSL_TCP -lbmethod RR
4 bind lb vserver mqtt_lb mqtt_svr1
5 bind lb vserver mqtt_lb mqtt_svr2
6 <!--NeedCopy-->
```

The following command adds a user virtual server for the newly added protocol MQTT\_SSL. Using MQTT\_SSL means the NetScaler appliance will do SSL offloading, because MQTT\_SSL was configured with SSL transport. The command also makes the load balancing virtual server, configured in previous step, the default load balancer.

```
add user vserver mqtt_vs MQTT_SSL 10.217.24.28 8765 -defaultLb
mqtt_lb
```

For end-to-end encryption, you also need to enable the SSL feature and bind a certkey to the user and default load balancing virtual servers. For more information, see the following topics:

[Add or update a certificate-key pair](#)

[Bind the certificate-key pair to the SSL virtual server](#)

```
1 enable ns feature SSL
2
3 add SSL certKey mqtt_svr_cert_key -cert server1.cert -key server1.key
4
5 bind ssl vserver mqtt_lb -certkeyName mqtt_svr_cert_key
6
7 bind ssl vserver mqtt_vs -certkeyName mqtt_svr_cert_key
8 <!--NeedCopy-->
```

## Tutorial - load balancing syslog messages by using protocol extensions

May 2, 2023

Syslog protocol available on the NetScaler appliance works only for the messages generated on the NetScaler appliance. It does not load balance the messages coming from external nodes. To load balance such messages, you need to use the protocol extensions feature and write the syslog message parsing logic by using the Lua 5.2 programming language.

### Code for parsing syslog message

The code only has the TCP client data callback function defined - client.on\_data(). For server data, it does not add a callback function and the server to client takes the fast native path. The code identifies

message boundary based on the trailing character. If the TCP packet contains more than one syslog messages, then we split the packet based on the trailing character and load balance each message.

```
1 --[[
2
3 Syslog event handler for TCP client data
4
5 ctxt - TCP client side App processing context.
6
7 data - TCP Data stream received.
8
9 --]]
10
11 function client.on_data(ctxt, payload)
12
13 local message = nil
14
15 local data_len
16
17 local data = payload.data
18
19 local trailing_character = "\n"
20
21 ::split_message::
22
23 -- Get the offset of trailing
24 character
25
26 local new_line_character_offset =
27 data:find(trailing_character)
28
29 -- If trailing character is not
30 found, then wait for more data.
31
32 if (not new_line_character_offset)
33 then
34
35 goto
36 need_more_data
37
38 end
39
40 -- Get the length of the current
41 message
42
43 data_len = data:len()
44
45 -- Check whether we have more than
46 one message
47
48 -- by comparing trailing character
49 offset and
```

```
43 -- current data length
44
45 if (data_len >
46 new_line_character_offset) then
47 -- If we have
48 -- more than one
49 -- message, then
50 -- split
51 -- the data into
52 -- two parts such
53 -- that first
54 -- part
55 -- will contain
56 -- message upto
57 -- trailing
58 -- character
59 -- offset and
60 -- second part
61 -- will contain
62 -- remaining
63 -- message.
64 message, data =
65 data:split(
66 new_line_character_offset
67)
68 else
69 message = data
70 data = nil
71 end
72
73 -- Send the data to the backend server.
74 ns.send(ctxt.output, "EOM", {
75 data = message }
76)
77
78 goto done
79
80 ::need_more_data::
81
82 -- Wait for more
83 -- data
```

```

79 ctxt:hold(data)
80
81 data = nil
82

## Configuring syslog protocol by using protocol extensions

May 2, 2023

The following steps add an user SYSLOG protocol to the NetScaler appliance.

Import the extension file to the NetScaler appliance, from either a web server (using HTTP) or your local workstation. For details about importing the extension file, see [Importing Extensions](#).

```
import ns extension local:syslog_parser.lua syslog_parser_code
```

Add a new user TCP-based protocol to the system by using the extension.

```
add user protocol USER_SYSLOG -transport TCP -extension syslog_parser_code
```

Add a service of type USER\_TCP to indicate that this is a user-defined protocol.

```
add service s1 10.102.90.112 USER_TCP 80
```

Add a user load balancing vserver and bind backend services to it.

```
1 add lb vs mysv USER_TCP
```

```
2
3 bind lb vs mysv s1
4 <!--NeedCopy-->
```

Add a user virtual server for the newly added protocol and make the load balancing virtual server configured in the previous step the default load balancer.

```
add user vs v_syslog USER_SYSLOG 10.217.24.28 80 -defaultlb mysv
```

## Protocol extensions command reference

May 2, 2023

The following table lists all the new commands added for custom protocols, and the existing commands that have been modified for custom protocols.

```
show lb persistentSessions [<vserv-name>]
```

- **CLI command:**

```
add user protocol <name> -transport (TCP | SSL)-extension <string> -comment <string>]]>
```

- **Description:**

Adds a new user protocol to the NetScaler appliance by using extensions. Currently only user protocols with transport value TCP or SSL are supported.

**Example:**

```
add user protocol MQTT -transport TCP -extension mqtt_code
```

- **CLI command:**

```
rm user protocol <name>
```

- **Description:**

Removes a user protocol previously added to the NetScaler appliance.

**Example:**

```
rm user protocol mqtt
```

- **CLI command:**

```
set user protocol <name> -comment <string>
```

- **Description:**

Changes settings for a user protocol previously added to the NetScaler appliance.

**Example:**

```
set user protocol mqtt -comment "MQTT protocol implementation"
```

- **CLI command:**

```
unset user protocol <name> -comment
```

- **Description:**

Removes settings for a user protocol previously added to the NetScaler appliance.

**Example:**

```
unset user protocol mqtt -comment "MQTT protocol implementation"
```

- **CLI command:**

```
update ns extension <extension name>
```

- **Description:**

Updates the implementation for a previously added user protocol by using extensions.

You can update the protocol implementation only if the protocol is not being used by any user virtual server.

**Example:**

```
update ns extension my-extension
```

- **CLI command:**

```
add lb vserver <name> [USER_TCP | USER_SSL_TCP] [-lbmethod
USER_TOKEN] [-persistencetype USERSESSION] [-timeout <value>]
```

- **Description:**

Adds a load balancing virtual server to the NetScaler appliance. This is an existing CLI command.

For load balancing user virtual servers, the service type to use is USER\_TCP or USER\_SSL\_TCP. The IP address and port are not allowed with user load balancing virtual servers.

For user load balancing virtual servers, only the ROUNDROBIN load balancing method is allowed, and the token value is provided by the extension code. Similarly, only USERSESSION persistence is allowed, and the persistence setting is provided by the extension code.

**Example:**

```
add lb vserver mysv USER_TCP -lbmethod ROUNDROBIN
```

**• CLI command:**

```
add user vserver <name> <userProtocol> <IPAddress> <port> -
defaultLB <string> [-params <string>] [-comment <string>]
```

**• Description:**

Adds a virtual server for a user protocol by using extensions. The configured default user load balancing virtual server is available to the TCP client data extension handler as `ctxt.output`. For a virtual server, extension parameters can be set by using the `-params` option with a name and a value pair. The corresponding parameter value is available to the extension handlers as `ctxt.vserver.params.<paramName>`.

**Example:**

```
add user vs v_mqtt MQTT 10.217.24.28 80 -defaultlb mysv
```

**• CLI command:**

```
rm user vserver <name>
```

**• Description:**

Removes a user virtual server previously added to to the NetScaler appliance.

**Example:**

```
rm user vserver v_mqtt
```

**• CLI command:**

```
set user vserver <name> [-IPAddress <ip_addr|ipv6_addr|*>] [-
defaultLB <string>] [-params <string>] [-comment <string>]
```

**• Description:**

Changes settings for a user virtual server previously added to to the NetScaler appliance. When an extension parameter is assigned a new value by the `-params` option, the old value is overwritten.

**Example:**

```
set user vs v_mqtt MQTT 10.217.24.28 -defaultlb mysv -comment "MQTT protocol imple-
mentation"
```

**• CLI command:**

```
unset user vserver <name> [-params] [-comment]
```

- **Description:**

Removes the settings for a user virtual server previously added to the NetScaler appliance. If you use the `–params` option to unset an extension parameter, the corresponding parameter value available to extension handlers is changed to nil.

**Example:**

```
unset user vs v_mqtt MQTT 10.217.24.28 -defaultlb mysv -comment "MQTT protocol implementation"
```

- **CLI command:**

```
show user protocol [<name>]
```

- **Description:**

Displays information about a user protocol, such as extension and callbacks.

**Example:**

```
show user protocol mqtt
```

- **CLI command:**

```
show user vserver [<name>]
```

- **Description:**

Displays information about a user virtual server.

**Example:**

```
show user vserver vs_mqtt
```

- **CLI command:**

```
stat user vserver [<name>]
```

- **Description:**

Displays statistics about a user virtual server.

**Example:**

```
stat user vserver vs_mqtt
```

- **CLI command:**

```
show lb persistentSessions [<vserv-name>]
```

- **Description:**

Displays information about persistent sessions. This is an existing CLI. For user protocols, the persistence type is shown as USERSESSION.

- **CLI command:**

```
rm lb vserver <name>
```

- **Description:**

Removes a user LB vserver previously added to the NetScaler appliance.

**Example:**

```
rm lb vserver mysv
```

- **CLI command:**

```
add service <name> <IPAddr> (USER_TCP | USER_SSL_TCP)<Port>
```

- **Description:**

Adds a backend service to be used for a user protocol. This is an existing CLI command with new service types USER\_TCP and USER\_SSL\_TCP.

**Example:**

```
add service mqtt_svr1 10.217.24.48 USER_TCP 1501
```

**Note:** The existing “set service and unset service” commands can be used to remove or change the settings of a previously added service for a user protocol.

- **CLI command:**

```
bind lb vserver <name> <serviceName>
```

- **Description:**

Binds a service to a user LB vserver. The service type should be USER\_TCP/USER\_SSL\_TCP for binding to an LB vserver with type of USER\_TCP/USER\_SSL\_TCP.

**Example:**

```
bind lb vserver mysv mqtt_svr1
```

- **CLI command:**

```
unbind lb vserver <name> <serviceName>
```

- **Description:**

Unbinds a previously bound service to a user LB vserver.

**Example:**

```
unbind lb vserver mysv mqtt_svr1
```

**• CLI command:**

```
rm service <name>
```

**• Description:**

Removes a service that is previously added for a user protocol.

**Example:**

```
rm service mqtt_svr1
```

## Troubleshooting protocol extensions

May 2, 2023

If your extension function is not behaving as expected, you can use extension tracing functionality to verify the behavior of your extension function. You can also add logging to your extension function by using the custom logging functionality, where you can define the log level to be captured on the NetScaler appliance.

### Custom logging

You can also add your own logging to your extension function. To do so, use the built-in `ns.logger:level()` function, where `level` is `emergency`, `alert`, `critical`, `error`, `warning`, `notice`, `info`, or `debug`. The parameters are the same as the C `printf()` function: a format string, and a variable number of arguments to supply values for the `%` specified in the format string. For example, you might add the following to the `COMBINE_HEADERS` function to log the result of a call:

```
1 local result_str = table.concat(combined_headers, "\\r\\n") .. "\\r\\n\\r\\n"
2
3 ns.logger:info("Result: %s", result_str)
4
5 return result_str
6 <!--NeedCopy-->
```

The above function would log the following message to `/var/log/ns.log` for the sample input shown in the abbreviated log messages examples in the Extension Tracing section above.

```
... : default NSEXTENSION Message 143 0 : "Result: Host: 10.217.24.7:2000^
M H1: abcd, 1234^M User-Agent: curl/7.24.0 (amd64-portbld-freebsd8.4)
libcurl/7.24.0 OpenSSL/0.9.8y zlib/1.2.3^M Accept: *//*^M H2: h2val1
, h2val2, h2val3^M ^M"
```

## Policy extensions

May 2, 2023

The policy extension feature enables you to write extension functions for built-in policy types. The extensions can be used in policy expressions, just like built-in functions. They are executed when the corresponding policy expressions are evaluated. This feature is useful for:

- Adding customized functions to existing Policies.
- Implementing logical constructs for complex customer requirements.

The policy extension feature addresses these limitations by enabling users to write extension functions for built in Policy types. The extensions can then be used in the policy expressions, just like built-in functions. They are executed when the corresponding policy expressions are evaluated.

The following table lists the policy types that can be used when writing an extension, and their associated mappings.

Policy Type	Mapped Policy Type	Output
TEXT_T	NSTEXT	String
BOOL_AT	NSBOOL	Boolean
NUM_AT	NSNUM	Number (double-precision floating point)
DOUBLE_AT	NSDOUBLE	Number (double-precision floating point)

### Prerequisites for using policy extensions

The imported functions must conform to the existing policy standards. Therefore:

- The function name must start with a letter and may contain numbers or underscores.
- The function name is treated as case insensitive by NetScaler policies.
- The function must return a single value even if the extension language returns multiple values.
- Functions with a variable number of arguments are not supported.

## How do policy extensions work?

The existing policies on a NetScaler appliance use an interpreter to evaluate the functions, which are imported in a policy extension file. When a user imports a new function in a policy extension file:

1. The extension file is validated for syntax and other conditions.
2. If the validation fails, the error is reported to the user.
3. If the validation succeeds, the extension file is imported to the NetScaler appliance and its contents can be used in policy expressions, just like any built-in policy function
  - a) If the policy expression evaluation returns an error during runtime, it is reported as an undef event and the associated error counter is incremented.

**Note:** If a policy undef event occurs and the policy rule contains one or more policy extension functions, the `show ns extension <name>` command displays the undef hits when applied to those policy extensions. If the extension function is aborted, the abort counter value is incremented.
  - b) If the policy expression evaluation is successful, expression evaluation resumes until the entire expression is evaluated, or until it is aborted because of an error.

If the extension function takes too long to run, it is aborted, and the error counter pertaining to that extension function is incremented. The extension function is sandboxed, which prevents:

- Excessive CPU usage on the NetScaler appliance.
- Excessive memory usage on the NetScaler appliance.
- Usage of harmful built-in libraries or third-party libraries or binaries.
- Long-running scripts that could potentially cause the NetScaler appliance to reboot.

## Configuring policy extensions

May 2, 2023

When your policy extension file is ready, import it to the NetScaler appliance. The import process copies the extension file into a directory on the NetScaler appliance and checks for syntax errors.

After the import, you have to make the extension file available for use in the policy expressions.

**Note:** The import command is used to download the file content from an external source `\<src\>`, or an internal source, onto the NetScaler file system. To load this file content into one or more packet engines for the first time, use the add command. If there is an update to the file content, the updated content can be downloaded to the NetScaler file system by issuing the import command with the overwrite argument. The command updates the contents in the file system. To load the updated content to one or more packet engines, use the update command.

## Configure policy extensions by using the CLI

1. Import the policy extension file to the NetScaler Appliance, from either a web server (using HTTP) or your local workstation.

- a) HTTP Import

If you have a web server available, you can store the extension file in the webserver directory and import it to the NetScaler appliance.

```
1 import ns extension <src> <name> [-comment<string>] [-
 overwrite]
2 <!--NeedCopy-->
```

**Example:**

```
1 import ns extension http://myhost/path/to/extension
 myextension -comment "Custom crc calculation"
2 <!--NeedCopy-->
```

- b) Local Import

You can use the SSH client to copy the extension file from your workstation to the /var/tmp directory of the NetScaler appliance

```
1 scp extension-file-name <ns-userid@ns-ip-addr>:/var/tmp
2 <!--NeedCopy-->
```

where,

- `extension-file-name` is the name of the extension file on your client machine.
- `ns-userid` is the NetScaler appliance user with permission to write to /var/tmp.
- `ns-ip-addr` is the NetScaler IP address.

After copying the file to the NetScaler appliance, run the import command on the NetScaler appliance.

```
1 import ns extension local:\<extension-file-name extension-name
 \>
2 <!--NeedCopy-->
```

**Note:** The CLI must be used to import a local extension file, by running the **import** command.

2. Add the policy extension to the packet engine for evaluation.

```
1 add ns extension <name> [-comment <string>]
2 <!--NeedCopy-->
```

**Example:**

```
1 add ns extension myextension
2 <!--NeedCopy-->
```

After an extension file is imported, you can update it, if you included the `-overwrite` parameter in the import command, or remove it. You can also display the details of an imported extension file.

### Update an extension file on the NetScaler appliance from the source

At the command prompt, type:

```
1 update ns extension <name>
2 <!--NeedCopy-->
```

**Note:** You can update the extension file only after importing the specified extension file to the NetScaler appliance with the `-overwrite` parameter.

#### Example:

```
1 update ns extension myextension
2 <!--NeedCopy-->
```

### Remove an extension file from the NetScaler appliance

At the command prompt type:

```
1 rm ns extension <name>
2 <!--NeedCopy-->
```

#### Example:

```
1 rm ns extension myextension
2 <!--NeedCopy-->
```

### Display the details of the specified extension function on the NetScaler appliance

At the command prompt, type:

```
1 show ns extension <name>
2 <!--NeedCopy-->
```

#### Example:

```
1 show ns extension myextension
2 <!--NeedCopy-->
```

## Configure policy extensions by using the GUI

1. Import the policy extension file to the NetScaler Appliance, from either a web server (using HTTP) or your local workstation.
  - a) Navigate to **AppExpert > Policy Extensions**, click **Policy Extension**, from the **Import From** drop-down list, select the URL for the location of the extension file that you want to import.
  - b) Navigate to **AppExpert > Policy Extensions, Policy Extension** and import the extension file by selecting File in the **Import From** drop-down list.
2. Add the policy extension to the packet engine for evaluation.

Navigate to **AppExpert > Policy Extensions** and, on the **Policy Extensions** tab, add the extension file.

## Update an extension file on the NetScaler appliance from the source

Navigate to **AppExpert > Policy Extensions** and, on the **Policy Extensions** tab, update the extension file.

## Remove an extension file from the NetScaler appliance

Navigate to **AppExpert > Policy Extensions** and, **Policy Extensions** tab, remove the extension file.

## Display the details of the specified extension function on the NetScaler appliance

Navigate to **AppExpert > Policy Extensions** and, on the **Policy Extensions Functions** tab, click the click drop-down list arrow of the extension function that you want to see the details.

## Policy extensions - use cases

May 2, 2023

Certain customer applications have requirements that cannot be addressed with existing policies and expressions. The policy extension feature enables customers to add customized functions to their applications to meet their requirement.

The following use cases illustrate the addition of new functions using the policy extension feature on the NetScaler appliance.

- Case 1: Custom hash
- Case 2: Collapse double slashes in URLs
- Case 3: Combine headers

### Case 1: Custom hash

The CUSTOM\_HASH function provides a mechanism to insert any type of hash value in the responses sent to the client. In this use case, the hash function is used to compute the hash of the query string for a rewrite HTTP request and insert an HTTP header named CUSTOM\_HASH with the computed value. The CUSTOM\_HASH function implements the DJB2 hash algorithm.

#### Sample Usage of CUSTOM\_HASH:

```
1 > add rewrite action test_custom_hash insert_http_header "CUSTOM_HASH"
 "HTTP.REQ.URL.QUERY.CUSTOM_HASH"
2 <!--NeedCopy-->
```

#### Sample Definition of CUSTOM\_HASH():

```
1 -- Extension function to compute custom hash on the text
2
3 -- Uses the djb2 string hash algorithm
4 function NSTEXT:CUSTOM_HASH() : NSTEXT
5
6 local hash = 5381
7
8 local len = string.len(self)
9
10 for i = 1, len do
11 hash = bit32.bxor((hash * 33), string.byte(self, i))
12
13 end
14
15 return tostring(hash)
16
17 end
18
19 <!--NeedCopy-->
```

#### Line-by-line description of the above sample:

```
1 function NSTEXT:CUSTOM_HASH() : NSTEXT
2
3 Defines the CUSTOM_HASH() function, with text input and a text return
 value.
4
5 local hash = 5381
6 local len = string.len(self)
7
8 Declares two local variables:
```

```
9
10 - hash. Accumulates the compute hash value and is seeded with the
 number 5381
11
12 - len. Sets to the length of the self input text string, using the
 built-in string.len() function.
13
14 for i = 1, len do
15 hash = bit32.bxor((hash * 33), string.byte(self, i))
16 end
17
18 Iterates through each byte of the input string and adds the byte to the
 hash. It uses the built-in string.byte() function to get the byte
 and the built-in bit32.bxor() function to compute the XOR of the
 existing hash value (multiplied by 33) and the byte.
19
20 return tostring(hash)
21
22 Calls the built-in tostring() function to convert the numeric hash
 value to a string and returns the string as the value of the
 function.
23 <!--NeedCopy-->
```

## Case 2: Collapse double slashes in URLs

Collapsing double slashes in URLs improves the website rendering time, because browsers parse the single slash URLs more efficiently. The single slash URLs also to maintain compatibility with applications that do not accept double slashes. The policy extension feature allows customers to add a function that replaces the double slashes with single slashes in the URLs. The following example illustrates the addition of a policy extension function that that collapses double slashes in URLs.

### Sample Definition of COLLAPSE\_DOUBLE\_SLASHES():

```
1 -- Collapse double slashes in URL to a single slash and return the
 result
2 function NSTEXT:COLLAPSE_DOUBLE_SLASHES() : NSTEXT
3
4 local result = string.gsub(self, "//", "/")
5
6 return result
7
8 end
9 <!--NeedCopy-->
```

### Line-by-line description of the above sample:

```
1 function NSTEXT:COLLAPSE_DOUBLE_SLASHES() : NSTEXT
2
3 Declares the COLLAPSE_DOUBLE_SLASHES() function with text input and
 return.
```

```
4
5 local result = string.gsub(self, "//", "/")
6
7 Declares a local variable named result and uses the built-in string.
 gsub() function to replace all double slashes with single slashes in
 the self input text.
8
9 The second parameter of string.gsub() is actually a regular expression
 pattern, although here a simple string is used for the pattern.
10
11 return result
12
13 Returns the resulting string.
14 <!--NeedCopy-->
```

### Case 3: Combine headers

Certain customer applications cannot handle multiple headers in a request. Also, parsing of duplicate headers with same header values, or multiple headers with same name but different values in a request, consumes time and network resources. The policy extension feature allows customers to add a function to combine these headers into single headers with a value combining the original values. For example, combining the values of the headers H1 and H2.

#### Original request:

```
1 GET /combine_headers HTTP/1.1
2 User-Agent: amigo unit test
3 Host: myhost
4 H2: h2val1
5 H1: abcd
6 Accept: */*
7 H2: h2val2
8 Content-Length: 0
9 H2: h2val3
10 H1: 1234
11 <!--NeedCopy-->
```

#### Modified request:

```
1 GET /combine_headers HTTP/1.1
2 User-Agent: amigo unit test
3 Host: myhost
4 H2: h2val1, h2val2, h2val3
5 H1: abcd, 1234
6 Accept: */*
7 Content-Length: 0
8 <!--NeedCopy-->
```

In general, this type of request modification is done using the Rewrite feature, using policy expressions to delineate the part of the request to be modified (the target) and the modification to be performed

(the string builder expression). However, policy expressions do not have the ability to iterate over an arbitrary number of headers.

The solution to this problem requires an extension to the policy facility. To do this, we will define an extension function, called COMBINE\_HEADERS. With this function, we can set up the following rewrite action:

```
> add rewrite action combine_headers_act replace 'HTTP.REQ.FULL_HEADER
.AFTER_STR("HTTP/1.1\r\n")' 'HTTP.REQ.FULL_HEADER.AFTER_STR("HTTP/1.1\r\n
").COMBINE_HEADERS'
```

Here, the rewrite target is HTTP.REQ.FULL\_HEADER.AFTER\_STR("HTTP/1.1\r\n"). The AFTER\_STR("HTTP/1.1\r\n") is required because FULL\_HEADER includes the first line of the HTTP request (e.g. GET /combine\_headers HTTP/1.1).

The string builder expression is HTTP.REQ.FULL\_HEADER.AFTER\_STR("HTTP/1.1\r\n").COMBINE\_HEADERS, where the headers (minus the first line) are fed into the COMBINE\_HEADERS extension function, which combines and returns the values for headers.

#### Sample Definition of COMBINE\_HEADERS():

```
1 -- Extension function to combine multiple headers of the same name
 into one header.
2
3
4
5 function NSTEXT:COMBINE_HEADERS(): NSTEXT
6
7 local headers = {
8 }
9 -- headers
10
11 local combined_headers = {
12 }
13 -- headers with final combined values
14 -- Iterate over each header (format "name:valuer\r\n")
15
16 -- and build a list of values for each unique header name.
17
18 for name, value in string.gmatch(self, "([^:]+):([^\r\n]*)\r\n"
19) do
20
21 if headers[name] then
22 local next_value_index = #(headers[name]) + 1
23
24 headers[name][next_value_index] = value
25
26 else
27
28 headers[name] = {
```

```
29 name .. ":" .. value }
30
31
32 end
33
34 end
35
36
37
38 -- iterate over the headers and concat the values with
39 separator ","
40
41 for name, values in pairs(headers) do
42 local next_header_index = #combined_headers + 1
43
44 combined_headers[next_header_index] = table.concat(values,
45 ",")
46
47 end
48
49
50 -- Construct the result headers using table.concat()
51
52 local result_str = table.concat(combined_headers, "\r\n") .. "\r\n\r\n"
53
54 return result_str
55
56 end
57 <!--NeedCopy-->
```

#### Line-by-line description of the above sample:

```
1 function NSTEXT:COMBINE_HEADERS(): NSTEXT
2
3 Defines the COMBINE_HEADERS extension function, with the text input
4 into the function from the policy expression and a text return type
5 to the policy expression.
6
7 local headers = {
8 }
9 -- headers
10 local combined_headers = {
11 }
12 -- headers with final combined values
13
14 Declares local variables headers and combined_headers and initialize
15 these variables to empty tables. headers will be a table of arrays
16 of strings, where each array holds one or more values for a header.
17 combined_headers will be an array of strings, where each array
18 element is a header with its combined values.
```

```
13
14 for name, value in string.gmatch(self, "([^:]+)([^\r\n]*)\r\n") do
15 . . .
16 end
17 <!--NeedCopy-->
```

This generic for loop parses each header in the input. The iterator is the built-in `string.gmatch()` function. This function takes two parameters: a string to search, and a pattern to use to match pieces of the string. The string to search is supplied by the implicit self parameter, which is the text for the headers input into the function.

The pattern is expressed using a regular expression (regex for short). This regex matches the header name and value for each header, which the HTTP standard defines as ***name:value\r\n***. The parentheses in the regex specify the matching parts to be extracted, so the regex schematic is ***(match-name):(match-value)\r\n***. The ***match-name*** pattern needs to match all characters except the colon. This is written `[^:]+`. `[^:]` is any character except `:` and `+` is one or more repetitions. Similarly, the ***match-value*** pattern has to match any characters except the `\r\n`, so it is written `[^\r\n]*`. `[^\r\n]` matches any character except `\r` and `\n` and `*` is zero or more repetitions. This makes the complete regex `([^:]+)([^\r\n]*)\r\n`.

The for statement uses a multiple assignment to set name and value to the two matches returned by the `string.gmatch()` iterator. These are implicitly declared as local variables within the body of the for loop.

```
1 if headers[name] then
2 local next_value_index = #(headers[name]) + 1
3 headers[name][next_value_index] = value
4 else
5 headers[name] = {
6 name .. ":" .. value }
7
8 end
9 <!--NeedCopy-->
```

These statements within the for loop put the header names and values into the headers table. The first time a header name is parsed (say H2: h2val1 in the example input), there is no headers entry for the name and `headers[name]` is nil.

Since nil is treated as false, the else clause is executed. This sets the headers entry for name to an array with one string value *name:value*.

**Note:** The array constructor in the else loop is equivalent to `{[1] = name .. ":" .. value}`, which sets the first element of the array.) For the first H2 header, it sets `headers["H2"] = {"H2:h2val1"}`.

On subsequent instances of a header, (say, H2: h2val2 in the example input). `headers[name]` is not nil, so the then clause is executed. This determines the next available index in the array value for `headers[name]`, and puts the header value into that index. For the second H2 header, it sets `headers["H2"] = {"H2:h2val1", "h2val2"}`.

```
1 for name, values in pairs(headers) do
2 local next_header_index = #combined_headers + 1
3 combined_headers[next_header_index] = table.concat(values, ",")
4 end
5 <!--NeedCopy-->
```

After the original headers have been parsed and the headers table filled in, this loop builds the `combined_headers` array. It uses the `pairs()` function as the for loop iterator.

Each call to `pairs()` returns the name and value of the next entry in the headers table.

The next line determines the next available index in the `combined_headers` array, and the next line sets that array element to the combined header. It uses the built-in `table.concat()` function, which takes as its arguments an array of strings and a string to use as a separator, and returns a string that is the concatenation of the array strings, separated by the separator.

For example, for `values = {"H2:h2val1", "h2val2"}`, this produces "H2:h2val1, h2val2"

```
1 local result_str = table.concat(combined_headers, "\r\n") .. "\r\n\r\n"
2 <!--NeedCopy-->
```

After the `combined_headers` array are built, it concatenates the elements into one string, and adds a double `\r\n` that terminates the HTTP headers.

```
1 return result_str
2 <!--NeedCopy-->
```

Returns a string as the result of the `COMBINE_HEADERS` extension function.

## Troubleshooting policy extensions

May 2, 2023

If your extension function is not behaving as expected, you can use extension tracing functionality to verify the behavior of your extension function. You can also add logging to your extension function by using the custom logging functionality, where you can define the log level to be captured on the NetScaler appliance.

This topic provides information on:

- Extension tracing
- Custom logging

## Extension tracing

To show what your extension function is doing, extension tracing functionality logs the execution of the function to the NetScaler system log ( /var/log/ns.log ). The trace logging uses the DEBUG log level, which normally is not enabled. Therefore, you have to enable ALL log levels. Then you can enable tracing by setting the -trace option of the set ns extension command. The available settings are:

- off turn off tracing (equivalent to unset ns extension -trace).
- calls trace function calls with arguments and function returns with the first return value.
- lines trace the above plus line numbers for executed lines.
- all trace the above plus local variables changed by executed lines.

### Example:

```
1 set audit syslogParams -loglevel ALL
2
3 set ns extension combine_headers -trace all
4 <!--NeedCopy-->
```

Each trace message has the format

log-header : **default** NSEXTENSION Message message-number 0 : "TRACE  
function-name CALL call-number: event"

Where,

- log-header supplies timestamps, the NetScaler IP address, and the Packet Engine ID.
- message-number is a sequential number identifying the log message.
- function-name is the extension function name.
- call-number is a sequential number for each extension function call. It can be used to group all the trace messages for an extension function call.
- event is one of the following:
  - CALL function-name ; parameter-values indicates that the function has been called with the specified parameters.
  - RETURN FROM function-name ; return = value indicates that a function has returned the specified (first) value. (Additional return values are not reported.)
  - LINE line-number ; variable-values indicates that a line has been executed and lists any variables with changed values.

Where,

- value or values is
  - a number, with or without a decimal point,

- a string, enclosed in double quotes and with escaped characters as described earlier,
  - a boolean true or false,
  - nil,
  - a table constructor, of the format {[key1]=value1,[key2]=value2, ...}.
- parameter-values is parameter1 = value1 ; parameter2 = value2 , ...
  - variable-values is variable1 = value1 ; variable2 = value2 , ...

An example of abbreviated log messages:

```
1 >shell tail -f /var/log/ns.log | grep TRACE | more
2
3 ... NSEXTENSION Message 3035 0 : "TRACE combine_headers CALL 30 : CALL
 COMBINE_HEADERS; self = "User-Agent: curl/7.24.0 (amd64-portbld-

38
39 ... NSEXTENSION Message 3120 0 : "TRACE combine_headers CALL 30 : CALL
 concat"
40
41 ... NSEXTENSION Message 3121 0 : "TRACE combine_headers CALL 30 :
 RETURN FROM concat; return = "User-Agent: curl/7.24.0 (amd64-portbld
 -freebsd8.4) libcurl/7.24.0 OpenSSL/0.9.8y zlib/1.2.3\r\nH1: abcd\r\
 nAccept: /**\r\nHost: 10.217.24.7\r\nH2: h2val1, h2val2, h2val3""
 ... NSEXTENSION Message 3122 0 : "TRACE combine_headers CALL 30 :
 LINE 25; result_str = "User-Agent: curl/7.24.0 (amd64-portbld-
 freebsd8.4) libcurl/7.24.0 OpenSSL/0.9.8y zlib/1.2.3\r\nH1: abcd\r\
 nAccept: /**\r\nHost: 10.217.24.7\r\nH2: h2val1, h2val2, h2val3\r\n\
 r\n""
42
43 ... NSEXTENSION Message 3123 0 : "TRACE combine_headers CALL 30 :
 RETURN FROM COMBINE_HEADERS; return = "User-Agent: curl/7.24.0 (
 amd64-portbld-freebsd8.4) libcurl/7.24.0 OpenSSL/0.9.8y zlib/1.2.3\r
 \nH1: abcd\r\nAccept: /**\r\nHost: 10.217.24.7\r\nH2: h2val1, h2val2
 , h2val3\r\n\r\n""
44 <!--NeedCopy-->

```

## Custom logging

You can also add your own logging to your extension function. To do so, use the built-in `ns.logger:level()` function, where *level* is emergency, alert, critical, error, warning, notice, info, or debug. The parameters are the same as the C `printf()` function: a format string, and a variable number of arguments to supply values for the % specified in the format string. For example, you might add the following to the `COMBINE_HEADERS` function to log the result of a call:

```

1 local result_str = table.concat(combined_headers, "\r\n") .. "\r\n\r\n"
2
3 ns.logger:info("Result: %s", result_str)
4
5 return result_str
6 <!--NeedCopy-->

```

The above function would log the following message to `/var/log/ns.log` for the sample input shown in the abbreviated log messages examples in the Extension Tracing section above.

```
... : default NSEXTENSION Message 143 0 : "Result: Host: 10.217.24.7:2000^
M H1: abcd, 1234^M User-Agent: curl/7.24.0 (amd64-portbld-freebsd8.4)
libcurl/7.24.0 OpenSSL/0.9.8y zlib/1.2.3^M Accept: */*^M H2: h2val1,
h2val2, h2val3^M ^M"
```

## Optimization

May 2, 2023

The NetScaler optimization features reduce transaction times between the clients and the servers, and they reduce bandwidth consumption. They also enhance server performance by offloading some tasks and making others more efficient.

---

Feature	Description
Client Keep-Alive	Handles multiple requests on a single client connection. The client does not have to negotiate a new connection for each request to the server.
HTTP Compression	Compresses HTTP responses sent from the servers to compression-aware browsers. The smaller responses reduce download time and save bandwidth.
Integrated Caching	Stores responses to client requests. Subsequent requests for the same content are served from the NetScaler cache instead of being forwarded to the origin server.
Front End Optimization	Reduces the load and render time of web pages by simplifying and optimizing the content served to the client browser. <b>Note:</b> Supported from NetScaler 10.5 onwards.

---

## Client keep-alive

November 2, 2023

The client keep-alive feature enables multiple clients requests to be sent on a single connection. This feature benefits transaction management. When the Client Keep-Alive mode is enabled on an appliance and the server response to the client request contains the Connection: close the HTTP header and performs the following tasks:

- Renames the existing Connection header name by shuffling the characters in the header name.
- Adds a new Connection: header with Keep-Alive as the value for the header.

The Client Keep-Alive mode enables the NetScaler appliance to process multiple requests and responses using the same socket connection. The feature keeps the connection between the client and the appliance (client-side connection) open even after the server closes the connection with the appliance. This allows multiple clients requests using a single connection and saves the round trips associated in opening and closing a connection. Client keep-alive is most beneficial in SSL sessions.

Client keep-alive is useful for the following scenarios:

- If the server does not support the client keep-alive.
- If the server supports but an application on the server does not support the client keep-alive.

**Note:**

Client keep-alive is applicable for HTTP and SSL traffic. Client-keep alive can be configured globally to handle all traffic. Also, you can activate it on specific services.

In the client keep-alive environment, the configured services intercept the client traffic and the client request is directed to the origin server. The server sends the response and closes the connection between the server and the appliance. If a “Connection: Close” header is present in the server response, the appliance corrupts this header in the client-side response, and the client-side connection is kept open. As a result, the client does not have to open a new connection for the next request. Instead, the connection to the server is reopened.

**Note:**

If a server sends back two “Connection: Close” headers, only one is edited. This results in significant delays on the client rendering of the object because a client does not assume that the object has been delivered completely until the connection is closed.

### Configure client keep-alive

Client keep-alive, by default, is disabled on the NetScaler, both globally and at service level. Therefore, you must enable the feature at the required scope.

**Note:**

If you enable the client keep-alive globally, it is enabled for all services, regardless of whether you enable it at the service level. Also, you must configure some HTTP parameters to specify the following:

- the maximum number of HTTP connections retained in the connection reuse pool.
- enable connection multiplexing, and enable persistence `Etag`.

**Note:**

When Persistent `Etag` is enabled, the `Etag` header includes information about the server that served the content. This ensures that cache validation conditional requests or browser requests, for that content, always reaches the same server.

### Configure client keep-alive by using NetScaler command interface

At the command prompt, do the following:

1. Enable client keep-alive on the NetScaler.
  - At global level - `enable ns mode cka`
  - At service level - `set service <name> -CKA YES`

**Note:**

Client keep-alive can be enabled only for HTTP and SSL services.

2. Configure HTTP parameters on the HTTP profile that is bound to one or more services.

```
1 set ns httpProfile <name> -maxReusePool <value> -conMultiplex
 ENABLED -persistentEtag ENABLED
2 <!--NeedCopy-->
```

**Note:**

Configure these parameters on the `nshttp_default _profile` HTTP profile, to make them available globally.

### Configure client keep-alive by using NetScaler GUI

1. Enable client keep-alive on the NetScaler.
  - At global level  
Navigate to **System > Settings**, click **Configure Modes** and select **Client side Keep Alive**.

- At service level

Navigate to **Traffic Management > Load Balancing > Services**, and select the required service. In the **Settings** section, select **Client Keep-Alive** check box.

2. Configure the required HTTP parameters on the HTTP profile that is bound to one or more services.
3. Navigate to **System > Profiles**, and on **HTTP Profiles** tab, select the required profile and update the required HTTP parameters.

## HTTP compression

May 2, 2023

For websites with compressible content, the HTTP compression feature implements lossless compression to alleviate latency, long download times, and other network-performance problems by compressing the HTTP responses sent from servers to compression-aware browsers. You can improve server performance by offloading the computationally intensive compression task from your servers to the NetScaler appliance.

The following table describes the capabilities of the HTTP compression feature:

---

Functionality	Description
Compression Ratio	Compression ratio depends on the types of files in the responses, but is always significant, noticeably reducing the amount of data transmitted over the network.
Browser Awareness	NetScaler serves compressed data to compression aware browsers only, reducing the transaction time between the client and the server. Most modern web browsers support HTTP compression.
Compression blocking	You can define content filters to selectively block compression by applying built-in actions.
Compression Caching	With the integrated caching feature enabled, subsequent requests for the same content are served from the local cache, reducing the number of round trips to the server and improving transaction times.

---

Functionality	Description
HTTPS Support	Compression is useful on SSL connections, because it reduces the amount of content that has to be encrypted, either on the server or by the NetScaler appliance, and decrypted by the client.
Intelligent Response Filtering	The NetScaler compression engine intelligently filters server responses based on defined compression parameters. For example, the compression engine detects zero-content-length responses and compressed responses and does not compress them. The detection of compressed responses enables origin sites to use server-based compression with the NetScaler compression feature.
Compression Switching	The NetScaler appliance transparently directs requests from compression aware clients to compression capable servers, so that responses to those clients are compressed, and responses to other clients are not delayed by compression processing.

---

## How HTTP compression works

A NetScaler can compress both static and dynamically generated data. It applies the GZIP or the DEFLATE compression algorithm to remove extraneous and repetitive information from the server responses and represent the original information in a more compact and efficient format. This compressed data is sent to the client's browser and uncompressed as determined by the browser's supported algorithm or algorithms (GZIP or DEFLATE).

NetScaler compression treats static and dynamic content differently.

- Static files are compressed only once, and a compressed copy is stored in local memory. Subsequent client requests for cached files are serviced from that memory.
- Dynamic pages are dynamically created each time a client requests them.

When a client sends a request to the server:

1. The client request arrives at the NetScaler. The ADC examines the headers and stores information about what kind of compression, if any, the browser supports.

2. The ADC forwards the request to the server and receives the response.
3. The NetScaler compression engine examines the server response for compressibility by matching it against policies.
4. If the response matches a policy associated with a compression action, and the client browser supports a compression algorithm specified by the action, the NetScaler applies the algorithm and sends the compressed response to the client browser.
5. The client applies the supported compression algorithm to decompress the response.

## Configure HTTP compression

By default, compression is disabled on the NetScaler. You must enable the feature before configuring it. If the feature is enabled, the ADC compresses server requests specified by compression policies.

To enable HTTP compression by using the CLI

Compression can be enabled for HTTP and SSL services only. You can enable it globally, so that it applies to all HTTP and SSL services, or you can enable it just for specific services.

At the command prompt, enter one of the following commands to enable compression globally or for a specific service:

- `enable ns feature cmp`
- OR
- `set service \<name\> -CMP YES`

To configure compression by using the GUI

Do one of the following:

To enable compression globally, navigate to System > Settings, click **Configure Basic Features**, and select HTTP Compression.

To enable compression for a specific service, navigate to **Traffic Management > Load Balancing > Services**, select the service, and click Edit. In the Settings group, click the pencil icon and enable Compression.

## Configuring a compression action

A compression action specifies the action to take when a request or response matches the rule (expression) in the policy with which the action is associated. For example, you can configure a compression policy that identifies requests that will be sent to a particular server, and associate the policy with an action that compresses the server's response.

There are four built-in compression actions:

- **COMPRESS:** Uses the GZIP algorithm to compress data from browsers that support either GZIP or both GZIP and DEFLATE. Uses the DEFLATE algorithm to compress data from browsers that support only the DEFLATE algorithm. If the browser does not support either algorithm, the browser's response is not compressed.
- **NOCOMPRESS:** Does not compress data.
- **GZIP:** Uses the GZIP algorithm to compress data for browsers that support GZIP compression. If the browser does not support the GZIP algorithm, the browser's response is not compressed.
- **DEFLATE:** Uses the DEFLATE algorithm to compress data for browsers that support the DEFLATE algorithm. If the browser does not support the DEFLATE algorithm, the browser's response is not compressed. After creating an action, you associate the action with one or more compression policies.

At the command prompt, enter the following command to create a compression action:

```
add cmp action <name> <cmpType> [-addVaryHeader <addVaryHeader> -varyHeaderValue<string>]
```

To configure a compression policy by using the CLI

A compression policy contains a rule, which is a logical expression that enables the NetScaler appliance to identify the traffic that should be compressed.

When the NetScaler receives an HTTP response from a server, it evaluates the built-in compression policies and any custom compression policies to determine whether to compress the response and, if so, the type of compression to apply. Priorities assigned to the policies determine the order in which the policies are matched against the requests.

At the command prompt, enter the following command to create a compression policy:

```
add cmp policy <name> -rule <expression> -resAction <string>
```

To create a compression action by using the GUI

Navigate to **Optimization > HTTP Compression > Actions**, click **Add**, and create a compression action to specify the type of compression to be performed on the HTTP response.

## Configuring a compression policy

A compression policy contains a rule, which is a logical expression that enables the NetScaler appliance to identify the traffic that should be compressed.

When the NetScaler receives an HTTP response from a server, it evaluates the built-in compression policies and any custom compression policies to determine whether to compress the response and, if so, the type of compression to apply. Priorities assigned to the policies determine the order in which the policies are matched against the requests.

The following table lists the built-in HTTP compression policies. These policies are activated globally when you enable compression.

Built-in Classic or Advanced policy	Description
ns_nocmp_mozilla_47, ns_adv_nocmp_mozilla_47	Prevents compression of CSS files when a request is sent from a Mozilla 4.7 browser.
ns_cmp_mscss, ns_adv_cmp_mscss	Compresses CSS files when the request is sent from a Microsoft Internet Explorer browser.
ns_cmp_msapp, ns_adv_cmp_msapp	Compresses files that are generated by the following applications: Microsoft Office Word, Microsoft Office Excel, Microsoft Office PowerPoint.
ns_cmp_content_type, ns_adv_cmp_content_type	Compresses data when the response contains Content-Type header and contains text.
ns_nocmp_xml_ie, ns_adv_nocmp_xml_ie	Prevents compression when a request is sent, from a Microsoft Internet Explorer browser and the response contains a Content-Type header and contains text or xml.

## Binding a compression policy

To put a compression policy into effect, you must bind it either globally, so that it applies to all traffic that flows through the NetScaler, or to a specific virtual server, so that the policy applies only to requests whose destination is the VIP address of that virtual server.

When you bind a policy, you assign it a priority. The priority determines the order in which the policies you define are evaluated. You can set the priority to any positive integer.

To bind a Compression Policy by using the CLI

At the command prompt, enter one of the following commands to bind a compression policy globally or to a specific virtual server:

- `bind cmp global <policyName> [-priority <positive_integer>] [-state (ENABLED|DISABLED)]...`
- `bind lb vserver <vserverName> -policyName <policyName> -type (Request|Response) -priority <positive_integer> )`

Repeat this command for each virtual server to which you want to bind the compression policy.

To bind a compression policy by using the GUI

Do one of the following:

At global level Navigate to **Optimization > HTTP Compression > Policies**, click **Policy Manager** and bind the required policies by specifying the relevant Bind Point and Connection Type (Request/Response).

At virtual server level

For load balancing virtual server, Navigate to **Traffic Management > Load Balancing > Virtual Servers**, select the required virtual server, click **Policies**, and bind the relevant policy.

For content switching virtual server, Navigate to **Traffic Management > Content Switching > Virtual Servers**, select the required virtual server, click **Policies**, and bind the relevant policy.

Set the Global Compression Parameters for Optimal Performance

Many users accept the default values for the global compression parameters, but you might be able to provide more effective compression by customizing these settings.

**Note**

After you configure the global compression parameters, you do not have to reboot your appliance. They get applied to the new flows immediately.

The following table describes the compression parameters that you can set on the NetScaler.

---

Compression Parameters	Description
Quantum size	Size, in KB, of the buffer maintained for accumulating server responses. The responses are compressed when the buffer size exceeds this value. For example, if you set the quantum size to 50 KB, the NetScaler compresses the buffer's contents when its size becomes larger than 50 KB. Minimum value: 1. Maximum value: 63488. Default: 57344.
Compression level	Level of compression to apply to server responses. Possible values: Best Speed, Best Compression, optimal.
Minimum HTTP response size	Minimum size, in bytes, of an HTTP response that is compressed. Responses smaller than the value specified by this parameter are sent without being compressed.
Bypass compression on CPU usage	NetScaler CPU usage, as a percentage, at or above which no compression is done. Default: 100.

Compression Parameters	Description
Policy Type*	Type of policies used for compression. Possible values: Classic, Advanced policy. Default: Classic.
Allow Server-side compression	Allow servers to send compressed data to the NetScaler.
Compress push packet	Upon receipt of a packet with a TCP PUSH flag, compress the accumulated packets immediately, without waiting for the quantum buffer to be filled.
External Cache	Issue a private response directive indicating that the response message is intended for a single user and must not be cached by a shared or proxy cache.

---

To configure HTTP compression by using the GUI

Do one of the following:

- To enable compression globally, navigate to **System > Settings**, click **Configure Basic Features**, and select **HTTP Compression**.
- To enable compression for a specific service, navigate to **Traffic Management > Load Balancing > Services**, select the service, and click **Edit**.
- In the **Settings** group, click the pencil icon and enable **Compression**.

To create a compression action by using the GUI

Navigate to **Optimization > HTTP Compression > Actions**, click **Add**, and create a compression action to specify the type of compression to be performed on the HTTP response

To create a compression policy by using the GUI

Navigate to **Optimization > HTTP Compression > Policies**, click **Add**, and create a compression policy by specifying the condition and the corresponding action to be run.

## Evaluate compression configuration

You can view the compression statistics in the dashboard utility or in an SNMP monitor. The dashboard utility displays summary and detailed statistics in a tabular and graphic format.

Optionally, you can also view statistics for a compression policy, including the number of requests that the policy counter increments during the policy based compression.

**Note**

- For more information about the statistics and charts, see the Dashboard help on the NetScaler appliance.
- For more information about SNMP, see [SNMP](#) topic.

To view compression statistics by using the CLI

At the command prompt, enter the following commands to display the compression statistics:

1. To display compression statistics summary.

```
stat cmp
```

**Note**

The `stat cmp policy` command displays statistics for Advanced policy compression policies only.

2. To display compression policy hits and details

```
show cmp policy \<name\>
```

3. To display detailed compression statistics

```
stat cmp -detail
```

To view compression statistics by using the dashboard:

In the Dashboard utility, you can display the following types of compression statistics:

- Select Compression to display a summary of the compression statistics.
- To display detailed compression statistics by protocol type, click the Details
- To display the rate of requests processed by the compression feature, click the Graphical View tab.

To view compression statistics by using SNMP

You can view the following compression statistics by using the SNMP network management application.

- Number of compression requests (OID: 1.3.6.1.4.1.5951.4.1.1.50.1)
- Number of compressed bytes transmitted (OID: 1.3.6.1.4.1.5951.4.1.1.50.2)
- Number of compressible bytes received (OID: 1.3.6.1.4.1.5951.4.1.1.50.3)
- Number of compressible packets transmitted (OID: 1.3.6.1.4.1.5951.4.1.1.50.4)
- Number of compressible packets received (OID: 1.3.6.1.4.1.5951.4.1.1.50.5)
- Ratio of compressible data received and compressed data transmitted (OID: 1.3.6.1.4.1.5951.4.1.1.50.6)
- Ratio of total data received to total data transmitted (OID: 1.3.6.1.4.1.5951.4.1.1.50.7)

To view more compression statistics by using the GUI

1. To display HTTP compression statistics:

Navigate to **Optimization > HTTP Compression** and click **Statistics**.

1. To display statistics of a compression policy.

Navigate to **Optimization > HTTP Compression > Policies** > select the policy, and click **Statistics**.

1. To display statistics of a compression policy label
2. Navigate to **Optimization > HTTP Compression > Policies** > select a policy label, and click **Statistics**.

## Offloading HTTP compression

Performing compression on a server can affect the server's performance. A NetScaler placed in front of your web servers and configured for HTTP compression offloads compression of both static and dynamic content, saving server CPU cycles and resources.

You can offload compression from the Web servers in either of two ways:

Disable compression on the web servers, enable the NetScaler Compression feature at a global level, and configure services for compression.

Leave the compression feature enabled on the web servers and configure the NetScaler appliance to remove the "Accept Encoding" header from all HTTP client requests. The servers then send uncompressed responses. The NetScaler compresses the server responses before sending them to the clients.

### Note

The second option does not work if the servers automatically compress all responses. The NetScaler does not attempt to compress a response that is already compressed.

The `Servercmp` parameter enables the NetScaler appliance to handle offload HTTP compression. By default, this parameter is set ON for the server to send compressed data to the NetScaler appliance. To offload HTTP compression, you need to set the `servercmp` parameter to OFF. At the command prompt, enter the following commands:

```
set service <service name> -CMP YES
```

Repeat this command for each service for which you want to enable compression.

```
show service <service name>
```

Repeat this command for each service, to verify that compression is enabled.

Save config

```
set cmp parameter -serverCmp OFF
```

**Note:**

When the `Servercmp` parameter is turned on and if the appliance receives compressed response from the server, the appliance does not further compress the data. Instead, it forwards the compressed response to the client.

## Integrated caching

November 2, 2023

The integrated cache provides in-memory storage on the NetScaler appliance and serves Web content to users without requiring a round trip to an origin server. For static content, the integrated cache requires little initial setup. After you enable the integrated cache feature and perform basic setup (for example, determining the amount of NetScaler appliance memory the cache is permitted to use), the integrated cache uses built-in policies to store and serve specific types of static content, including simple webpages and image files. You can also configure the integrated cache to store and serve dynamic content that is marked as non-cacheable by Web and application servers (for example, database records and stock quotes).

**Note:**

The term Integrated Cache can be interchangeably used with AppCache; note that from a functionality point of view, both terms mean the same.

When a request or response matches the rule (logical expression) specified in a built-in policy or a policy that you have created. The NetScaler appliance performs the action associated with the policy. By default, all policies store cached objects in and retrieve them from the default content group. You can create your own content groups for different types of content.

To enable the appliance to find cached objects in a content group, you can configure selectors. The selectors match cached objects against expressions, or you can specify parameters for finding objects in the content group. If you use selectors as recommended by Citrix, configure them first, so that you can specify selectors when you configure content groups. Next, set up any content groups that you want to add, so that they are available when you configure the policies. To complete the initial configuration, create policy banks by binding each policy to a global bind point or a virtual server. Or, you can bind a label that can be called from other policy banks.

Integrated caching can be improved using pre-loading cached object method before they are scheduled to expire. To manage the handling of cached data, you can configure caching-related headers inserted into the responses. The integrated cache can also act as a forward proxy for other cache servers.

**Note:**

Integrated caching requires some familiarity with HTTP requests and responses. For information about the structure of HTTP data, see *Live HTTP Headers* at "<http://livehttpheaders.mozdev.org/>."

**How integration cache works**

The integrated cache monitors HTTP and SQL requests that flow through the NetScaler appliance and compares the requests with stored policies. Depending on the outcome, the integrated cache feature either searches the cache for the response or forwards the request to the origin server. For HTTP requests, integrated caching serves as partial content from the cache in response to single byte-range and multi-part byte-range requests.

Cached data is compressed if the client accepts compressed content. You can configure expiration times for a content group, and you can selectively expire entries in a content group.

Data that is served from the integrated cache is a hit, and data served from the origin is a cache miss, as described in the following table.

---

Transaction Type	Specification
Cache Hit	Responses that the NetScaler appliance serves from the cache, including: Static objects, for example, image files and static webpages, 200 OK pages, 203 Non-Authoritative Response pages, 300 Multiple Choices pages, 301 Moved Permanently pages, 302 Found pages, 304 Not Modified pages, These responses are known as positive responses. The NetScaler appliance also caches the following negative responses: 307 Temporary Redirect pages, 403 Forbidden pages, 404 Not Found pages, 410 Gone pages. To further improve performance, you can configure the NetScaler appliance to cache more types of content.
Storable Cache Miss	For a storable cache miss, the NetScaler appliance fetches the response from the origin server, and stores the response in the cache before serving it to the client.

Transaction Type	Specification
Non-Storable Cache Miss	A non-storable cache miss is inappropriate for caching. By default, any response that contains the following status codes is a non-storable cache miss: 201, 202, 204, 205, 206 status codes, All 4xx codes, except 403, 404 and 410, 5xx status codes

**Note:**

To integrate dynamic caching with your application infrastructure, use the NITRO API to issue cache commands remotely. For example, you can configure triggers that expire cached responses when a database table is updated.

To ensure the synchronization of cached responses with the data on the origin server, you configure expiration methods. When the NetScaler appliance receives a request that matches an expired response, it refreshes the response from the origin server.

**Note:**

Citrix recommends that you synchronize the times on the NetScaler appliance and one or more back-end servers.

## How dynamic cache works

Dynamic caching evaluates HTTP requests and responses based on parameter-value pairs, strings, string patterns, or other data. For example, suppose that a user searches for Bug 31231 in a bug reporting application. The browser sends the following request on the user's behalf:

```

1 GET /mybugreportingsystem/mybugreport.dll?IssuePage&RecordId=31231&
 Template=view&TableId=1000
2
3 Host: mycompany.net
4
5 User-Agent: Mozilla/5.0 (Windows; U; Windows NT 5.1; en-US; rv:1.9)
 Gecko/2008052906 Firefox/3.0
6
7 Accept: text/html,application/xhtml+xml,application/xml;q=0.9,*/*;q
 =0.8
8
9 Accept-Language: en-us,en;q=0.5
10 <!--NeedCopy-->
```

In this example, GET requests for this bug reporting application always contain the following parameters:

- IssuePage
- RecordID
- Template
- TableId

GET requests do not update or alter the data, so you can configure these parameters in caching policies and selectors, as follows:

- You configure a caching policy that looks for the string `mybugreportingsystem` and the GET method in HTTP requests. This policy directs matching requests to a content group for bugs.
- In the content group for bugs, you configure a `hit` selector that matches various parameter-value pairs, including `IssuePage`, `RecordID`, and so on.

**Note**

A browser can send multiple GET requests based on one user action. The following is a series of three separate GET requests that a browser issues when a user searches for a bug based on a bug ID.

```
1 GET /mybugreportingsystem/mybugreport.dll?IssuePage&RecordId=31231&
 Template=view&TableId=1000
2
3 GET /mybugreportingsystem/mybugreport.dll?IssuePage&Template=
 viewbtns&RecordId=31231&TableId=1000
4
5 GET /mybugreportingsystem/mybugreport.dll?IssuePage&Template=
 viewbody&RecordId=31231&tableid=1000
6 <!--NeedCopy-->
```

To fulfill these requests, multiple responses are sent to the user's browser, and the webpage that the user sees is an assembly of the responses.

If a user updates a bug report, the corresponding responses in the cache must be refreshed with data from the origin server. The bug reporting application issues HTTP POST requests when a user updates a bug report. In this example, you configure the following to ensure that POST requests trigger invalidation in the cache:

- A request-time invalidation policy that looks for the string `mybugreportingsystem` and the POST HTTP request method, and directs matching requests to the content group for bug reports.
- An invalidation selector for the content group for bug reports that expires cached content based on the `RecordID` parameter. This parameter appears in all the responses, so the invalidation selector can expire all relevant items in the cache.

The following excerpt shows a POST request that updates the sample bug report.

```
1 POST /mybugreportingsystem/mybugreport.dll?TransitionForm HTTP/1.1\r\n
```

```
2
3 User-Agent: Mozilla/4.0 (compatible; MSIE 6.0; Windows NT 5.0)
 Opera 7.23 [en]\r\n
4
5 Host: mybugreportingsystem\r\n
6
7 Cookie: ttSearch.134=%23options%3Afalse%23active%23owner%3Afalse%23
 unowned%3Afalse%23submitter%3Afalse%23incsub%3Atrue;
8
9 Cookie2: $Version=1\r\n
10
11 . . .
12
13 \r\n
14
15 ProjectId=2&RecordId=31231&TableId=1000&TransitionId=1&Action=
 Update&CopyProjectId=0&ReloadForm=0&State=&RecordLockId=49873+
 issues+in+HTTP&F43. . .
16 <!--NeedCopy-->
```

When the NetScaler appliance receives this request, it does the following:

- Matches the request with an invalidation policy.
- Finds the content group that is named in the policy.
- Applies the invalidation selector for this content group and expires all responses that match RecordID=31231.

When a user issues a new request for this bug report, the NetScaler appliance goes to the origin server for updated copies of all the responses that are associated with the report instance. It stores the responses in the content group, and serves them to the user's browser, which reassembles the report and displays it.

## Configure integrated cache

To use the integrated cache, you must install the license and enable the feature. After you enable the integrated cache, the NetScaler® appliance automatically caches static objects as specified by built-in policies and generates statistics on cache behavior. (Built-in policies have an underscore in the initial position of the policy name.)

Even if the built-in policies are adequate for your situation, you might want to modify the global attributes. For example, you might want to modify the amount of NetScaler appliance memory allocated to the integrated cache.

If you would like to observe cache operation before changing settings, see [“Displaying Cached Objects and Cache Statistics.”](#)

**Note:**

The NetScaler cache is an in-memory store that is purged when you restart the appliance.

To install integrated cache license

- An integrated cache license is required.
- Obtain a license code from Citrix, go to the command line interface, and log in.

At the command line interface, copy the license file to the `/nsconfig/license` folder.

- Reboot the NetScaler appliance by using the following command:

```
reboot
```

**To enable integrated caching:**

When you enable integrated caching, the NetScaler appliance begins caching server responses. If you have not configured any policies or content groups, the built-in policies store cached objects in the Default content group.

At the command prompt, type one of the following commands to enable or disable integrated caching:

```
enable ns feature IC
```

**Configure global attributes for caching**

Global attributes apply to all cached data. You can specify the amount of NetScaler memory allocated to the integrated cache, via header insertion. A criterion for verifying that a cached object must be served. The maximum length of a POST body permitted in the cache, whether to bypass policy evaluation for HTTP GET requests, and an action to take when a policy cannot be evaluated.

The cache memory capacity is limited only by the memory of the hardware appliance. Also, any packet engine (central distribution hub of all incoming TCP requests) in the nCore NetScaler appliance is aware of objects cached by other packet engines in the nCore NetScaler appliance.

**Note:**

When the default global memory limit is set as 0 and the Integrated Caching (IC) feature is enabled, the appliance does not cache any objects. For caching, you must explicitly configure the global memory limit. However, if you enable “set authentication, authorization, and auditing parameter enableStaticPageCaching” option, there will be some default memory configured in the appliance. This memory is insufficient for caching large Objects and so it is necessary to assign a higher memory limit for IC. You can perform this by configuring the “set cache parameter –mem-Limit” command. The new setting is applied only after you save the configuration and reboot the

appliance.

You can modify the global memory limit configured for caching objects. However, when you update the global memory limit to a value lower than the existing value (for example, from 10 GB to 4 GB), the appliance continues to use the memory limit.

It means that even though the integrated caching limit is configured to some value, the actual limit used can be higher. This excessive memory is however released when the objects are removed from cache.

The output of the `show cache parameter` command indicates the configured value (memory Usage limit) and the actual value being used (memory usage limit (active value)).

At the command prompt, type:

```
1 set cache parameter [-memLimit <MBytes>] [-via <string>] [-
 verifyUsing <criterion>] [-maxPostLen <positiveInteger>] [-
 prefetchMaxPending <positiveInteger>] [-enableBypass(YES|NO)] [-
 undefAction (NOCACHE|RESET)]
2 <!--NeedCopy-->
```

### Enable integrated caching by NetScaler GUI

Navigate to **System > Settings**, click **Configure Basic Features**, and select **Integrated Caching**.

### Configure global settings for caching by using the NetScaler GUI

Navigate to **Optimization > Integrated Caching**, click **Change Cache Settings**, and configure the global settings for caching.

### Set up built-in content group, pattern set, and policies for Integrated Cache

The NetScaler appliance includes a built-in integrated caching configuration that you can use for caching content. The configuration consists of a content group called `ctx_cg_poc`, a pattern set called `ctx_file_extensions`, and a set of integrated cache policies. In the content group `ctx_cg_poc`, only objects that are 500 KB or smaller are cached. The content is cached for 86000 seconds, and the memory limit for the content group is 512 MB. The pattern set is an indexed array of common extensions for file-type matching.

The following table lists the built-in integrated caching policies. By default, the policies are not bound to any bind point. You must bind the policies to a bind point if you want the NetScaler appliance to evaluate traffic against the policies. The policies cache objects in the `ctx_cg_poc` content group.

Integrated caching policy name	Policy rule
_cacheVPNStaticObjects	HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE).CONTAINS_IN("ctx_file_extensions").BETWEEN(101,150)
_cacheTCPVPNStaticObjects	HTTP.REQ.URL.ENDSWITH(".css")
_cacheOCVPNStaticObjects	HTTP.REQ.URL.ENDSWITH(".pdf")
_cacheWFStaticObjects	HTTP.REQ.URL.ENDSWITH(".js")
_mayNoCacheReq	HTTP.RES.HEADER("Content-Type").CONTAINS("application/x-javascript")
_noCacheRest	TRUE

## Flush cache configuration

You can flush a cache group, cache groups, or cache object locator. Following are the commands to flush cache objects.

At the command prompt, type:

```
flush cache contentgroup all
```

### Example

```

1 0x00000089bae000000004 DEFAULT GET //1.1.1.1:80/html/index.
 html?name=hello
2 0x00000089bae000000005 DEFAULT GET //1.1.1.1:80/html/index.
 html?name=hi
3
4 Flush cache contentGroup all
5 done
6
7 `flush cache contentgroup <content group name>`
8 <!--NeedCopy-->
```

### Example:

```

1 0x00000089bae000000004 DEFAULT GET //1.1.1.1:80/html/index.
 html?name=hello
2 0x00000089bae000000005 DEFAULT GET //1.1.1.1:80/html/index.
 html?name=hi
3
4 Flush cache ob -| 0x00000089bae000000004
5 done
6
```

```

7 `flush cache object (-locator <positive_integer> | (-url <URL> (-host <
 string> [-port <port>] [-groupName <string>] [-httpMethod (GET |
 POST))]))`
8 <!--NeedCopy-->

```

**Example:**

```

1 0x00000089bae000000006 DEFAULT GET //1.1.1.1:80/html/index.html
2
3 flush cache ob -URL /html/index.html -host 1.1.1.1 -groupName
 DEFAULT
4 done
5 <!--NeedCopy-->

```

**Flush cache configuration by using the NetScaler GUI**

Complete the steps to configure cache flushing using the NetScaler GUI

1. Navigate to **Optimization > Content Groups**.
2. In the **Content Groups** detailed pane, click **Add**.
3. In the **Create Cache Content Groups** page, set the following parameter under **Others** tab:
  - a) Flush Cache. Select the check box to flush the cache object.
4. Click **Create** and **Close**.

**Configure integrated caching for various scenarios**

The following section describes the configuration of integrated caching on NetScaler appliance for various scenarios.

Starting from NetScaler 9.2 release, the integrated caching has more memory for caching. The integrated caching memory is only limited by the memory available on the hardware appliance. You can allocate up to 50 percent of the available memory to the integrated caching feature.

To set the memory allocation for the cache by using the CLI

At the command prompt, type:

```
set cache parameter -memlimit <value>
```

**Note:**

The default global memory limit for integrated caching is zero. Therefore, even if you enable the integrated caching feature, the NetScaler appliance does not cache any objects until the global memory limit is explicitly set.

The following section instructs you to configure integrated caching on different scenarios.

**Note:**

The memory limit of the NetScaler appliance is identified when the appliance starts. Therefore, any changes to the memory limit require you to restart the appliance to make the changes applicable across the packet engines.

**Integrated caching is enabled and cache memory limit is set to non-zero**

Consider a scenario, where you start the appliance, the integrated caching feature is enabled and the global memory limit is set to a positive number. The memory you had set earlier is allocated to the integrated caching feature during the boot process. You might want to change the memory limit to another value depending on the available memory on the appliance.

**Configuring by using the CLI**

1. Display the cache parameter

```
1 > show cache parameter
2 Integrated cache global configuration:
3 Memory usage limit: 500 MBytes
4 Memory usage limit (active value): 500 MBytes
5 Maximum value for Memory usage limit: 843 MBytes
6 Via header: NS-CACHE-9.3: 18
7 Verify cached object using: HOSTNAME_AND_IP
8 Max POST body size to accumulate: 0 bytes
9 Current outstanding prefetches: 0
10 Max outstanding prefetches: 4294967295
11 Treat NOCACHE policies as BYPASS policies: YES
12 Global Undef Action: NOCACHE
13 <!--NeedCopy-->
```

1. Set a non-zero memory limit

```
set cache parameter -memlimit 600
```

**Note:**

The preceding command displays the following warning message: **Warning: To use a new Integrated Cache memory limit, save the configuration and restart the NetScaler appliance.**

1. Save the configuration

```
save config
```

1. From the shell prompt, run the following command to verify in the configuration file.

```
root@ns# cat /nsconfig/ns.conf | grep memLimit
```

1. Change the memory limit

```
set cache parameter -memLimit 600 -via NS-CACHE-9.3: 18 -verifyUsing
HOSTNAME_AND_IP -maxPostLen 0 -enableBypass YES -undefAction NOCACHE
```

1. Reboot the appliance

```
root@ns# reboot
```

1. Verify the new value for the memory limit

```
1 > show cache parameter
2 Integrated cache global configuration:
3 Memory usage limit: 600 MBytes
4 Memory usage limit (active value): 600 MBytes
5 Maximum value for Memory usage limit: 843 MBytes
6 Via header: NS-CACHE-9.3: 18
7 Verify cached object using: HOSTNAME_AND_IP
8 Max POST body size to accumulate: 0 bytes
9 Current outstanding prefetches: 0
10 Max outstanding prefetches: 4294967295
11 Treat NOCACHE policies as BYPASS policies: YES
12 Global Undef Action: NOCACHE
13 <!--NeedCopy-->
```

After all packet engines start successfully, the integrated caching feature negotiates the memory you had configured. If the appliance cannot use the configured memory, then the memory is allocated accordingly. If the available memory is less than the one you allocated, the appliance recommends a lesser number. The integrated caching feature uses same as the active value.

### **Integrated caching is disabled and cache memory limit is set to non-zero**

In this scenario, when you start the appliance, the integrated caching feature is disabled and the global memory limit is set to a positive number. Therefore, no memory is allocated to the integrated caching during the boot process.

### **Configuring by using the CLI**

1. Display the cache parameter

```
1 > show cache parameter
2 Integrated cache global configuration:
3 Memory usage limit: 600 MBytes
4 Maximum value for Memory usage limit: 843 MBytes
5 Via header: NS-CACHE-9.3: 18
6 Verify cached object using: HOSTNAME_AND_IP
7 Max POST body size to accumulate: 0 bytes
```

```
8 Current outstanding prefetches: 0
9 Max outstanding prefetches: 4294967295
10 Treat NOCACHE policies as BYPASS policies: YES
11 Global Undef Action: NOCACHE
12 <!--NeedCopy-->
```

1. Set a new memory limit

```
set cache parameter -memlimit 500
```

**Note:**

The preceding command displays the following warning message: **Warning: Feature not enabled [IC]**.

1. Save the configuration

```
save config
```

1. From the shell prompt, run the following command to verify in the configuration file

```
root@ns# cat /nsconfig/ns.conf | grep memLimit
```

1. Change the memory limit

```
set cache parameter -memLimit 500 -via NS-CACHE-9.3: 18 -verifyUsing
HOSTNAME_AND_IP -maxPostLen 0 -enableBypass YES -undefAction NOCACHE
```

1. Verify the new value for the memory limit

```
1 > show cache parameter
2 Integrated cache global configuration:
3 Memory usage limit: 500 MBytes
4 Maximum value for Memory usage limit: 843 MBytes
5 Via header: NS-CACHE-9.3: 18
6 Verify cached object using: HOSTNAME_AND_IP
7 Max POST body size to accumulate: 0 bytes
8 Current outstanding prefetches: 0
9 Max outstanding prefetches: 4294967295
10 Treat NOCACHE policies as BYPASS policies: YES
11 Global Undef Action: NOCACHE
12 <!--NeedCopy-->
```

1. Enable the integrated caching feature

```
enable ns feature IC
```

1. Verify the new value for the memory limit

```
1 > show cache parameter
2 Integrated cache global configuration:
3 Memory usage limit: 500 Mbytes
4 Memory usage limit (active value): 500 Mbytes
5 Maximum value for Memory usage limit: 843 MBytes
6 Via header: NS-CACHE-9.3: 18
7 Verify cached object using: HOSTNAME_AND_IP
8 Max POST body size to accumulate: 0 bytes
9 Current outstanding prefetches: 0
10 Max outstanding prefetches: 4294967295
11 Treat NOCACHE policies as BYPASS policies: YES
12 Global Undef Action: NOCACHE
13 <!--NeedCopy-->
```

**Note:**

500 MB of memory is allocated to the integrated caching feature.

1. Save the configuration to ensure that the memory is automatically allocated to the feature when the appliance is restarted.

**Integrated caching is enabled and cache memory is set to zero**

In this scenario, when you start the appliance, the integrated caching feature is enabled and the global memory limit is set to zero. Therefore, no memory is allocated to the integrated caching during the boot process.

**Configuring by using the CLI**

1. Verify the memory limits set in the ns.conf file from shell prompt

```
root@ns# cat ns.conf | grep memLimit
```

1. Change the memory limit

```
set cache parameter -memLimit 0 -via NS-CACHE-9.3: 18 -verifyUsing
HOSTNAME_AND_IP -maxPostLen 4096 -enableBypass YES -undefAction
NOCACHE
```

1. Verify the value for the memory limit

```
1 > show cache parameter
2 Integrated cache global configuration:
3 Memory usage limit: 0 Mbytes
4 Maximum value for Memory usage limit: 843 MBytes
5 Via header: NS-CACHE-9.3: 18
6 Verify cached object using: HOSTNAME_AND_IP
7 Max POST body size to accumulate: 0 bytes
```

```

8 Current outstanding prefetches: 0
9 Max outstanding prefetches: 4294967295
10 Treat NOCACHE policies as BYPASS policies: YES
11 Global Undef Action: NOCACHE
12 <!--NeedCopy-->

```

**Note:**

The memory limit is set to 0 MB and no memory is allocated to the integrated caching feature.

1. Set the memory limits to ensure the integrated caching feature caches objects

```
set cache parameter -memLimit 600
```

Once you run the preceding command, the appliance negotiates memory for the integrated caching feature and the available memory is assigned to the feature. It results in appliance caching objects without restarting the appliance.

1. Verify the value for the memory limit

```

1 > show cache parameter
2 Integrated cache global configuration:
3 Memory usage limit: 600 Mbytes
4 Memory usage limit (active value): 600 Mbytes
5 Maximum value for Memory usage limit: 843 MBytes
6 Via header: NS-CACHE-9.3:
7 Verify cached object using: HOSTNAME_AND_IP
8 Max POST body size to accumulate: 0 bytes
9 Current outstanding prefetches: 0
10 Max outstanding prefetches: 4294967295
11 Treat NOCACHE policies as BYPASS policies: YES
12 Global Undef Action: NOCACHE
13 <!--NeedCopy-->

```

**Note:**

600 MB of memory is allocated to the integrated caching feature.

1. Save the configuration. Ensure that the memory is automatically allocated to the feature when the appliance is restarted.
2. Verify the memory limits set in the ns.conf file from shell prompt

```
root@ns# cat /nsconfig/ns.conf | grep memLimit
```

1. Change the memory limit

```
set cache parameter -memLimit 600 -via NS-CACHE-9.3: -verifyUsing
HOSTNAME_AND_IP -maxPostLen 4096 -enableBypass YES -undefAction
NOCACHE
```

## Integrated caching is disabled and cache memory is set to zero

In this scenario, when you start the appliance, the integrated caching feature is disabled and the global memory limit is set to zero. Therefore, no memory is allocated to the integrated caching during the boot process.

### Configuring by using the CLI

1. Verify the memory limits set in the ns.conf file from shell prompt

```
root@ns# cat /nsconfig/ns.conf | grep memLimit
```

1. Change the memory limit

```
set cache parameter -memLimit 0 -via NS-CACHE-9.3: 18 -verifyUsing
 HOSTNAME_AND_IP -maxPostLen 4096 -enableBypass YES -undefAction
 NOCACHE
```

1. Verify the value for the memory limit

```
1 > show cache parameter
2 Integrated cache global configuration:
3 Memory usage limit: 0 Mbytes
4 Maximum value for Memory usage limit: 843 MBytes
5 Via header: NS-CACHE-9.3: 18
6 Verify cached object using: HOSTNAME_AND_IP
7 Max POST body size to accumulate: 0 bytes
8 Current outstanding prefetches: 0
9 Max outstanding prefetches: 4294967295
10 Treat NOCACHE policies as BYPASS policies: YES
11 Global Undef Action: NOCACHE
12 <!--NeedCopy-->
```

#### Note:

The memory limit is set to 0 MB and no memory is allocated to the integrated caching feature. Also, when you run any cache configuration command, the following warning message is displayed: **Warning: Feature not enabled [IC]**.

1. Enable the integrated caching feature

```
enable ns feature IC
```

#### Note:

At this stage, when you enable the integrated caching feature, the appliance does not allocate memory to the feature. As a result, no object is cached to the memory. Also, when you run

any cache configuration command, the following warning message is displayed: **No memory is configured for IC. Use set cache parameter command to set the memory limit.**

1. Set the memory limits to ensure the integrated caching feature caches objects

```
set cache parameter -memLimit 500
```

Once you run the preceding command, the appliance negotiates memory for the integrated caching feature and the available memory is assigned to the feature. It results in the appliance caching objects without restarting the appliance.

**Note:**

The order in which you enable the feature and set the memory limits is important. If you set the memory limits before enabling the feature, then the following warning message is displayed:

**Warning: Feature not enabled [IC].**

1. Verify the value for the memory limit

```

1 > show cache parameter
2 Integrated cache global configuration:
3 Memory usage limit: 500 Mbytes
4 Memory usage limit (active value): 500 Mbytes
5 Maximum value for Memory usage limit: 843 MBytes
6 Via header: NS-CACHE-9.3:
7 Verify cached object using: HOSTNAME_AND_IP
8 Max POST body size to accumulate: 0 bytes
9 Current outstanding prefetches: 0
10 Max outstanding prefetches: 4294967295
11 Treat NOCACHE policies as BYPASS policies: YES
12 Global Undef Action: NOCACHE
13 <!--NeedCopy-->
```

**Note:**

500 MB of memory is allocated to the integrated caching feature.

1. Save the configuration

```
save config
```

1. Verify the memory limits set in the ns.conf file from shell prompt

```
root@ns# cat /nsconfig/ns.conf | grep memLimit
```

1. Change the memory limit

```
set cache parameter -memLimit 500 -via NS-CACHE-9.3: 18 -verifyUsing
HOSTNAME_AND_IP -maxPostLen 4096 -enableBypass YES -undefAction
NOCACHE
```

## Configure selectors and basic content groups

May 2, 2023

You can configure selectors and apply them to content groups. When you add a selector to one or more content groups, you specify whether the selector is to be used for identifying cache requests or identifying cached objects to be invalidated (expired). Selectors are optional. Alternatively, you can configure content groups to use [hit](#) parameters and invalidation parameters. However, Citrix recommends that you configure selectors.

After configuring selectors, or deciding to use parameters instead, you are ready to set up a basic content group. After creating the basic content group, you need to decide how objects should be expired from the cache, and configure cache expiration. You can further modify the cache as described in [Improving Cache Performance](#) and [Configuring Cookies, Headers, and Polling](#), but you might first want to configure caching policies.

### Note

Content group parameters and selectors are used only at request time, and you typically associate them with policies that use `MAY_CACHE` or `MAY_NOCACHE` actions.

### Advantages of selectors

A selector is a filter that locates particular objects in a content group. If you do not configure a selector, the Citrix® ADC appliance looks for an exact match in the content group. This can lead to multiple copies of the same object residing in a content group. For example, a content group that does not have a selector may need to store URLs for `host1.domain.com\mypage.htm`, `host2.domain.com\mypage.htm`, and `host3.domain.com\mypage.htm`. In contrast, a selector can match just the URL (`mypage.html`, using the expression `http.req.url`) and the domain (`.com`, using the expression `http.req.hostname.domain`), allowing the requests to be satisfied by the same URL.

Selector expressions can perform simple matching of parameters (for example, to find objects that match a few query string parameters and their values). A selector expression can use Boolean logic, arithmetic operations, and combinations of attributes to identify objects (for example, segments of a URL stem, a query string, a string in a POST request body, a string in an HTTP header, a cookie). Selectors can also perform programmatic functions to analyze information in a request. For example, a selector can extract text in a POST body, convert the text into a list, and extract a specific item from the list.

For more information about expressions and what you can specify in an expression, see [Policies and Expressions](#).

## Use parameters Instead of selectors

Although Citrix recommends the use of selectors with a content group, you can instead configure [hit](#) parameters and invalidation parameters. For example, suppose that you configure three [hit](#) parameters in a content group for bug reports: BugID, Issuer, and Assignee. If a request contains BugID=456, with Issuer=RohitV and Assignee=Robert, the NetScaler appliance can serve responses that match these parameter-value pairs.

Invalidation parameters in a content group expire cached entries. For example, suppose that BugID is an invalidation parameter and a user issues a POST request to update a bug report. An invalidation policy directs the request to this content group, and the invalidation parameter for the content group expires all cached responses that match the BugID value. (The next time a user issues a GET request for this report, a caching policy can enable the NetScaler appliance to refresh the cached entry for the report from the origin server.)

Note that the same parameter can be used as a [hit](#) parameter or an invalidation parameter.

Content groups extract request parameters in the following order:

- URL query
- POST body
- Cookie header

After the first occurrence of a parameter, regardless of where it occurred in the request, all its subsequent occurrences are ignored. For example, if a parameter exists both in the URL query and in the POST body, only the one in the URL query is considered.

If you decide to use hit and invalidation parameters for a content group, configure the parameters when you configure the content group.

Note: Citrix recommends that you use selectors rather than parameterized content groups, because selectors are more flexible and can be adapted to more types of data.

## Configure a selector

A content group can use a hit selector to retrieve cache hits or use an invalidation selector to expired cached objects and fetch new ones from the origin server.

A selector contains a name and a logical expression, called an *advanced expression*.

For more information about advanced expressions, see [Policies and Expressions](#).

To configure a selector, you assign it a name and enter one or more expressions. As a best practice, a selector expression should include the URL stem and host, unless there is a strong reason to omit them.

To configure a selector by using the CLI

At the command prompt, type:

```
add cache selector \<selectorName\> (\<rule\> ...)
```

For information about configuring the expression or expressions, see [To configure a selector expression by using the command line interface](#).

```
1 >add cache selector product_selector "http.req.url.query.value(\"
 ProductId\")" "http.req.url.query.value(\"BatchNum\")" "http.req.url
 .query.value(\"depotLocation\")"
2
3 > add cache selector batch_selector "http.req.url.query.value(\"
 ProductId\")" "http.req.url.query.value(\"BatchId\")" "http.req.url.
 query.value(\"depotLocation\")"
4
5 > add cache selector product_id_selector "http.req.url.query.value(\"
 ProductId\")"
6
7 > add cache selector batchnum_selector "http.req.url.query.value(\"
 BatchNum\")" "http.req.url.query.value(\"depotLocation\")"
8
9 > add cache selector batchid_selector "http.req.url.query.value(\"
 depotLocation\")" "http.req.url.query.value(\"BatchId\")"
10
11 <!--NeedCopy-->
```

To configure a selector by using the GUI

Navigate to **Optimization > Integrated Caching > Cache Selectors**, and add the cache selector.

## Content groups

A content group is a container for cached objects that can be served in a response. When you first enable the integrated cache, cacheable objects are stored in a content group named Default. You can create content groups that have unique properties. For example, you can define separate content groups for image data, bug reports, and stock quotes, and you can configure the stock quote content group to be refreshed more often than the other groups.

You can configure expiration of an entire content group or selected entries in a content group.

The data in a content group can be static or dynamic, as follows:

- **Static content groups.** Finds an exact match between the URL stem and host name on the request and the URL stem and host name of the response.
- **Dynamic content groups.** Looks for objects that contain particular parameter-value pairs, arbitrary strings, or string patterns. Dynamic content groups are useful when caching data that is updated frequently (for example, a bug report or a stock quote).

### Serve a request from a content group

1. A user enters search criteria for an item, such as a bug report, and clicks the Find button in an HTML form.
2. The browser issues one or more HTTP GET requests. These requests contain parameters (for example, the bug owner, bug ID, and so on).
3. When the NetScaler appliance receives the requests, it searches for a matching policy, and if it finds a caching policy that matches these requests, it directs the requests to a content group.
4. The content group looks for appropriate objects in the content group, based on criteria that you configure in a selector.

For example, the content group can retrieve responses that match `NameField=username` and `BugID=ID`.

1. If it finds matching objects, the NetScaler appliance can serve them to the user's browser, where they are assembled into a complete response (for example, a bug report).

### Invalidate an object in a content group

1. A user modifies data (for example, the user modifies the bug report and clicks the Submit button).
2. The browser sends this data in the form of one or more HTTP requests. For example, it can send a bug report in the form of several HTTP POST requests that contain information about the bug owner and bug ID.
3. The NetScaler appliance matches the requests against invalidation policies. Typically, these policies are configured to detect the HTTP POST method.
4. If the request matches an invalidation policy, the NetScaler appliance searches the content group that is associated with this policy, and expires responses that match the configured criteria for invalidation.

For example, an invalidation selector can find responses that match `NameField=username` and `BugID=ID`.

1. The next time the NetScaler appliance receives a GET request for these responses, it fetches refreshed versions from the origin server, caches the refreshed responses, and serves these responses to the user's browser, where they are assembled into a complete bug report.

### **Set up a basic content group**

By default, all cached data is stored in the default content group. You can configure more content groups and specify these content groups in one or more policies.

You can configure content groups for static content, and you must configure content groups for dynamic content. You can modify the configuration of any content group, including the default group.

To set up a basic content group by using the command line interface

At the command prompt, type:

```
add cache contentgroup <name> (-hitSelector <hitSelectorName> -
invalSelector <invalidationSelectorName> | -hitParams <hitParamName>
-invalParams<invalidationParamName>)-type <type> [-relExpiry <sec> |
-relExpiryMilliSec <msec>] [-heurExpiryParam <positiveInteger>]

add cache contentgroup Products_Details -hitSelector product_selector
-invalSelector id_selector

add cache contentgroup bugrep -hitParams IssuePage RecordID Template
TableId -invalParams RecordID -relExpiry 864000
```

To set up a basic content group by using the GUI

Navigate to **Optimization > Integrated Caching > Content Groups**, and create the content group.

### Expire or flush cached objects

If a response does not have an Expires header or a Cache-Control header with an expiration time (Max-Age or Smax-Age), you must expire objects in a content group by using one of the following methods:

- Configure content group expiration settings to determine whether and how long to keep the object.
- Configure an invalidation policy and action for the content group. For more information, see [Configuring Policies for Caching and Invalidation](#).
- Expire the content group or objects within it manually.

After a cached response expires, the NetScaler appliance refreshes it the next time the client issues a request for the response. By default, when the cache is full, the NetScaler appliance replaces the least recently used response first.

The following list describes methods for expiring cached responses using settings for a content group. Typically, these methods are specified as a percent or in seconds:

- **Manual.** Manually invalidate all responses in a content group or all responses in the cache.
- **Response-based.** Specific expiration intervals for positive and negative responses. Response-based expiry is considered only if the Last-Modified header is missing in the response.
- **Heuristic expiry.** For responses that have a Last-Modified header, the heuristic expiry specifies the amount of time taken from when the response was modified (calculated as the current time minus the Last-Modified time, multiplied by the heuristic expiry value). For example, if a

Last-Modified header indicates that a response was updated 2 hours ago, and the heuristic expiry setting is 10%, cached objects expire after 0.2 hours. This method assumes that frequently updated responses must be expired more often.

- **Absolute or relative.** Specify an exact (absolute) time when the response expires every day, in HH:MM format, local time, or GMT. Local time may not work in all time zones.

Relative expiration specifies some seconds or milliseconds from the time a cache miss causes a trip to the origin server to the expiration of the response. If you specify relative expiration in milliseconds, enter a multiple of 10. This form of expiration works for all positive responses. Last-Modified, Expires, and Cache-Control headers in the response are ignored.

Absolute and relative expiration overrides any expiration information in the response itself.

- **On download.** The option Expire After Complete Response Received expires a response when it is downloaded. This is useful for frequently updated responses, for example, stock quotes. By default, this option is disabled.

Enabling both Flash Cache and Expire After Complete Response Received accelerates the performance of dynamic applications. When you enable both options, the NetScaler appliance fetches only one response for a block of simultaneous requests.

- **Pinned.** By default, when the cache is full the NetScaler appliance replaces the least recently used response first. The NetScaler appliance does not apply this behavior to content groups that are marked as pinned.

If you do not configure expiration settings for a content group, the following are more options for expiring objects in the group:

- Configure a policy with an INVALID action that applies to the content group.
- Enter the names of content groups when configuring a policy that uses an INVALID action.

### How expiration methods are applied

Expiration works differently for positive and negative responses. Positive and negative responses are described in the table, *Expiration of Positive, and Negative Responses* mentioned below.

The following are rules of thumb for understanding the expiration method that is applied to a content group:

- You can control whether the NetScaler appliance evaluates response headers when deciding whether to expire an object.
- Absolute and relative expiration causes the NetScaler appliance to ignore the response headers (they override any expiration information in the response).

- Heuristic expiration settings and “Weak Positive” and “Weak Negative” expiration (labeled as **Default** values in the configuration utility) cause the NetScaler appliance to examine the response headers. These settings work together as follows:
  - The value in an Expires or Cache-Control header overrides these content group settings.
  - For positive responses that lack an Expires or Cache-Control header but have a Last-Modified header, the NetScaler appliance compares heuristic expiration settings with the header value.
  - For positive responses that lack an Expires, Cache-Control, or Last-Modified header, the NetScaler appliance uses the “weak positive” value.
  - For negative responses that lack an Expires or Cache-Control header, the NetScaler appliance uses the “weak negative” value.

The following table describes how these methods are applied.

Response type	Expiration header type	Content Group Setting	Period the Object Remains in the Cache
Positive	Any header	Expire Content After (relExpiry) with no other settings	Use the value of the <b>Expire Content After</b> setting.
Positive	Any header	Expire Content At (absExpiry) with no other settings	Subtract current date from the value of the <b>Expire Content At</b> setting.
Positive	Any header	Expire Content After (relExpiry) and Expire content at (absExpiry)	Use the smaller of the two values for the content group settings. See the previous rows in this table.
Positive	Last-Modified (with any other headers)	Heuristic (heurExpiry Param) with any other setting	Subtract the Last-Modified date from the current date, multiply the result by the value of the heuristic expiry setting, and then divide by 100.
Positive	Last-Modified (with any other headers)	Default (positive) (weakPosRel Expiry) and no other setting	Use the value of the Default (positive) expiry setting.

Response type	Expiration header type	Content Group Setting	Period the Object Remains in the Cache
Positive	Expires or Cache-Control: Max-Age header is present	Last-Modified header is absent, Heuristic (heurExpiry Param), Default (positive) (weakPosRel Expiry), or both	Subtract the current date from the Expires or the Cache-Control:Max-Age date.
Positive	no caching headers	Default (positive) (weakPosRel Expiry) and any other expiration setting	Use the value of the Default (positive) setting.
Positive	no caching headers	Heuristic (heurExpiry Param) is present, Default (positive) (weakPosRel Expiry) setting is absent.	If the Last-Modified header is absent, the response is not cached or it is cached with an Already Expired status. If the Last-Modified header is present, use the heuristic expiry value.
Negative	Expires or Cache-Control:Max-Age	Expire Content After (relExpiry), Expire Content At (absExpiry), or both settings	Subtract the current date from the value of the Expires header, or use the value of the Cache-Control:Max-Age header.
Negative	Expires or Cache-Control headers are absent	Expire Content After (relExpiry), Expire Content At (absExpiry), or both settings	Response is not cached, or is cached with an Already Expired status.
Negative	Expires or Cache-Control:Max-Age	Any setting	Subtract the current date from the Expires or Cache-Control:Max-Age date.
Negative	Expires and Cache-Control:Max-Age headers are absent	Default (negative) (weakNegRel Expiry)	Use the value of the Default (negative) setting.

Response type	Expiration header type	Content Group Setting	Period the Object Remains in the Cache
Negative	Expires and Cache-Control:Max-Age headers are absent	Any setting other than Default (negative) (weakNegRel Expiry)	Object is not cached or is cached with an Already Expired status.

### Expire a content group by manual method

You can manually expire all of the entries in a content group.

To manually expire all responses in a content group by using the command line interface

At the command prompt, type:

```
expire cache contentGroup <name>
```

To manually expire all responses in a content group by using the GUI

Navigate to **Optimization > Integrated Caching > Content Groups**, select the content group, and click Invalidate to expire all the responses in a content group.

To manually expire all responses in the cache by using the GUI

Navigate to **Optimization > Integrated Caching > Content Groups**, and click Invalidate All to expire all the responses in cache.

### Configure periodic expiration of a content group

You can configure a content group so that it performs selective or full expiration of its entries. The expiration interval can be fixed or relative.

To configure content group expiration by using the command line interface

At the command prompt, type:

```
set cache contentgroup \<name> (-relExpiry|-relExpiryMilliSec|-absExpiry|-absExpiryGMT| -heurExpiryParam|-weakPosRelExpiry|-weakNegRelExpiry | -expireAtLastBye)\<expirationValue>
```

To configure content group expiration by using the GUI

Navigate to **Optimization > Integrated Caching > Content Groups**, select the content group, and specify expiry method.

## Expire individual responses

Expiring a response forces the NetScaler appliance to fetch a refreshed copy from the origin server. Responses that do not have validators, for example, [ETag](#) or Last-Modified headers, cannot be revalidated. As a result, flushing these responses has the same effect as expiring them.

To expire a cached response in a content group for static data, you can specify a URL that must match the stored URL. If the cached response is part of a parameterized content group, you must specify the group name and the exact URL stem. The host name and the port number must be the same as in the host HTTP request header of the cached response. If the port is not specified, port 80 is assumed.

To expire individual responses in a content group by using the command line interface

At the command prompt, type:

```
expire cache object -url <URL> -host <hostName> [-port <port>] [-groupname<contentGroupName>] [-httpMethod GET|POST]
```

To expire individual responses in a content group by using the CLI

At the command prompt, type the following command:

```
expire cache object -locator <positiveInteger>
```

To expire a cached response by using the GUI

Navigate to **Optimization > Integrated Caching > Cached Objects**, select the cached response, and expire.

To expire a response by using the GUI

Navigate to **Optimization > Integrated Caching > Cached Objects**, click **Search** and, set the search criteria to find the required cached response and expire.

## Flushing responses in a content group

You can remove, or flush, all responses in a content group, some responses in a group, or all responses in the cache. Flushing a cached response frees up memory for new cached responses.

### Note:

To flush responses for more than one object at a time, use the configuration utility method. The command line interface does not offer this option.

To flush responses from a content group by using the command line interface

At the command prompt, type:

```
flush cache contentGroup <name> [-query <queryString> | [-selectorValue <selectorExpressionIDList> -host <hostName>]]
```

To flush responses from a content group by using the GUI

1. Navigate to **Optimization > Integrated Caching > Content Groups**.
2. In the details pane, flush the responses as follows:
  - To flush all responses in all content groups, click **Invalidate All**, and flush all the responses.
  - To flush responses in a particular content group, select the content group, click **Invalidate**, and flush all the responses.

**Note:**

If this content group uses a selector, you can selectively flush responses by entering a string in the Selector value text box, entering a host name in the Host text box. Then click **Flush and OK**. The Selector value can be a query string of up to 2319 characters that is used for parameterized invalidation.

If the content group uses an invalidation parameter, you can selectively flush responses by entering a string in the **Query** field.

If the content group uses an invalidation parameter and Invalidate objects belonging to the target host is configured, enter strings in the **Query and Host** fields.

To flush a cached response by using the command line interface

At the command prompt, type:

```
flush cache object -locator <positiveInteger> | -url <URL> -host <
hostName> [-port <port>] [-groupName <contentGroupName>] [-httpMethod
GET|POST]
```

To flush a cached response by using the GUI

Navigate to **Optimization > Integrated Caching > Cached Objects**, select the cached object, and flush.

### Deleting a content group

You can remove a content group if it is not used by any policy that stores responses in the cache. If the content group is bound to a policy, you must first remove the policy. Removing the content group removes all responses stored in that group.

You cannot remove the Default, BASEFILE, or Deltas group. The Default group stores cached responses that do not belong in any other content group.

To delete a content group by using the command line interface

At the command prompt, type:

```
rm cache contentgroup <name>
```

To delete a content group by using the GUI

Navigate to **Optimization > Integrated Caching > Content Groups**, select the content group, and delete.

## Configure policies for caching and invalidation

May 2, 2023

Policies enable the integrated cache to determine whether to try to serve a response from the cache or the origin. The NetScaler appliance provides built-in policies for integrated caching, and you can configure more policies. When you configure a policy, you associate it with an action. An action either caches the objects to which the policy applies or invalidates (expires) the objects. Typically, you based caching policies on information in GET and POST requests. You typically base invalidation policies on the presence of the POST method in requests, along with other information. You can use any information in a GET or POST request in a caching or an invalidation policy.

You can view some of the built-in policies in the integrated cache's Policies node in the configuration utility. The built-in policy names begin with an underscore (\_).

Actions determine what the NetScaler appliance does when traffic matches a policy. The following actions are available:

- **Caching actions.** Policies that you associate with the CACHE action store responses in the cache and serve them from the cache.
- **Invalidation actions.** Policies that you associate with the INVALID action immediately expire cached responses and refresh them from the origin server. For Web-based applications, invalidation policies often evaluate POST requests.
- **“Do not cache” actions.** Policies that you associate with a NOCACHE action never store objects in the cache.
- **Provisionally cache actions.** Policies that you associate with a MAYCACHE or MAYNOCACHE action depend on the outcome of more policy evaluations.

Although the integrated cache does not store objects specified by the LOCK method, you can invalidate cached objects upon receipt of a LOCK request. For invalidation policies only, you can specify LOCK as a method by using the expression `http.req.method.eq("lock")`. Unlike policies for GET and POST requests, you must enclose the LOCK method in quotes because the NetScaler appliance recognizes this method name as a string only.

After you create a policy, you bind it to a particular point in the overall processing of requests and responses. Although you create a policy before binding it, you must understand how the bind points affect the order of processing before you create your policies.

The policies bound to a particular bind point constitute a policy bank. You can use goto expressions to modify the order of execution in a policy bank. You can also invoke policies in other policy banks. In addition, you can create labels and bind policies to them. Such a label is not associated with a processing point, but the policies bound to it can be invoked from other policy banks.

**Actions to associate with integrated caching policies**

The following table describes actions for integrated caching policies.

Action	Specification
CACHE	Serves a response from the cache if the response has not expired. If the response must be fetched from the origin server, the NetScaler appliance caches the response before serving it. Even data that is updated and accessed frequently can be cached. For example, stock quotes are updated frequently, but they can be cached so that they can be served quickly to multiple users. If necessary, cached data can be refreshed immediately after it is downloaded. A CACHE action can be overridden by built-in policies.
NOCACHE	Always fetches the response from the origin server and marks the response as non-storable. You typically configure NOCACHE policies for data that is sensitive or personalized.

---

Action	Specification
MAY_CACHE	Used in a request-time policy, this setting provisionally enables a response to be stored in a content group, pending evaluation of response-time policies. The following are possible: 1. If a matching response-time policy has a CACHE action but does not specify a content group, the response is stored in the Default group unless built-in policies override this policy. 2. If a matching response-time policy has a CACHE action and specifies the same content group as the one in the request-time policy, the response is stored in the named content group unless built-in policies override this policy. 3. If a matching response-time policy has a CACHE action but specifies a different content group from the one in the request-time policy, a NOCACHE action is applied. 4. If a matching response-time policy has a NOCACHE action, perform a NOCACHE action. 5. If there is no matching response-time policy, a CACHE action is applied, unless a built-in policy overrides this policy.
MAY_NOCACHE	For a request-time policy, this setting provisionally prevents caching the response. At response time, one of the following actions is taken: - If no response-time policy matches the request, the final action is NOCACHE. - If a matching response-time policy contains a CACHE action, the final action is CACHE, unless built-in policies override this policy. - If a matching response-time policy contains a NOCACHE action, the final action is NOCACHE. -If a matching response-time policy has a CACHE action but does not specify a content group, the final action is to CACHE the response in the Default content group, unless built-in policies override this policy.

Action	Specification
INVAL	Expires cached responses. Depending on how the policy and the content group are configured, all responses in one or more content groups are expired, or selected objects in the content group are expired. Note: You can specify INVAL actions in request-time policies only.

---

## Bind points for a policy

You can bind the policy to one of the following bind points:

- **A global policy bank.** These are the request-time default, request-time override, response-time default, and response-time override policy banks, as described in “[Order of Policy Evaluation](#).”
- **A virtual server.** Policies that you bind to a virtual server are processed after the global override policies and before the global default policies, as described in “[Order of Policy Evaluation](#).” When binding a policy to a virtual server, you bind it to either request-time or response-time processing.
- **An ad-hoc policy label.** A policy label is a name assigned to a policy bank. In addition to the global labels, the integrated cache has two built-in custom policy labels:
  - `_reqBuiltinDefaults`. This policy label, by default, is invoked from the request-time default policy bank.
  - `_resBuiltinDefaults`. This policy label, by default, is invoked from the response-time default policy bank.

You can also define new policy labels. Policies bound to a user-defined policy label must be invoked from within a policy bank for one of the built-in bind points.

### Important:

You must bind a policy with an INVAL action to a request-time override or a response-time override bind point. To delete a policy, you must first unbind it.

## Order of policy evaluation

For an advanced policy to take effect, you must ensure that the policy is invoked at some point during the NetScaler appliance’s processing of traffic. To specify the invocation time, you associate the policy with a bind point. The following are the bind points, listed in order of evaluation:

- **Request-time override.** If a request matches a request-time override policy, by default the request-time policy evaluation ends and the NetScaler appliance stores the action that is associated with the matching policy.
- **Request-time load balancing virtual server.** If policy evaluation cannot be completed after all the request-time override policies are evaluated, the NetScaler appliance processes request-time policies that are bound to load balancing virtual servers. If the request matches one of these policies, evaluation ends and the NetScaler appliance store the action that is associated with the matching policy.
- **Request-time content switching virtual server.** Policies that are bound to this bind point are evaluated after the request-time policies that are bound to load balancing virtual servers.
- **Request-time default.** If policy evaluation cannot be completed after all the request-time, virtual server-specific policies are evaluated, the NetScaler appliance processes the request-time default policies. If the request matches a request-time default policy, by default the request-time policy evaluation ends and the NetScaler appliance stores the action that is associated with the matching policy.
- **Response-time override.** Similar to request-time override policy evaluation.
- **Response-time load balancing virtual server.** Similar to request-time virtual server policy evaluation.
- **Response-time content switching virtual server.** Similar to request-time virtual server policy evaluation.
- **Response-time default.** Similar to request-time default policy evaluation.

You can associate multiple policies with each bind point. To control the order of evaluation of the policies associated with the bind point you configure a priority level. In the absence of any other flow control information, policies are evaluated according to priority level, starting with the lowest numeric priority value.

**Note:**

Request-time policies for POST data or cookie headers must be invoked during request-time override evaluation, because the built-in request-time policies in the integrated cache return a **NOCACHE** action for POST requests and a **MAY\_NOCACHE** action for requests with cookies. You would associate **MAY\_CACHE** or **MAY\_NOCACHE** actions with a request-time policy that points to a parameterized content group. The response time policy determines whether the transaction is stored in the cache.

## Configure a policy for integrated caching

You configure new policies to handle data that the built-in policies cannot process. You configure separate policies for caching, preventing caching from occurring, and for invalidating cached data. Following are the main components of a policy for integrated caching:

- Rule: A logical expression that evaluates an HTTP request or response.
- Action: You associate a policy with an action to determine what to do with a request or response that matches the policy rule.

Content groups: You associate the policy with one or more content groups to identify where the action is to be performed.

To configure a policy for caching by using the command line interface

At the command prompt, type:

```
add cache policy <policyName> -rule <expression> -actionCACHE|MAY_CACHE
|NOCACHE|MAY_NOCACHE [-storeInGroup <contentGroupName>] [-undefAction
NOCACHE|RESET]
> add cache policy image_cache -rule "http.req.url.contains("\jpg
\")|| http.req.url.contains("\jpeg\")"-action CACHE -storeingroup
myImages_group -undefaction NOCACHE
> add cache policy bugReportPolicy -rule "http.req.url.query.contains
("\IssuePage\")"-action CACHE -storeInGroup bugReportGroup
> add cache policy my_form_policy -rule "http.req.header("\Host
\").contains("\my.company.com\")&& http.req.method.eq("\GET\")&&
http.req.url.query.contains("\v=7\")"-action CACHE -storeInGroup
my_form_event
> add cache policy viewproducts_policy -rule "http.req.url.contains
("\viewproducts.aspx\")"-action CACHE -storeInGroup Product_Details
```

To configure a policy for invalidation by using the command line interface

At the command prompt, type:

```
1 add cache policy <policyName> -rule <expression> -action INVALID [-
 invalObjects "\<contentGroupName1>[,<selectorName1>"]. . .]] | [-
 invalGroup \<contentGroupName1>[, <contentGroupName2>. . .]] [-
 undefAction NOCACHE|RESET]
2 <!--NeedCopy-->
```

```
1 > add cache policy invalidation_events_policy -rule "http.req.header("
 Host").contains("my.company.com") && http.req.method.eq("GET") &&
 http.req.url.query.contains("v=8") -action INVALID -invalObjects
 my_form_event -undefaction NOCACHE
2 <!--NeedCopy-->
```

```
1 > add cache policy inval_all -rule "http.req.method.eq("POST") && http.
 req.url.contains("jpeg")" -action INVALID -invalGroups myImages_group
 myApps_group PDF_group
2 <!--NeedCopy-->
```

```

1 > add cache policy bugReportInvalidationPolicy -rule "http.req.url.
 query.contains(\"TransitionForm\")" -action INVAL -invalObjects
 bugReport`
2 `> add cache policy editproducts_policy -rule "http.req.url.contains
 (\"editproducts.aspx\")" -action INVAL -invalObjects "
 Product_Details,batchnum_sel" "Products_In_Depots,batchid_sel"
3 <!--NeedCopy-->

```

To configure a policy for caching or invalidation by using the GUI

Navigate to **Optimization > Integrated Caching > Policies**, and create the new policy.

### Globally binding an integrated caching policy

When you globally bind a policy, it is available to all virtual servers on the NetScaler appliance.

To bind an integrated caching policy globally by using the command line interface:

At the command prompt, type:

```

1 bind cache global <policy> -priority <positiveInteger> [-
 typeREQ_OVERRIDE|REQ_DEFAULT|RES_OVERRIDE|RES_DEFAULT] [-
 gotoPriorityExpression <expression>] [-invoke <labelType> <labelName
 >]
2 <!--NeedCopy-->

```

```

1 > bind cache global myCachePolicy -priority 100 -type req_default
2 <!--NeedCopy-->

```

#### Note:

The type argument is optional for globally bound policies, to maintain backward compatibility with policies that you defined using earlier versions of the NetScaler appliance. If you omit the type, the policy is bound to REQ\_DEFAULT or RES\_DEFAULT, depending on whether the policy rule is a response-time or a request-time expression. If the rule contains both request time and response time parameters, it is bound to RES\_DEFAULT. Following is an example of a binding that omits the type

Following is an example of a binding that omits the type.

```
> bind cache global myCache Policy 200
```

To bind an integrated caching policy globally by using the configuration utility

Navigate to **Optimization > Integrated Caching**, click **Cache Policy Manager** and bind policies by specifying the relevant bind point and connection type (Request/Response).

## Bind an integrated caching policy to a virtual server

When you bind a policy to a virtual server, it is available only to requests and responses that match the policy and that flow through the relevant virtual server.

When using the GUI, you can bind the policy using the configuration dialog box for the virtual server. This enables you to view all of the policies from all NetScaler modules that are bound to this virtual server. You can also use the **Policy Manager configuration** dialog for the integrated cache. This enables you to view only the integrated caching policies that are bound to the virtual server.

To bind an integrated caching policy to a virtual server by using the command line interface:

At the command prompt, type:

```
1 bind lb vserver <name>@ -policyName <policyName> -priority <
 positiveInteger> -type(REQUEST|RESPONSE)
2 <!--NeedCopy-->
```

```
1 bind cs vserver <name>@ -policyName <policyName> -priority <
 positiveInteger> -type(REQUEST|RESPONSE)
2 <!--NeedCopy-->
```

To bind an integrated caching policy to a virtual server by using the configuration utility (virtual server method)

- CS Virtual Server - Navigate to **Traffic Management > Content Switching > Virtual Servers**, select the virtual server, and bind relevant cache policies.
- LB Virtual Server - Navigate to **Traffic Management > Load Balancing > Virtual Servers**, select the virtual server, and bind relevant cache policies.

To bind an integrated caching policy to a virtual server by using the GUI (Policy Manager method).

Navigate to **Optimization > Integrated Caching**, click **Cache Policy Manager**, and bind cache policies by specifying the relevant bind point and connection type.

### Note:

You can bind cache policies to both load balancing virtual server and content switching virtual server by selecting the appropriate bind point.

## How to cache compressed and uncompressed versions of a file

By default, a client that can handle compression can be served uncompressed responses or compressed responses in gzip, deflate, compress, and pack200-gzip format. If the client handles compression, an `Accept-Encoding: compression` format header is sent in the request. The compression type accepted by the client must match the compression type of the cached object. For ex-

ample, a `cached.gz` file cannot be served in response to a request with an `Accept-Encoding: deflate` header.

A client that cannot handle compression is served a cache miss if the cached response is compressed.

For dynamic caching, you need to configure two content groups, one for compressed data and one for uncompressed versions of the same data. The following is an example of configuring the selectors, content groups, and policies for serving uncompressed files from the cache to clients that cannot handle compression, and serving compressed versions of the same files to the client that can handle compression.

```
add cache selector uncompressed_response_selector http.req.url "http.
req.header(\"Host\")"

add cache contentGroup uncompressed_group -hitSelector uncompressed_responst_s
-invalSelector uncomp_resp_sel

add cache policy cache_uncompressed -rule "HTTP.REQ.URL.CONTAINS(\"
xyz\")&& !HTTP.REQ.HEADER(\"Accept-Encoding\").EXISTS"-action CACHE -
storeInGroup uncompressed_group

bind cache global cache_uncompressed -priority 100 -gotoPriorityExpression
END -type REQ_OVERRIDE

add cache selector compressed_response_selector HTTP.REQ.URL "HTTP.
REQ.HEADER(\"Host\")""HTTP.REQ.HEADER(\"Accept-Encoding\")"

add cache contentGroup compressed_group -hitSelector compressed_response_selec

add cache policy cache_compressed -rule "HTTP.REQ.URL.CONTAINS(\"
xyz\")&& HTTP.REQ.HEADER(\"Accept-Encoding\").EXISTS"-action CACHE -
storeInGroup compressed_group

bind cache global cache_compressed -priority 200 -gotoPriorityExpression
END -type REQ_OVERRIDE
```

### **Configure a policy bank for caching**

All of the policies that are associated with a particular bind point are collectively known as a policy bank. In addition to configuring priority levels for policies in a bank, you can modify the order of evaluation in a bank by configuring Goto expressions. You can further modify the evaluation order by invoking an external policy bank from within the current policy bank. You can also configure new policy banks, to which you assign your own labels. Because such policy banks are not bound to any point

in the processing cycle, they can be invoked only from within other policy banks. For convenience, policy banks whose labels do not correspond to a built-in bind point are called policy labels.

In addition to controlling the order of policy evaluation by binding the policy and assigning a priority level, as described in “[Binding Policies](#)”, you can establish the flow within a bank of policies by configuring a Goto expression. A Goto expression overrides the flow that is determined by the priority levels. You can also control the evaluation flow by invoking an external policy bank after evaluating an entry in the current bank. Evaluation always returns to the current bank after evaluation has completed.

The following table summarizes the entries to control evaluation in a policy bank.

---

<b>Attribute</b>	<b>Specifies</b>
Name	The name of a policy, or, to invoke another policy bank without evaluating the policy, the keyword NOPOLICY. You can specify NOPOLICY more than once in a policy bank, but you can specify a named policy only once.
Priority	An integer. The lower the integer, the higher the priority.
Goto Expression	Determines the next policy or policy bank to evaluate. You can provide one of the following values: 1. NEXT: Go to the policy with the next higher priority. 2. END: Stop evaluation. 3. USE_INVOCATION_RESULT: Applicable if this entry invokes another policy bank. If the final Goto in the invoked bank has a value of END, evaluation stops. If the final Goto is anything other than END, the current policy bank performs a NEXT. 4. Positive number: Priority number of the next policy to be evaluated. 5. Numeric expression: Expression that produces the priority number of the next policy to be evaluated. The Goto can only proceed forward in a policy bank. Omitting the Goto expression is the same as specifying END.

Attribute	Specifies
Invocation Type	Designates a policy bank type. The value can be one of the following - 1. Request virtual server: Invokes request-time policies that are associated with a virtual server. 2. Response virtual server: Invokes response-time policies that are associated with a virtual server. 3. Policy label: Invokes another policy bank, as identified by the policy label for the bank.
Invocation Name	Name of a virtual server or a policy label, depending on the value that you specified for the Invocation Type.

The integrated cache has two built-in policy labels, and you can configure more policy labels:

`_reqBuiltInDefaults`: This policy label is invoked from the request-time default bind point.

`_resBuiltInDefaults`: This policy label is invoked from the response-time default bind point.

To invoke a policy label in a caching policy bank by using the command line interface

At the command prompt, type:

```
1 bind cache polycylabel <labelName> -policname<policyName> -priority<
 priority> [-gotoPriorityExpression <gotopriorityExpression>] [-
 invoke <labelType> <labelName>]
2 <!--NeedCopy-->
```

To invoke a policy label in a caching policy bank by using the GUI:

1. Navigate to **Optimization > Integrated Caching**, click **Cache policy manager**, and specify the relevant bind point (Override Global or Default Global) and connection type to view the list of policies bound to this bind point.
2. If you want to invoke a policy label without evaluating a policy, click **NOPOLICY**.

**Note:**

To invoke an external policy bank, click the field in the Invoke Type column, and select the type of policy bank that you want to invoke at this point in the policy bank. This can be a global label or a virtual server bank. In the Invoke Name field, enter the label or virtual server name.

To invoke a caching policy label in a virtual server policy bank by using the command line interface

At the command prompt, type:

```
1 bind lb vserver <name>@ -policyName <policyName>|<NOPOLICY-CACHE> -
 priority<positiveInteger> -gotoPriorityExpression <expression> -type
 REQUEST|RESPONSE -invoke<labelType> <labelName>
2 <!--NeedCopy-->
```

```
1 bind cs vserver <name> -policyName <policyName>|<NOPOLICY-CACHE> -
 priority<positiveInteger> -gotoPriorityExpression <expression> -type
 REQUEST|RESPONSE -invoke<labelType> <labelName>
2 <!--NeedCopy-->
```

To invoke a caching policy label in a virtual server policy bank by using the GUI

1. Navigate to **Traffic Management > Load Balancing/Content Switching > Virtual Servers**, select the virtual server, and click **Policies**.
2. If you are configuring an existing entry in this bank, skip this step. If you are adding a new policy to this policy bank, or you want to use the “dummy”NOPOLICY entry, click **Add** and do one of the following:
  - To configure a new policy, click Cache and configure the new policy as described in [Configuring a Policy in the Integrated Cache](#).
  - To invoke a policy bank without processing a policy a rule, select the **NOPOLICY-CACHE** option.

**Note:**

To invoke an external policy bank, click the field in the Invoke Type column, and select the type of policy bank that you want to invoke at this point in the policy bank. This can be a global label or a virtual server bank. In the Invoke Name field, enter the label or virtual server name.

## Configure a policy label in an integrated cache

In addition to configuring policies in a policy bank for one of the built-in bind points or a virtual server, you can create caching policy labels and configure banks of policies for these new labels.

A policy label for the integrated cache can be invoked only from one of the bind points that you can view in the Policy Manager in the **Integrated Caching** details pane (request override, request default, response override, or response default) or the built-in policy labels `\\_reqBuiltinDefaults` and `\\_resBuiltinDefaults`. You can invoke a policy label any number of times unlike a policy, which can only be invoked once.

The NetScaler GUI provides an option to rename a policy label. Renaming a policy label does not affect the process of evaluation of the policies bound to the label.

**Note:**

You can use the `NOPOLICY` “dummy” policy to invoke any policy label from another policy bank. The `NOPOLICY` entry is a placeholder that does not process a rule.

To configure a policy label for caching by using the command line interface

At the command prompt, type the following command to create a policy label and verify the configuration:

- `add cache policylabel <labelName> -evaluates (REQ|RES)`
- `show cache policylabel <labelName>`

Invoke this policy label from a policy bank.

To configure a policy label for caching by using the GUI:

Navigate to **Optimization > Integrated Caching > Policy Labels**, add a policy label, and bind the cached policies.

**Note:**

To ensure that the NetScaler processes the policy label at the right time, configure an invocation of this label in one of the policy banks that are associated with the built-in bind points.

To rename a policy label by using the GUI:

Navigate to **Optimization > Integrated Caching > Policy Labels** select the policy label, and rename.

## Unbind and delete an integrated caching policy and policy label

You can unbind a policy from a policy bank, and you can delete it. To delete the policy, you must first unbind it. You can also remove a policy label invocation and delete a policy label. To delete the policy label, you must first remove any invocations that you have configured for the label.

You cannot unbind or delete the labels for the built-in bind points (request default, request override, response default, and response override).

To unbind a global caching policy by using the command line interface

At the command prompt, type:

```
unbind cache global <policy>
```

To unbind a virtual server-specific caching policy by using the command line interface

At the command prompt, type:

```
(unbind lb vserver|unbind cs vserver)<vserverName> -policyName <
policyName> -type(REQUEST|RESPONSE)
```

To delete a caching policy by using the command line interface

At the command prompt, type:

```
rm cache policy <policyName>
```

To unbind a caching policy by using the GUI:

Navigate to **Optimization > Integrated Caching**, click **Cache Policy Manager**, and unbind policies by specifying the relevant bind point and connection type (Request/Response).

To delete a policy label invocation by using the GUI:

1. Navigate to **Optimization > Integrated Caching**, click **Cache policy manager**, and specify the relevant binding point (load balancing virtual server or content switching virtual server) and connection type to view the list of cache policies bound to this virtual server.
2. In the policy Invoke column, clear the entry.

## Cache support for database protocols

May 2, 2023

The integrated cache feature monitors and caches database request as determined by the cache policies. Users must configure the cache policies for MYSQL and MSSQL protocols as the NetScaler appliance does not provide any default policies. When configuring the default protocols, remember the request-based policies support only CACHE and INVALID actions, while the response-based policies support only "NOCACHE" action. After configuring the policies, you must bind them to virtual servers. MYSQL and MSSQL policies, both request and response, are bound only to virtual servers.

Before creating a cache policy, you must create a cache content group of type MYSQL or MSSQL. When you create a cache content group, associate at least one select selector with it. See [Setting Up a Basic Content Group](#) for setting up a cache content group.

The following example explains how to configure and verify cache support for SQL protocols.

```
1 > enable feature IC
2 > set cache parameter -memlimit 100
3 > add cache selector sel1 mssql.req.query.text
4
5 > add cache contentgroup cg1 -type "MSSQL" -hitselector "sel1" -
 invalselector "inval_sel" -relExpiry "500" -maxResSize
6 "100"
7 > add cache policy cp1 -rule "mssql.req.query.command.contains(\"
 select\")" -action "CACHE" -storeInGroup "cg1"
```

```

 8 > add cache policy cp2 -invalObjects "cg1" -rule "mssql.req.query.text
 .contains(\"insert\")" -action "INVAL"
 9 > add db user user1 -password "Pass1"
10 > add service svc_sql_1 10.102.147.70 mssql 64834 -healthMonitor "NO" -
 downstateflush "ENABLED"
11 > add lb vserver lb_mssql1 mssql 10.102.147.77 1433 -lbmethod "
 roundrobin"
12 > bind lb vserver lb_mssql1 svc_sql_1
13 > bind lb vserver lb_mssql1 -policyName cp1 -type "REQUEST" -priority
 "2"
14 > bind lb vserver lb_mssql1 -policyName cp2 -type "REQUEST" -priority
 "1"
15
16 > show cache selector sel1
17 Name:sel1
18 Expressions:
19 1)mssql.req.query.text
20 > show cache policy cp1
21 Name:cp1
22 Rule:mssql.req.query.command.contains("select")
23 CacheAction:CACHE
24 Stored in group: cg1
25 UndefAction:Use Global
26 Hits:2
27 Undef Hits:0
28 Policy is bound to following entities
29 1) Bound to:
30 REQ VSERVER lb_mssql1
31 Priority:2
32 GotoPriorityExpression: END
33 <!--NeedCopy-->

```

**Note:**

The methods for reducing flash crowds, as explained in [Reducing Flash Crowds](#), are not supported for MYSQL and MSSQL protocols.

## Configure expressions for caching policies and selectors

November 2, 2023

A request-time expression examines data in the request-time transaction, and a response-time expression examines data in a response-time transaction. In a policy for caching, if an expression matches data in a request or response, the NetScaler appliance takes the action associated with the policy. In a selector, request-time expressions are used to find matching responses that are stored in a content group.

Before configuring policies and selectors for the integrated cache, you need to know, at minimum, the host names, paths, and IP addresses that appear in HTTP request and response URLs. And you probably need to know the format of entire HTTP requests and responses. Programs such as Live HTTP Headers <http://livehttpheaders.mozdev.org/>) or HTTPFox <https://addons.mozilla.org/en-US/firefox/addon/6647> can help you investigate the structure of the HTTP data that your organization works with.

Following is an example of an HTTP GET request for a stock quote program:

```

1 GET /quote.dll?page=dynamic&mode=data&mode=stock&symbol=CTXS&page=multi
 &selected=CTXS&random=0.00792039478975548 HTTP/1.1
2
3 Host: quotes.mystockquotes.com
4
5 User-Agent: Mozilla/5.0 (Windows; U; Windows NT 5.1; en-US; rv:1.9)
 Gecko/2008052906 Firefox/3.0
6
7 Accept: text/html,application/xhtml+xml,application/xml;q=0.9,*/*;q=0.8
8
9 Accept-Language: en-us,en;q=0.5
10
11 Accept-Encoding: gzip,deflate,compress,pack200-gzip
12
13 Accept-Charset: ISO-8859-1,utf-8;q=0.7,*;q=0.7
14
15 Keep-Alive: 300
16
17 Connection: keep-alive
18
19 Referer: http://quotes.mystockquotes.com/quote.dll?mode=stock&symbol=
 CTXS&page=multi&selected=CTXS
20
21 Cookie: __qca=1210021679-72161677-10297606
22 <!--NeedCopy-->

```

When configuring an expression, note the following limitations:

Expression Type	Restrictions
Request	Do not configure request-time expressions in a policy with a CACHE or NOCACHE action. Use MAY_CACHE or MAY_NOCACHE instead.

Expression Type	Restrictions
Response	Configure response-time expressions in caching policies only. Selectors can use only request-time expressions, Do not configure response-time expressions in a policy with an INVALID action. Note: Do not configure response-time expressions in a policy with a CACHE action and a parameterized content group. Use the MAY_CACHE action.

**Note:**

For a comprehensive discussion of advanced expressions, see [Policies and Expression](#).

## Expression syntax

Following are the basic components of the syntax:

- Separate keywords with periods (.), as follows:

```
http.req.url
```

- Enclose string values in parentheses and quotes, as follows:

```
http.req.url.query.contains("this")
```

- When configuring an expression from the command line, you must escape internal quote marks (the quotes that delimit the values in the expression, as opposed to the quotes that delimit the expression). One method is to use a slash, as followings:

```
\ "abc\"
```

Selector expressions are evaluated in order of appearance, and multiple expressions in a selector definition are joined by a logical AND. Unlike selector expressions, you can specify Boolean operators and modify the precedence in an advanced expression for a policy rule.

## Configure an expression in a caching policy or a selector

**Note:**

The syntax for a policy expression is different from a selector expression. For a comprehensive discussion of advanced expressions, see “Policies and Expressions.”

To configure a policy expression by using the command line interface

1. Start the policy definition as described in “Globally Binding an Integrated Caching Policy.”
2. To configure the policy rule, delimit the entire rule in quotes, and delimit string values within the rule in escaped quotes.

The following is an example:

```
“http.req.url.contains(“jpg”)”
```

---

To add Boolean values, insert &&,  

---

- 1.

The following are examples:

```
"http.req.url.contains(\"jpg\") || http.req.url.contains(\"jpeg\")"
```

```
"http.req.url.query.contains(\"IssuePage\")"
```

```
"http.req.header(\"Host\")contains(\"my.company.com\")&& http.req.method.eq(\"GET\")&& http.req.url.query.contains(\"v=7\")"
```

1. To configure an order of evaluation for the constituent parts of a compound

```
"http.req.url.contains(\"jpg\") || (http.req.url.contains(\"jpeg\")&& http.req.method.eq(\"GET\"))"
```

To configure a selector expression by using the command line interface:

1. Start the selector definition as described in “About Content Groups.”
2. To configure the selector expression, delimit the entire rule in quotes, and delimit string values within the rule in escaped quotes.

The following is an example:

```
"http.req.url.contains(\"jpg\")"
```

---

You cannot add Boolean values, insert &&,  

---

- 1.

The following are examples:

```
1 "http.req.url.query.value(\"ProductId\")" "http.req.url.query.value(\"BatchNum\")" "http.req.url.query.value(\"depotLocation\")"
2 <!--NeedCopy-->
```

To configure a policy or selector expression by using the GUI

1. Start the policy or selector definition as described in “To configure a policy for caching or invalidation by using the configuration utility” or “To configure a selector by using the configuration utility.”
  2. In the **Expression** field, you can either manually type the Advanced policy by clicking Switch to Classic Syntax or create new expression using **Expression Editor**.
- 

To insert an operator between two parts of a compound expression, click the Operators button and select the operator type. The following is an example of a configured expression with a Boolean OR (signaled by double vertical bars,

---

- 3.
4. Click **Frequently Used Expressions** drop-down list to insert the commonly used expressions.
5. To test the expression, click the **Evaluate**. In the **Expression Evaluator** dialog box, select the Flow Type that matches the expression. In the data field, paste the HTTP request or response that you hope to parse using the expression, and click **Evaluate**.

## Display cached objects and cache statistics

You can view particular cached objects, and you can view summary statistics on cache requests, misses, and memory usage. The statistics provide insight on the amount of data that is being served from the cache, what items are responsible for the largest performance benefit, and what you can tune to improve cache performance.

This section includes the following details:

- Viewing Cached Objects
- Finding Particular Cached Responses
- Viewing Cache Statistics

## View cached objects

After enabling caching, you can view details for cached objects. For example, you can view the following items:

- Response sizes and header sizes
- Status codes
- Content groups
- **E**T**a**g, Last-Modified, and Cache-Control headers
- Request URLs

- Hit parameters
- Destination IP addresses
- Request and response times

To view a list of cached objects by using the command line interface

At the command prompt, type:

```
show cache object
```

---

<b>Properties</b>	<b>Description</b>
Response size (bytes)	The size of the response header and body.
Response header size (bytes)	The size of the header portion of the response.
Response status code	The status code sent with the response.
ETag	The ETag header inserted in the response. Typically, this header indicates whether the response has changed recently.
Last-Modified	The Last-Modified header inserted in the response. This header indicates the date that the response was last changed.
Cache-Control	The Cache-Control header inserted in the response.
Date	The Date header that indicates when the response was sent.
Contentgroup	The content group where the response is stored.
Complex match	If this object was cached based on parameterized values, this field value is YES.
Host	The host specified in the URL that requested this response.
Host port	The listen port for the host specified in the URL that requested this response
URL	The URL issued for the stored response.
Destination IP	The IP address of the server from which this response was fetched.
Destination port	The listen port for the destination server.
Hit parameters	If the content group that stores the response uses hit parameters, they are listed in this field.

<b>Properties</b>	<b>Description</b>
Hit selector	If this content group uses a hit selector, it is listed in this field.
Inval selector	If this content group uses an invalidation selector, it is listed in this field.
Selector Expressions	If this content group uses a selector, this field displays the expression that defines the selection rule.
Request time	The time in milliseconds since the request was issued.
Response time	The time in milliseconds since the cache started to receive the response.
Age	Amount of time the object has been in the cache.
Expiry	Amount of time after which the object is marked as expired.
Flushed	Whether the response has been flushed after expiry.
Prefetch	If Prefetch has been configured for this content group, the amount of time before expiry during which the object is fetched from the origin. Prefetch does not apply to negative objects (for example, 404 “object not found” responses).
Current readers	Approximately the current number of requests being served. When a response with a Content-Length header object is being downloaded, the current misses and the current readers values are each typically 1. When a chunked response object is being downloaded, the current misses value is typically 1, but the current readers value is typically 0, because the chunked response that is served to the client does not come from the integrated caching buffers.
Current misses	The current number of requests that resulted in a cache miss and fetching from the origin server. This value is typically 0 or 1. If Poll Every Time is enabled for a content group, the count can be greater than 1.

<b>Properties</b>	<b>Description</b>
Hits	The number of cache hits for this object.
Misses	The number of cache misses for this object
Compression format	The type of compression applied to this object. Compression formats include gzip, deflate, compress, and pack200-gzip.
HTTP version in response	The version of HTTP that was used to send the response.
Weak etag present in response	Strong etag headers change if the bits of an entity change. Strong headers are based on the octet values of an object. Weak etag headers change if the meaning of an entity changes. Weak etag values are based on semantic identity. Weak etags values start with a “W.”
Negative marker cell	A marker object is cacheable, but it does not yet meet all the criteria for being cached. For example, the object may exceed the maximum response size for the content group. A marker cell is created for objects of this type. The next time a user sends a request for this object, a cache miss is served.
Reason marker created	The reason a marker cell was created (for example, “Waiting for minhit,”“Content-length response data is not in group size limit”).
Auto poll every time	If the integrated cache receives an already expired 200 OK response with validators (either the Last-Modified or the ETag response headers) it stores the response and marks it as Auto-PET (automatically poll every time).
NetScaler Etag inserted in response	A variation of the ETag header generated by the NetScaler appliance. A value of YES appears if the NetScaler inserts an Etag in the response.
Full response present in cache	Indicates whether this is a complete response.
Destination IP verified by DNS	Indicates whether DNS resolution was performed when storing the object.

<b>Properties</b>	<b>Description</b>
Object stored through a cache forward proxy	Indicates whether this response was stored due to a forward proxy that is configured in the integrated cache.
Object is a Delta basefile	A response that is delta-compressed.
Waiting for minhits	Indicates whether this content group requires a minimum number of origin servers hit before caching a response.
Minhit count	If this content group requires a minimum number of origin server requests before caching an object, this field displays a count of the number of requests received so far.
HTTP Request Method	The method, GET or POST, used in the request that obtained this object.
Stored by policy	The name of the caching policy that caused this object to be stored. A value of NOT AVAILABLE indicates that the policy has been deactivated or deleted. A value of NONE indicates that the object did not match a visible policy, but was stored according to internal criteria for caching.
Application firewall metadata exists	This parameter is used when the application firewall and the integrated cache are both enabled. The application firewall analyzes the contents of a response page, stores its metadata (for example, URLs and forms contained in page), and exports the metadata with the response to the cache. The cache stores the page and the metadata, and when the cache serves the page, it sends the metadata back to the request's session.
HTTP callout object, name, type, response	These cells indicate whether this data was stored as a result of an HTTP Callout expression, and provide information about various aspects of the callout and the corresponding response. For more information about HTTP callouts, see "HTTP Callouts".

---

To view cached objects by using the GUI

Navigate to **Optimization > Integrated Caching > Cache Objects**. You can view all the cached objects and sort them accordingly as per your requirement.

### Find particular cached responses

You can find individual items in the cache based on search criteria. There are different methods for finding cached items, depending on whether the content group that contains the data uses hit and invalidation selectors, as follows:

- If the content group uses selectors, you can only conduct the search using the Locator ID for the cached item.
- If the content group does not use selectors, you conduct the search using criteria such as URL, host, content group name.

When searching for a cached response, you can locate some items by URL and host. If the response is in a content group that uses a selector, you can find it only by using a Locator number (for example, 0x00000000ad7af00000050). To save a Locator number for later use, right-click the entry and select **Copy**. For more information about selectors, see “[Configuring Selectors and Basic Content Groups](#).”

To display cached responses in content groups that do not have a selector by using the command line interface

At the command prompt, type:

```
show cache object [-locator <positiveInteger>] | [(-url <URL> (-host <hostName> [-port <port>] [-groupName <contentGroupName>] [-httpMethod GET | POST])) | [-HttpStatus <positive integer>] | -group <contentGroupName> | -ignoreMarkerObjects (ON | OFF) | -includeNotReadyObjects (ON | OFF)]
```

To display cached responses in content groups that have a selector by using the command line interface

At the command prompt, type:

```
show cache object -locator <locatorString> MarkerObjects (ON | OFF) | -includeNotReadyObjects (ON | OFF) | [-HttpStatus<positive integer>]
```

To display cached responses in content groups that do not have a selector by using the configuration utility

Navigate to **Optimization > Integrated Caching > Cache Objects**, click Search, and set the search criteria to view the required cached response.

If you have not yet configured any content groups, all of the objects are in the Default group.

## View cache statistics

The following table summarizes the detailed cache statistics that you can view.

Counter	Description
Hits	Responses that are found in and served from the integrated cache. Includes static objects such as image files, pages with status codes 200, 203, 300, 301, 302, 304, 307, 403, 404, 410, and responses that match a user-defined policy with a CACHE action.
Misses	Intercepted HTTP requests where the response was ultimately fetched from origin server.
Requests	Total cache requests plus total cache misses.
Non-304 hits	If the user requests an item more than once, and the item in the cache is unchanged since the last time the NetScaler appliance served it, the NetScaler appliance serves a 304 response instead of the cached object.
This statistic indicates how many items the NetScaler appliance served from the cache, excluding 304 responses.	
304 hits	Number of 304 (object not modified) responses the NetScaler appliance served from the cache.
304 hit ratio (%)	Percentage of 304 responses that the NetScaler appliance served, relative to other responses.
Hit ratio (%)	Percentage of responses that the NetScaler appliance served from the cache (cache requests) relative to responses that could not be served from the cache.
Origin bandwidth saved (%)	An estimate of the processing capacity that the NetScaler appliance saved on the origin server due to serving responses from the cache.
Bytes served by the NetScaler	Total number of bytes that the NetScaler appliance served from the origin server and the cache.
Bytes served by cache	Total number of bytes that the NetScaler appliance served from the cache.

Counter	Description
Byte hit ratio(%)	Percentage of data that the NetScaler appliance served from the cache, relative to all of the data in all served responses.
Compressed bytes from cache	Amount of data, in bytes, that the NetScaler appliance served in compressed form.
Storable misses	If the NetScaler appliance does not find a requested object in the cache, it fetches the object from the origin server. This is known as a cache miss. A storable cache miss can be stored in the cache.
Non-storable misses	A non-storable cache miss cannot be stored in the cache.
Misses	All cache misses.
Revalidations	Max-Age setting in a Cache-Control header determines, in number of seconds, when an intervening cache must revalidate the content with the integrated cache before serving it to the user.
For more information, see “Inserting a Cache-Control Header.”	
Successful revalidations	Number of revalidations that have been performed.
For more information, see “Inserting a Cache-Control Header.”	
Conversions to conditional req	A user-agent request for a cached PET object is always converted to a conditional request and sent to the origin server.
For more information, see “Polling the Origin Server Every Time a Request Is Received.”	
Storable miss ratio (%)	Storable cache misses as a percentage of non-storable cache misses.
Successful reval ratio (%)	Successful revalidations as a percentage of all revalidation attempts.
For more information, see “Inserting a Cache-Control Header.”	

Counter	Description
<p>Expire at last byte</p> <p>For more information, see “Example of Performance Optimization.”</p> <p>Flashcache misses</p>	<p>Number of times that the cache expired content immediately after receiving the last body byte. Only applicable to positive responses, as described in the table “Cache Hits and Misses.”</p> <p>If you enable Flash Cache, the cache allows only one request to reach the server, eliminating flash crowds. This statistic indicates the number of Flash Cache requests that were cache misses.</p>
<p>For more information, “Queuing Requests to the Cache.”</p> <p>Flashcache hits</p>	<p>Number of Flash Cache requests that were cache hits.</p>
<p>For more information, see “Queuing Requests to the Cache.”</p> <p>Parameterized inval requests</p>	<p>Requests that match a policy with an invalidation (INVALID) action and a content group that uses an invalidation selector or parameters to selectively expire cached objects in the group.</p>
<p>Full inval requests</p>	<p>Requests that match an invalidation policy where the invalGroups parameter is configured and expires one or more content groups.</p>
<p>Inval requests</p>	<p>Requests that match an invalidation policy and result in expiration of specific cached responses or entire content groups.</p>
<p>Parameterized requests</p>	<p>Number of cache requests that were processed using a policy with a parameterized content group.</p>
<p>Parameterized non-304 hits</p>	<p>Number of cache requests that were processed using a policy with a parameterized content group, where full cached response was found, and the response was not a 304 (object not updated) response.</p>

---

Counter	Description
Parameterized 304 hits	Number of cache requests that were processed using a policy with a parameterized content group, where the cached object was found, and the object was a 304 (object not updated) response.
Total parameterized hits	Number of cache requests that were processed using a policy with a parameterized content group, where the cached object was found.
Parameterized 304 hit ratio (%)	Percentage of 304 (object not updated) responses that were found using a parameterized policy, relative to all cache hits.
Poll every time requests	If Poll Every Time is enabled, the NetScaler appliance always consults the origin server before serving a stored object.
For more information, see “Polling the Origin Server Every Time a Request Is Received.”	
Poll every time hits	Number of times a cache hit was found using the Poll Every Time method.
For more information, see “Polling the Origin Server Every Time a Request Is Received.”	
Poll every time hit ratio (%)	Percentage of cache hits using the Poll Every Time method, relative to all searches for cached objects using Poll Every Time. For more information, see “Polling the Origin Server Every Time a Request Is Received.”
Maximum memory (KB)	Maximum amount of memory in the NetScaler appliance that is allocated to the cache. For more information, see “Configuring Global Attributes for Caching.”
Maximum memory active value (KB)	Maximum amount of memory (active value) that will be set after the memory is allocated to the cache. For more information, see “How to Configure the Integrated Caching Feature of a NetScaler Appliance for various Scenarios.”
Utilized memory (KB)	Amount of memory that is actually being used.
Memory allocation failures	Number of failed attempts to utilize memory for the purpose of storing a response in the cache.

Counter	Description
Largest response so far	Largest response in bytes found in either the cache or the origin server and sent to the client.
Cached objects	Number of objects in the cache, including responses that have not yet been fully downloaded and responses that have been expired but not yet flushed.
Marker objects	Marker objects are created when a response exceeds the maximum or minimum response size for the content group, or has not yet received the minimum number of hits for the content group.
Hits being served	Number of hits that have been served from the cache.
Misses being handled	Responses that were fetched from the origin server, stored in the cache, and then served. Should approximate the number for storable misses. Does not include non-storable misses.

**To view summary cache statistics by using the command line interface:**

At the command prompt, type:

To view summary cache statistics by using the GUI

1. Click the **Dashboard** tab at the top of the page.
2. Scroll down to the **Integrated Caching** section of the window.
3. To see detailed statistics, click the More...link at the bottom of the table.

To view specific cache statistics by using the GUI

1. Click the **Reporting** tab at the top of the page.
2. Under Built-In Reports, expand **Integrated Cache**, and then click the report with the statistics you want to view.
3. To save the report as a template, click **Save As** and name the report. The saved report appears under **Custom** Reports.

## Display cached objects and cache statistics

May 2, 2023

You can view particular cached objects, and you can view summary statistics on cache hits, misses, and memory usage. The statistics provide insight on the amount of data that is being served from the cache, what items are responsible for the largest performance benefit, and what you can tune to improve cache performance.

This section includes the following details:

- Viewing Cached Objects
- Finding Particular Cached Responses
- Viewing Cache Statistics

## View cached objects

After enabling caching, you can view details for cached objects. For example, you can view the following items:

- Response sizes and header sizes
- Status codes
- Content groups
- ETag, Last-Modified, and Cache-Control headers
- Request URLs
- Hit parameters
- Destination IP addresses
- Request and response times

To view a list of cached objects by using the command line interface

At the command prompt, type:

```
show cache object
```

---

Properties	Specification
Response size (bytes)	The size of the response header and body.
Response header size (bytes)	The size of the header portion of the response.
Response status code	The status code sent with the response.
ETag	The ETag header inserted in the response. Typically, this header indicates whether the response has changed recently.
Last-Modified	The Last-Modified header inserted in the response. This header indicates the date that the response was last changed.
Cache-Control	The Cache-Control header inserted in the response.
Date	The Date header that indicates when the response was sent.

---

Properties	Specification
<a href="#">Contentgroup</a>	The content group where the response is stored.
Complex match	If this object was cached based on parameterized values, this field value is YES.
Host	The host specified in the URL that requested this response.
Host port	The listen port for the host specified in the URL that requested this response
URL	The URL issued for the stored response.
Destination IP	The IP address of the server from which this response was fetched.
Destination port	The listen port for the destination server.
Hit parameters	If the content group that stores the response uses hit parameters, they are listed in this field.
Hit selector	If this content group uses a hit selector, it is listed in this field.
Inval selector	If this content group uses an invalidation selector, it is listed in this field.
Selector Expressions	If this content group uses a selector, this field displays the expression that defines the selection rule.
Request time	The time in milliseconds since the request was issued.
Response time	The time in milliseconds since the cache started to receive the response.
Age	Amount of time the object has been in the cache.
Expiry	Amount of time after which the object is marked as expired.
Flushed	Whether the response has been flushed after expiry.
Prefetch	If Prefetch has been configured for this content group, the amount of time before expiry during which the object is fetched from the origin. Prefetch does not apply to negative objects (for example, 404 “object not found” responses).

Properties	Specification
Current readers	Approximately the current number of hits being served. When a response with a Content-Length header object is being downloaded, the current misses and the current readers values are each typically 1. When a chunked response object is being downloaded, the current misses value is typically 1, but the current readers value is typically 0, because the chunked response that is served to the client does not come from the integrated caching buffers.
Current misses	The current number of requests that resulted in a cache miss and fetching from the origin server. This value is typically 0 or 1. If Poll Every Time is enabled for a content group, the count can be greater than 1.
Hits	The number of cache hits for this object.
Misses	The number of cache misses for this object.
Compression format	The type of compression applied to this object. Compression formats include gzip, deflate, compress, and pack200-gzip.
HTTP version in response	The version of HTTP that was used to send the response.
Weak <code>etag</code> present in response	Strong <code>etag</code> headers change if the bits of an entity change. Strong headers are based on the octet values of an object. Weak <code>etag</code> headers change if the meaning of an entity changes. Weak <code>etag</code> values are based on semantic identity. Weak <code>etags</code> values start with a “W.”
Negative marker cell	A marker object is cacheable, but it does not yet meet all the criteria for being cached. For example, the object may exceed the maximum response size for the content group. A marker cell is created for objects of this type. The next time a user sends a request for this object, a cache miss is served.

Properties	Specification
Reason marker created	The reason a marker cell was created (for example, “Waiting for minhit,” “Content-length response data is not in group size limit”).
Auto poll every time	If the integrated cache receives an already expired 200 OK response with validators (either the Last-Modified or the ETag response headers) it stores the response and marks it as Auto-PET (automatically poll every time).
NetScaler Etag inserted in response	A variation of the ETag header generated by the NetScaler appliance. A value of YES appears if the NetScaler inserts an Etag in the response.
Full response present in cache	Indicates whether this is a complete response.
Destination IP verified by DNS	Indicates whether DNS resolution was performed when storing the object.
Object stored through a cache forward proxy	Indicates whether this response was stored due to a forward proxy that is configured in the integrated cache.
Object is a Delta basefile	A response that is delta-compressed.
Waiting for minhits	Indicates whether this content group requires a minimum number of origin servers hit before caching a response.
Minhit count	If this content group requires a minimum number of origin servers hit before caching an object, this field displays a count of the number of hits received so far.
HTTP Request Method	The method, GET or POST, used in the request that obtained this object.
Stored by policy	The name of the caching policy that caused this object to be stored. A value of NOT AVAILABLE indicates that the policy has been deactivated or deleted. A value of NONE indicates that the object did not match a visible policy, but was stored according to internal criteria for caching.

Properties	Specification
Application firewall metadata exists	This parameter is used when the application firewall and the integrated cache are both enabled. The application firewall analyzes the contents of a response page, stores its metadata (for example, URLs and forms contained in page), and exports the metadata with the response to the cache. The cache stores the page and the metadata, and when the cache serves the page, it sends the metadata back to the request's session.
HTTP callout object, name, type, response	These cells indicate whether this data was stored as a result of an HTTP Callout expression, and provide information about various aspects of the callout and the corresponding response. For more information about HTTP callouts, see "HTTP Callouts".

## Find particular cached responses

You can find individual items in the cache based on search criteria. There are different methods for finding cached items, depending on whether the content group that contains the data uses hit and invalidation selectors, as follows:

If the content group uses selectors, you can only conduct the search using the Locator ID for the cached item.

If the content group does not use selectors, you conduct the search using criteria such as URL, host, content group name.

When searching for a cached response, you can locate some items by URL and host. If the response is in a content group that uses a selector, you can find it only by using a Locator number (for example, 0x0000000ad7af0000050). To save a Locator number for later use, right-click the entry and select Copy. For more information about selectors, see "Configuring Selectors and Basic Content Groups."

To display cached responses in content groups that do not have a selector by using the command line interface

At the command prompt, type:

```
show cache object [-locator <positiveInteger>] | [(-url <URL> (-host <hostName> [-port <port>]) [-groupName <contentGroupName>]) [-
```

```
httpMethod GET | POST])) | [-httpStatus<positive integer>] | -group <
contentGroupName> | -ignoreMarkerObjects (ON | OFF) | -includeNotReadyObjects
(ON | OFF)]
```

To display cached responses in content groups that have a selector by using the command line interface

At the command prompt, type:

```
show cache object -locator <locatorString> MarkerObjects (ON | OFF)
| -includeNotReadyObjects (ON | OFF) | [-httpStatus<positive integer
>]
```

To display cached responses in content groups that do not have a selector by using the GUI

Navigate to **Optimization > Integrated Caching > Cache Objects**, click **Search**, and set the search criteria to view the required cached response.

If you have not yet configured any content groups, all of the objects are in the Default group.

To display cached responses in content groups that have a selector by using the GUI

Navigate to **Optimization > Integrated Caching > Cache Objects**, click **Search**, and set the selector search criteria to view the required cached response.

## View cache statistics

The following table summarizes the cache statistics.

Counter

Specification

## Viewing cache statistics

Updated: 2013-10-28

The following table summarizes the detailed cache statistics that you can view.

Counter	Specifies
Hits	Responses that are found in and served from the integrated cache. Includes static objects such as image files, pages with status codes 200, 203, 300, 301, 302, 304, 307, 403, 404, 410, and responses that match a user-defined policy with a CACHE action..
Misses	Intercepted HTTP requests where the response was ultimately fetched from origin server.
Requests	Total cache hits plus total cache misses.
Non-304 hits	If the user requests an item more than once, and the item in the cache is unchanged since the last time the NetScaler appliance served it, the NetScaler appliance serves a 304 response instead of the cached object. This statistic indicates how many items the NetScaler appliance served from the cache, excluding 304 responses.
304 hits	Number of 304 (object not modified) responses the NetScaler appliance served from the cache.
304 hit ratio (%)	Percentage of 304 responses that the NetScaler appliance served, relative to other responses.
Hit ratio (%)	Percentage of responses that the NetScaler appliance served from the cache (cache hits) relative to responses that could not be served from the cache.
Origin bandwidth saved (%)	An estimate of the processing capacity that the NetScaler appliance saved on the origin server due to serving responses from the cache.
Bytes served by the NetScaler	Total number of bytes that the NetScaler appliance served from the origin server and the cache.
Bytes served by cache	Total number of bytes that the NetScaler appliance served from the cache.
Byte hit ratio(%)	Percentage of data that the NetScaler appliance served from the cache, relative to all of the data in all served responses.

Counter	Specifies
Compressed bytes from cache	Amount of data, in bytes, that the NetScaler appliance served in compressed form.
Storable misses	If the NetScaler appliance does not find a requested object in the cache, it fetches the object from the origin server. This is known as a cache miss. A storable cache miss can be stored in the cache.
Non-storable misses	A non-storable cache miss cannot be stored in the cache.
Misses	All cache misses.
Revalidations	Max-Age setting in a Cache-Control header determines, in number of seconds, when an intervening cache must revalidate the content with the integrated cache before serving it to the user. For more information, see “Inserting a Cache-Control Header.”
Successful revalidations	Number of revalidations that have been performed. For more information, see “Inserting a Cache-Control Header.”
Conversions to conditional req	A user-agent request for a cached PET object is always converted to a conditional request and sent to the origin server. For more information, see “Polling the Origin Server Every Time a Request Is Received.”
Storable miss ratio (%)	Storable cache misses as a percentage of non-storable cache misses.
Successful reval ratio (%)	Successful revalidations as a percentage of all revalidation attempts. For more information, see “Inserting a Cache-Control Header.”
Expire at last byte	Number of times that the cache expired content immediately after receiving the last body byte. Only applicable to positive responses, as described in the table “Cache Hits and Misses.” For more information, see “Example of Performance Optimization.”

---

Counter	Specifies
Flash cache misses	If you enable Flash Cache, the cache allows only one request to reach the server, eliminating flash crowds. This statistic indicates the number of Flash Cache requests that were cache misses. For more information, “Queuing Requests to the Cache.”
Flashcache hits	Number of Flash Cache requests that were cache hits. For more information, see “Queuing Requests to the Cache.”
Parameterized inval requests	Requests that match a policy with an invalidation (INVAL) action and a content group that uses an invalidation selector or parameters to selectively expire cached objects in the group.
Full inval requests	Requests that match an invalidation policy where the invalGroups parameter is configured and expires one or more content groups.
Inval requests	Requests that match an invalidation policy and result in expiration of specific cached responses or entire content groups.
Parameterized requests	Number of cache requests that were processed using a policy with a parameterized content group.
Parameterized non-304 hits	Number of cache requests that were processed using a policy with a parameterized content group, where full cached response was found, and the response was not a 304 (object not updated) response.
Parameterized 304 hits	Number of cache requests that were processed using a policy with a parameterized content group, where the cached object was found, and the object was a 304 (object not updated) response.
Total parameterized hits	Number of cache requests that were processed using a policy with a parameterized content group, where the cached object was found.

Counter	Specifies
Parameterized 304 hit ratio (%)	Percentage of 304 (object not updated) responses that were found using a parameterized policy, relative to all cache hits.
Poll every time requests	If Poll Every Time is enabled, the NetScaler appliance always consults the origin server before serving a stored object. For more information, see “Polling the Origin Server Every Time a Request Is Received.”
Poll every time hits	Number of times a cache hit was found using the Poll Every Time method. For more information, see “Polling the Origin Server Every Time a Request Is Received.”
Poll every time hit ratio (%)	Percentage of cache hits using the Poll Every Time method, relative to all searches for cached objects using Poll Every Time. For more information, see “Polling the Origin Server Every Time a Request Is Received.”
Maximum memory (KB)	Maximum amount of memory in the NetScaler appliance that is allocated to the cache. For more information, see “Configuring Global Attributes for Caching.”
Maximum memory active value (KB)	Maximum amount of memory (active value) that will be set after the memory is actually allocated to the cache. For more information, see “How to Configure the Integrated Caching Feature of a NetScaler Appliance for various Scenarios.”
Utilized memory (KB)	Amount of memory that is actually being used.
Memory allocation failures	Number of failed attempts to utilize memory for the purpose of storing a response in the cache.
Largest response so far	Largest response in bytes found in either the cache or the origin server and sent to the client.
Cached objects	Number of objects in the cache, including responses that have not yet been fully downloaded and responses that have been expired but not yet flushed.

Counter	Specifies
Marker objects	Marker objects are created when a response exceeds the maximum or minimum response size for the content group, or has not yet received the minimum number of hits for the content group.
Hits being served	Number of hits that have been served from the cache.
Misses being handled	Responses that were fetched from the origin server, stored in the cache, and then served. Should approximate the number for storable misses. Does not include non-storable misses.

To view summary cache statistics by using the command line interface

At the command prompt, type:

```
stat cache
```

To view specific cache statistics by using the command line interface

At the command prompt, type:

To view summary cache statistics by using the GUI

1. Click the **Dashboard** tab at the top of the page.
2. Scroll down to the Integrated Caching section of the window.
3. To see detailed statistics, click the More...link at the bottom of the table.

To view specific cache statistics by using the GUI

1. Click the Reporting tab at the top of the page.
2. Under Built-In Reports, expand Integrated Cache, and then click the report with the statistics you want to view.
3. To save the report as a template, click Save As and name the report. The saved report appears under Custom Reports.

## Improve cache performance

May 2, 2023

You can improve the performance of the integrated cache, including handling simultaneous requests for the same cached data, avoiding delays that are associated with refreshing cached responses from the origin server, and ensuring that a response is requested often enough to be worth caching.

### Reduce flash crowds

Flash crowds occur when many users simultaneously request the same data. The requests in a flash crowd can become cache misses if you configured the cache to serve hits only after the entire object is downloaded.

The following techniques can reduce or eliminate flash crowds:

- **PREFETCH:** Refreshes a positive response before it expires to ensure that it never becomes stale or inactive. For more information, see “Refreshing a Response Prior to Expiration”section.
- **Cache buffering:** Starts serving a response to multiple clients when it receives the response header from the origin server, rather than waiting for the entire response to be downloaded. The only limit on the number of clients that can download a response simultaneously is the available system resources. The NetScaler appliance downloads and serves responses even if the client that initiated the download halts before the download is complete. If the response exceeds the cache size or if the response is chunked, the cache stops storing the response, but service to the clients is not disrupted.
- **Flash Cache:** Flash Cache queues requests to the cache, and allows only one request to reach the server at a time.

For more information, see “Queuing Requests to the Cache”section.

## Refresh a response before expiration

To ensure that a cached response is fresh whenever it is needed, the PREFETCH option refreshes a response before its calculated expiration time. The prefetch interval is calculated after receiving the first client request. From that point onward, the NetScaler appliance refreshes the cached response at a time interval that you configure in the PREFETCH parameter.

This setting is useful for data that is updated frequently between requests. It does not apply to negative responses (for example, 404 messages).

To configure prefetch for a content group by using the command line interface

At the command prompt, type:

```
set cache contentgroup <name> -prefetch YES [-prefetchPeriod <seconds> | -prefetchPeriodMilliSec <milliseconds>] [-prefetchMaxPending <positiveInteger>]
```

\*To configure prefetch for a content group by using the GUI

Navigate to **Optimization > Integrated Caching > Content Groups**, and select the **content group**.

On **Others** tab, in the Flash Crowd and Prefetch group, select **Prefetch** option, and specify the values in the Interval and Maximum number of pending prefetches text boxes.

## Queue requests to the cache

The Flash Cache option queues requests that arrive simultaneously (a flash crowd), retrieves the response, and distributes it to all the clients whose requests are in the queue. If, during this process, the response becomes non-cacheable, the NetScaler appliance stops serving the response from the cache and instead serves the origin server's response to the queued clients. If the response is not available, the clients receive an error message.

Flash Cache is disabled by default. You cannot enable Poll Every Time (PET) and Flash Cache on the same content group.

One disadvantage of Flash Cache is if the server replies with an error (for example, a 404 that is quickly remedied), the error is fanned out to the waiting clients.

### Note:

If Flash Cache is enabled, in some situations the NetScaler appliance is unable to correctly match the Accept-Encoding header in the client request with the Content-Encoding header in the response. The NetScaler appliance can assume that these headers match and mistakenly serve a hit. As a work-around, you can configure Integrated Caching policies to disallow serving hits to clients that do not have an appropriate Accept-Encoding header.

To enable Flash Cache by using the command line interface

At the command prompt, type:

```
set cache contentgroup <contentGroupName> -flashcache yes
```

To enable Flash Cache by using the GUI

Navigate to **Optimization > Integrated Caching > Content Groups**, and select the content group.

On **Others** tab, in the Flash Crowd and Prefetch group, select **Prefetch** option.

### Cache a response after a client halts a download

You can set the Quick Abort parameter to continue caching a response, even if the client halts a request before the response is in the cache.

If the downloaded response size is less than or equal to the Quick Abort size, the NetScaler appliance stops downloading the response. If you set the Quick Abort parameter to 0, all downloads are halted.

To configure quick abort size by using the command line interface

At the command prompt, type:

```
set cache contentgroup <name> -quickAbortSize <integerInKBytes>
```

To configure quick abort size by using the GUI

1. Navigate to **Optimization > Integrated Caching > Content Groups**, and select the content group.
2. On **Memory** tab, set the relevant value in Quick Abort: Continue caching if more than text box.

### Requiring a minimum number of server hits before caching

You can configure the minimum number of times that a response must be found on the origin server before it can be cached. You must consider increasing the minimum hits if the cache memory fills up quickly and has a lower-than-expected hit ratio.

The default value for the minimum number of hits is 0. This value caches the response after the first request.

To configure the minimum number of hits that are required before caching by using the command line interface

At the command prompt, type:

```
set cache contentgroup <name> -minhits <positiveInteger>
```

To configure the minimum number of hits that are required before caching by using the GUI

1. Navigate to **Optimization > Integrated Caching > Content Groups**, and select the content group.
2. On **Memory** tab, set the relevant value in Do not cache, if hits are less than the text box.

## Example for performance optimization

In this example, a client accesses a stock quote. Stock quotes are highly dynamic. You configure the integrated cache to serve the same stock quote to concurrent clients without sending multiple requests to the origin server. The stock quote expires after it is downloaded to the clients, and the next request is fetched from the origin server. This ensures that the quote is always up to date.

The following task overview describes the steps to configure the cache for the stock quote application.

Configure caching for a stock quote application

Create a content group for stock quotes

For more information, see “About Content Groups.”

Configure the following for this content group:

1. On the **Expiry Method** tab, select the Expire after complete response received check box.
2. On the **Others** tab, select the **Flash Cache** check box, and click **Create**.
3. Add a cache policy to cache the stock quotes.

For more information, see “Configuring a Policy in the Integrated Cache.”

Configure the following for the policy

1. In the **Action and Store in Group lists**, select **CACHE** and select the group that you defined in the previous step.
2. Click **Add**, and in the **Add Expression** dialog box configure an expression that identifies stock quote requests, for example: `http.req.url.contains(“cgi-bin/stock-quote.pl”)`
3. Activate the policy.

For more information, see “Globally Binding an Integrated Caching Policy.” In this example, you bind this policy to request-time override processing and set the priority to a low value.

## Configure cookies, headers, and polling

November 2, 2023

This topic explains how to configure cache manages cookies, HTTP headers, and origin server polling. This includes modifying the default behavior that causes the cache to diverge from documented standards, overriding HTTP headers that might cause cacheable content to not be stored in the cache, and configuring cache to always poll the origin for updated content.

## Divergence of cache behavior from the standards

By default, the integrated cache adheres to the following RFC standards:

- RFC 2616, “HTTP HTTP/1.1”
- The caching behaviors described in RFC 2617, “HTTP Authentication: Basic and Digest Access Authentication”
- The caching behavior described in RFC 2965, “HTTP State Management Mechanism”

The built-in policies and the Default content group attributes ensure conformance with most of these standards.

The default integrated cache behavior diverges from the specification as follows:

- There is a limited support for the Vary header. By default, any response containing a Vary header is considered to be non-cacheable unless it is compressed. A compressed response contains content-encoding: gzip, content-encoding: deflate, or content-encoding: pack200-gzip and is cacheable even if it contains the Vary: Accept-encoding header.
- The integrated cache ignores the values of the headers cache-control: no-cache and cache-control: private. For example, a response that contains cache-control: no-cache="Set-Cookie" is treated as if the response contained Cache-Control: no-cache. By default, the response is not cached.
- An image (content-type = image/\*) is always considered cacheable, even if an image response contains set-cookie or set-cookie2 headers, or if an image request contains a cookie header. The integrated cache removes set-cookie and set-cookie2 headers from a response before caching it. This diverges from RFC 2965. You can configure RFC-compliant behavior as follows:

```
1 add cache_policy rfc_compliant_images_policy -rule "http.res.header.set
 -cookie2.exists || http.res.header.set-cookie.exists" -action
 NOCACHE
2
3
4 bind cache global rfc_compliant_images_policy -priority 100 -type REQ\
 _OVERRIDE
5 <!--NeedCopy-->
```

- The following cache-control headers in a request force an RFC-compliant cache to reload a cached response from the origin server:

Cache-control: max-age=0

Cache-control: no-cache

To guard against denial-of-service attacks, this behavior is not the default.

- By default, the caching module considers a response to be cacheable unless a response header state otherwise. To make this behavior RFC 2616 compliant, set `-weakPosRelExpiry` and `-weakNegResExpiry` to 0 for all content groups.

## Remove cookies from a response

Cookies are often personalized for a user, and typically should not be cached. The `Remove Response Cookies` parameter removes `Set-Cookie` and `Set-Cookie2` headers before caching a response. By default, the `Remove Response Cookies` option for a content group prevents caching of responses with `Set-Cookie` or `Set-Cookie2` headers.

### Note:

When images are cached, the built-in behavior is to remove the `Set-Cookie` and `Set-Cookie2` headers before caching, no matter how the content group is configured.

Citrix recommends that you accept the default `Remove Response Cookies` for every content group that stores embedded responses, for example, images.

To configure `Remove Response Cookies` for a content group by using the command line interface:

At the command prompt, type:

```
set cache contentgroup <name> -removeCookies YES
```

## Configure Remove Response Cookies for a content group by using the NetScaler GUI

1. Navigate to **Optimization > Integrated Caching > Content Groups**, and select the content group.
2. On **Others** tab, in the **Settings** group, select Remove response cookies option.

## Inserting HTTP headers at response time

The integrated cache can insert HTTP headers in responses that result from cache requests. The NetScaler appliance does not alter headers in responses that result from cache misses.

The following table describes headers that you can insert in a response.

---

Header	Specification
Age	Provides the age of the response in seconds, calculated from the time the response was generated at the origin server. By default, the cache inserts an Age header for every response that is served from the cache.
via	Lists protocols and recipients between the start and end points for a request or a response. The NetScaler appliance inserts a Via header in every response that it serves from the cache. The default value of the inserted header is <code>NS-CACHE-10.0: last octet of the NetScaler IP address.</code> For more information, see “Configuring Global Attributes for Caching.”
Tag	The cache supports response validation using Last-Modified and Tag headers to determine if a response is stale. The cache inserts an Tag in a response only if it caches the response and the origin server has not inserted its own Tag header. The Tag value is an arbitrary unique number. The Tag value for a response changes if it is refreshed from the origin server, but it stays the same if the server sends a 304 (object not updated) response. Origin servers typically do not generate validators for dynamic content because dynamic content is considered non-cacheable. You can override this behavior. With Tag header insertion, the cache is permitted to not serve full responses. Instead, the user agent is required to cache the dynamic response sent by the integrated cache the first time. To force a user agent to cache a response, you configure the integrated cache to insert an Tag header and replace the origin-provided Cache-Control header.

Header	Specification
Cache-Control	<p>The NetScaler appliance typically does not modify cacheability headers in responses that is serves from the origin server. If the origin server sends a response that is labeled as non-cacheable, the client treats the response as non-cacheable even if the NetScaler appliance caches the response. To cache dynamic responses in a user agent, you can replace Cache-Control headers from the origin server. This applies only to user agents and other intervening caches. They do not affect the integrated cache.</p>

Header	Specification
Age	<p>Provides the age of the response in seconds, calculated from the time the response was generated at the origin server. By default, the cache inserts an Age header for every response that is served from the cache.</p>
via	<p>Lists protocols and recipients between the start and end points for a request or a response. The NetScaler appliance inserts a Via header in every response that it serves from the cache. The default value of the inserted header is “NS-CACHE-9.2: last octet of the NetScaler IP address.” For more information, see “Configuring Global Attributes for Caching.”</p>

Header	Specification
Tag	<p>The cache supports response validation using the Last-Modified and Tag headers to determine if a response is stale. The cache inserts an <a href="#">Tag</a> in a response only if it caches the response and the origin server has not inserted its own <a href="#">Tag</a> header. The <a href="#">Tag</a> value is an arbitrary unique number. The <a href="#">Tag</a> value for a response changes if it is refreshed from the origin server, but it stays the same if the server sends a 304 (object not updated) response. Origin servers typically do not generate validators for dynamic content because dynamic content is considered non-cacheable. You can override this behavior. With <a href="#">Tag</a> header insertion, the cache is permitted to not serve full responses. Instead, the user agent is required to cache the dynamic response sent by the integrated cache the first time. To force a user agent to cache a response, you configure the integrated cache to insert an <a href="#">Tag</a> header and replace the origin-provided Cache-Control header.</p>
Cache-Control	<p>The NetScaler appliance typically does not modify cacheability headers in responses that it serves from the origin server. If the origin server sends a response that is labeled as non-cacheable, the client treats the response as non-cacheable even if the NetScaler appliance caches the response. To cache dynamic responses in a user agent, you can replace Cache-Control headers from the origin server. This applies only to user agents and other intervening caches. They do not affect the integrated cache.</p>

### **Insert an age, via, or Tag header**

The following procedures describe how to insert Age, Via, and ETag headers.

### Insert an Age, Via, or Etag header by using the NetScaler command interface:

At the command prompt, type:

```
set cache contentgroup <name> -insertVia YES -insertAge YES -insertETag
YES
```

### Configure the Age, Via, or Etag header by using the NetScaler GUI

1. Navigate to **Optimization > Integrated Caching > Content Groups**, and select the **content group**.
2. On the **Others** tab, in the HTTP Header Insertions group, select the **Via, Age, or ETag** options, as appropriate.
3. The values for the other header types are calculated automatically. You configure the Via value in the main settings for the cache.

### Insert a cache-control header

When the integrated cache replaces a Cache-Control header that the origin server inserted, it also replaces the Expires header. The new Expires header contains an expiration time in the past. This ensures that HTTP/1.0 clients and caches (that do not understand the Cache-Control header) do not cache the content.

### Insert a cache-control header by using the NetScaler command interface

At the command prompt, type:

```
set cache contentgroup <name> -cacheControl <value>
```

### Insert a cache-control header by using the NetScaler GUI

1. Navigate to **Optimization > Integrated Caching > Content Groups**, and
  - a) Click the **Expiry Method** tab, clear the heuristic and default expiry settings and set the relevant value in the Expire content after text box.
  - b) Click **Others** tab and type the header you want to insert in the Cache-Control text box. Alternatively, click Configure to set the Cache-Control directives in cached responses.

### Ignore cache-control and pragma headers in requests

By default, the caching module processes Cache-Control and Pragma headers. The following tokens in the Cache-Control headers are processed as described in RFC 2616.

- max-age
- max-stale
- only-if-cached
- no-cache

A Pragma: no-cache header in a request is treated in the same way as a Cache-Control: no-cache header.

If you configure the caching module to ignore the Cache-Control and Pragma headers, a request that contains a Cache-Control: No-Cache header causes the NetScaler appliance to retrieve the response from the origin server, but the cached response is not updated. If the caching module processes the Cache-Control and Pragma headers, the cached response is refreshed.

The following table summarizes the implications of various settings for these headers and the Ignore Browser's Reload Request setting.

<b>Setting for Ignore</b>		
<b>Cache-Control and Pragma Headers</b>	<b>Setting for Ignore Browser's Reload Request</b>	<b>Outcome</b>
Yes	Yes or No	Ignore the Cache-Control and Pragma headers from the client, including the Cache-Control: no-cache directive.
No	Yes	The Cache-Control: no-cache header produces a cache miss, but a response that is already in the cache is not refreshed.
No	No	A request that contains a Cache-Control: no-cache header causes a cache miss and the stored response is refreshed.

To ignore Cache-Control and Pragma headers in a request by using the command line interface

At the command prompt, type:

```
set cache contentgroup <name> -ignoreReqCachingHdrs YES
```

To ignore browser reload requests by using the command line interface

At the command prompt, type:

```
set cache contentgroup <name> -ignoreReloadReq NO
```

**Note:**

By default, the `-ignoreReloadReq` parameter is set to YES.

### Ignore Cache-Control and Pragma headers in a request by using the GUI

1. Navigate to **Optimization > Integrated Caching > Content Groups**, and select the content group.
2. On the **Others** tab, in the **Settings** group, select **Ignore Cache-control and Pragma Headers** in the **Requests** option.

#### Example of a policy to ignore Cache-Control headers:

In the following example, you configure a request-time override policy to cache responses that contain Content-type: image/\* regardless of the Cache-Control header in the response.

To configure a request-time override policy to cache all responses with image/\*

Flush the cache using the Invalidate All option.

Configure a new cache policy, and direct the policy to a particular content group. For more information, see “Configuring a Policy in the Integrated Cache.”

Ensure the content group that the policy uses is configured to ignore Cache-Control headers, as described in “Ignoring Cache-Control and Pragma Headers in Requests.”

Bind the policy to the request-time override policy bank.

For more information, see [Globally Binding an Integrated Caching Policy](#) topic.

### Poll origin server every time a request is received

You can configure the NetScaler appliance to always consult the origin server before serving a stored response. This is known as Poll Every Time (PET). When the NetScaler appliance consults the origin server and the PET response has not expired, a full response from the origin server does not overwrite cached content. This property is useful when serving client-specific content.

After a PET response expires, the NetScaler appliance refreshes it when the first full response arrives from the origin server.

The Poll Every Time (PET) function works as follows:

For a cached response that has validators in the form of a Tag or a Last-Modified header, if the response expires it is automatically marked PET and cached.

You can configure PET for a content group.

If you configure a content group as PET, every response in the content group is marked PET. The PET content group can store responses that do not have validators. Responses that are automatically marked PET are always expired. Responses that belong to a PET content group can expire after a delay, based on how you configure the content group.

Two types of requests are affected by polling:

- **Conditional Requests:** A client issues a conditional request to ensure that the response that it has is the most recent copy. A user-agent request for a cached PET response is always converted to a conditional request and sent to the origin server. A conditional request has validators in the `If-Modified-Since` or `If-None-Match` headers. The `If-Modified-Since` header contains the time from the `Last-Modified` header. An `If-None-Match` header contains the response's `Tag` header value. If the client's copy of the response is fresh, the origin server replies with 304 Not Modified. If the copy is stale, a conditional response generates a 200 OK that contains the entire response.
- **Non-Conditional Requests:** A non-conditional request can only generate a 200 OK that contains the entire response.

---

Origin Server Response	Action
Send the full response	The origin server sends the response as-is to the client. If the cached response has expired, it is refreshed.
304 Not Modified	The following header values in the 304 response are merged with the cached response and the cached response is served to the client: <code>Date</code> , <code>Expires</code> , <code>Age</code> , <code>Cache-Control</code> header <code>Max-Age</code> , and <code>S-Maxage</code> tokens
401 Unauthorized; 400 Bad Request; 405 Method Not Allowed; 406 Not Acceptable; 407 Proxy Authentication Required	The origin's response is served as-is to the client. The cached response is not changed.
Any other error response, for example, 404 Not Found	The origin's response is served as-is to the client. The cached response is removed.

---

**Note:**

The `Poll Every Time` parameter treats the affected responses as non-storable.

To configure poll every time by using the command line interface

At the command prompt, type:

```
add cache contentgroup <contentGroupName> -pollEveryTime YES
```

### Poll by using the GUI

1. Navigate to **Optimization > Integrated Caching > Content Groups**, and select the content group.
2. On the **Others** tab, in the Settings group, select **Poll every time (validate cached content with origin for every request)** option.

### PET and client-specific content

The PET function can ensure that content is customized for a client. For example, a website that serves content in multiple languages examines the Accept-Language request header to select the language for the content that it is serving. For a multi-language website where English is the predominant language, all English language content can be cached in a PET content group. This ensures that every request goes to the origin server to determine the language for the response. If the response is English, and the content has not changed, the origin server can serve a 304 Not Modified to the cache.

The following example shows commands to cache English responses in a PET content group, configure a named expression that identifies English responses in the cache, and configure a policy that uses this content group and named expression. Bold is used for emphasis:

```
1 add cache contentgroup EnglishLanguageGroup -pollEveryTime YES
2 add expression containsENExpression -rule "http.res.header(\\\"Content-
 Language\\\").contains(\\\"en\\\")"
3 add cache policy englishPolicy -rule containsENExpression -action CACHE
 -storeInGroup englishLanguageGroup
4 bind cache policy englishPolicy -priority 100 -precedeDefRules NO
5 <!--NeedCopy-->
```

### PET and authentication, authorization, and auditing

Outlook Web Access (OWA) is a good example of dynamically generated content that benefits from PET. All mail responses (\*.EML objects) have an **ETag** validator that enables them to be stored as PET responses.

Every request for a mail response travels to the origin server, even if the response is cached. The origin server determines whether the requestor is authenticated and authorized. It also verifies that the response exists in the origin server. If all results are positive, the origin server sends a 304 Not Modified response.

## Configure integrated cache as a forward proxy

May 2, 2023

The integrated cache can service as a forward proxy device that passes requests to other NetScaler appliances or to other types of cache servers. You configure the integrated cache as a forward proxy by identifying the IP addresses of the cache server or servers. After configuring the forward proxy, the NetScaler appliance sends requests that contain the configured IP address on to the cache server instead of involving the integrated cache.

To configure the NetScaler as a forward cache proxy by using the command line interface

At the command prompt, type:

```
add cache forwardProxy <IPAddress> <port>
```

To configure the NetScaler as a forward cache proxy by using the GUI

1. Navigate to **Optimization > Integrated Caching > Forward Proxy**, and add a forward proxy by specifying the IP address and port number.

## Default settings for the integrated cache

May 2, 2023

The NetScaler integrated cache feature provides built-in policies with default settings and initial settings for the Default content group. The information in this section defines the parameters for the built-in policies and Default content group.

### Default caching policies

The integrated cache has built-in policies. The NetScaler appliance evaluates the policies in a particular order, as discussed in the following sections.

You can override these built-in policies with a user-defined policy that is bound to a request-time override or response-time override policy bank.

#### Note

If you configured policies prior to release 9.0 and specified the `-precedeDefRules` parameter when binding the policies, they are automatically assigned to override-time bind points during migration.

## View default policies

The built-in policy names start with an underscore (\_). You can view the built-in policies from the command line and the administrative console using the `show cache policy` command.

## Default request policies

You can override the following built-in request time policies by configuring new policies and binding them to the request-time override processing point. In the following policies, note that the `MAY_NOCACHE` action stipulates that the transaction is cached only when there is a user-configured or built-in `CACHE` directive at response time.

The following policies are bound to the `_reqBuiltinDefaults` policy label. They are listed in priority order.

Do not cache a response for a request that uses any method other than GET.

The policy name is `_nonGetReq`. The following is the policy rule:

```
!HTTP.REQ.METHOD.eq(GET)
```

Set a `NOCACHE` action for a request with header value that contains `If-Match` or `If-Unmodified-Since`.

The policy name is `_advancedConditionalReq`. The following is the policy rule:

```
HTTP.REQ.HEADER("If-Match").EXISTS || HTTP.REQ.HEADER("If-Unmodified-Since").EXISTS
```

Set a `MAY_NOCACHE` action for a request with the following header values: `Cookie`, `Authorization`, `Proxy-authorization`, or a request which contains the `NTLM` or `Negotiate` header.

The policy name is `_personalizedReq`. The following is the policy rule:

```
HTTP.REQ.HEADER("Cookie").EXISTS || HTTP.REQ.HEADER("Authorization").EXISTS || HTTP.REQ.HEADER("Proxy-Authorization").EXISTS || HTTP.REQ.IS_NTLM_OR_NEGOTIATE
```

## Default response policies

You can override the following default response-time policies by configuring new policies and binding them to the response-time override processing point.

The following policies are bound to the `_resBuiltinDefaults` policy label and are evaluated in the order in which they are listed:

1. Do not cache HTTP responses unless they are of type 200, 304, 307, 203 or if the types are between 400 and 499 or between 300 and 302.

The policy name is **\_uncacheableStatusRes**. The following is the policy rule:

```
!((HTTP.RES.STATUS.EQ(200)) || (HTTP.RES.STATUS.EQ(304)) || (HTTP.RES.STATUS.BETWEEN(400,499)) || (HTTP.RES.STATUS.BETWEEN(300, 302)) || (HTTP.RES.STATUS.EQ(307)) || (HTTP.RES.STATUS.EQ(203)))
```

2. Do not cache an HTTP response if it has a Vary header with a value of anything other than Accept-Encoding.

The compression module inserts the Vary: Accept-Encoding header. The name of this expression is **\_uncacheableVaryRes**. The following is the policy rule:

```
((HTTP.RES.HEADER("Vary").EXISTS)&& ((HTTP.RES.HEADER("Vary").INSTANCE(1).LENGTH > 0) || (!HTTP.RES.HEADER("Vary").STRIP_END_WS.SET_TEXT_MODE(IGNORECASE).eq("Accept-Encoding"))))
```

3. Do not cache a response if its Cache-Control header value is No-Cache, No-Store, or Private, or if the Cache-Control header is not valid.

The policy name is **\_uncacheableCacheControlRes**. The following is the policy rule:

```
((HTTP.RES.CACHE_CONTROL.IS_PRIVATE) || (HTTP.RES.CACHE_CONTROL.IS_NO_CACHE) || (HTTP.RES.CACHE_CONTROL.IS_NO_STORE) || (HTTP.RES.CACHE_CONTROL.IS_INVALID))
```

4. Cache responses if the Cache-Control header has one of the following values: Public, Must-Revalidate, Proxy-Revalidate, Max-Age, S-Maxage.

The policy name is **\_cacheableCacheControlRes**. The following is the policy rule:

```
((HTTP.RES.CACHE_CONTROL.IS_PUBLIC) || (HTTP.RES.CACHE_CONTROL.IS_MAX_AGE) || (HTTP.RES.CACHE_CONTROL.IS_MUST_REVALIDATE) || (HTTP.RES.CACHE_CONTROL.IS_PROXY_REVALIDATE) || (HTTP.RES.CACHE_CONTROL.IS_S_MAXAGE))
```

5. Do not cache responses that contain a Pragma header.

The name of the policy is **\_uncacheablePragmaRes**. The following is the policy rule:

```
HTTP.RES.HEADER("Pragma").EXISTS
```

6. Cache responses that contain an Expires header.

The name of the policy is **\_cacheableExpiryRes**. The following is the policy rule:

```
HTTP.RES.HEADER("Expires").EXISTS
```

7. If the response contains a Content-Type header with a value of Image, remove any cookies in the header and cache it.

The name of the policy is **\_imageRes**. The following is the policy rule:

```
HTTP.RES.HEADER("Content-Type").SET_TEXT_MODE(IGNORECASE).STARTSWITH("image/")
```

You can configure the following content group to work with this policy:

```
add cache contentgroup nocookie -group -removeCookies YES
```

8. Do not cache a response that contains a Set-Cookie header.

The name of the policy is **\_personalizedRes**. The following is the policy rule:

---

```
HTTP.RES.HEADER("Set-Cookie").EXISTS
```

---

## Restrictions on default policies

You cannot override the following built-in request time policies with user-defined policies.

These policies are listed in priority order.

1. Do not cache any responses if the corresponding HTTP request lacks a GET or POST method.
2. Do not cache any responses for a request if the HTTP request URL length plus host name exceeds 1744 bytes.
3. Do not cache a response for a request that contains an If-Match header.
4. Do not cache a request that contains an If-Unmodified-Since header.

### Note

This is different from the If-Modified-Since header.

1. Do not cache a response if the server does not set an expiry header.

You cannot override the following built-in response time policies. These policies are evaluated in the order in which they are listed:

1. Do not cache responses that have an HTTP response status code of 201, 202, 204, 205, or 206.
2. Do not cache responses that have an HTTP response status code of 4xx, with the exceptions of status codes 403, 404, and 410.
3. Do not cache responses if the response type is FIN terminated, or the response does not have one of the following attributes: Content-Length, or Transfer-Encoding: Chunked.
4. Do not cache the response if the caching module cannot parse its Cache-Control header.

## Initial settings for the default content group

When you first enable integrated caching, the NetScaler appliance provides one predefined content group named the Default content group. For detailed information, see [Default content group settings](#) table.

## Troubleshooting

May 2, 2023

If the integrated cache feature does not work as expected after you have configured it, you can use some common tools to access NetScaler resources and diagnose the problem.

### Resources for troubleshooting

For more information about the resources available for troubleshooting and sample configurations, see [Resource for troubleshooting](#) PDF file.

## Front end optimization

March 20, 2024

### Note:

Front end optimization is available if you have an Advanced or Premium NetScaler license and are running NetScaler release 12.1 or later.

The HTTP protocols that underlie web applications were originally developed to support the transmission and rendering of simple webpages. New technologies such as JavaScript and cascading style sheets (CSS), and new media types such as Flash videos and graphics-rich images, place heavy demands on front-end performance, that is, on performance at the browser level.

The NetScaler front end optimization (FEO) feature addresses such issues and reduces the load time and render time of webpages by:

- Reducing the number of requests.
- Required for rendering each page.
- Reducing the number of bytes in page responses.

Simplifying and optimizing the content served to the client browser.

You can customize your FEO configuration to provide the best results for your users. NetScalers support numerous web content optimizations for both desktop and mobile users. The following tables describe the front-end optimizations provided by the FEO feature, and the operations performed on different types of files.

## Optimizations performed by the FEO feature

Web Optimization	Problem	What NetScaler FEO feature does	Benefits
Inlining	Client browsers often send multiple requests to servers for loading external CSS, images, and JavaScript associated with the webpage.	CSS inline, JavaScript inline, CSS combine	Loading the external CSS, images, and JavaScript inline with the HTML files improves page-rendering time. This optimization is beneficial for content that is viewed only once, and for mobile devices that have limited cache sizes.
Minification	Data fetched from servers includes inessential characters such as white spaces, comments, and newline characters. The time that browsers spend in processing such data creates website latency.	CSS minification, JavaScript minification, Removal of HTML comments	Minified files consume less bandwidth and avoid the latency caused by special processing.
Image optimization	Mobile browsers often have slow connection speeds and limited cache memory. Downloading the images on mobile clients consumes more bandwidth, processing time, and cache space, resulting in website latency.	JPEG optimization, CSS image inlining, <b>Image shrink-to</b> attributes, GIF to PNG conversion, HTML image inlining, WebP image conversion, JPEG, GIF, PNG to JPEG-XR image conversion	Reduces the image to the size indicated in the image tag by NetScaler, enabling client browsers to load images faster.

Web Optimization	Problem	What NetScaler FEO feature does	Benefits
Repositioning	Inefficient processing of external CSS, images, and JavaScript increases page-load time.	Image lazy loading, CSS move to Head, JavaScript move to end	Repositions HTML elements, to reduce rendering time for webpages and enable client browsers to load the objects faster.
Connection Management	Many browsers set limits on the number of simultaneous connections that can be established to a single domain. This can cause browsers to download webpage resources one at a time, resulting in higher browsers time.	Domain sharding	Overcomes the connection limitation, which improves page-rendering time by enabling client browsers to download more resources in parallel.

### Web Optimizations on different file types:

NetScaler can perform web optimizations on CSS, images, Javascript, and HTML. For more information, see [Web Optimizations PDF](#).

#### Note:

The front end optimization feature supports ASCII characters only. It does not support the Unicode character set.

### How front end optimization works

After the NetScaler receives the response from the server:

1. Parses the contents of the page, creates an entry in the cache (wherever applicable), and applies the FEO policy.

For example, a NetScaler can apply the following optimization rules:

- Remove white spaces or comments present within a CSS or JavaScript.
- Combine one or more CSS files to one file.
- Convert GIF image format to PNG format.

2. Rewrites the embedded objects and saves the optimized content in the cache, with a different signature than the one used for the initial cache entry.
3. For subsequent requests, fetches the optimized objects from the cache, not from the server, and forwards the responses to the client.

\*\*

Remove extraneous information such as white spaces and comments.

The period during which the browser can use the cached resource without checking to see if fresh content is available on the server.

## Configure front end optimization

Optionally, you can change the values of the front end optimization global settings. Otherwise, begin by creating actions that specify the optimization rules to be applied to the embedded objects.

After configuring actions, create policies, each with a rule specifying a type of request for which to optimize the response, and associate the actions with the policies.

### Note:

The NetScaler evaluates front end optimization policies at request time only, not at response time.

To put the policies into effect, bind them to bind points. You can bind a policy globally, so that it applies to all traffic that flows through the NetScaler, or you can bind the policy to a load balancing or content switching virtual server of type HTTP or SSL. When you bind a policy, assign it a priority. A lower priority number indicates a higher value. The NetScaler applies the policies in the order of their priorities.

For more information on how to configure front end optimization with NetScaler, see the following video:

[This is an embedded video. Click the link to watch the video](#)

## Prerequisites

Front end optimization requires the NetScaler integrated caching feature to be enabled. Also, you must perform the following integrated caching configurations:

- Allocate cache memory.
- Set the maximum response size and memory limit for a default cache content group.

For more information on configuring integrated caching, see [Integrated Caching](#).

**Note:**

The term Integrated Cache can be interchangeably used with AppCache; note that from a functionality point of view, both terms mean the same.

**Configure front end optimization by using NetScaler command interface**

At the command prompt, do the following:

1. Enable the front end optimization feature.

```
enable ns feature FEO
```

1. Create one or more front end optimization actions.

```
add feo action <name> [-imgShrinkToAttrib] [-imgGifToPng] ...
```

**Example:** To add a front end optimization action for converting images in GIF format to PNG format and extending the cache expiry period:

```
add feo action allact -imgGifToPng -pageExtendCache
```

1. [Optional] Specify non-default values for front end optimization global settings.

```
set feo parameter [-cacheMaxage <integer>] [-JpegQualityPercent <integer>] [-cssInlineThresSize <integer>] [-inlineJsThresSize <integer>] [-inlineImgThresSize <integer>]
```

Example: To specify the cache maximum expiry period:

```
set feo parameter -cacheMaxage 10
```

1. Create one or more front end optimization policies.

```
add feo policy <name> <rule> <action>
```

Example: To add a front end optimization policy and associate it with the above specified allact action:

```
1 >add feo policy pol1 TRUE all act
2 >add feo policy pol1 "(HTTP.REQ.URL.CONTAINS(\"testsite\"))" allact1
3 <!--NeedCopy-->
```

1. Bind the policy to a load balancing or content switching virtual server, or bind it globally.

```
bind lb vserver <name> -policyName <string> -priority <num>
```

```
bind cs vserver <name> -policyName <string> -priority <num>
```

```
bind feo global <policyName> <priority> -type <type> <gotoPriorityExpression>
```

Example: To apply the front end optimization policy to a virtual server named “abc”:

```
bind lb vserver abc -policyName pol1 -priority 1 -type NONE
```

Example: To apply the front end optimization policy for all the traffic reaching the ADC:

```
bind feo global pol1 100 -type REQ_DEFAULT
```

1. Save the configuration. `save ns config`

## Configure front end optimization by using the GUI

1. Navigate to **Optimization > Front End Optimization > Actions**, and click **Add** and create a front end optimization action by specifying the relevant details.
2. [Optional] Specify the front end optimization global settings.
3. Navigate to **Optimization > Front End Optimization**, and on the right-pane, under Settings, click **Change Front End Optimization** settings and specify the front end optimization global settings.
4. Create a front end optimization policy.
5. Navigate to **Optimization > Front End Optimization > Policies**, click **Add** and create a front end optimization policy by specifying the relevant details.
6. Bind the policy to a load balancing or content switching virtual server.
  - a) Navigate to **Optimization > Front End optimization > Policies**.
  - b) Select a front end optimization policy and click **Policy Manager**.
  - c) Under **Front End Optimization Policy Manager**, bind the front end optimization policy to a load balancing or content switching virtual server.

## Verify front end optimization configuration

The dashboard utility displays summary and detailed statistics in tabular and graphic formats. You can view the FEO statistics to evaluate your FEO configuration.

Optionally, you can also display statistics for an FEO policy, including the number of select that the policy counter increments during the policy based FEO.

### Note:

For more information about statistics and charts, see the Dashboard help on the NetScaler appliance.

## View FEO statistics by using the CLI

At the command prompt, type the following commands to display a summary of FEO statistics, FEO policy select and details, and detailed FEO statistics, respectively:

- `stat feo` Note: The `stat feo` policy command displays statistics only for advanced FEO policies.
- `show feo policy name`
- `stat feo -detail`

## View FEO statistics on NetScaler dashboard

In the dashboard GUI, you can:

- Select Front End Optimization to display a summary of FEO statistics.
- Click the **Graphical View** tab to display the rate of requests processed by the FEO feature.

### Sample optimization:

Refer to the [Sample PDF](#) for some examples of content optimization actions that are applied on HTML content and the embedded objects within the HTML content.

## Media classification

May 2, 2023

Understanding the type of traffic in the network helps network administrators to manage bandwidth consumption for optimal network performance. The media classification mode monitors and displays the statistics of media traffic going through the NetScaler appliance.

With this mode enabled, a network administrator can collect stats showing the amount of data accessed, and the types of devices from which the media files have been accessed. The NetScaler appliance also supports byte-range requests in this mode.

Currently the NetScaler appliance can monitor and display statistics for the following media file types:

---

Media	File type
Microsoft Smooth Streaming	Video
Apple Live Streaming	Video

Media	File type
Audio Data Transport Stream (ADTS)	Audio
Advanced Audio Coding (AAC)	Audio
Flash Video (FLV)	Audio and Video
3GP	Audio and Video

The appliance can display stats for the following devices:

Device Platform	Device Type
iOS	iPad and iPod
Android	Mobiles and tablets
Laptop or Desktop	Windows laptop and desktop computers
Others	Other mobile devices (mobiles and tablets)

The network administrators can check the following stats counters to know the amount of data accessed through the NetScaler appliance for various media traffic types.

Media File Name	Stats Counter
Microsoft Smooth Streaming	<p><a href="#">mcmssmthstrmvid</a>—This counter records the total number of Microsoft Smooth Streaming videos served by the NetScaler appliance; <a href="#">Mcmssmthstrvidpl</a>—This counter records the total number of Microsoft Smooth Streaming video playlists served by the NetScaler appliance; <a href="#">Mcmssmthstrmvidbytes</a>—This counter records the total number of data bytes served for Microsoft Smooth Streaming media traffic on the NetScaler appliance; <a href="#">Mcmssmthstrmplvidbytespl</a>—This counter records the total number of Microsoft Smooth Streaming playlist bytes served by the NetScaler appliance.</p>

Media File Name	Stats Counter
Apple Live Streaming	<p><code>mccapplelivestrmngvid</code>—This counter records the total number of Apple Live Streaming videos served by the NetScaler appliance. <code>Mccapplelivestrmngvidpl</code>—This counter records the total number of Apple Live Streaming video playlists served by the NetScaler appliance. <code>Mcapplelivestreamingvidbytes</code>—This counter records the total number of data bytes served for Apple Live Streaming media traffic on the NetScaler appliance. <code>Mcapplelivestreamingplaylistvidbytespl</code>—This counter records the total number of Apple Live Playlist bytes served by the NetScaler appliance.</p>
Audio Data Transport Stream (ADTS)	<p><code>mcadtsaudio</code>—This counter records the total number of ADTS audio clips served by the NetScaler appliance. <code>Mcadtsaudiobytes</code>—This counter records the total number of data bytes served for ADTS media traffic on the NetScaler appliance.</p>
Advanced Audio Coding (AAC)	<p><code>mcaacaudio</code>—This counter records the total number of AAC audio clips served by the NetScaler appliance. <code>Mcaacaudiobytes</code>—This counter records the total number of data bytes served for AAC media traffic on the NetScaler appliance.</p>
Flash Video (FLV)	<p><code>Mcflvvid</code>—This counter records the total number of flash videos served by the NetScaler appliance. <code>Mcflvvidbytes</code>—This counter records the total number of data bytes served for flash videos on the NetScaler appliance.</p>
3GP	<p><code>mc3gpvidbytes</code>—This counter records the total number of data bytes served for 3GP media traffic on the NetScaler appliance.</p>

The NetScaler appliance detects media file types by their signatures in the *initial body bytes* of the responses. For example, the initial body bytes for an mp4 file have the following signature in the response:

```
...ftypmp42 ...isommp42...moov...lmvhd.....c.\!.c.\!..
```

The NetScaler appliance detects the client device type by the *user agent string* that the client device includes in the HTTP GET request. For example, a window phone using a UC browser has the following user agent string in the HTTP GET request:

```
User-Agent: **UCWEB**/2.0 (**Windows**; U; wds 8.10; en-US; HTC; 8X
by HTC)U2/1.0.0
```

## Enable media classification

By default, media classification is disabled on the NetScaler appliance. You have to enable the mode before using it.

To enable media classification by using the command line interface

At the command prompt, type:

```
enable ns mode Mediaclassification
```

To enable media classification by using the GUI

Enable media classification on NetScaler appliance

Navigate to **System > Settings > Configure Modes** and select **Media Classification**.

To view media traffic statistics on the NetScaler appliance

Navigate to **Optimization** and click **Media Classification** to view the media traffic statistics.

## Verify media classification statistics

You can view the media traffic statistics in the dashboard utility or using the command line interface. The dashboard utility displays summary and detailed statistics in a tabular and graphic format.

### Note

For more information about statistics and charts, see the Dashboard help on your NetScaler appliance.

To View media classification statistics by using the command line interface

At the command prompt, type one of the following commands to display a summary of media classification statistics, display detailed statistics, or clear the display:

```
stat Mediaclassification
```

```
stat Mediaclassification -detail
```

```
stat Mediaclassification -clearstats
```

To view Media Classification statistics on the Dashboard

In the **Dashboard** utility, you can display the following types of media classification statistics:

1. Select **Media Classification** to display a summary of the media traffic statistics.
2. To display detailed media traffic statistics, click the **Details**.
3. To clear the media traffic statistics, click **Clear**.

## Reputation

May 2, 2023

NetScaler offers reputation based security. Using reputation assessment to determine the risk of processing requests, you can take actions such as blocking or dropping certain requests to improve the performance of your application.

The NetScaler IP reputation feature uses IP reputation checks to prevent Zero day attacks and provide protection against malicious sources associated with web attacks, phishing activity, or web scanning.

For more details, see [IP Reputation](#).

## IP Reputation

October 30, 2023

IP reputation is a tool that identifies IP addresses that send unwanted requests. Using the IP reputation list you can reject requests that are coming from an IP address with a bad reputation. Optimize Web Application Firewall performance by filtering requests that you do not want to process. Reset, drop a request, or even configure a responder policy to take a specific responder action.

The following are some attacks that you can prevent by using IP Reputation:

- **Virus Infected personal computers.** (home PCs) are the single biggest source of Spam on the internet. IP Reputation can identify the IP address that is sending unwanted requests. IP reputation can be especially useful for blocking large scale DDoS, DoS, or anomalous SYN flood attacks from known infected sources.

- **Centrally managed and automated botnet.** Attackers have gained popularity for stealing passwords, because it doesn't take long when hundreds of computers work together to crack your password. It is easy to launch botnet attacks to figure out passwords that use commonly used dictionary words.
- **Compromised web-server.** Attacks are not as common because awareness and server security have increased, so hackers and spammers look for easier targets. There are still web servers and online forms that hackers can compromise and use to send spam (such as viruses and porn). Such activity is easier to detect and quickly shut down, or block with a reputation list such as SpamRats.
- **Windows Exploits.** (such as Active IPs offering or distributing malware, shell code, rootkits, worms, or viruses).
- **Known spammers and hackers.**
- **Mass e-mail marketing campaigns.**
- **Phishing Proxies** (IP addresses hosting phishing sites, and other fraud such as ad click fraud or gaming fraud).
- **Anonymous proxies** (IPs providing proxy and anonymization services including The Onion Router aka TOR).

A NetScaler appliance uses **Webroot** as the service provider for a dynamically generated malicious IP database and the metadata for those IP addresses. Metadata might include geolocation details, threat category, threat count, and so on. The Webroot threat Intelligence engine receives real-time data from millions of sensors. It automatically and continuously captures, scans, analyses and scores the data, using advanced machine learning and behavioral analysis. Intelligence about a threat is continually updated.

The NetScaler appliance validates an incoming request for its bad reputation using the Webroot's IP reputation database. The database has a huge collection of IP address classified based IP threat categories. Following are the IP threat categories and its description.

- **Spam Sources.** Spam Sources includes Tunneling Spam messages through proxy, anomalous SMTP activities, Forum Spam activities.
- **Windows Exploits.** The Windows Exploits category includes active IP Address offering or distributing malware, shell code, rootkits, worms, or viruses
- **Web Attacks.** The Web Attacks category includes cross site scripting, iFrame injection, SQL injection, cross domain injection, or domain password brute force attack
- **Botnets.** The Botnet category includes Botnet C&C channels, and infected zombie machine controlled by Bot master
- **Scanners.** The Scanners category includes all reconnaissance such as probes, host scan, domain scan and password brute force attack
- **Denial of Service.** The Denial of Services category includes DOS, DDOS, anomalous sync flood, anomalous traffic detection

- **Reputation.** Deny access from IP addresses currently known to be infected with malware. This category also includes IPs with average low Webroot Reputation Index score. Enabling this category prevents access from sources identified to contact malware distribution points.
- **Phishing.** The Phishing category includes IP addresses hosting phishing sites, other kinds of fraud activities such as Ad Click Fraud or Gaming fraud
- **Proxy.** The Proxy category includes IP addresses providing proxy and def services.
- **Mobile Threats.** The Mobile Threats category includes IP addresses of malicious and unwanted mobile applications. This category leverages data from the Webroot mobile threat research team.
- **Tor Proxy.** The Tor Proxy category includes IP addresses acting as exit nodes for the Tor Network. Exit nodes are the last point along the proxy chain and make a direct connection to the originator's intended destination.

When a threat is detected anywhere in the network, the IP address is flagged as malicious and all appliances connected to the network are immediately protected. The dynamic changes in the IP addresses are processed with high speed and accuracy by using advanced machine learning.

As stated in the data sheet from Webroot, the Webroot's sensor network identifies many key IP threat types, including spam sources, Windows exploits, botnets, scanners, and others. (See the flow diagram on the data sheet.)

The NetScaler appliance uses an `iprep` client process to get the database from Webroot. The `iprep` client uses the HTTP GET method to get the absolute IP list from Webroot for the first time. Later, it checks delta changes once every 5 minutes.

**Important:**

- Make sure that the NetScaler appliance has Internet access and DNS is configured before you use the IP Reputation feature.
- To access the Webroot database, the NetScaler appliance must be able to connect to **api.bcti.brightcloud.com** on **port 443**. Each node in the HA or cluster deployment gets the database from Webroot and must be able to access this Fully Qualified Domain Name (FQDN).
- Webroot hosts its reputation database in AWS currently. Therefore, NetScaler must be able to resolve AWS domains for downloading the reputation db. Also, the firewall must be open for AWS domains.

**Note:**

Each packet engine requires at least 4 GB to function properly when the IP Reputation feature is enabled.

**Advanced policy Expressions.** Configure the IP Reputation feature by using advanced policy expres-

sions (Advanced policy expressions) in the policies bound to supported modules, such as Web Application Firewall and responder. The following are two examples showing expressions that can be used to detect whether the client IP address is malicious.

1. **CLIENT.IP.SRC.IPREP\_IS\_MALICIOUS:** This expression evaluates to TRUE if the client is included in the malicious IP list.
2. **CLIENT.IP.SRC.IPREP\_THREAT\_CATEGORY (CATEGORY):** This expression evaluates to TRUE if the client IP is malicious IP and is in the specified threat category.
3. **CLIENT.IPV6.SRC.IPREP\_IS\_MALICIOUS and CLIENT.IPV6.SRC.IPREP\_THREAT\_CATEGORY:** This expression evaluates to TRUE if the client IP is of type IPv6 and it is a malicious IP address in a specified threat category.

Following are the possible values for the threat category:

SPAM\_SOURCES, WINDOWS\_EXPLOITS, WEB\_ATTACKS, BOTNETS, SCANNERS, DOS, REPUTATION, PHISHING, PROXY, NETWORK, CLOUD\_PROVIDERS, MOBILE\_THREATS, TOR\_PROXY.

**Note:**

The IP reputation feature checks both source and destination IP addresses. It detects malicious IPs in the header. If the PI Expression in a policy can identify the IP address, the IP reputation check determines whether it is malicious.

**IPRep log message.** The `/var/log/iprep.log` file contains useful messages that capture information about communication with the Webroot database. The information can be about the credentials used during Webroot communication, failure to connect with Webroot, information included in an update (such as the number of IP addresses in the database).

**Creating a blocklist or allowlist of IPs using a policy data set.** You can maintain an allow list to allow access to specific IP addresses that are blocklisted in the Webroot database. You can also create a customized block list of IP addresses to supplement the Webroot reputation check. These lists can be created by using a policy **data set**. A data set is a specialized form of pattern set that is ideally suited for IPv4 or IPv6 address matching. To use data sets, first create the data set and bind IPv4 or IPv6 addresses to it. When configuring a policy for comparing a string in a packet, use an appropriate operator and pass the name of the pattern set or data set as an argument.

To create an allow list of addresses to treat as exceptions during IP reputation evaluation:

- Configure the policy so that the PI expression evaluates to False even if an address in the allow list is listed as malicious by Webroot (or any service provider).

**Enabling or disabling IP reputation.** IP reputation is a part of the general reputation feature, which is license based. When you enable or disable the reputation feature, it enables or disables IP Reputation.

**General procedure.** Deploying IP reputation involves the following tasks

- Verify that the license installed on the NetScaler appliance has IP reputation support. Premium and standalone application firewall licenses support the IP reputation feature.
- Enable the IP reputation and application firewall features.
- Add an application firewall profile.
- Add an application firewall policy using the PI expressions to identify the malicious IP addresses in the IP Reputation database.
- Bind the application firewall policy to an appropriate bind point.
- Verify that any request received from a malicious address gets logged in the `ns.log` file to show that the request was processed as specified in the profile.

### Configure the IP reputation feature using the CLI

At the command prompt, type:

- `enable feature reputation`
- `disable feature reputation`

The following examples show how you can add an application firewall policy using the PI expression to identify malicious addresses. You can use the built-in profiles, or add a profile, or configure an existing profile to invoke the desired action when a request matches a policy match.

Examples 3 and 4 show how to create a policy dataset to generate a block list or an allow list of IP addresses.

#### Example 1:

The following command creates a policy that identifies malicious IP addresses and block the request if a match is triggered:

```
add appfw policy pol1 CLIENT.IP.SRC.IPREP_IS_MALICIOUS APPFW_BLOCK
add appfw policy pol1 CLIENT.IPv6.SRC.IPREP_IS_MALICIOUS APPFW_BLOCK
add appfw policy pol1 "HTTP.REQ.HEADER(\"X-Forwarded-For\").TYPECAST_IPv6_ADDR
.IPREP_IS_MALICIOUS"APPFW_RESET
```

#### Example 2:

The following command creates a policy that uses the reputation service to check the client IP address in the `X-Forwarded-For` header and reset the connection if a match is triggered.

```
> add appfw policy pol1 "HTTP.REQ.HEADER(\"X-Forwarded-For\").TYPECAST_IP_ADDR
.IPREP_IS_MALICIOUS"APPFW_RESET**
```

#### Example 3:

The following example shows how to add a list to add exceptions that allow specified IP addresses:

```
> add policy dataset Allow_list1 ipv4
```

```
> bind policy dataset Allow_list1 10.217.25.17 -index 1
> bind policy dataset Allow_list1 10.217.25.18 -index 2
```

The following example shows how to add a list to add exceptions that allow specified IPv6 addresses:

```
1 add policy dataset Allow_list_ipv6 ipv6
2 bind policy dataset Allow_list_ipv6 fe80::98c7:d8ff:fe3a:b562 -index 1
3 bind policy dataset Allow_list_ipv6 fe80::98c7:d8ff:fe3a:b563 -index 2
4
5 <!--NeedCopy-->
```

#### Example 4:

The following example shows how to add the customized list to flag specified IP addresses as malicious:

```
> add policy dataset Block_list1 ipv4
> bind policy dataset Block_list1 10.217.31.48 -index 1
> bind policy dataset Block_list1 10.217.25.19 -index 2
```

The following example shows how to add the customized list to flag specified IPv6 addresses as malicious.

```
1 add policy dataset Block_list_ipv6 ipv6
2 bind policy dataset Block_list_ipv6 fe80::98c7:d8ff:ff3b:b562 -index 1
3 bind policy dataset Block_list_ipv6 fe80::ffc7:d8ff:fe3a:b562 -index 2
4 <!--NeedCopy-->
```

#### Example 5:

The following example shows a policy expression to block the client IP in the following conditions:

- It matches an IP address configured in the customized Block\_list1 (example 4)
- It matches an IP address listed in the Webroot database unless relaxed by inclusion in the Allow\_list1 (example 3).

```
1 > add appfw policy "Ip_Rep_Policy" "((CLIENT.IP.SRC.IPREP_IS_MALICIOUS
 || CLIENT.IP.SRC.TYPECAST_TEXT_T.CONTAINS_ANY(\"Block_list1\")) && !
 (CLIENT.IP.SRC.TYPECAST_TEXT_T.CONTAINS_ANY(\"Allow_list1\")))"
 APPFW_BLOCK
2 <!--NeedCopy-->
```

The following example shows a policy expression to block the client IPv6 in the following conditions:

1. It matches an IPv6 address configured in the customized Block\_list\_ipv6 (example 4)
2. It matches an Ipv6 address listed in the Webroot database unless relaxed by inclusion in the Allow\_list\_ipv6 (example 3).

```
1 add appfw policy "Ip_Rep_v6_Policy" "((CLIENT.IPV6.SRC.
 IPREP_IS_MALICIOUS || CLIENT.IPV6.SRC.TYPECAST_TEXT_T.CONTAINS_ANY
 (\\"Block_list_ipv6\\")) && ! (CLIENT.IPV6.SRC.TYPECAST_TEXT_T.
 CONTAINS_ANY(\\"Allow_list_ipv6\\")))" APPFW_BLOCK
2 <!--NeedCopy-->
```

### Using Proxy server:

If the NetScaler appliance does not have direct access to the internet and is connected to a proxy, configure the IP Reputation client to send requests to the proxy.

Configure a proxy user name and password on the proxy server for an additional layer of security for your appliance.

At the command prompt, type:

```
set reputation settings -proxyServer <proxy server ip> -proxyPort <
proxy server port> -proxyUsername <username> -proxyPassword <password
>
```

### Example:

```
> set reputation settings proxyServer 10.102.30.112 proxyPort 3128 -
proxyUsername defaultusername -proxyPassword defaultpassword
> set reputation settings -proxyServer testproxy.citrite.net -proxyPort
3128 -proxyUsername defaultusername -proxyPassword defaultpassword
> unset reputation settings -proxyserver -proxyport -proxyUsername -
proxyPassword
> sh reputation settings
```

#### Note:

The Proxy Server IP can be an IP address or a fully qualified domain name (FQDN).

## Configure IP reputation by using NetScaler GUI

1. Navigate to the **System > Settings**. In the **Modes and Features** section, click the link to access the **Configure Advanced Features** pane and enable the **Reputation** checkbox.
2. Click **OK**.

## To configure a proxy server by using the NetScaler GUI

1. On the **Configuration** tab, navigate to **Security > Reputation**.
2. Under **Settings**, click **Change Reputation Settings** to configure a proxy server.

3. Enable or disable the reputation feature.
4. Enter the following details to configure the proxy server:
  - a) **Proxy Server** - It can be an IP address or a fully qualified domain name (FQDN).
  - b) **Proxy port** - It accepts values between [1–65535].
  - c) **Proxy Username** –Provide a user name for proxy server authentication.
  - d) **Proxy Password** - Provide a password for proxy server authentication.

**Note:**

The **proxyUsername** and **proxyPassword** fields are enabled if the **proxyServer** and **proxyPort** fields are configured.

### Create an allow list and a block list of client IP addresses using the GUI

1. On the **Configuration** tab, navigate to **AppExpert > Data Sets**.
2. Click **Add**.
  - In the **Create Data Set** (or **Configure Data set**) pane, provide a meaningful name for the list of the IP addresses. The name must reflect the purpose of the list.
  - Select **Type** as **IPv4** or **IPv6**.
  - Click **Insert** to add an entry.
  - In the **Configure Policy dataset binding** pane, add an IPv4 or IPv6 format IP address in the Value input box.
  - Provide an index.
  - Add a comment that explains the purpose of the list. This step is optional, but is recommended because a descriptive comment is helpful in managing the list.

Similarly, you can create a block list and add the IP addresses that are to be considered malicious.

Also see, [Pattern sets and data sets](#) for more details regarding using data sets and configuring Advanced policy expressions.

Configure an application firewall policy by using the NetScaler GUI

1. On the **Configuration** tab, navigate to **Security > Application Firewall > Policies > Firewall**. Click **Add** to add a policy using the PI expression to use IP reputation.

You can also use the Expression editor to build your own policy expression. The list shows preconfigured options that are useful for configuring an expression using the threat categories.

## Highlights

- Quickly and accurately stop bad traffic at the network's edge from known malicious IP addresses posing different types of threats. You can block the request without parsing the body.
- Dynamically configure IP reputation functionality for multiple applications.
- Secure your network against data breach without a performance penalty, and consolidate protections onto a single service fabric using fast and easy deployments.
- You can do IP Reputation checks on source and destination IPs.
- You can also inspect the headers to detect malicious IPs.
- IP reputation check is supported in both forward proxy and reverse proxy deployments.
- The IP Reputation process connects with Webroot and updates the database every 5 minutes.
- Each node in the High Availability (HA) or Cluster deployment gets the database from Webroot.
- The IP reputation data is shared across all partitions in admin-partition deployments.
- You can use an AppExpert data set to create lists of IP addresses to add exceptions for IPs block-listed in the Webroot database. You can also create your own customized block list to designate specific IPs as malicious.
- The `iprep.db` file is created in the `/var/nslog/iprep` folder. Once created, it is not deleted even if the feature is disabled.
- When the reputation feature is enabled, the NetScaler Webroot database is downloaded. After that, it is updated every 5 minutes.
- The Webroot database major version is version: 1.
- The minor version gets updated every day. The update version is incremented after every 5 minutes and is reset back to 1 when the minor version is incremented.
- PI expressions enable you to use IP reputation with other features, such as responder and rewrite.
- The IP addresses in the database are in decimal notation.

## Debugging tips

- If you cannot see the reputation feature in the GUI, verify that you have the right license.
- Monitor the messages in `var/log/iprep.log` for debugging.
- **Webroot connectivity:** If you see the `ns iprep: Not able to connect/resolve WebRoot` message, make sure that the appliance has internet access and DNS is configured.
- **Proxy server:** If you see the `ns iprep: iprep_curl_download: 88 curl_easy_perform failed. Error code: 5 Err msg:couldnt resolve proxy name` message, make sure that the proxy server configuration is accurate.
- **IP Reputation feature not working:** The IP Reputation process takes about five minutes to start after you enable the reputation feature. The IP reputation feature might not work for that duration.

- **Database download:** If the IP DB data download is failing after enabling the IP Reputation feature, the following error is seen in the logs.

```
iprep: iprep_curl_download:86 curl_easy_perform failed. Error code:7
Err msg:Couldn't connect to server
```

**Solution:** Allow the out-bound traffic to the following URLs or configure a proxy to resolve the issue.

```
1 localdb-ip-daily.brightcloud.com:443
2 localdb-ip-rtu.brightcloud.com:443
3 api.bcti.brightcloud.com:443
4 localdb-ipv6-daily.brightcloud.com:443
5 ipce-daily.brightcloud.com:443
6 ipce-rtu.brightcloud.com:443
7 <!--NeedCopy-->
```

## SSL offload and acceleration

May 2, 2023

A NetScaler appliance configured for SSL acceleration transparently accelerates SSL transactions by offloading SSL processing from the server. To configure SSL offloading, you configure a virtual server to intercept and process SSL transactions, and send the decrypted traffic to the server (unless you configure end-to-end encryption, in which case the traffic is re-encrypted). Upon receiving the response from the server, the appliance completes the secure transaction with the client. From the client's perspective, the transaction seems to be directly with the server. A NetScaler configured for SSL acceleration also performs other configured functions, such as load balancing.

Configuring SSL offloading requires an SSL certificate and key pair, which you must obtain if you do not already have an SSL certificate. Other SSL-related tasks that you might need to perform include managing certificates, managing certificate revocation lists, configuring client authentication, and managing SSL actions and policies.

A non-FIPS NetScaler appliance stores the server's private key on the hard disk. On a FIPS appliance, the key is stored in a cryptographic module known as a hardware security module (HSM).

All NetScaler appliances that do not support a FIPS card (including virtual appliances) support the Thales nShield® Connect and SafeNet external HSMs. (MPX 9700/10500/12500/15500 appliances do not support an external HSM.)

**Note:** FIPS-related options for some of the SSL configuration procedures described in this document are specific to a FIPS-enabled NetScaler appliance.

## SSL offloading configuration

December 28, 2023

To configure SSL offloading, you must enable SSL processing on the NetScaler appliance and configure an SSL based virtual server. The virtual server will intercept SSL traffic, decrypt the traffic, and forward it to a service that is bound to the virtual server. To secure time-sensitive traffic, such as media streaming, you can configure a DTLS virtual server. To enable SSL offloading, you must import a valid certificate and key and bind the pair to the virtual server.

### Note

From release 13.1 build 17.x, protocols lower than TLSv1.2 are disabled on the SSL internal services. If the default (enhanced) profile is enabled, then the `ns_default_ssl_profile_internal_frontend` profile is bound to the SSL internal services and SSLv3, TLSv1.0, and TLSv1.1 protocols are disabled in the profile.

### Enable SSL

To process SSL traffic, you must enable SSL processing. You can configure SSL based entities, such as virtual servers and services, without enabling SSL processing. However, they do not work until SSL processing is enabled.

### Enable SSL processing by using the CLI

At the command prompt, type:

```
1 enable ns feature ssl
2
3 show ns feature
4 <!--NeedCopy-->
```

### Example:

```
1 enable ns feature SSL
2 Done
3 show ns feature
4
5 Feature Acronym Status
6 -----
7 1) Web Logging WL OFF
8 2) Surge Protection SP ON
9 3) Load Balancing LB ON
10 .
11 .
```

```

12 .
13 9) SSL Offloading SSL ON
14 .
15 .
16 .
17 24) NetScaler Push push OFF
18 Done
19 <!--NeedCopy-->

```

### Enable SSL processing by using the GUI

Navigate to **System > Settings** and, in the **Modes and Features** group, click **Configure Basic Features**, and click **SSL Offloading**.

### Configure services

On the NetScaler appliance, a service represents a physical server or an application on a physical server. Once configured, services are in the disabled state until the appliance can reach the physical server on the network and monitor its status.

### Add a service by using the CLI

At the command prompt, type the following commands to add a service and verify the configuration:

```

1 add service <name> (<IP> | <serverName>) <serviceType> <port>
2 show service <serviceName>
3 <!--NeedCopy-->

```

### Example:

```

1 add service sslsvc 198.51.100.225 SSL 443
2
3 Done
4
5 sh ssl service sslsvc
6
7 Advanced SSL configuration for Back-end SSL Service sslsvc:
8 DH: DISABLED
9 DH Private-Key Exponent Size Limit: DISABLED Ephemeral
 RSA: DISABLED
10 Session Reuse: ENABLED Timeout: 300 seconds
11 Cipher Redirect: DISABLED
12 SSLv2 Redirect: DISABLED
13 ClearText Port: 0
14 Server Auth: DISABLED

```

```

15 SSL Redirect: DISABLED
16 Non FIPS Ciphers: DISABLED
17 SNI: DISABLED
18 OCSP Stapling: DISABLED
19 SSLv2: DISABLED SSLv3: ENABLED TLSv1.0: ENABLED TLSv1.1:
 ENABLED TLSv1.2: ENABLED TLSv1.3: DISABLED
20 Send Close-Notify: YES
21 Strict Sig-Digest Check: DISABLED
22 Zero RTT Early Data: ???
23 DHE Key Exchange With PSK: ???
24 Tickets Per Authentication Context: ???
25
26 ECC Curve: P_256, P_384, P_224, P_521
27
28 1) Cipher Name: DEFAULT_BACKEND
29 Description: Default cipher list for Backend SSL session
30 Done
31 <!--NeedCopy-->

```

### Modify or remove a service by using the CLI

To modify a service, use the `set service` command, which is just like using the `add service` command, except that you enter the name of an existing service.

To remove a service, use the `rm service` command, which accepts only the `<name>` argument.

```

1 rm service <servicename>
2 <!--NeedCopy-->

```

#### Example:

```

1 rm service sslsvc
2 <!--NeedCopy-->

```

To modify a service, use the `set service` command, select any parameter, and change its setting.

```

1 set service <name> (<IP> | <serverName>) <serviceType> <port>
2 <!--NeedCopy-->

```

#### Example:

```

1 set service sslsvc 198.51.100.225 SSL 443
2 <!--NeedCopy-->

```

### Configure a service by using the GUI

Navigate to **Traffic Management > Load Balancing > Services**, create a service, and specify the protocol as SSL.

## SSL virtual server configuration

Secure sessions require establishing a connection between the client and an SSL-based virtual server on the NetScaler appliance. The SSL virtual server intercepts SSL traffic, decrypts it and processes it before sending it to services that are bound to the virtual server.

**Note:** The SSL virtual server is marked as down on the NetScaler appliance until a valid certificate / key pair and at least one service are bound to it. An SSL based virtual server is a load balancing virtual server of protocol type SSL or SSL\_TCP. The load balancing feature must be enabled on the NetScaler appliance.

### Add an SSL-based virtual server by using the CLI

At the command prompt, type the following commands to create an SSL-based virtual server and verify the configuration:

```
1 add lb vserver <name> (serviceType) <IPAddress> <port>
2 show ssl vserver <name>
3 <!--NeedCopy-->
```

### Example:

```
1 add lb vserver sslvs SSL 192.0.2.240 443
2 Done
3
4 sh ssl vserver sslvs
5
6 Advanced SSL configuration for VServer sslvs:
7 DH: DISABLED
8 DH Private-Key Exponent Size Limit: DISABLED Ephemeral
9 RSA: ENABLED Refresh Count: 0
10 Session Reuse: ENABLED Timeout: 120 seconds
11 Cipher Redirect: DISABLED
12 SSLv2 Redirect: DISABLED
13 ClearText Port: 0
14 Client Auth: DISABLED
15 SSL Redirect: DISABLED
16 Non FIPS Ciphers: DISABLED
17 SNI: DISABLED

### Modify or remove an SSL-based virtual server by using the CLI

To modify the load balancing properties of an SSL virtual server, use the `set lb vserver` command. The set command is similar to the `add lb vserver` command, except that you enter the name of an existing virtual server. To modify the **SSL** properties of an SSL-based virtual server, use the `set ssl vserver` command. For more information, see the “SSL virtual server parameters” section later in this page.

To remove an SSL virtual server, use the `rm lb vserver` command, which accepts only the `<name>` argument.

### Configure an SSL-based virtual server by using the GUI

Navigate to **Traffic Management > Load Balancing > Virtual Servers**, create a virtual server, and specify the protocol as SSL.

### Bind services to the SSL virtual server

The ADC appliance forwards decrypted SSL data to servers in the network. To forward data, services representing these physical servers must be bound to the virtual server that receives the SSL data.

Typically, the link between the ADC appliance and the physical server is secure. Therefore, data transfer between the appliance and the physical server does not have to be encrypted. However, you can provide end-to-end-encryption by encrypting data transfer between the appliance and the server. For details, see [Configure SSL offloading with end-to-end encryption](#).

**Note:** Enable the load balancing feature on the ADC appliance before you bind services to the SSL based virtual server.

### Bind a service to a virtual server by using the CLI

At the command prompt, type the following commands to bind the service to the virtual server and verify the configuration:

```

1 bind lb vserver <name> <serviceName>
2 show lb vserver <name>
3 <!--NeedCopy-->

```

**Example:**

```

1 bind lb vserver sslvs sslsvc
2 Done
3
4 sh lb vserver sslvs
5
6 sslvs (192.0.2.240:443) - SSL Type: ADDRESS

39 <!--NeedCopy-->

```

**Unbind a service from a virtual server by using the CLI**

At the command prompt, type the following command:

```

1 unbind lb vserver <name> <serviceName>

```

```
2 <!--NeedCopy-->
```

**Example:**

```
1 unbind lb vserver sslvs sslsvc
2 Done
3 <!--NeedCopy-->
```

**Bind a service to a virtual server by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open a virtual server and click the **Load Balancing Virtual Server Service Bindings** tile under the **Services and Service Groups** section.
3. In the **Load Balancing Virtual Server Service Binding** page, click the **Add Bindings** tab, click **Click to select** under **Select Service**, and select the checkbox next to the service to be bound.
4. Click **Select** and click **Bind**.

**Configure a server name indication (SNI) virtual server for secure hosting of multiple sites**

Virtual hosting is used by web servers to host more than one domain name with the same IP address. The appliance supports hosting of multiple secure domains by offloading SSL processing from the web servers using transparent SSL services or virtual server-based SSL offloading. However, when multiple websites are hosted on the same virtual server, the SSL handshake is completed before the expected host name is sent to the virtual server. As a result, the appliance cannot determine which certificate to present to the client after a connection is established. This problem is resolved by enabling SNI on the virtual server. SNI is a Transport Layer Security (TLS) extension used by the client to provide the host name during handshake initiation. The ADC appliance compares this host name to the common name and, if it does not match, compares it to the subject alternative name (SAN). If the name matches, the appliance presents the corresponding certificate to the client.

A wildcard SSL certificate helps enable SSL encryption on multiple subdomains if the same organization controls these domains and the second-level domain name is the same. For example, a wildcard certificate issued to a sports network using the common name “\*.sports.net” can be used to secure domains, such as “login.sports.net” and “help.sports.net”. It cannot secure the “login.ftp.sports.net” domain.

**Note:**

On an ADC appliance, only the domain name, URL, and email ID DNS entries in the **SAN** field are compared.

You can bind multiple server certificates to a single SSL virtual server or transparent service using the `-SNICert` option. The virtual server or service issues these certificates if SNI is enabled on the virtual server or service. You can enable SNI at any time.

### Bind multiple server certificates to a single SSL virtual server by using the CLI

At the command prompt, type the following commands to configure SNI and verify the configuration:

```
1 set ssl vservice <vServerName>@ [-SNIEnable (ENABLED | DISABLED)]
2
3 bind ssl vservice <vServerName>@ -certkeyName <string> -SNICert
4
5 show ssl vservice <vServerName>
6 <!--NeedCopy-->
```

To bind multiple server certificates to a transparent service by using the CLI, replace `vservice` with `service` and `vservername` with service name in the preceding commands.

**Note:** Create the SSL service with the `-clearTextPort 80` option.

### Bind multiple server certificates to a single SSL virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Open an SSL virtual server and, in **Certificates**, select **Server Certificate**.
3. Add a certificate or select a certificate from the list, and click **Server Certificate for SNI**.
4. In **Advanced Settings**, select **SSL Parameters**.
5. Click **SNI Enable**.

### Support for SNI on the back-end service

**Note:** SNI is not supported on a DTLS back-end service.

The NetScaler appliance supports Server Name Indication (SNI) at the back end. That is, the common name is sent as the server name in the client hello to the back-end server for successful completion of the handshake. This support helps meet federal system integrator customer security requirements. Also, SNI provides the advantage of using only one port instead of opening hundreds of different IP addresses and ports on a firewall.

Federal system integrator customer security requirements include support for Active Directory Federation Services (ADFS) 3.0 in 2012R2 and WAP servers. To meet this requirement, support for SNI at the back end on a NetScaler appliance is required.

**Note:**

For SNI to work, the server name in the client hello must match the host name configured on the back-end service that is bound to an SSL virtual server. For example, if the host name of the back-end server is `www.mail.example.com`, the SNI-enabled back-end service must be configured with the server name as <https://www.mail.example.com>. And this host name must match the server name in the client hello.

**Support for dynamic SNI on the back-end service**

The NetScaler appliance supports dynamic SNI on the back-end TLS connections. That is, the appliance learns the SNI in the client connection and uses it in the server-side connection. You no longer need to specify a common name in the SSL service, service group, or profile. The common name received in the SNI extension of the Client Hello message is forwarded to the back-end SSL connection.

Earlier, you had to configure static SNI on SSL services, service groups, and SSL profiles. As a result, only the configured static SNI extension was sent to the server. If a client needed to access multiple domains at the same time, the ADC appliance was not able to send the SNI received from the client to the back-end service. Instead, it sent the static common name that was configured. Now, if the back-end server is configured for multiple domains, the server can respond with the correct certificate based on the SNI received in the Client Hello message from the appliance.

**Point to Note:**

- SNI must be enabled on the front end and the correct SNI certificate bound to the SSL virtual server. If you don't enable SNI on the front end, the SNI information is not passed to the back end.
- When server authentication is enabled, the server certificate is verified by the CA certificate and the common name/SAN entries in the server certificate are matched with the SNI. Therefore, the CA certificate must be bound to the service.
- Reuse of back-end connection and SSL session is based on SNI when dynamic SNI is enabled.

SSL monitors do not send SNI when dynamic SNI is enabled. For SNI-based probing, attach a back-end profile on which static SNI is configured to the SSL monitors. The monitor must be configured with the same custom header as SNI.

**Configure SNI on the back-end service by using the CLI**

At the command prompt, type:

```
1 add service <name> <IP> <serviceType> <port>
2
3 add lb vserver <name> <IPAddress> <serviceType> <port>
4
5 bind lb vserver <name> <serviceName>
6
7 set ssl service <serviceName> -SNIEnable ENABLED -commonName <string>
8
9 set ssl profile <name> -SNIEnable ENABLED
10 <!--NeedCopy-->
```

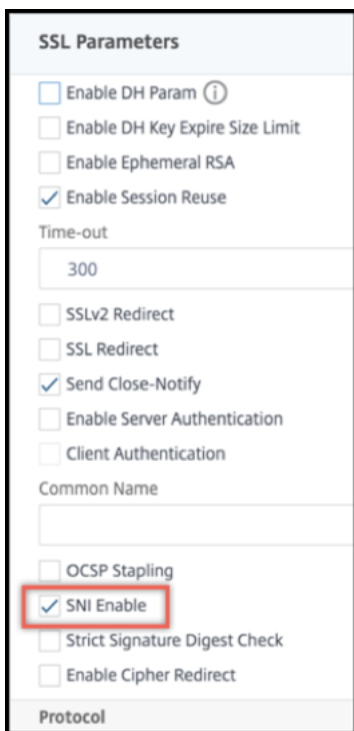

**Example:**

```
1 add service service_ssl 198.51.100.100 SSL 443
2
3 add lb vserver ssl-vs 203.0.113.200 SSL 443
4
5 bind lb vserver ssl-vs service_ssl
6
7 set ssl service service_ssl -SNIEnable ENABLED - commonName www.
 example.com
8
9 set ssl profile sslprof -SNIEnable ENABLED
10 <!--NeedCopy-->
```

**Configure SNI on the back-end service by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Services**.
2. Select an SSL service, and in **Advanced Settings**, click **SSL Parameters**.
3. Click **SNI Enable**.

**Configure SNI on the SSL profile by using the GUI**

1. Navigate to **System > Profiles > SSL Profile**.
2. Click **Add**.
3. In **Basic Settings**, select **SNI Enable**.

Basic Settings			
Name	ns_default_ssl_profile_backend	Session Reuse	ENABLED
SSL Profile Type	BackEnd	Session Timeout	300
PUSH Encryption Trigger	Always	Cipher Redirect	DISABLED
Encryption trigger packet count	45	Server Authentication	DISABLED
Push Flag	Auto (PUSH flag is not set)	Common Name	
PUSH encryption trigger timeout (ms)	1	OCSP Stapling	DISABLED
Encryption trigger timeout (10 ms ticks)	100	SSL Redirect	DISABLED
Deny SSL Renegotiation	ALL	<b>SNI Enable</b>	<b>ENABLED</b>
SSL quantum size (KBytes)	8192	Send Close-Notify	YES
DH Param	DISABLED	Non-FIPS Ciphers	DISABLED
DH Key Expire Size Limit	DISABLED	Strict CA checks	NO
Ephemeral RSA	DISABLED	Enable Client Authentication using bound CA Chain	DISABLED
SSL Log Profile	-	SSLv3	DISABLED
Strict Signature Digest Check	DISABLED	TLSv1	ENABLED
HSTS	DISABLED	TLSv11	ENABLED
Max Age	0	TLSv12	ENABLED
Include Subdomains	NO	TLSv13	DISABLED
Preload	NO	Zero RTT Early Data	DISABLED
SSL Sessions Interception	DISABLED	DHE Key Exchange with PSK	NO
Verify Server Certificate For Reuse On SSL Interception	ENABLED		
SSL Interception Client Renegotiation	ENABLED	Skip Client Certificate Policy Check	DISABLED
SSL Interception OCSP Check	ENABLED		
Maximum SSL Sessions Per Server On SSL Interception	10		
TLS13 Session Tickets Per Authcontext	1		

4. Click **OK**.

## Bind a secure monitor to an SNI-enabled back-end service

You can bind secure monitors of type HTTP, HTTP-ECV, TCP, or TCP-ECV to the back-end services and service groups that support SNI. However, the monitor probes do not send the SNI extension if dynamic SNI is enabled. To send SNI probes, enable static SNI in the back-end SSL profile and bind the profile to the monitor. Set the custom header in the monitor to the server name that is sent as the SNI extension in the client hello of the monitor probe.

**Configure and bind a secure monitor to an SNI-enabled back-end service by using the CLI** At the command prompt, type:

```
1 add lb monitor <monitorName> <type> -secure YES
2 add ssl profile <name> -sslProfileType BackEnd
3 set lb monitor <monitorName> <type> -customHeaders <string> -sslprofile
 <backend ssl profile>
4 set ssl profile <name> -sniEnable ENABLED -commonName <string>
5 bind service <name> -monitorName <string>
6 <!--NeedCopy-->
```

### Example:

```
1 add ssl profile sni_backend_profile -sslProfileType BackEnd
2 set ssl profile sni_backend_profile -sniEnable ENABLED -commonName
 example.com
3 add lb monitor http-ecv-mon HTTP-ECV -secure YES
4 set monitor http-ecv-mon HTTP-ECV -customHeaders "Host: example.com\r\n
 " -sslprofile sni_backend_profile
5 bind service ssl_service -monitorName http-ecv-mon
6 <!--NeedCopy-->
```

## Configure and bind a secure monitor to an SNI enabled back-end service by using the GUI

1. Navigate to **System > Profiles > SSL Profiles**.
2. Click **Add**.
3. Specify a name for the profile and in **SSL Profile Type**, select **Backend**.

**SSL Profile**

**Basic Settings**

Name\*  
sni\_backend\_profile

SSL Profile Type\*  
BackEnd

PUSH Encryption Trigger\*  
Always

Encryption trigger packet count  
45

Push Flag\*  
Auto (PUSH flag is not set)

4. Specify the common name (same as the host header) and select **SNI Enable**.

Enable Session Reuse  
Session Timeout  
 Enable Cipher Redirect  
 Skip Client Certificate Policy Check  
 Server Authentication  
**Common Name**  
example.com  
 OCSP Stapling  
 SSL Redirect  
 **SNI Enable**  
 Send Close-Notify  
 Non-FIPS Ciphers  
 Strict CA checks  
 Enable Client Authentication using bound CA Chain

5. Click **OK**.
6. Navigate to **Traffic Management > Load Balancing > Monitor**.
7. Click **Add**.
8. Specify a name for the monitor. In **Type**, select HTTP, HTTP-ECV, TCP, or TCP-ECV.
9. Specify a **Custom Header**.

The screenshot shows the 'Create Monitor' configuration page. The 'Name' field is set to 'http-ecv-mon'. The 'Type' is set to 'HTTP-ECV'. Under the 'Basic Parameters' section, the 'Interval' is set to 5 seconds and the 'Response Time-out' is set to 2 seconds. The 'Custom Header' field contains 'Host: example.com\r\n'. The 'Send String' field is empty.

10. Select **Secure**.
11. In **SSL Profile**, select the back-end SSL profile created in the preceding steps.
12. Click **Create**.
13. Navigate to **Traffic Management > Load Balancing > Services**.
14. Select an SSL service and click **Edit**.
15. In **Monitors**, click **Add Binding**, select the monitor created in the preceding steps, and click **Bind**.

### Configure and bind a secure monitor to an SNI-enabled back-end service by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Monitor**.
2. Add a monitor of type **HTTP-ECV** or **TCP-ECV**, and specify a **Custom Header**.
3. Select **Create**.
4. Navigate to **Traffic Management > Load Balancing > Services**.
5. Select an SSL service and click **Edit**.
6. In **Monitors**, click **Add Binding**, select the monitor created in step 3, and click **Bind**.

### Allow the handshake to continue for an unknown server name

#### Note

This feature is available in release 13.1 build 45.x and later.

When SNI is enabled, and the NetScaler appliance receives a client hello with an unknown server name, it terminates the SSL handshake. From release 13.1 build 45.x, the appliance allows the SSL handshake to continue even for an unknown server name, and leaves the decision to the client to drop or complete the handshake. You can configure this setting on a front-end SSL profile when SNI is **ENABLED** using the `allowUnknownSNI` parameter.

Keep this parameter disabled if you need to use a forward action for an SNI-based rule. For example, you have enabled SNI on virtual server v1 and configured a policy to forward all requests for a specific domain (www.example.com) to virtual server v2. Earlier, any requests received on v1 for this domain are automatically forwarded to v2. However, if the `allowunknownSNI` parameter is enabled then the request is processed on v1. The parameter must be disabled for the appliance to process the request on v1.

### Configure allow unknown SNI using the CLI

At the command prompt, type:

```
set ssl profile default_profile -SNIEnable Enabled -allowUnknownSNI <
DISABLED/ENABLED>
```

The `allowunknownSNI` parameter is disabled by default. As a result, the appliance aborts the handshake for an unknown server name. To enable this setting, type:

```
set ssl profile default_profile -SNIEnable Enabled -allowUnknownSNI
ENABLED
```

### Configure allow unknown SNI using the GUI

1. Navigate to **System > Profiles > SSL Profile**.
2. If you add a profile, select **FrontEnd** in the **SSL Profile Type** list. Otherwise, you can edit an existing front-end profile.
3. Select **Allow Unknown SNI**.
4. Click **OK** and then click **Done**.

### Add or update a certificate-key pair

#### Notes:

If you don't have an existing certificate and key, see [Create a certificate](#).

To create an ECDSA certificate-key pair, click [Create an ECDSA certificate-key pair](#).

Password protected certificate-key pairs are always added successfully. In builds earlier to 13.0 build 79.x, if a strong password option was enabled on a NetScaler appliance, sometimes the password protected certificate-key pairs were not added. However, the certificate-key configuration is lost if you downgrade to an earlier build. Also, in the NITRO API response for certificate-key pairs, the `passplain` variable is sent instead of the `passcrypt` variable.

For any SSL transaction, the server needs a valid certificate and the corresponding private and public key pair. The SSL data is encrypted with the server's public key, which is available through the server's certificate. Decryption requires the corresponding private key. The password of the private key used while adding an SSL certificate-key pair is saved using a unique encryption key for each NetScaler appliance.

The ADC appliance offloads SSL transactions from the server. Therefore, the server's certificate and private key must be present on the appliance, and the certificate must be paired with its corresponding private key. This certificate-key pair must be bound to the virtual server that processes the SSL transactions.

**Note:** The default certificate on a NetScaler appliance is 2048 bits. In earlier builds, the default certificate was 512 bits or 1024 bits. After upgrading to release 11.0, you must delete all your old certificate-key pairs starting with "ns-", and then restart the appliance to automatically generate a 2048-bit default certificate.

Both the certificate and the key must be in local storage on the NetScaler appliance before they can be added to the appliance. If your certificate or key file is not on the appliance, upload it to the appliance before you create the pair.

**Important:** Certificates and keys are stored in the `/nsconfig/ssl` directory by default. If your certificates or keys are stored in any other location, you must provide the absolute path to the files on the NetScaler appliance. The NetScaler FIPS appliances do not support external keys (non-FIPS keys). On a FIPS appliance, you cannot load keys from a local storage device such as a hard disk or flash memory. The FIPS keys must be present in the Hardware Security Module (HSM) of the appliance.

Only RSA keys are supported on NetScaler appliances.

Set the notification period and enable the expiry monitor to issue a prompt before the certificate expires.

The NetScaler appliance supports the following input formats of the certificate and the private-key files:

- PEM - Privacy Enhanced Mail
- DER - Distinguished Encoding Rule
- PFX - Personal Information Exchange

The software automatically detects the format. Therefore, you are no longer required to specify the

format in the inform parameter. If you do specify the format (correct or incorrect), the software ignores it. The format of the certificate and the key file must be the same.

**Note:** A certificate must be signed by using one of the following hash algorithms:

- MD5
- SHA-1
- SHA-224
- SHA-256
- SHA-384
- SHA-512

An MPX appliance supports certificates of 512 or more bits, up to the following sizes:

- 4096-bit server certificate on the virtual server
- 4096-bit client certificate on the service
- 4096-bit CA certificate (includes intermediate and root certificates)
- 4096-bit certificate on the back-end server
- 4096-bit client certificate (if client authentication is enabled on the virtual server)

A VPX virtual appliance supports certificates of 512 or more bits, up to the following sizes:

- 4096-bit server certificate on the virtual server
- 4096-bit client certificate on the service
- 4096-bit CA certificate (includes intermediate and root certificates)
- 4096-bit certificate on the back-end server
- 4096-bit client certificate (if client authentication is enabled on the virtual server)

The following table shows the RSASSA-PSS parameter sets supported by the NetScaler appliance. RSASSA-PSS algorithms are supported in the X.509 certificate path validation.

Public Key OID	Mask Generation Function (MGF)	MGF Digest Function	Signature Digest Function	Salt Length
rsaEncryption	MGF1	SHA-256	SHA-256	32 bytes
rsaEncryption	MGF1	SHA-384	SHA-384	48 bytes
rsaEncryption	MGF1	SHA-512	SHA-512	64 bytes

**Note**

A NetScaler SDX appliance supports certificates of 512 or more bits. Each NetScaler VPX instance hosted on the appliance supports the preceding certificate sizes for a VPX virtual appliance. However, if an SSL chip is assigned to an instance, that instance supports the certificate sizes sup-

ported by an MPX appliance.

### Add a certificate-key pair by using the CLI

At the command prompt, type the following commands to add a certificate-key pair and verify the configuration:

```

1 add ssl certKey <certkeyName> -cert <string>[(-key <string> [-password
]) | -fipsKey <string>] [-inform (DER | PEM)] [<passplain>] [-
 expiryMonitor (ENABLED | DISABLED) [-notificationPeriod <
 positive_integer>]]
2
3 show ssl certKey [<certkeyName>]
4 <!--NeedCopy-->

```

#### Example:

```

1 add ssl certKey sslckey -cert server_cert.pem -key server_key.pem -
 password ssl -expiryMonitor ENABLED -notificationPeriod 30
2 Done
3 Note: For FIPS appliances, replace -key with -fipskey
4
5 show ssl certKey sslckey
6 Name: sslckey Status: Valid, Days to expiration
7 :8418
8 Version: 3
9 Serial Number: 01
10 Signature Algorithm: md5WithRSAEncryption
11 Issuer: C=US,ST=SJ,L=SJ,O=NS,OU=NSSSL,CN=www.root.com
12 Validity
13 Not Before: Jul 15 02:25:01 2005 GMT
14 Not After : Nov 30 02:25:01 2032 GMT
15 Subject: C=US,ST=SJ,L=SJ,O=NS,OU=NSSSL,CN=www.server.com
16 Public Key Algorithm: rsaEncryption
17 Public Key size: 2048
18 Done
19 <!--NeedCopy-->

```

### Update or remove a certificate-key pair by using the CLI

To modify the expiry monitor or notification period in a certificate-key pair, use the `set ssl certkey` command. To replace the certificate or key in a certificate-key pair, use the `update ssl certkey` command. The `update ssl certkey` command has an extra parameter for overriding the domain check. For both commands, enter the name of an existing certificate-key pair. To remove an SSL certificate-key pair, use the `rm ssl certkey` command, which accepts only the `<certkeyName>` argument.

#### Example:

```
1 set ssl certKey <certkeyName> [-expiryMonitor (ENABLED | DISABLED)
2 [-notificationPeriod <positive_integer>]]
3
4 update ssl certKey <certkeyName> [-cert <string> [-password]] [-key
5 <string> | -fipsKey <string>] [-inform <inform>] [-noDomainCheck
6]
6 <!--NeedCopy-->
```

### Add or update a certificate-key pair by using the GUI

1. Navigate to **Traffic Management > SSL > Certificates > Server**.
2. Enter the values for the following parameters and click **Install**.
  - Certificate-Key Pair Name - Name for the certificate and private-key pair.
  - Certificate File Name - Signed certificate received from the certificate authority.
  - Key File Name - Name of and, optionally, the path to the private-key file that is used to form the certificate-key pair.

### Log certificate-key pair loading failure during reboot

After a certificate file or a private key file is uploaded into the NetScaler memory, any changes to the source files are not reflected unless the appliance is rebooted. The reboot might fail for reasons, such as the following:

- The certificate file is updated but the key file is not updated.
- The updated file is corrupted.
- The new key file is password protected.
- The password has changed.

These failures are logged in `/var/log/ns.log`. You can view the file using the `tail -f /var/log/ns.log` command.

To log this failure, the following changes are introduced:

1. A digest attribute is created for a certificate-key pair when you add or update a certificate file and a key file to the appliance. If there is no key file (for example in a FIPS or an HSM config), a digest is created only for the certificate file.

**Note:**

The certificate file name and the private-key file name must include only the following characters:

---

```
1 - a to z (lower case)
2 - A to Z (upper case)
3 - 0 to 9 (numbers)
4 - / (forward slash)
5 - . (period)
6 - _ (underscore)
7 - : (colon)
8 - - (hyphen)
9 <!--NeedCopy-->
```

2. When the appliance reboots, the digest in the configuration file is compared with the digest calculated for the certificate and key file (optional) on the appliance. If there is a mismatch, an error message is logged.

## Bind the certificate-key pair to the SSL virtual server

Important: Link any intermediate certificates to this certificate before binding the certificate to an SSL virtual server. For information about linking certificates, see [Create a chain of certificates](#).

The certificate being used for processing SSL transactions must be bound to the virtual server that receives the SSL data. If you have multiple virtual servers receiving SSL data, a valid certificate-key pair must be bound to each of them.

Use a valid, existing SSL certificate that you have uploaded to the NetScaler appliance. As an alternative for testing purposes, create your own SSL certificate on the appliance. Intermediate certificates created by using a FIPS key on the appliance cannot be bound to an SSL virtual server.

During the SSL handshake, in the certificate request message during client authentication, the server lists the distinguished names (DN) of all the certificate authorities (CA) bound to the server. The server accepts a client certificate only from this list. If you do not want the DN name of a specific CA certificate to be sent to the SSL client, set the `skipCA` flag. This setting indicates that the particular CA certificate's distinguished name must not be sent to the SSL client.

For details on how to create your own certificate, see [Managing Certificates](#).

Note: Citrix recommends that you use only valid SSL certificates issued by a trusted certificate authority.

## Bind an SSL certificate-key pair to a virtual server by using the CLI

At the command prompt, type the following commands to bind an SSL certificate-key pair to a virtual server and verify the configuration:

```
1 - bind ssl vserver <vServerName> -certkeyName <certificate-KeyPairName>
 > -CA -skipCAName
```

```
2 - show ssl vs vserver <vServerName>
3 <!--NeedCopy-->
```

**Example:**

```
1 bind ssl vs vs1 -certkeyName cert2 -CA -skipCAName
2 Done
3 sh ssl vs vs1
4
5 Advanced SSL configuration for VServer vs1:
6
7 DH: DISABLED
8
9 Ephemeral RSA: ENABLED Refresh Count: 0
10
11 Session Reuse: ENABLED Timeout: 120 seconds
12
13 Cipher Redirect: DISABLED
14
15 SSLv2 Redirect: DISABLED

### Unbind an SSL certificate-key pair from a virtual server by using the CLI

If you try to unbind a certificate-key pair from a virtual server by using the `unbind ssl certKey <certKeyName>` command, an error message appears. The error appears because the syntax of the command has changed. At the command prompt, type the following command:

```

1 unbind ssl vserver <vServerName> -certkeyName <string>
2 <!--NeedCopy-->

```

#### Example:

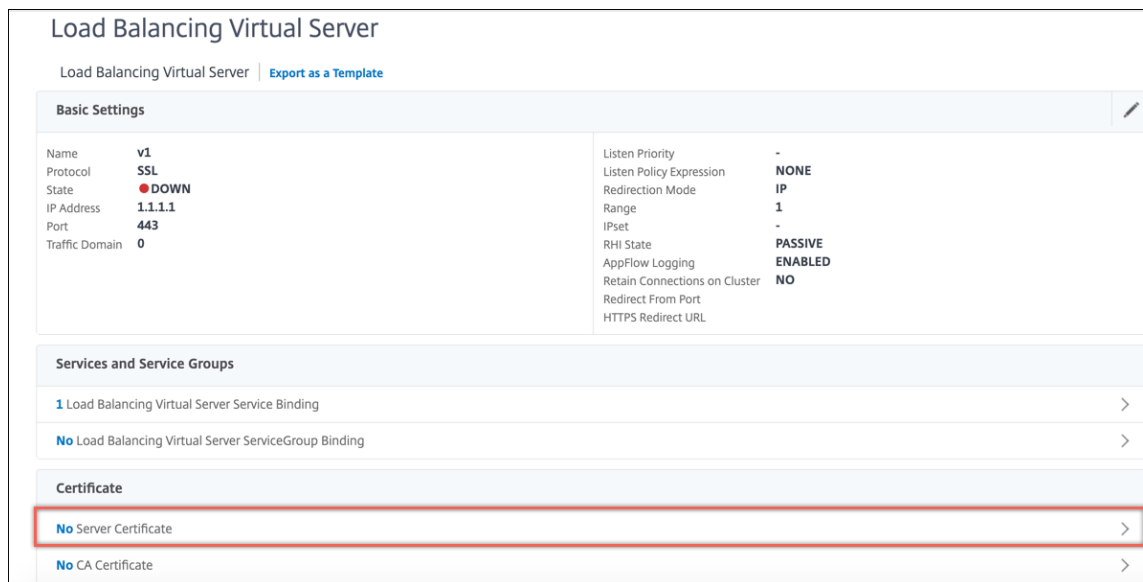

```

1 unbind ssl vserver vssl -certkeyName sslkey
2 <!--NeedCopy-->

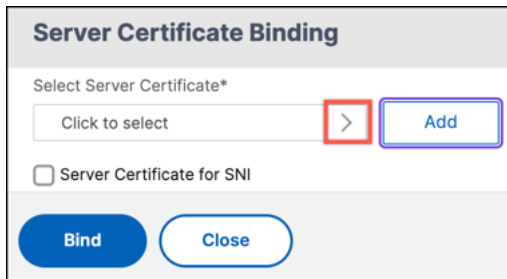

```

### Bind an SSL certificate-key pair to a virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers** and open an SSL virtual server. Click inside the **Certificate** section.

2. Click the arrow to select the certificate-key pair.

3. Select the certificate-key pair from the list.
4. Bind the certificate-key pair to the virtual server. To add a server certificate as an SNI certificate, select **Server Certificate for SNI**.

### SSL virtual server parameters

Set the advanced SSL configuration for an SSL virtual server. You can also set many of these parameters in an SSL profile. For information about the parameters that can be set in an SSL profile, see [SSL profile parameters](#).

#### Set SSL virtual server parameters by using the CLI

At the command prompt, type:

```

1 set ssl vserver <vServerName>@ [-clearTextPort <port>] [-dh (ENABLED |
 DISABLED) -dhFile <string>] [-dhCount <positive_integer>][-
 dhKeyExpSizeLimit (ENABLED | DISABLED)] [-eRSA (ENABLED |
 DISABLED)] [-eRSACount <positive_integer>]] [-sessReuse (ENABLED |
 DISABLED)][-sessTimeout <positive_integer>]] [-cipherRedirect (
 ENABLED | DISABLED)] [-cipherURL <URL>]] [-sslv2Redirect (ENABLED |
 DISABLED)][-sslv2URL <URL>]] [-clientAuth (ENABLED | DISABLED)] [-
 clientCert (Mandatory | Optional)]] [-sslRedirect (ENABLED |
 DISABLED)][-redirectPortRewrite (ENABLED | DISABLED)] [-ssl2 (
 ENABLED | DISABLED)] [-ssl3 (ENABLED | DISABLED)] [-tls1 (
 ENABLED | DISABLED)] [-tls11 (ENABLED | DISABLED)] [-tls12 (
 ENABLED | DISABLED)][-tls13 (ENABLED | DISABLED)] [-SNIEnable (
 ENABLED | DISABLED)][-ocspStapling (ENABLED | DISABLED)] [-
 pushEncTrigger <pushEncTrigger>] [-sendCloseNotify (YES | NO)] [-
 dtlsProfileName <string>] [-sslProfile <string>] [-HSTS (ENABLED |
 DISABLED)][-maxage <positive_integer>] [-IncludeSubdomains (YES |
 NO)][-strictSigDigestCheck (ENABLED | DISABLED)] [-
 zeroRttEarlyData (ENABLED | DISABLED)] [-
 tls13SessionTicketsPerAuthContext <positive_integer>] [-
 dheKeyExchangeWithPsk (YES | NO)]
2 <!--NeedCopy-->

```

## Diffie-Hellman (DH) parameters

To use ciphers on the appliance that require a DH key exchange to set up the SSL transaction, enable DH key exchange on the appliance. Configure other settings based on your network.

To list the ciphers for which DH parameters must be set by using the CLI, type: `sh cipher DH`.

To list the ciphers for which DH parameters must be set by using the configuration utility, navigate to **Traffic Management > SSL > Cipher Groups**, and double-click **DH**.

For details on how to enable DH key exchange, see [Generate a Diffie-Hellman \(DH\) key](#).

**Configure DH parameters by using the CLI** At the command prompt, type the following commands to configure DH parameters and verify the configuration:

```
1 - `set ssl vserver <vserverName> -dh <Option> -dhCount <
 RefreshCountValue> -filepath <string>
2 - show ssl vserver <vServerName>`
3 <!--NeedCopy-->
```

### Example:

```
1 set ssl vserver vs-server -dh ENABLED -dhFile /nsconfig/ssl/ns-server.
 cert -dhCount 1000
2 Done
3
4 show ssl vserver vs-server
5
6 Advanced SSL configuration for VServer vs-server:
7 DH: ENABLED
8 Ephemeral RSA: ENABLED Refresh Count: 1000
9 Session Reuse: ENABLED Timeout: 120 seconds
10 Cipher Redirect: DISABLED
11 SSLv2 Redirect: DISABLED
12 ClearText Port: 0
13 Client Auth: DISABLED
14 SSL Redirect: DISABLED
15 Non FIPS Ciphers: DISABLED
16 SNI: DISABLED
17 OCSP Stapling: DISABLED
18 HSTS: DISABLED
19 HSTS IncludeSubDomains: NO
20 HSTS Max-Age: 0
21 SSLv2: DISABLED SSLv3: ENABLED TLSv1.0: ENABLED TLSv1.2:
 ENABLED TLSv1.2: ENABLED
22
23 1) Cipher Name: DEFAULT
24 Description: Predefined Cipher Alias
25 Done
26 <!--NeedCopy-->
```

### Configure DH parameters by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In the **SSL Parameters** section, select **Enable DH Param**, and specify a refresh count and file path.

### Ephemeral RSA

Ephemeral RSA allows export clients to communicate with the secure server even if the server certificate does not support export clients (1024-bit certificate). If you want to prevent export clients from accessing the secure web object or resource, you need to disable ephemeral RSA key exchange.

By default, this feature is enabled on the NetScaler appliance, with the refresh count set to zero (infinite use).

#### Note:

The ephemeral RSA key is automatically generated when you bind an export cipher to an SSL or TCP-based SSL virtual server or service. When you remove the export cipher, the eRSA key is not deleted. It is reused later when another export cipher is bound to an SSL or TCP-based SSL virtual server or service. The eRSA key is deleted when the system restarts.

**Configure ephemeral RSA by using the CLI** At the command prompt, type the following commands to configure ephemeral RSA and verify the configuration:

```
1 set ssl vserver <vServerName> -eRSA (enabled | disabled) -eRSACount <
 positive_integer>
2 show ssl vserver <vServerName>
3 <!--NeedCopy-->
```

#### Example:

```
1 set ssl vserver vs-server -eRSA ENABLED -eRSACount 1000
2 Done
3
4 show ssl vserver vs-server
5
6 Advanced SSL configuration for VServer vs-server:
7 DH: DISABLED
8 Ephemeral RSA: ENABLED Refresh Count: 1000
9 Session Reuse: ENABLED Timeout: 120 seconds
10 Cipher Redirect: DISABLED
11 SSLv2 Redirect: DISABLED
12 ClearText Port: 0
13 Client Auth: DISABLED
14 SSL Redirect: DISABLED
15 Non FIPS Ciphers: DISABLED
16 SNI: DISABLED
```

```

17 OCSP Stapling: DISABLED
18 HSTS: DISABLED
19 HSTS IncludeSubDomains: NO
20 HSTS Max-Age: 0
21 SSLv2: DISABLED SSLv3: ENABLED TLSv1.0: ENABLED TLSv1.2:
 ENABLED TLSv1.2: ENABLED
22
23 1) Cipher Name: DEFAULT
24 Description: Predefined Cipher Alias
25 Done
26 <!--NeedCopy-->

```

### Configure ephemeral RSA by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In the **SSL Parameters** section, select **Enable Ephemeral RSA**, and specify a refresh count.

### Session reuse

For SSL transactions, establishing the initial SSL handshake requires CPU-intensive public key encryption operations. Most handshake operations are associated with the exchange of the SSL session key (client key exchange message). When a client session is idle for some time and is then resumed, the SSL handshake is typically conducted all over again. With session reuse enabled, session key exchange is avoided for session resumption requests received from the client.

Session reuse is enabled on the NetScaler appliance by default. Enabling this feature reduces server load, improves response time, and increases the number of SSL transactions per second (TPS) that the server can support.

**Configure session reuse by using the CLI** At the command prompt, type the following commands to configure session reuse and verify the configuration:

```

1 set ssl vserver <vServerName> -sessReuse (ENABLED | DISABLED) -
 sessTimeout <positive_integer>
2 show ssl vserver <vServerName>
3 <!--NeedCopy-->

```

### Example:

```

1 set ssl vserver vs-ssl -sessreuse enabled -sesstimeout 600
2 Done
3
4 show ssl vserver vs-ssl
5
6 Advanced SSL configuration for VServer vs-ssl:
7 DH: DISABLED

```

```
8 Ephemeral RSA: ENABLED Refresh Count: 1000
9 Session Reuse: ENABLED Timeout: 600 seconds
10 Cipher Redirect: DISABLED
11 SSLv2 Redirect: DISABLED
12 ClearText Port: 0
13 Client Auth: DISABLED
14 SSL Redirect: DISABLED
15 Non FIPS Ciphers: DISABLED
16 SNI: DISABLED
17 OCSP Stapling: DISABLED
18 HSTS: DISABLED
19 HSTS IncludeSubDomains: NO
20 HSTS Max-Age: 0
21 SSLv2: DISABLED SSLv3: ENABLED TLSv1.0: ENABLED TLSv1.2:
 ENABLED TLSv1.2: ENABLED
22
23 1) CertKey Name: Auth-Cert-1 Server Certificate
24
25 1) Cipher Name: DEFAULT
26 Description: Predefined Cipher Alias
27 Done
28 <!--NeedCopy-->
```

### Configure session reuse by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In the **SSL Parameters** section, select **Enable Session Reuse**, and specify a time for which to keep the session active.

### SSL protocol settings

The NetScaler appliance supports the SSLv3, TLSv1, TLSv1.1, and TLSv1.2 protocols. Each of these protocols can be set on the appliance as required by your deployment and the type of clients that connect to the appliance.

TLS protocol versions 1.0, 1.1, and 1.2 are more secure than older versions of the TLS/SSL protocol. However, to support legacy systems, many TLS implementations maintain backward compatibility with the SSLv3 protocol. In an SSL handshake, the highest protocol version common to the client and the SSL virtual server configured on the NetScaler appliance is used.

In the first handshake attempt, a TLS client offers the highest protocol version that it supports. If the handshake fails, the client offers a lower protocol version. For example, if a handshake with TLS version 1.1 is not successful, the client attempts to renegotiate by offering the TLSv1.0 protocol. If that attempt is unsuccessful, the client reattempts with the SSLv3 protocol. A “man in the middle” (MITM) attacker can break the initial handshake and trigger renegotiation with the SSLv3 protocol,

and then exploit a vulnerability in SSLv3. To mitigate such attacks, you can disable SSLv3 or not allow renegotiation using a downgraded protocol. However, this approach might not be practical if your deployment includes legacy systems. An alternative is to recognize a signaling cipher suite value (TLS\_FALLBACK\_SCSV) in the client request.

A TLS\_FALLBACK\_SCSV value in a client hello message indicates to the virtual server that the client has previously attempted to connect with a higher protocol version and that the current request is a fallback. If the virtual server detects this value, and it supports a version higher than the one indicated by the client, it rejects the connection with a fatal alert. The handshake succeeds if one of the following conditions is met:

- TLS\_FALLBACK\_SCSV value is not included in the client hello message.
- The protocol version in the client hello is the highest protocol version supported by the virtual server.

**Configure SSL protocol support by using the CLI** At the command prompt, type the following commands to configure SSL protocol support and verify the configuration:

```

1 set ssl vserver <vServerName> -ssl2 (ENABLED | DISABLED) -ssl3 (
 ENABLED | DISABLED) -tls1 (ENABLED | DISABLED) -tls11 (ENABLED |
 DISABLED) -tls12 (ENABLED | DISABLED)
2
3 show ssl vserver <vServerName>
4 <!--NeedCopy-->

```

#### Example:

```

1 set ssl vserver vs-ssl -tls11 ENABLED -tls12 ENABLED
2 Done
3
4 sh ssl vs vs-ssl
5

### Configure SSL protocol support by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In the **SSL Parameters** section, select a protocol to enable.

### Close-notify

A close-notify is a secure message that indicates the end of SSL data transmission. A close-notify setting is required at the global level. This setting applies to all virtual servers, services, and service groups. For information about the global setting, see the “Global SSL parameters” section later in this page.

In addition to the global setting, you can set the close-notify parameter at the virtual server, service, or service group level. You therefore have the flexibility of setting the parameter for one entity and unsetting it for another entity. However, make sure that you set this parameter at the global level. Otherwise, the setting at the entity level does not apply.

**Configure close-notify at the entity level by using the CLI** At the command prompt, type any of the following commands to configure the close-notify feature and verify the configuration:

1. To configure at the virtual server level, type:

```

1 set ssl vserver <vServerName> -sendCloseNotify (YES | NO)
2 show ssl vserver <vServerName>
3 <!--NeedCopy-->

```

1. To configure at the service level, type:

```

1 set ssl service <serviceName> -sendCloseNotify (YES | NO)
2 show ssl service <serviceName>
3 <!--NeedCopy-->

```

1. To configure at the service group level, type:

```
1 set ssl serviceGroup <serviceName> -sendCloseNotify (YES | NO)
2 show ssl serviceGroup <serviceName>
3 <!--NeedCopy-->
```

**Example:**

```
1 set ssl vserver sslsvr -sendCloseNotify YES
2
3 Done
4 <!--NeedCopy-->
```

**Configure the close-notify feature at the entity level by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and open a virtual server.
2. In the **SSL Parameters** section, select **Send Close-Notify**.

**Global SSL parameters**

Advanced customization of your SSL configuration addresses specific issues. You can use the `set ssl parameter` command or the configuration utility to specify the following:

- Quantum size to be used for SSL transactions.
- CRL memory size.
- OCSP cache size.
- Deny SSL renegotiation.
- Set the PUSH flag for decrypted, encrypted, or all records.
- Drop requests if the client initiates the handshake for one domain and sends an HTTP request for another domain.
- Set the time after which encryption is triggered.  
Note: The time that you specify applies only if you use the `set ssl vserver` command or the configuration utility to set timer-based encryption.
- NDCPP compliance certificate check –Applies when the appliance acts as a client (back-end connection). During certificate verification, ignore the common name if SAN is present in the SSL certificate.
- Enable a heterogeneous cluster of Cavium chip-based appliances, such as MPX 14000, and Intel Coletto chip-based appliances, such as MPX 15000 appliances with a different number of packet engines.
- Enable secure renegotiation at the back end.
- Adaptive SSL traffic control.

## Configure global SSL parameters by using the CLI

At the command prompt, type the following commands to configure advanced SSL settings and verify the configuration:

```

1 set ssl parameter [-quantumSize <quantumSize>] [-crlMemorySizeMB <
 positive_integer>] [-strictCAChecks (YES | NO)] [-sslTriggerTimeout
 <positive_integer>] [-sendCloseNotify (YES | NO)] [-
 encryptTriggerPktCount <positive_integer>] [-denySSLReneg <
 denySSLReneg>] [-insertionEncoding (Unicode|UTF-8)] [-ocspCacheSize
 <positive_integer>] [- pushFlag <positive_integer>] [-
 dropReqWithNoHostHeader (YES | NO)] [-pushEncTriggerTimeout <
 positive_integer>] [-ndcppComplianceCertCheck (YES | NO)] [-
 heterogeneousSSLHW (ENABLED | DISABLED)]
2 show ssl parameter
3 <!--NeedCopy-->

```

### Example:

```

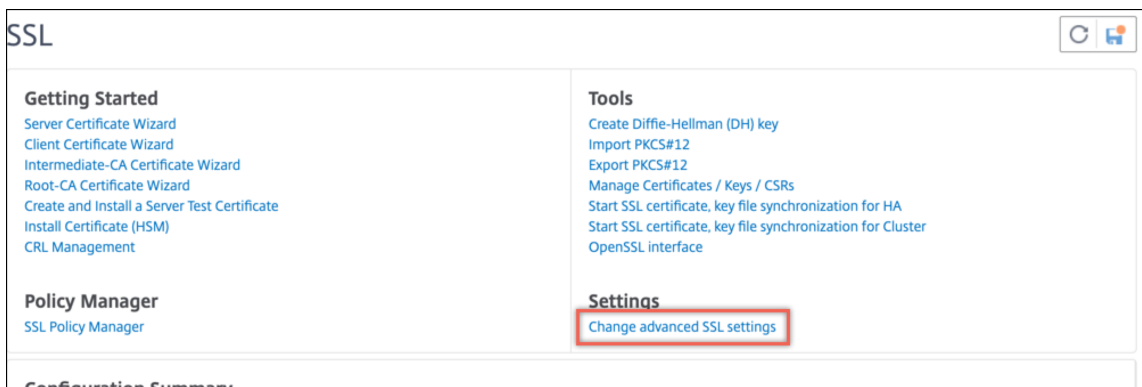

1 set ssl parameter -quantumSize 8 -crlMemorySizeMB 256 -strictCAChecks
 no -ssltriggerTimeout 100 -sendClosenotify no -
 encryptTriggerPktCount 45 -denySSLReneg NONSECURE -insertionEncoding
 unicode -ocspCacheSize 10 -pushFlag 3 -dropReqWithNoHostHeader YES
 -pushEncTriggerTimeout 100 ms -ndcppComplianceCertCheck YES
2 Done
3
4 show ssl parameter

31 NDCPP Compliance Certificate Check : YES
32 Heterogeneous SSL HW (Cavium and Intel Based) : ENABLED
33 Done
34 <!--NeedCopy-->
```

**Configure NDcPP compliance certificate check by using the GUI**

1. Navigate to **Traffic Management > SSL** and, in the **Settings** group, select **Change advanced SSL settings**.

2. Select **NDCPP Compliance Certificate Check**. Click **OK**.

**Support for secure renegotiation at the back end of a NetScaler appliance**

**Note:** This feature is supported in release 13.0 build 58.x and later. In earlier releases and builds, only non-secure renegotiation was supported on the back end.

The feature is supported on the following platforms:

- VPX
- MPX platforms containing N2 or N3 chips
- Intel Coletto SSL chip-based platforms

The feature is not yet supported on the FIPS platform.

Secure renegotiation is denied by default on the back end of an ADC appliance. That is, the `denySSLReneg` parameter is set to ALL (default).

To allow secure renegotiation on the back end, select from one of the following settings for the `denySSLReneg` parameter:

- NO
- FRONTEND\_CLIENT
- FRONTEND\_CLIENTSERVER
- NONSECURE

**Enable secure renegotiation by using the CLI** At the command prompt, type:

```
set ssl parameter -denySSLReneg <denySSLReneg>
```

**Example:**

```
1 set ssl parameter -denySSLReneg NONSECURE
2 Done
3
4 sh ssl parameter
5 Advanced SSL Parameters

31 SSL Interception Maximum Error Cache Memory : 0 Bytes
32 NDCPP Compliance Certificate Check : NO
33 Heterogeneous SSL HW (Cavium and Intel Based) : DISABLED
34 Crypto Operation Queue Limit : 150%
35 Done
36 <!--NeedCopy-->

```

### Enable secure renegotiation by using the GUI

1. Navigate to **Traffic Management > SSL > Change advanced SSL settings**.
2. Set **Deny SSL Renegotiation** to any value other than ALL.

### Adaptive SSL traffic control

**Note:** This feature is supported in release 13.0 build 58.x and later.

When high traffic is received on the appliance and the crypto acceleration capacity is full, the appliance

starts queuing connections to process later. Currently, the size of this queue is fixed at 64 K and the appliance starts dropping connections if this value is exceeded.

Users can configure a value that is a percentage of the actual capacity. As a result, the appliance drops new connections if the number of elements in the queue is greater than the limit that is adaptively and dynamically calculated. This approach controls incoming SSL connections and prevents excessive resource consumption and other failures, such as load balancing monitoring failure or slow response to secure applications, on the appliance.

If the queue is empty, the appliance can continue to accept connections. If the queue is not empty, the crypto system has reached its capacity and the appliance starts queuing connections.

The limit is calculated based on:

- The actual capacity of the appliance.
- Value configured by the user as a percentage of the actual capacity. The default value is set to 150%.

For example, if the actual capacity of an appliance is 1000 operations/second at a given time and the default percentage is configured, the limit after which the appliance drops connections is 1500 (150% of 1000).

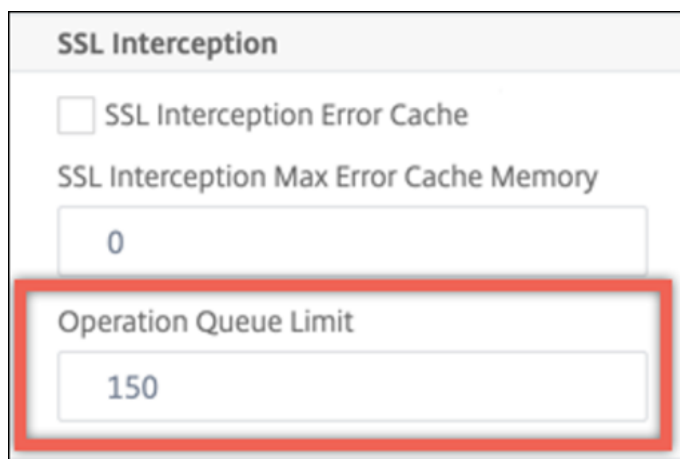

**To configure the operation queue limit by using the CLI** At the command prompt, type:

```
set ssl parameter -operationQueueLimit <positive_integer>
```

**Operation Queue Limit** - Limit in percentage of capacity of the crypto operations queue beyond which new SSL connections are not accepted until the queue is reduced. Default value: 150. Minimum value: 0. Maximum value: 10000.

**To configure the operation queue limit by using the GUI**

1. Navigate to **Traffic Management > SSL**.
2. In **Settings**, click **Change advanced SSL settings**.
3. Type a value in **Operation Queue Limit**. The default is 150.
4. Click **OK**.

The screenshot shows the 'SSL Interception' configuration page. It includes a checkbox for 'SSL Interception Error Cache' which is unchecked. Below it is a text input field for 'SSL Interception Max Error Cache Memory' containing the value '0'. The 'Operation Queue Limit' field, which contains the value '150', is highlighted with a red rectangular border.

## Heterogeneous cluster deployments

You can form a heterogeneous cluster deployment of NetScaler MPX appliances with a different number of packet engines by setting the SSL parameter “Heterogeneous SSL HW” to ENABLED. For example, to form a cluster of Cavium chip-based appliances (MPX 14000 or similar) and Intel Coletto chip-based appliances (MPX 15000 or similar), enable the SSL parameter “Heterogeneous SSL HW.” To form a cluster of platforms using the same chip, keep the default value (DISABLED) for this parameter.

### Notes:

The following features are not supported in a heterogeneous cluster:

- VPX instances hosted on NetScaler SDX appliances.
- SSLv3 protocol on SSL entities, such as virtual server, services, service groups, and internal services.
- Software crypto acceleration CPU threshold (using hardware and software to improve ECDSA and ECDHE cipher performance).

For more information about the platforms supported in a heterogeneous cluster, see <https://docs.citrix.com/en-us/citrix-adc/current-release/clustering/support-for-heterogeneous-cluster.html>.

**Enable a heterogeneous cluster using the CLI** At the command prompt, type:

```
set ssl parameter -heterogeneousSSLHW ENABLED
```

### Enable a heterogeneous cluster using the GUI

1. Navigate to **Traffic Management > SSL** and, in the **Settings** group, select **Change advanced SSL settings**.

2. Select **Heterogeneous SSL HW**. Click **OK**.

The screenshot shows a configuration window with several options. The 'Heterogeneous SSL HW' checkbox is checked and highlighted with a red rectangular box. Other options include 'Strict CA checks', 'Drop requests for SNI enabled SSL sessions if host header is absent', 'Enable Default Profile', 'Insert Certificate Space', 'NDcPP Compliance Certificate Check', and 'Hybrid FIPS Mode'. There are also sections for 'PUSH Flag Insertion' and 'SSL Interception'.

### PUSH flag based encryption trigger mechanism

The encryption trigger mechanism that is based on the PSH TCP flag now enables you to do the following:

- Merge consecutive packets in which the PSH flag is set into a single SSL record, or ignore the PSH flag.
- Perform timer-based encryption, in which the time-out value is set globally by using the `set ssl parameter -pushEncTriggerTimeout <positive_integer>` command.

**Configure PUSH flag-based encryption by using the CLI** At the command prompt, type the following commands to configure PUSH flag-based encryption and verify the configuration:

```
1 set ssl vserver <vServerName> [-pushEncTrigger <pushEncTrigger>]
2
3 show ssl vserver
4 <!--NeedCopy-->
```

### Example:

```
1 set ssl vserver vserver1 -pushEncTrigger always
2
3 Done
4
5 sh ssl vserver vserver1
6
7 Advanced SSL configuration for VServer vserver1:
8 DH: DISABLED
```

```

9 DH Private-Key Exponent Size Limit: DISABLED Ephemeral

33 Done
34 <!--NeedCopy-->

```

### Configure PUSH flag-based encryption by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual servers** and open an SSL virtual server.
2. In the **SSL Parameters** section, from the **PUSH Encryption Trigger** list, select a value.

### Support for TLS1.2 signature hash algorithm

The NetScaler appliance is completely TLS1.2 signature hash extension compliant.

In an SSL handshake, a client sends a list of supported signature hash algorithms. The client indicates to the server which signature hash algorithm pairs might be used in the SSL handshake messages (SKE and CCV) by using the “signature\_algorithms” extension. The “extension\_data” field of this extension contains a “supported\_signature\_algorithms” value in the Client Hello message. The SSL handshake proceeds if the server supports one of these signature hash algorithms. If the server does not support any of these algorithms, the connection is dropped.

Similarly, if the server requests a client certificate for client authentication, the Certificate Request message contains a “supported\_signature\_algorithms” value. The client certificate is selected based on this signature hash algorithm.

**Note:**

The NetScaler appliance acts as a server to a client and as a client to the back-end server.

The appliance supports only RSA-SHA1 and RSA-SHA256 on the front end, and RSA-MD5, RSA-SHA1, and RSA-SHA256 on the back end.

The MPX/SDX/VPX appliance supports the following signature hash combinations. On an SDX appliance, if an SSL chip is assigned to a VPX instance, the cipher support of an MPX appliance applies. Otherwise, the normal cipher support of a VPX instance applies.

- On a VPX instance and on an MPX/SDX appliance without N3 chips:
  - RSA-MD5
  - RSA-SHA1
  - RSA-SHA224
  - RSA-SHA256
  - RSA-SHA384
  - RSA-SHA512
  
- On an MPX/SDX appliance with N3 chips:
  - RSA-MD5
  - RSA-SHA1
  - RSA-SHA224
  - RSA-SHA256
  - RSA-SHA384
  - RSA-SHA512
  - ECDSA-SHA1
  - ECDSA-SHA224
  - ECDSA-SHA256
  - ECDSA-SHA384
  - ECDSA-SHA512

By default, all the signature hash algorithms are enabled. However, you can enable only a few signature hash algorithms by using the following command:

```
1 set ssl parameter -sigDigestType <sigDigestType>
2
3 Parameters
4
5 sigDigestType
```

```

6
7 Signature digest algorithms supported by the appliance. The platform
 determines the list of algorithms supported by default.
8
9 On VPX: RSA-MD5 RSA-SHA1 RSA-SHA224 RSA-SHA256 RSA-SHA384
 RSA-
10
11 SHA512
12
13 On MPX with N3 cards: RSA-MD5 RSA-SHA1 RSA-SHA224 RSA-
14
15 SHA256 RSA-SHA384 RSA-SHA512 ECDSA-SHA1 ECDSA-SHA224
 ECDSA-
16
17 SHA256 ECDSA-SHA384 ECDSA-SHA512
18
19 Other MPX Platforms: RSA-MD5 RSA-SHA1 RSA-SHA224 RSA-
 SHA256 RSA-SHA384 RSA-
20
21 SHA512.
22
23 set ssl parameter -sigDigestType RSA-SHA224 RSA-SHA256 RSA-SHA384
 RSA-SHA512
24 <!--NeedCopy-->

```

**Validate the peer certificate** According to RFC 5246, the peer certificate must be signed using one of the signature hash algorithms included in the Client Hello extension. You can use the `strictSigDigestCheck` parameter. Depending on the signature hash list sent by the client, if you enable `strictSigDigestCheck`, the appliance returns a certificate signed by one of the signature hash algorithms mentioned in the Client Hello extension. If the peer does not have a proper certificate, the connection is dropped. If this parameter is disabled, the signature hash is not checked in the peer certificate.

You can configure a strict signature digest check on an SSL virtual server and service. If you enable this parameter on an SSL virtual server, the server certificate sent by the server must be signed by one of the signature hash algorithms listed in the Client Hello extension. If client authentication is enabled, then the client certificate received by the server must be signed using one of the signature hash algorithms listed in the certificate request sent by the server.

If you enable this parameter on an SSL service, the server certificate received by the client must be signed by one of the signature hash algorithms listed in the Client Hello extension. The client certificate must be signed using one of the signature hash algorithms listed in the certificate request message.

If the default profile is enabled, you can use it to configure a strict signature digest check on an SSL virtual server, SSL service, and SSL profile.

**Configure a strict signature digest check on an SSL virtual server, service, or profile by using the****CLI** At the command prompt, type:

```

1 set ssl vserver <vServerName> -strictSigDigestCheck (ENABLED |
 DISABLED)
2
3 set ssl service <serviceName> -strictSigDigestCheck (ENABLED |
 DISABLED)
4
5 set ssl profile <name>-strictSigDigestCheck (ENABLED | DISABLED)
6
7 Parameters
8
9 strictSigDigestCheck
10
11 Check whether peer entity certificate is signed using one
 of the signature-hash algorithms supported by the
 NetScaler appliance.
12
13 Possible values: ENABLED, DISABLED
14
15 Default: DISABLED
16 <!--NeedCopy-->

```

**Example:**

```

1 set ssl vserver v1 -strictSigDigestCheck Enabled
2 set ssl service s1 -strictSigDigestCheck Enabled
3 set ssl profile p1 -strictSigDigestCheck Enabled
4 <!--NeedCopy-->

```

**Important:**

If DH, ECDHE, or ECDSA ciphers are configured on the appliance, the SKE message must be signed using one of the signature-hashes common to the client list and the list configured on the appliance. If there is no common signature hash, the connection is dropped.

**Configure SSL for ADC Admin UI access**

A certificate-key pair is required for HTTPS access to the configuration utility and for secure remote procedure calls. On a NetScaler MPX appliance or a VPX virtual appliance, a certificate-key pair is automatically bound to the internal services. However, this certificate might not be trusted by browsers. You must upload valid CA certificates in the browser to complete the authentication without any errors.

**Configure secure HTTPS by using the CLI**

To configure secure HTTPS by using the CLI, follow these steps:

1. Add a certificate-key pair.

```
1 add certkey server -cert servercert -key serverkey
2 <!--NeedCopy-->
```

2. Bind this certificate-key pair to the following internal services.

```
1 bind ssl service nshttps-127.0.0.1-443 -certkeyname server
2
3 bind ssl service nshttps-::11-443 -certkeyname server
4 <!--NeedCopy-->
```

## Configure secure HTTPS by using the GUI

To configure secure HTTPS by using the GUI, follow these steps:

1. Navigate to **Traffic Management > SSL > Certificates**.
2. In the details pane, click **Install**.
3. In the **Install Certificate** dialog box, type the certificate details.
4. Click **Install**, and then click **Close**.
5. Navigate to **Traffic Management > Load Balancing > Services**.
6. In the details pane, on the **Action** tab, click **Internal Services**.
7. Select `nshttps-127.0.0.1-443` from the list, and then click **Open**.
8. On the **SSL Settings** tab, in the **Available** pane, select the certificate created in step 4, click **Bind**, and then click **OK**.
9. Select `nshttps-::11-443` from the list, and then click **Open**.
10. On the **SSL Settings** tab, in the **Available** pane, select the certificate created in step 4, click **Bind**, and then click **OK**.
11. Click **OK**.

## Support for TLS 1.3 protocol

July 11, 2023

The NetScaler VPX and NetScaler MPX appliances now support the TLS 1.3 protocol, specified in RFC 8446.

### Notes:

- TLS 1.3 hardware acceleration is supported on the following platforms:
  - MPX 5900

- MPX/SDX 8900
- MPX/SDX 9100
- MPX/SDX 15000
- MPX/SDX 15000-50G
- MPX/SDX 16000
- MPX/SDX 26000
- MPX/SDX 26000-50S
- MPX/SDX 26000-100G

- Software-only support for the TLS 1.3 protocol is available on all other NetScaler MPX and SDX appliances except NetScaler FIPS appliances.
- TLS 1.3 is only supported with the enhanced profile. To enable the enhanced profile, see [Enable the default profile](#). The terms “default” and “enhanced” are used interchangeably for SSL profile.
- To use TLS 1.3, you must use a client that conforms to the RFC 8446 specification.

### Supported NetScaler features

The following SSL features are supported:

SSL features	Support on the front end	Support on the back end
Cipher suite TLS 1.3-AES256-GCM-SHA384 (0x1302)	Yes	Yes
Cipher suite TLS 1.3_CHACHA20_POLY1305_SHA256 (0x1303)	Yes	Yes
Cipher suite TLS 1.3-AES128_GCM-SHA256 (0x1301)	Yes	Yes
ECC curve P_256 for ephemeral DH key exchange	Yes	Yes
ECC curve P_384 for ephemeral DH key exchange	Yes	Yes
ECC curve P_521 for ephemeral DH key exchange	Yes	Yes

SSL features	Support on the front end	Support on the back end
Abbreviated handshakes when ticket-based session resumption is enabled	Yes	No
0-RTT early application data	Yes	No
Replay attack protection for 0-RTT early application data	Yes	*NA
Optional or mandatory certificate-based client authentication, with support for OCSP and CRL validation of peer certificates	Yes	Yes
Server name extension: server certificate selection by using SNI	Yes	*NA
Application protocol negotiation (ALPN) by using the application_level_protocol_negotiation extension	Yes	Yes
OCSP stapling	Yes	*NA
Log messages and AppFlow records are produced for TLS 1.3 handshakes	Yes	Yes
Optional logging of TLS 1.3 traffic secrets by the <code>nstrace</code> packet capture utility	Yes	Yes
Interoperability with TLS peers implementing RFC 8446. For example, Mozilla Firefox, Google Chrome, and OpenSSL.	Yes	Yes

\*NA - not applicable

## Configuration

TLS 1.3 is disabled by default on an SSL profile. Although you can enable TLS 1.3 on the legacy profile, some features, such as abbreviated handshakes when ticket-based session resumption is enabled and 0-RTT early application data are not supported on the legacy profile.

### Add a front-end SSL profile by using the CLI

At the command prompt, type:

```
1 add ssl profile tls13profile -tls13 ENABLED
2 <!--NeedCopy-->
```

### Example:

```
1 sh ssl profile tls13profile
2 1) Name: tls13profile (Front-End)
3 SSLv3: DISABLED TLSv1.0: ENABLED TLSv1.1: ENABLED
4 TLSv1.2: ENABLED TLSv1.3: ENABLED
5 Client Auth: DISABLED
6 Use only bound CA certificates: DISABLED
7 Strict CA checks: NO
8 Session Reuse: ENABLED Timeout: 120 seconds
9 DH: DISABLED
10 DH Private-Key Exponent Size Limit: DISABLED Ephemeral RSA:
11 ENABLED Refresh Count: 0
12 Deny SSL Renegotiation ALL
13 Non FIPS Ciphers: DISABLED
14 Cipher Redirect: DISABLED
15 SSL Redirect: DISABLED
16 Send Close-Notify: YES
17 Strict Sig-Digest Check: DISABLED
18 Zero RTT Early Data: DISABLED
19 DHE Key Exchange With PSK: NO
20 Tickets Per Authentication Context: 1
21 Push Encryption Trigger: Always
22 PUSH encryption trigger timeout: 1 ms
23 SNI: DISABLED
24 OCSP Stapling: DISABLED
25 Strict Host Header check for SNI enabled SSL sessions: NO
26 Push flag: 0x0 (Auto)
27 SSL quantum size: 8 kB
28 Encryption trigger timeout 100 mS
29 Encryption trigger packet count: 45
30 Subject/Issuer Name Insertion Format: Unicode
31
32 SSL Interception: DISABLED
33 SSL Interception OCSP Check: ENABLED
34 SSL Interception End to End Renegotiation: ENABLED
35 SSL Interception Maximum Reuse Sessions per Server: 10
36 Session Ticket: DISABLED
```

```

35 HSTS: DISABLED
36 HSTS IncludeSubDomains: NO
37 HSTS Max-Age: 0
38
39 ECC Curve: P_256, P_384, P_224, P_521
40
41 1) Cipher Name: DEFAULT Priority :1
42 Description: Predefined Cipher Alias
43 Done
44 <!--NeedCopy-->

```

### Add a front-end SSL profile by using the GUI

1. Navigate to **System > Profiles**. Select **SSL Profiles**.
2. Click **Add** and specify a name for the profile.
3. In **Protocol**, select **TLSv13**.

4. Click **OK** and then click **Done**.

### Add a back-end SSL profile by using the CLI

At the command prompt, type:

```

1 add ssl profile profile1 -sslprofileType BackEnd -tls13 ENABLED
2 <!--NeedCopy-->

```

#### Example:

```

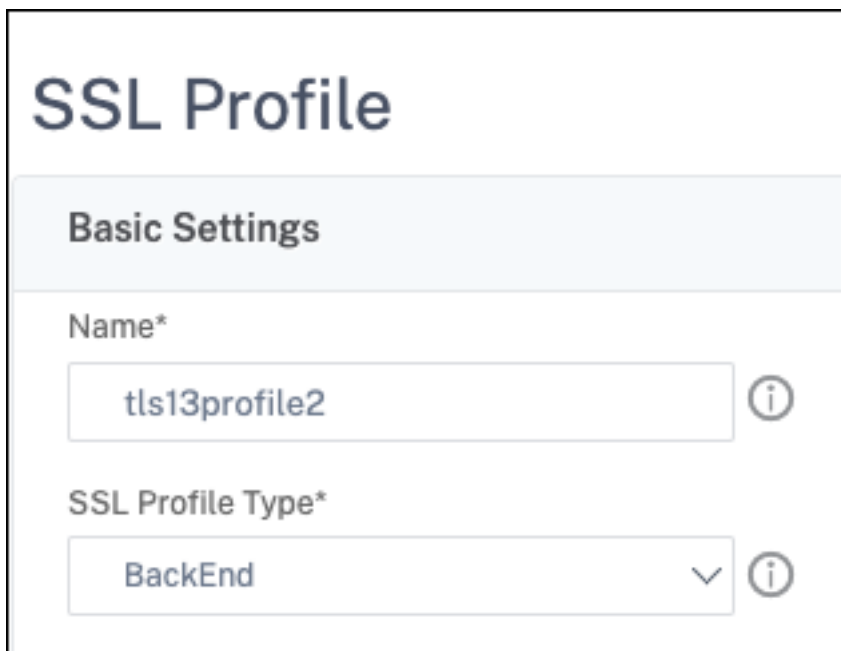

1 add ssl profile tls13profile2 -sslprofileType BackEnd
2
3 sh ssl profile tls13profile2
4
5 1) Name: tls13profile2 (Back-End)
6

```

```
7 SSLv3: DISABLED TLSv1.0: ENABLED TLSv1.1: ENABLED TLSv1.2:
 ENABLED TLSv1.3: ENABLED
8 Server Auth: DISABLED
9 Use only bound CA certificates: DISABLED
10 Strict CA checks: NO
11 Session Reuse: ENABLED Timeout: 300 seconds
12 DH: DISABLED
13 Ephemeral RSA: DISABLED
14 Deny SSL Renegotiation ALL
15 Non FIPS Ciphers: DISABLED
16 Cipher Redirect: DISABLED
17 SSL Redirect: DISABLED
18 Send Close-Notify: YES
19 Strict Sig-Digest Check: DISABLED
20 Push Encryption Trigger: Always
21 PUSH encryption trigger timeout: 1 ms
22 SNI: DISABLED
23 OCSP Stapling: DISABLED
24 Strict Host Header check for SNI enabled SSL sessions: NO
25 Push flag: 0x0 (Auto)
26 SSL quantum size: 8 kB
27 Encryption trigger timeout 100 mS
28 Encryption trigger packet count: 45
29 Allow Extended Master Secret: NO
30 ECC Curve: P_256, P_384, P_224, P_521
31
32 1) Cipher Name: DEFAULT_BACKEND Priority :1
33 Description: Predefined Cipher Alias
34
35 Done
36 <!--NeedCopy-->
```

### Add a back-end SSL profile by using the GUI

1. Navigate to **System > Profiles**. Select **SSL Profiles**.
2. Click **Add** and specify a name for the profile.
3. In **SSL Profile Type**, select **BackEnd**.

**SSL Profile**

**Basic Settings**

Name\*

tls13profile2 ⓘ

SSL Profile Type\*

BackEnd ▼ ⓘ

4. In **Protocol**, select **TLSv13**.
5. Click **OK** and then click **Done**.

#### Bind an SSL profile to an SSL virtual server by using the CLI

At the command prompt, type:

```
set ssl vservice <vserviceName> -sslProfile <profile-name>
```

#### Example:

```
set ssl vservice ssl-vs -sslProfile tls13profile
```

#### Bind an SSL profile to an SSL virtual server by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and select an SSL virtual server.
2. Click **Edit**.
3. In **Advanced Settings**, click **SSL Profile**.
4. Select the TLS 1.3 profile created earlier.
5. Click **OK** and then click **Done**.

#### Bind an SSL profile to an SSL service by using the CLI

At the command prompt, type:

```
set ssl service <serviceName> -sslProfile <profile-name>
```

**Example:**

```
set ssl service ssl-service -sslProfile tls13profile2
```

**Note:**

A warning appears if you bind a front-end profile to an SSL service.

**Bind an SSL profile to an SSL service by using the GUI**

1. Navigate to **Traffic Management > Load Balancing > Services**, and select an SSL service.
2. Click **Edit**.
3. In **Advanced Settings**, click **SSL Profile**.
4. Select the TLS 1.3 profile created earlier.
5. Click **OK** and then click **Done**.

**SSL profile parameters for TLS 1.3 protocol****Note:**

Only **tls13** applies to a back-end SSL profile.

1. Enable or disable TLS 1.3 parameters in an SSL profile.

**tls13:** State of TLS 1.3 protocol support for the SSL profile.

Possible values: ENABLED, DISABLED

Default value: DISABLED

```
1 set ssl profile tls13profile -tls13 enable
2 <!--NeedCopy-->
```

```
1 set ssl profile tls13profile -tls13 disable
2 <!--NeedCopy-->
```

2. Set the number of session tickets issued.

**tls13SessionTicketsPerAuthContext:** Number of tickets the SSL virtual server issues when TLS 1.3 is negotiated, ticket-based resumption is enabled, and either (1) a handshake completes or (2) client authentication completes after the handshake.

This value can be increased to enable peers to open multiple parallel connections using a fresh ticket for each connection.

No tickets are sent if resumption is disabled.

Default value: 1

Minimum value: 1

Maximum value: 10

```
1 set ssl profile tls13profile -tls13sessionTicketsPerAuthContext 1
2
3 set ssl profile tls13profile -tls13sessionTicketsPerAuthContext 10
4 <!--NeedCopy-->
```

### 3. Set DH key exchange.

**dheKeyExchangeWithPsk**: Specifies whether an SSL virtual server requires a DHE key exchange to occur when a preshared key is accepted during a TLS 1.3 session resumption handshake. A DHE key exchange ensures forward secrecy, even if ticket keys are compromised, at the expense of extra resources required to carry out the **DHE** key exchange.

Available settings work as follows, if session ticket is enabled:

**YES**: DHE key exchange is required when a pre-shared key is accepted, regardless of whether the client supports the key exchange. The handshake is aborted with a fatal alert, if the client does not support DHE key exchange when offering a pre-shared key.

**NO**: DHE key exchange is performed when a pre-shared key is accepted, only if requested by the client.

Possible values: YES, NO

Default value: NO

```
1 set ssl profile tls13profile dheKeyExchangeWithPsk yes
2
3 set ssl profile tls13profile dheKeyExchangeWithPsk no
4 <!--NeedCopy-->
```

### 4. Enable or disable 0-RTT early data acceptance.

**zeroRttEarlyData**: State of TLS 1.3 early application data. Applicable settings work as follows:

**ENABLED**: Early application data might be processed before the handshake is complete.

**DISABLED**: Early application data is ignored.

Possible values: ENABLED, DISABLED

Default value: DISABLED

```
1 set ssl profile tls13profile -zeroRttEarlyData ENABLED
2
3 set ssl profile tls13profile -zeroRttEarlyData DISABLED
4 <!--NeedCopy-->
```

## Default cipher group

The default cipher group includes TLS 1.3 ciphers.

```
1 sh cipher DEFAULT
2 1) Cipher Name: TLS1-AES-256-CBC-SHA Priority : 1
3 Description: SSLv3 Kx=RSA Au=RSA Enc=AES(256) Mac=SHA1
4 HexCode=0x0035
5
6 2) Cipher Name: TLS1-AES-128-CBC-SHA Priority : 2
7 Description: SSLv3 Kx=RSA Au=RSA Enc=AES(128) Mac=SHA1
8 HexCode=0x002f
9
10 ...
11
12 27) Cipher Name: TLS 1.3-AES256-GCM-SHA384 Priority : 27
13 Description: TLS 1.3 Kx=any Au=any Enc=AES-GCM(256) Mac=AEAD
14 HexCode=0x1302
15
16 28) Cipher Name: TLS 1.3-CHACHA20-POLY1305-SHA256 Priority : 28
17 Description: TLS 1.3 Kx=any Au=any Enc=CHACHA20/POLY1305(256)
18 Mac=AEAD HexCode=0x1303
19
20 29) Cipher Name: TLS 1.3-AES128-GCM-SHA256 Priority : 29
21 Description: TLS 1.3 Kx=any Au=any Enc=AES-GCM(128) Mac=AEAD
22 HexCode=0x1301
23
24 Done
25 <!--NeedCopy-->
```

```
1 sh cipher DEFAULT_BACKEND
2 1) Cipher Name: TLS1-AES-256-CBC-SHA Priority : 1
3 Description: SSLv3 Kx=RSA Au=RSA Enc=AES(256) Mac=SHA1
4 HexCode=0x0035
5
6 2) Cipher Name: TLS1-AES-128-CBC-SHA Priority : 2
7 Description: SSLv3 Kx=RSA Au=RSA Enc=AES(128) Mac=SHA1
8 HexCode=0x002f
9
10 ...
11
12 27) Cipher Name: TLS 1.3-AES256-GCM-SHA384 Priority : 27
13 Description: TLS 1.3 Kx=any Au=any Enc=AES-GCM(256) Mac=AEAD
14 HexCode=0x1302
15
16 28) Cipher Name: TLS 1.3-CHACHA20-POLY1305-SHA256 Priority : 28
17 Description: TLS 1.3 Kx=any Au=any Enc=CHACHA20/POLY1305(256)
18 Mac=AEAD HexCode=0x1303
19
20 29) Cipher Name: TLS 1.3-AES128-GCM-SHA256 Priority : 29
21 Description: TLS 1.3 Kx=any Au=any Enc=AES-GCM(128) Mac=AEAD
22 HexCode=0x1301
23
24 Done
25 <!--NeedCopy-->
```

## Limitations

- TLS 1.3 is not supported on a NetScaler FIPS appliance.
- Only RSA certificates with 1024-bit and larger keys are supported in a TLS 1.3 handshake.

## Security restrictions

TLS 1.3 server operators must keep in mind the following security restrictions for backward compatibility outlined in RFC 8446. The default configuration on a NetScaler appliance is compliant with these restrictions. However, a NetScaler appliance does not enforce these rules.

- The security of RC4 cipher suites is considered insufficient as described in RFC7465. Implementations must not offer or negotiate RC4 cipher suites for any version of TLS.
- Old versions of TLS allowed the use of low strength ciphers. Ciphers with a strength less than 112 bits must not be offered or negotiated for any version of TLS.
- The security of SSL 3.0 [SSLv3] is considered insufficient as described in RFC7568, and must not be negotiated. Disable SSLv3 when TLS 1.3 is enabled (SSLv3 is disabled by default).

### Note:

For information about troubleshooting protocols that run over TLS 1.3, see [Decrypting TLS 1.3 traffic from packet trace](#).

## SSL certificates

May 2, 2023

An SSL certificate, which is a part of any SSL transaction, is a digital data form (X509) that identifies a company (domain) or an individual. The certificate has a public key component that is visible to any client that wants to initiate a secure transaction with the server. The corresponding private key, which resides securely on the NetScaler appliance, is used to complete asymmetric key (or public key) encryption and decryption.

You can obtain an SSL certificate and key in either of the following ways:

- From an authorized certificate authority (CA), such as Verisign
- By generating a new SSL certificate and key on the NetScaler appliance

Alternately, you can use an existing SSL certificate on the appliance.

Certificates are categorized into four types by the NetScaler appliance:

- **Server certificates:** A server certificate authenticates the server's identity to the client. On the front-end, the ADC appliance acts as a server. You bind a server certificate and a private key to an SSL virtual server on the ADC appliance.

- **Client certificates:** A client certificate authenticates the client's identity to the server. On the back-end, the ADC appliance acts as a client. You bind a client certificate and private key to the SSL service or service group on the ADC appliance.
- **CA certificates:** CA certificates issue the end-user certificates (client and server certificates). A CA certificate can be a trusted root CA (self-signed by the certificate authority) or an intermediate CA (signed by a trusted root CA). Typically, CA certificates do not need private keys.
- **Unknown certificates:** All other certificates fall in this category.

**Important:** Citrix recommends that you use certificates obtained from authorized CAs, such as Verisign, for all your SSL transactions. Use certificates generated on the NetScaler appliance for testing purposes only, not in any live deployment.

- If while adding a certificate-key pair, you add a certificate file with the same name as an existing certificate file, the original certificate file is overwritten with no warning. This action might cause issues after the appliance is restarted because the original certificate file is no longer available in the `/nsconfig/ssl` directory.
- Removing any certificate or key files in a cluster environment restricts further configuration on the ADC appliance. Add the files back at the same location to make any configuration changes.

**Note:** You can use the ADM SSL dashboard for ease of SSL certificate management and set notifications for certificates that are unused or soon to expire. For more information, see [SSL certificate management](#).

## Create a certificate

December 28, 2023

A certificate authority (CA) is an entity that issues digital certificates for use in public key cryptography. Applications, such as web browsers, that conduct SSL transactions trust certificates issued or signed by a Certificate Authority. These applications maintain a list of the CAs that they trust. If any of the trusted CAs sign the certificate being used for the secure transaction, the application proceeds with the transaction.

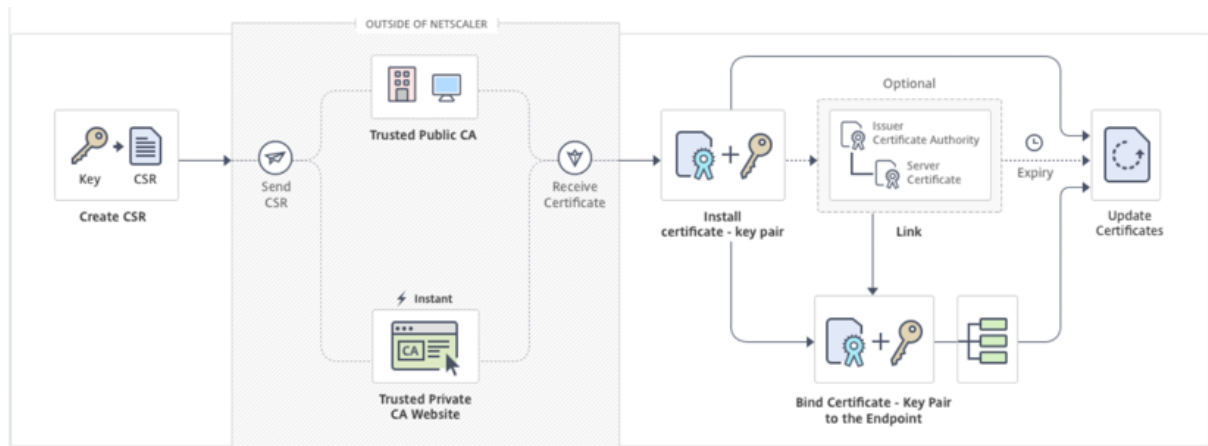

**Caution:** Citrix recommends that you use certificates obtained from authorized CAs, such as Verisign, for all your SSL transactions. Use certificates generated on the NetScaler appliance for testing purposes only, not in any live deployment.

To import an existing certificate and key, see [Import a Certificate](#).

Perform the following steps to create a certificate and bind it to an SSL virtual server. The only special characters allowed in the file names are underscore and dot. Special characters are not allowed as the first character in the file name.

- Create a private key.
- Create a certificate signing request (CSR).
- Submit the CSR to a certificate authority.
- Create a certificate-key pair.
- Bind the certificate-key pair to an SSL virtual server

The following diagram illustrates the workflow.

## How to create and install a new certificate

This is an embedded video. [Click the link to watch the video](#)

### Create a private key

#### Notes:

- From release 12.1 build 49.x, you can use the AES256 algorithm with PEM key format to encrypt a private key on the appliance. AES with 256-bit key is more mathematically efficient and secure compared to the 56-bit key of the Data Encryption Standard (DES).
- From release 12.1 build 50.x, you can create an RSA key in PKCS#8 format.

The private key is the most important part of a digital certificate. By definition, this key is not to be shared with anyone and must be kept securely on the NetScaler appliance. Any data encrypted with the public key can be decrypted only by using the private key.

The certificate that you receive from the CA is valid only with the private key that was used to create the CSR. The key is required for adding the certificate to the NetScaler appliance.

The appliance supports only the RSA encryption algorithms for creating private keys. You can submit either type of private key to the certificate authority (CA). The certificate that you receive from the CA

is valid only with the private key that was used to create the CSR. The key is required for adding the certificate to the NetScaler appliance.

**Important:**

- Be sure to limit access to your private key. Anyone who has access to your private key can decrypt your SSL data.
- The length of the SSL key name allowed includes the length of the absolute path name if the path is included in the key name.

All SSL certificates and keys are stored in the `/nsconfig/ssl` folder on the appliance. For added security, you can use the DES or triple DES (3DES) algorithm to encrypt the private key stored on the appliance.

**Create an RSA private key by using the CLI**

At the command prompt, type:

```
1 create ssl rsakey <keyFile> <bits> [-exponent (3 | F4)] [-keyform (
 DER | PEM)] [-des | -des3 | -aes256] {
2 -password }
3 [-pkcs8]
4 <!--NeedCopy-->
```

**Example:**

```
1 create rsakey testkey 2048 -aes256 -password 123456 -pkcs8
2 <!--NeedCopy-->
```

**Create an RSA private key by using the GUI**

1. Navigate to **Traffic Management > SSL > SSL Files**.
2. In the **Keys** tab, select **Create RSA Key**.
3. Enter values for the following parameters and click **Create**.
  - **Key Filename** - Name for and, optionally, path to the RSA key file. `/nsconfig/ssl/` is the default path.
  - **Key Size** - Size, in bits, of the RSA key. Can range from 512 bits to 4096 bits.
  - **Public Exponent Value** - Public exponent for the RSA key. The exponent is part of the cipher algorithm and is required for creating the RSA key.
  - **Key Format** - The format in which the RSA key file is stored on the appliance.
  - **PEM Encoding Algorithm** - Encrypt the generated RSA key by using the AES 256, DES, or Triple-DES (DES3) algorithm. By default, private keys are unencrypted.

- **PEM Passphrase** - If the private key is encrypted, enter a passphrase for the key.

The screenshot shows the 'Create RSA Key' configuration page. It contains the following fields and options:

- Key Filename\***: A dropdown menu with 'Choose File' and a selected value of 'RSA\_Key'. A help icon (?) is present.
- Key Size(bits)\***: A text input field containing '2048'. A help icon (?) is present.
- Public Exponent Value\***: A dropdown menu with 'F4' selected. A help icon (?) is present.
- Key Format\***: A dropdown menu with 'PEM' selected. A help icon (?) is present.
- PEM Encoding Algorithm**: A dropdown menu with 'AES256' selected. A help icon (?) is present.
- PEM Passphrase**: A text input field with masked characters (\*\*\*\*\*). A help icon (?) is present.
- Confirm PEM Passphrase**: A text input field with masked characters (\*\*\*\*\*). A help icon (?) is present.
- PKCS8**: A checked checkbox with a help icon (?) next to it.

**Select an AES256 encoding algorithm in an RSA key by using the GUI**

1. Navigate to **Traffic Management > SSL > SSL Files > Create RSA Key**.
2. In **Key Format**, select **PEM**.
3. In **PEM Encoding Algorithm**, select **AES256**.

4. Select **PKCS8**.

### Create a certificate signing request by using the CLI

At the command prompt, type:

```
1 create ssl certreq <reqFile> -keyFile <input_filename> | -fipsKeyName <
 string>) [-keyForm (DER | PEM) {
2 -PEMPassPhrase }
3] -countryName <string> -stateName <string> -organizationName <string>
 -organizationUnitName <string> -localityName <string> -commonName
 <string> -emailAddress <string> {
4 -challengePassword }
5 -companyName <string> -digestMethod (SHA1 | SHA256)
6 <!--NeedCopy-->
```

#### Example:

```
1 create ssl certreq priv_csr_sha256 -keyfile priv_2048_2 -keyform PEM -
 countryName IN -stateName Karnataka -localityName Bangalore -
 organizationName Citrix -organizationUnitName NS -digestMethod
 SHA256
2 <!--NeedCopy-->
```

### Create a certificate signing request by using the GUI

1. Navigate to **Traffic Management > SSL**.
2. In **SSL Certificate**, click **Create Certificate Signing Request (CSR)**.
3. In **Digest Method**, select **SHA256**.

See [Create a CSR](#) for more information.

### Support for subject alternative name in a certificate signing request

The subject alternative name (SAN) field in a certificate allows you to associate multiple values, such as domain names and IP addresses, with a single certificate. In other words, you can secure multiple domains, such as `www.example.com`, `www.example1.com`, `www.example2.com`, with a single certificate.

Some browsers, such as Google Chrome, no longer support a common name in a certificate signing request (CSR). They enforce SAN in all publicly trusted certificates.

The NetScaler appliance supports adding SAN values when creating a CSR. You can send a CSR with a SAN entry to a certificate authority to obtain a signed certificate with that SAN entry. When the

appliance receives a request, it checks for a matching domain name in the SAN entries in the server certificate. If a match is found, it sends the certificate to the client and completes the SSL handshake. You can use the CLI or the GUI to create a CSR with SAN values.

**Note:** The NetScaler appliance processes only DNS based SAN values.

### Create a CSR with the subject alternative name by using the CLI

```

1 create ssl certReq <reqFile> (-keyFile <input_filename> | -fipsKeyName
 <string>) [-subjectAltName <string>] [-keyform (DER | PEM) {
2 -PEMPassPhrase }
3] -countryName <string> -stateName <string> -organizationName <string>
 [-organizationUnitName <string>] [-localityName <string>] [-
 commonName <string>] [-emailAddress <string>] {
4 -challengePassword }
5 [-companyName <string>] [-digestMethod (SHA1 | SHA256)]
6 <!--NeedCopy-->

```

#### Parameters:

**subjectAltName:** The subject alternative name (SAN) is an extension to X.509 that allows various values to be associated with a security certificate using a subjectAltName field. These values are called “Subject Alternative Names”(SAN). Names include:

1. IP addresses (Prefix with “IP:”Example: IP:198.51.10.5 IP:192.0.2.100)
2. DNS names (Prefix with “DNS:”Example: DNS:www.example.com DNS:www.example.org DNS:www.example.net)

On the command line, enter values within quotation marks. Separate two values with a space. Quotation marks are not required in the GUI.

Maximum Length: 127

#### Example:

```

1 create certReq test1.csr -keyFile test1.ky -countryName IN -stateName
 Kar -organizationName citrix -commonName ctx.com -subjectAltName "
 DNS:*.example.com DNS:www.example.org DNS:www.example.net"
2 <!--NeedCopy-->

```

#### Note:

On a FIPS appliance, you must replace the key file name with the FIPS key name if you create the FIPS key directly on the appliance.

```

1 create certReq <csrname> -fipsKeyName fipskey.ky -countryName IN -
 stateName Kar -organizationName citrix -commonName ctx.com -
 subjectAltName "DNS:www.example.com DNS:www.example.org DNS:www.
 example.net"

```

```
2 <!--NeedCopy-->
```

## Create a CSR by using the GUI

1. Navigate to **Traffic Management > SSL > SSL Files**.
2. In the **CSR** tab, click **Create Certificate Signing Request (CSR)**.
3. Enter the values and click **Create**.

## Limitations

To use SAN when creating an SSL certificate, you must explicitly specify the SAN values. The values are not read automatically from the CSR file.

## Submit the CSR to the Certificate Authority

Most certificate authorities (CA) accept certificate submissions by email. The CA returns a valid certificate to the email address from which you submit the CSR.

The CSR is stored in the `/nsconfig/ssl` folder.

## Generate a test certificate

### Note:

To generate a server test certificate, see [Generating a Server Test Certificate](#).

The NetScaler appliance has a built-in CA tools suite that you can use to create self-signed certificates for testing purposes.

**Caution:** Because the NetScaler appliance signs these certificates, and not an actual CA, you must not use them in a production environment. If you attempt to use a self-signed certificate in a production environment, users receive a “certificate invalid” warning each time the virtual server is accessed.

The appliance supports creation of the following types of certificates

- Root-CA certificates
- Intermediate-CA certificates
- End-user certificates
  - server certificates
  - client certificates

Before generating a certificate, create a private key and use that to create a certificate signing request (CSR) on the appliance. Then, instead of sending the CSR out to a CA, use the NetScaler CA Tools to generate a certificate.

### Create a certificate by using a wizard

1. Navigate to **Traffic Management > SSL**.
2. In the details pane, under **Getting Started**, select the wizard for the type of certificate that you want to create.
3. Follow the instructions on the screen.

### Create a root-CA certificate by using the CLI

At the command prompt, type the following command:

```
1 create ssl cert <certFile> <reqFile> <certType> [-keyFile <
 input_filename>] [-keyform (DER | PEM)] [-days <positive_integer>]
2 <!--NeedCopy-->
```

In the following example, csreq1 is the CSR and rsa1 is the private key that was created earlier.

#### Example:

```
1 create ssl cert cert1 csreq1 ROOT_CERT -keyFile rsa1 -keyForm PEM -days
 365
2
3 Done
4 <!--NeedCopy-->
```

### Create an intermediate-CA certificate by using the CLI

```
1 create ssl cert <certFile> <reqFile> <certType> [-keyFile <
 input_filename>] [-keyform (DER | PEM)] [-days <positive_integer>]
 [-certForm (DER | PEM)] [-CAcert <input_filename>] [-CAcertForm (
 DER | PEM)] [-CAkey <input_filename>] [-CAkeyForm (DER | PEM)]
 [-CAserial <output_filename>]
2 <!--NeedCopy-->
```

In the following example, csr1 is the CSR created earlier. Cert1 and rsa1 are the certificate and corresponding key of the self-signed (root-CA) certificate, and pvtkey1 is the private key of the intermediate-CA certificate.

#### Example:

```

1 create ssl cert certsy csr1 INTM_CERT -CAcert cert1 -CAkey rsakey1 -
 CAserial 23
2 Done
3
4 create ssl rsakey pvtkey1 2048 -exponent F4 -keyform PEM
5 Done
6 <!--NeedCopy-->

```

### Create a root-CA certificate by using the GUI

Navigate to **Traffic Management > SSL** and, in the Getting Started group, select **Root-CA Certificate Wizard**, and configure a root CA certificate.

### Create an intermediate-CA certificate by using the GUI

Navigate to **Traffic Management > SSL** and, in the Getting Started group, select **Intermediate-CA Certificate Wizard**, and configure an intermediate CA certificate.

### Create an end-user certificate

An end-user certificate can be a client certificate or a server certificate. To create a test end-user certificate, specify the Intermediate CA certificate or the self-signed root-CA certificate.

**Note:** To create an end-user certificate for production use, specify a trusted CA certificate and send the CSR to a certificate authority (CA).

### Create a test end-user certificate by using the command line interface

```

1 create ssl cert <certFile> <reqFile> <certType> [-keyFile <
 input_filename>] [-keyform (DER | PEM)] [-days<positive_integer>]
 [-certForm (DER | PEM)] [-CAcert <input_filename>] [-CACertForm (
 DER | PEM)] [-CAkey<input_filename>] [-CAkeyForm (DER | PEM)] [-
 CAserial <output_filename>]
2 <!--NeedCopy-->

```

If there is no intermediate certificate, use the certificate (cert1) and private key (rsakey1) values of the root-CA certificate in `CAcert` and `CAkey`.

#### Example:

```

1 create ssl cert cert12 csr1 SRVR_CERT -CAcert cert1 -CAkey rsakey1 -
 CAserial 23
2

```

```

3 Done
4 <!--NeedCopy-->

```

If there is an intermediate certificate, use the certificate (`certsy`) and private key (`pvtkey1`) values of the intermediate certificate in `CAcert` and `CAkey`.

**Example:**

```

1 create ssl cert cert12 csr1 SRVR_CERT -CAcert certsy -CAkey pvtkey1 -
 CAserial 23
2
3 Done
4 <!--NeedCopy-->

```

## Create a self-signed SAN Certificate using OpenSSL

To create a self-signed SAN certificate with multiple subject alternate names, perform the following steps:

1. Create an OpenSSL configuration file on your local computer by editing the fields related as per the company requirements.

**Note:** In the following example, the configuration file is “`req.conf`”.

```

1 [req]
2 distinguished_name = req_distinguished_name
3 x509_extensions = v3_req
4 prompt = no
5 [req_distinguished_name]
6 C = US
7 ST = VA
8 L = SomeCity
9 O = MyCompany
10 OU = MyDivision
11 CN = www.company.com
12 [v3_req]
13 keyUsage = keyEncipherment, dataEncipherment
14 extendedKeyUsage = serverAuth
15 subjectAltName = @alt_names
16 [alt_names]
17 DNS.1 = www.company.net
18 DNS.2 = company.com
19 DNS.3 = company.net
20 <!--NeedCopy-->

```

2. Upload the file to the `/nsconfig/ssl` directory on the NetScaler appliance.
3. Log on to NetScaler CLI as `nsroot` user and switch to the shell prompt.
4. Run the following command to create the certificate:

```
1 cd /nsconfig/ssl
2 openssl req -x509 -nodes -days 730 -newkey rsa:2048 -keyout cert.
 pem -out cert.pem -config req.conf -extensions 'v3_req'
3 <!--NeedCopy-->
```

5. Run the following command to verify the certificate:

```
1 openssl x509 -in cert.pem -noout -text
2 Certificate:
3 Data:
4 Version: 3 (0x2)
5 Serial Number:
6 ed:90:c5:f0:61:78:25:ab
7 Signature Algorithm: md5WithRSAEncryption
8 Issuer: C=US, ST=VA, L=SomeCity, O=MyCompany, OU=MyDivision, CN=
 www.company.com
9 Validity
10 Not Before: Nov 6 22:21:38 2012 GMT
11 Not After : Nov 6 22:21:38 2014 GMT
12 Subject: C=US, ST=VA, L=SomeCity, O=MyCompany, OU=MyDivision, CN=
 www.company.com
13 Subject Public Key Info:
14 Public Key Algorithm: rsaEncryption
15 RSA Public Key: (2048 bit)
16 Modulus (2048 bit):
17 ...
18 Exponent: 65537 (0x10001)
19 X509v3 extensions:
20 X509v3 Key Usage:
21 Key Encipherment, Data Encipherment
22 X509v3 Extended Key Usage:
23 TLS Web Server Authentication
24 X509v3 Subject Alternative Name:
25 DNS:www.company.net, DNS:company.com, DNS:company.net
26 Signature Algorithm: md5WithRSAEncryption ...
27 <!--NeedCopy-->
```

## Install, link, and update certificates

April 12, 2024

To install a certificate, see [Add or update a certificate-key pair](#).

### Note:

NetScaler supports PEM, DER, and PFX (PKCS12) certificate formats.

- PEM can have .crt, .pem, or .cer extension.

- DER has .der extension.
- PFX can have .p12 or .pfx extension.

Typically, the file name extension does not matter. The contents of the file are encoded differently, which decides the format, and the certificate is parsed accordingly.

### Link certificates

Many server certificates are signed by multiple hierarchical Certificate Authorities (CA), which means that the certificates form a chain like the following:

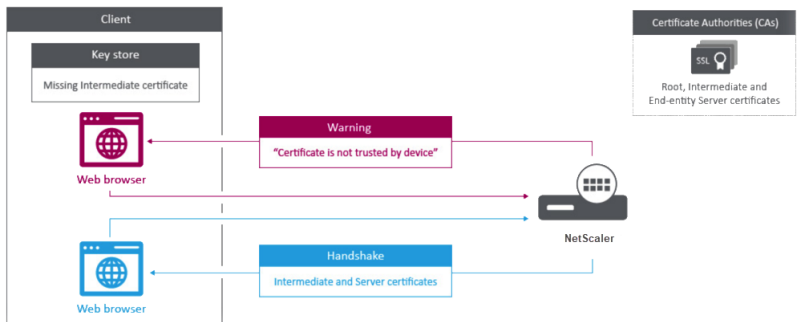

Sometimes, the Intermediate CA is split into a primary and secondary intermediate CA certificate. Then the certificates form a chain like the following:

Client machines usually contain the root CA certificate in their local certificate store, but not one or more intermediate CA certificates. The ADC appliance must send one or more intermediate CA certificates to the clients.

**Note:** The appliance must not send the root CA certificate to the client. The Public Key Infrastructure (PKI) trust relationship model requires root CA certificates to be installed on clients through an out-of-band method. For example, the certificates are included with the operating system or web browser. The client ignores a root CA certificate sent by the appliance.

Sometimes, an intermediate CA that standard web browsers do not recognize as a trusted CA, issues the server certificate. In this case, one or more CA certificates must be sent to the client with the server's own certificate. Otherwise, the browser terminates the SSL session because it fails to authenticate the server certificate.

Refer to the following sections to add the server and intermediate certificates:

- Manual certificate linking
- Automated certificate linking
- Create a chain of certificates

## How to link an intermediate authority certificate

This is an embedded video. [Click the link to watch the video](#)

### Manual certificate linking

**Note:** This feature is not supported on the NetScaler FIPS platform and in a cluster setup.

Instead of adding and linking individual certificates, you can now group a server certificate and up to nine intermediate certificates in a single file. You can specify the file's name when adding a certificate-key pair. Before you do so, make sure that the following prerequisites are met.

- The certificates in the file are in the following order:
  - Server certificate (must be the first certificate in the file)
  - Optionally, a server key
  - Intermediate certificate 1 (ic1)
  - Intermediate certificate 2 (ic2)
  - Intermediate certificate 3 (ic3), and so on

Note: Intermediate certificate files are created for each intermediate certificate with the name “<certificatebundlename>.pem\_ic<n>” where n is between 1 and 9. For example, bundle.pem\_ic1, where **bundle** is the name of the certificate set and ic1 is the first intermediate certificate in the set.
- Bundle option is selected.
- No more than nine intermediate certificates are present in the file.

The file is parsed and the server certificate, intermediate certificates, and server key (if present) are identified. First, the server certificate and key are added. Then, the intermediate certificates are added, in the order in which they were added to the file, and linked accordingly.

An error is reported if any of the following conditions exist:

- A certificate file for one of the intermediate certificates exists on the appliance.
- The key is placed before the server certificate in the file.
- An intermediate certificate is placed before the server certificate.
- Intermediate certificates are not placed in the file in the same order as they are created.

- No certificates are present in the file.
- A certificate is not in the proper PEM format.
- The number of intermediate certificates in the file exceeds nine.

### Add a certificate set by using the CLI

At the command prompt, type the following commands to create a certificate set and verify the configuration:

```
1 add ssl certKey <certkeyName> -cert <string> -key <string> -bundle (YES
 | NO)
2
3 show ssl
4
5 show ssl certlink
6 <!--NeedCopy-->
```

#### Note:

Starting from NetScaler release 14.1 build 21.x, the length of the path is increased from 63 to 255 characters for the certificate and key parameters.

In the following example, the certificate set (bundle.pem) contains the following files:

Server certificate (bundle) linked to bundle\_ic1

First intermediate certificate (bundle\_ic1) linked to bundle\_ic2

Second intermediate certificate (bundle\_ic2) linked to bundle\_ic3

Third intermediate certificate (bundle\_ic3)

```
1 add ssl certKey bundletest -cert bundle9.pem -key bundle9.pem -bundle
 yes
2
3 sh ssl certkey
4
5 1) Name: ns-server-certificate

### Add a certificate set by using the GUI

1. Navigate to **Traffic Management > SSL > Certificates > CA Certificates**.
2. In the details pane, click **Install**.
3. In the **Install Certificate** dialog box, type the details, such as the certificate and key file name, and then select **Certificate Bundle**.
4. Click **Install**, and then click **Close**.

### Automated certificate linking

**Note:** This feature is available from release 13.0 build 47.x.

You no longer have to manually link a certificate to its issuer all the way to the root certificate. If the intermediate CA certificates and the root certificate are present on the appliance, you can click the **Link** button in the end user certificate.

The potential chain appears.

Click **Link Certificate** to link all the certificates.

## Create a chain of certificates

Instead of using a set of certificates (a single file), you can create a chain of certificates. The chain links the server certificate to its issuer (the intermediate CA). This approach requires that the intermediate CA certificate file is installed on the ADC appliance, and the client application must trust one of the certificates in the chain. For example, link Cert-Intermediate-A to Cert-Intermediate-B, where Cert-Intermediate-B is linked to Cert-Intermediate-C, which is a certificate trusted by the client application.

**Note:** The appliance supports sending a maximum of 10 certificates in the chain of certificates sent to the client (one server certificate and nine CA certificates).

## Create a certificate chain by using the CLI

At the command prompt, type the following commands to create a certificate chain and verify the configuration. (Repeat the first command for each new link in the chain.)

```
1 link ssl certkey <certKeyName> <linkCertKeyName>
2 show ssl certlink
3 <!--NeedCopy-->
```

### Example:

```
1 link ssl certkey siteAcertkey CAcertkey
2 Done
3
4 show ssl certlink
5
6 linked certificate:
7 1) Cert Name: siteAcertkey CA Cert Name: CAcertkey
8 Done
9 <!--NeedCopy-->
```

## Create a certificate chain by using the GUI

1. Navigate to **Traffic Management > SSL > Certificates**.
2. Select a server certificate, and in the **Action** list, select **Link**, and specify a CA certificate name.

## Support for SSL certificate bundle

The current design for a certificate bundle has the following drawbacks:

- Adding a certificate bundle adds multiple commands in the configuration. Therefore, you cannot add another certificate bundle if the two bundles share a common intermediate certificate.

- Removing a certificate bundle is a manual process. You must manually remove the files in a specific order.
- Updating a certificate bundle is not supported.
- Cluster is not supported.

The new design for a certificate bundle resolves all these issues. The new entity works on a certificate bundle file. Therefore, there is no need to create files for each intermediate certificate. Removal is also simple with this new entity.

Two certificate bundles can share part of the intermediate certificate chain. You can also add a certificate-key pair using the same server certificate and key that is also part of a certificate bundle.

**Note:**

Starting from NetScaler release 14.1 build 21.x, the length of the path is increased from 63 to 255 characters for the certificate and key parameters in the following commands:

```
1 - add ssl certKeyBundle
2 - update ssl certKeyBundle
```

In the following example:

1. Certificate bundle bundle1.pem contains server certificate (S1) and intermediate certificates (IC1 and IC2).
2. Server certificate is server\_cert.pem (S1).
3. Intermediate certificates are ic1.pem (IC1) and ic2.pem (IC2).

You can add a certificate bundle that contains S1, IC1, and IC2.

```
add ssl certkeybundle b1 -bundlefile bundle1.pem
```

You can also add a certificate-key pair using S1 and IC1.

```
add ssl certkey server-cert -cert server_cert.pem
```

```
add ssl certkey ic1 -cert ic1.pem
```

**Important!**

- Bundle creation fails if the following order is not met:
  - Server certificate (SC) must be placed at the top of the bundle file.
  - IC[1-9] are intermediate certificates. IC[i] is issued by IC[i+1]. The certificates must be placed in a sequence, and all the intermediate certificates must be present in the bundle.
- Certificates must be of PEM format only.
- Server certificate key (SCK) can be placed anywhere in the bundle.
- A maximum of 9 intermediate certificates are supported.

### To add a certificate bundle using the CLI

At the command prompt, type:

```
add ssl certKeyBundle <bundle_name> -bundlefile <bundle_file_name> -
passplain <>
```

#### Example:

```
add ssl certkeyBundle cert_bundle -bundlefile bundle_4096.pem
```

### To add a certificate bundle using the GUI

1. Navigate to **Traffic Management > SSL > Certificate Key Bundle**.
2. Click **Install**.
3. Specify a name for the bundle, browse to the location of the bundle on the appliance or your local computer, and select a file.
4. Click **Create**.

### To update a certificate bundle using the CLI

#### Note:

The update command is available in release 14.1 build 12.x and later.

At the command prompt, type:

```
update ssl certKeyBundle [-bundlefile <input_filename>]
```

#### Example:

```
update ssl certKeyBundle cert_bundle -bundlefile bundle_4096_updated.
pem
```

### To update a certificate bundle using the GUI

1. Navigate to **Traffic Management > SSL > Certificate Key Bundle**.
2. Select a bundle and click **Update**.
3. Browse to the location of the bundle on the appliance or your local computer, and select a file.
4. Click **OK**.

**To remove a certificate bundle using the CLI**

At the command prompt, type:

```
rm ssl certKeyBundle <bundle_name>
```

**Example:**

```
rm ssl certkeybundle cert_bundle
```

**To remove a certificate bundle using the GUI**

1. Navigate to **Traffic Management > SSL > Certificate Key Bundle**.
2. Select a bundle and click **Delete**.
3. In the confirmation dialog box, click **Yes**.

**To bind a certificate bundle to an SSL virtual server using the CLI**

At the command prompt, type:

```
bind ssl vserver <vip-name> -certkeybundleName <certkeybundle_name> [-SNICertkeybundle]
```

**Example:**

```
1 bind ssl vserver v_server -certkeyBundleName cert_bundle
2
3 show ssl certkeyBundle cert_bundle
4

## To bind a certificate bundle to an SSL virtual server using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Select an SSL virtual server and click **Edit**.
3. In the **Certificate** section of the **Load Balancing Virtual Server** page, click **Bundle Certificate**.
4. In the **Certificate Key Bundle Binding** page, do one of the following:
  - a) Select a bundle: Click the right-arrow (>) and select a bundle. Click **Select**.
  - b) Add a bundle: Click **Add**. Browse to the location of the bundle on the appliance or your local computer and click **Create**.

5. Click **Bind**.**To bind a certificate bundle to an SSL virtual server as an SNI certificate bundle using the CLI**

At the command prompt, type:

```
bind ssl vserver <vip-name> -certkeybundleName b2 -SNICertkeybundle
```

**Example:**

```
1 bind ssl vserver v_server -certkeyBundleName cert_bundle -
 sniCertkeybundle
2

### To bind a certificate bundle to an SSL virtual server as an SNI certificate bundle using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Select an SSL virtual server and click **Edit**.
3. In the **Certificate** section, click **Bundle Certificate**.
4. In the **Certificate Key Bundle Binding** page, do one of the following:
  - a) Select a bundle: Click the right-arrow (“>”) and choose a bundle from the list. Click **Select**.
  - b) Add a bundle: Click **Add**. Browse to the location of the bundle on the appliance or your local computer and click **Create**.
5. Select **SNICertKey Bundle**.
6. Click **Bind**.

### To unbind a certificate bundle from an SSL virtual server using the CLI

At the command prompt, type:

```
unbind ssl vserver <vip-name> -certkeybundleName <certkeybundle_name>
[-SNICertkeybundle]
```

#### Example:

```
unbind ssl vserver v_server -certkeybundleName cert_bundle
```

### To unbind a certificate bundle from an SSL virtual server using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. Select an SSL virtual server and click **Edit**.
3. In the **Certificate** section, click **Bundle Certificate**.
4. In the **SSL Virtual Server Certkey Bundle Binding** page, select a bundle, and click **Unbind**.
5. In the confirmation dialog box, click **Yes**.
6. Click **Close**.
7. Click **Done**.

### User scenarios for certificate bundle binding

The following scenarios explain how the ADC appliance processes a request related to certificate bundles.

#### Scenario 1: A certificate-key pair and a certificate bundle containing the same server certificate is bound to the same SSL virtual server

While binding a certificate-key pair and a certificate bundle containing the same server certificate to the same SSL virtual server, the order of commands determines the final binding.

For example,

- Certificate bundle bundle1.pem contains server certificate S1 and intermediate certificates IC1 and IC2.
- Certificate file server\_cert.pem contains S1.

Both bundle1.pem and server\_cert.pem have the same server certificate S1.

If the following commands are run in the specified order, the server certificate binding to the SSL virtual server replaces the certificate bundle binding to that virtual server.

1. `add ssl certkeybundle b1 -bundlefile bundle1.pem`
2. `add ssl certkey server_cert -cert server_cert.pem`
3. `bind ssl vserver v1 -certkeybundle b1`
4. `bind ssl vserver v1 -cert server_cert`

#### Scenario 2: Two certificate bundles contain the same intermediate certificate chain

You can add two certificate bundles with the same intermediate certificate chain. The two bundles act as independent entities.

In the following example, certificate bundle bundle-1 contains server certificate S1 and intermediate certificates IC1 and IC2 in that order. Certificate bundle bundle-2 contains server certificate S2 and intermediate certificates IC1 and IC2 in that order.

- Certificate bundle bundle1.pem (S1, IC1, IC2)
- Certificate bundle bundle2.pem (S2, IC1, IC2)

When S1 in bundle-1 is selected in the SSL handshake process, the intermediate certificate chain of bundle-1 is sent to the client.

```
add ssl certkeybundle bundle-1 -bundlefile bundle1.pem
add ssl certkeybundle bundle-2 -bundlefile bundle2.pem
```

### **Scenario 2: Two certificate bundles contain some common intermediate certificates in the chain**

You can add two certificate bundles with some common intermediate certificates in the chain.

In the following example, bundle-1 contains server certificate S1 and intermediate certificates IC1 and IC2. Certificate bundle bundle-2 contains server certificate S2 and intermediate certificates IC1, IC2, and IC3.

Certificate bundle bundle1.pem (S1, IC1, IC2)  
Certificate bundle bundle2.pem (S2, IC1, IC2, IC3)

```
add ssl certkeybundle bundle-1 -bundlefile bundle1.pem
add ssl certkeybundle bundle-2 -bundlefile bundle2.pem
```

When S1 in bundle-1 is selected in the SSL handshake process, the intermediate certificate chain of bundle-1 is sent to the client. That is, (S1→IC1→IC2) is sent to the client. IC3 is not added.

When S2 in bundle-2 is selected in the SSL handshake process, the intermediate certificate chain of bundle-2 only sent to the client. That is, (S1→IC1→IC2→IC3) is sent to the client.

### **Limitations of certificate bundle**

- Monitoring the status of a certificate in the certificate bundle is not supported.
- Certificate bundles can be bound only to SSL virtual servers.
- OCSP stapling is not supported.

#### **Note**

Update operations are supported on certificate bundles from release 14.1 build 12.x. You can

now directly update a certificate bundle. Previously, you had to first unbind and delete a bundle, and then add and bind a certificate bundle.

### Update an existing server certificate

To change an existing server certificate manually, you must perform the following steps:

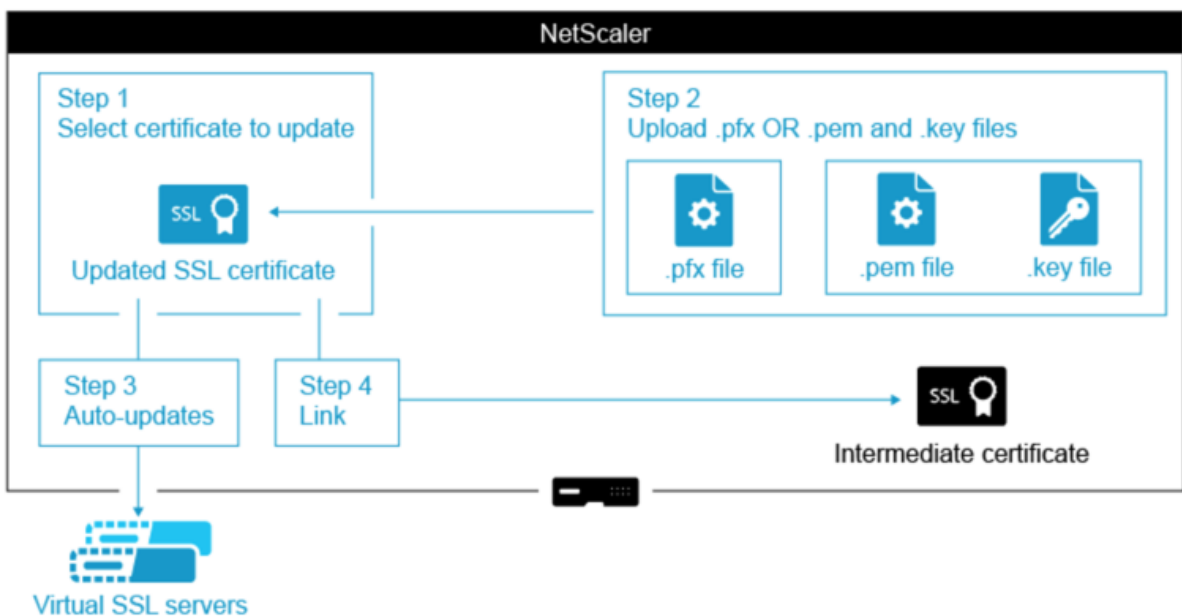

1. Unbind the old certificate from the virtual server.
2. Remove the certificate from the appliance.
3. Add the new certificate to the appliance.
4. Bind the new certificate to the virtual server.

To reduce downtime when replacing a certificate-key pair, you can update an existing certificate. If you want to replace a certificate with a certificate that was issued to a different domain, you must disable domain checks before updating the certificate.

To receive notifications about certificates due to expire, you can enable the expiry monitor.

When you remove or unbind a certificate from a configured SSL virtual server or service, the virtual server or service becomes inactive. They are active after a new valid certificate is bound to them. To reduce downtime, you can use the update feature to replace a certificate-key pair that is bound to an SSL virtual server or an SSL service.

Overview diagram of how to update an SSL certificate on the NetScaler appliance.

**Note:**

Starting from NetScaler release 14.1 build 21.x, the length of the path is increased from 63 to 255

characters for the certificate and key parameters.

## How to update an existing certificate

This is an embedded video. [Click the link to watch the video](#)

### Update an existing certificate-key pair by using the CLI

At the command prompt, type the following commands to update an existing certificate-key pair and verify the configuration:

```
1 update ssl certkey <certkeyName> -cert <string> -key <string>
2
3 show ssl certKey <certkeyName>
4 <!--NeedCopy-->
```

#### Example:

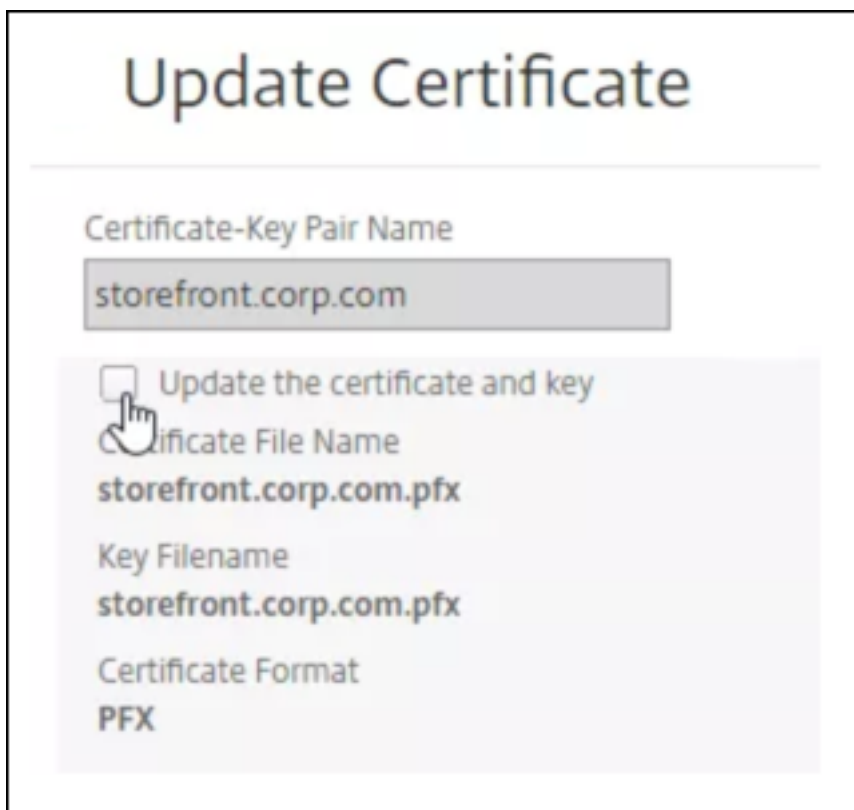

```
1 update ssl certkey siteAcertkey -cert /nsconfig/ssl/cert.pem -key /
 nsconfig/ssl/pkey.pem
2
3 Done
4
5 show ssl certkey siteAcertkey
6
7 Name: siteAcertkey Status: Valid
8 Version: 3
9 Serial Number: 02
10 Signature Algorithm: md5WithRSAEncryption
11 Issuer: /C=US/ST=CA/L=Santa Clara/O=siteA/OU=Tech
12 Validity
13 Not Before: Nov 11 14:58:18 2001 GMT
14 Not After: Aug 7 14:58:18 2004 GMT
15 Subject: /C=US/ST=CA/L=San Jose/O=CA/OU=Security
16 Public Key Algorithm: rsaEncryption
17 Public Key size: 2048
18 Done
19 <!--NeedCopy-->
```

### Update an existing certificate-key pair by using the GUI

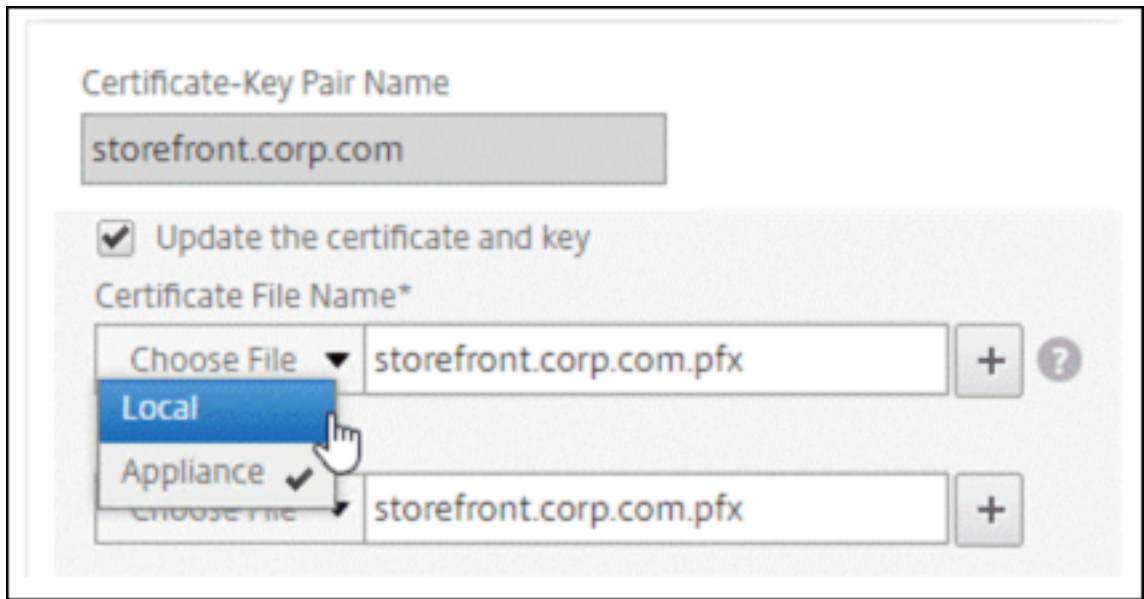

1. Navigate to **Traffic Management > SSL > Certificates > Server Certificates**.
2. Select the certificate that you want to update, and click **Update**.

3. Select **Update the certificate and key**.

4. In **Certificate File Name**, click **Choose File > Local**, and browse to the updated .pfx file or certificate PEM file.

- If you upload a .pfx file, you are prompted to specify the .pfx file password.
  - If you upload a certificate pem file, you must also upload a certificate key file. If the key is encrypted, you must specify the encryption password.
5. If the common name of the new certificate does not match the old certificate, then select **No Domain Check**.
  6. Click **OK**. All the SSL virtual servers to which this certificate is bound are automatically updated.

## Update Certificate

Certificate-Key Pair Name  
storefront.corp.com

Update the certificate and key

Certificate File Name\*  
Choose File ▼ storefront.corp.com.pfx + ?

Password\*  
..... 🔍 ?

No Domain Check

Notify When Expires

**No** SNMP Trap destination found. Notification will not be sent until a trap d

Notification Period  
30

7. After replacing the certificate, you might have to update the certificate link to a new intermediate certificate. For more information about updating an intermediate certificate without breaking the links, see [Update an intermediate certificate without breaking the links](#).
  - Right-click the updated certificate, and click **Cert Links**, to see if it is linked to an intermediate certificate.
  - If the certificate is not linked, then right-click the updated certificate, and click **Link** to link it to an intermediate certificate. If you don't see an option to link, then you must first have to install a new intermediate certificate on the appliance under the **CA Certificates** node.

### Update an existing CA certificate

The steps to update an existing CA certificate are the same as updating an existing server certificate. The only difference is that you do not need a key in the case of CA certificates.

**Update Certificate**

Certificate-Key Pair Name  
SSL-certificate-test

Update the certificate and key

Certificate File Name\*  
Choose File

No Domain Check

Notify When Expires

### Disable domain checks

When an SSL certificate is replaced on the appliance, the domain name mentioned on the new certificate must match the domain name of the certificate being replaced. For example, if you have a certificate issued to abc.com, and you are updating it with a certificate issued to def.com, the certificate update fails.

However, if you want the server that has been hosting a particular domain to host a new domain, disable the domain check before updating its certificate.

### Disable the domain check for a certificate by using the CLI

At the command prompt, type the following commands to disable the domain check and verify the configuration:

```
1 update ssl certKey <certkeyName> -noDomainCheck
2
3 show ssl certKey <certkeyName>
4 <!--NeedCopy-->
```

### Example:

```
1 update ssl certKey sv -noDomainCheck
2
3 Done
```

```
4
5 show ssl certkey sv
6
7 Name: sv
8 Cert Path: /nsconfig/ssl/complete/server/server_rsa_512.pem
9 Key Path: /nsconfig/ssl/complete/server/server_rsa_512.ky
10 Format: PEM
11 Status: Valid, Days to expiration:9349
12 Certificate Expiry Monitor: DISABLED
13 Done
14 <!--NeedCopy-->
```

### Disable the domain check for a certificate by using the GUI

1. Navigate to **Traffic Management > SSL > Certificates**, select a certificate, and click **Update**.
2. Select **No Domain Check**.

### Replace the default certificate of an ADC appliance with a trusted CA certificate that matches the host name of the appliance

The following procedure assumes that the default certificate (`ns-server-certificate`) is bound to the internal services.

1. Navigate to **Traffic Management > SSL > SSL Certificates > Create Certificate Request**.
2. In common name, type `test.citrixadc.com`.
3. Submit the CSR to a trusted certificate authority.
4. After receiving the certificate from the trusted CA, copy the file to the `/nsconfig/ssl` directory.
5. Navigate to **Traffic Management > SSL > Certificates > Server Certificates**.
6. Select the default server certificate (`ns-server-certificate`) and click **Update**.
7. In the **Update Certificate** dialog box, in **Certificate File Name**, browse to the certificate received from the CA after signing.
8. In the **Key File Name** field, specify the default private key file name (`ns-server.key`).
9. Select **No Domain Check**.
10. Click **OK**.

### Enable the expiry monitor

An SSL certificate is valid for a specific period. A typical deployment includes multiple virtual servers that process SSL transactions, and the certificates bound to them can expire at different times. An expiry monitor configured on the appliance creates entries in the appliance's syslog and ns audit logs when a certificate configured is due to expire.

If you want to create SNMP alerts for certificate expiration, you must configure them separately.

### Enable an expiry monitor for a certificate by using the CLI

At the command prompt, type the following commands to enable an expiry monitor for a certificate and verify the configuration:

```
1 set ssl certKey <certkeyName> [-expiryMonitor (ENABLED | DISABLED) [-
 notificationPeriod <positive_integer>]]
2
3 show ssl certKey <certkeyName>
4 <!--NeedCopy-->
```

#### Example:

```
1 set ssl certKey sv -expiryMonitor ENABLED - notificationPeriod 60
2 Done
3 <!--NeedCopy-->
```

### Enable an expiry monitor for a certificate by using the GUI

1. Navigate to **Traffic Management > SSL > Certificates**, select a certificate, and click **Update**.
2. Select **Notify When Expires**, and optionally specify a notification period.

### Update an intermediate certificate without breaking the links

You can update an intermediate certificate without breaking any existing links. The ‘AuthorityKeyIdentifier’ extension, in the linked certificate issued by the certificate to be replaced, must not contain an authority certificate serial number (‘authorityCertSerialNumber’) field. If the ‘AuthorityKeyIdentifier’ extension contains a serial number field, then the certificate serial numbers of the old and new certificate must be the same. You can update any number of certificates in the link, one at a time, if the preceding condition is met. Previously, the links broke if an intermediate certificate was updated.

For example, there are four certificates: [CertA](#), [CertB](#), [CertC](#), and [CertD](#). Certificate [CertA](#) is the issuer for [CertB](#), [CertB](#) is the issuer for [CertC](#), and so on. If you want to replace an intermediate certificate [CertB](#) with [CertB\\_new](#), without breaking the link, the following condition must be met:

The certificate serial number of [CertB](#) must match the certificate serial number of [CertB\\_new](#) if both of the following conditions are met:

- The [AuthorityKeyIdentifier](#) extension is present in [CertC](#).
- This extension contains a serial number field.

If the common name in a certificate changes, while updating the certificate specify `nodomaincheck`.

In the preceding example, to change “www.example.com” in `CertD` to “\*.example.com,” select the “No Domain Check” parameter.

### Update the certificate by using the CLI

At the command prompt, type:

```
1 update ssl certKey <certkeyName> -cert <string> [-password] -key <
 string> [-noDomainCheck]
2 <!--NeedCopy-->
```

#### Example:

```
1 update ssl certkey siteAcertkey -cert /nsconfig/ssl/cert.pem -key /
 nsconfig/ssl/pkey.pem -noDomainCheck
2 <!--NeedCopy-->
```

### Display a certificate chain

A certificate contains the name of the issuing authority and the subject to whom the certificate is issued. To validate a certificate, you must look at the issuer of that certificate and confirm if you trust the issuer. If you do not trust the issuer, you must see who issued the issuer certificate. Go up the chain until you reach the root CA certificate or an issuer that you trust.

As part of the SSL handshake, when a client requests a certificate, the appliance presents a certificate and the chain of issuer certificates present on the appliance. An administrator can view the certificate chain for the certificates present on the appliance and install any missing certificates.

### View the certificate chain for the certificates present on the appliance by using the CLI

At the command prompt, type:

```
1 show ssl certchain <cert_name>
2 <!--NeedCopy-->
```

#### Examples

There are 3 certificates: c1, c2, and c3. Certificate c3 is the root CA certificate and signs c2, and c2 signs c1. The following examples illustrate the output of the `show ssl certchain c1` command in different scenarios.

**Scenario 1:**

Certificate c2 is linked to c1, and c3 is linked to c2.

Certificate c3 is a root CA certificate.

If you run the following command, the certificate links up to the root CA certificate are displayed.

```
1 show ssl certchain c1
2
3 Certificate chain details of certificate name c1 are:
4 1) Certificate name: c2 linked; not a root
 certificate
5 2) Certificate name: c3 linked; root certificate
6 Done
7 <!--NeedCopy-->
```

**Scenario 2:**

Certificate c2 is linked to c1.

Certificate c2 is not a root CA certificate.

If you run the following command, the information that certificate c3 is a root CA certificate but is not linked to c2 is displayed.

```
1 show ssl certchain c1
2
3 Certificate chain details of certificate name c1 are:
4 1) Certificate Name: c2 linked; not a root
 certificate
5 2) Certificate Name: c3 not linked; root certificate
6 Done
7 <!--NeedCopy-->
```

**Scenario 3:**

Certificate c1, c2, and c3 are not linked but are present on the appliance.

If you run the following command, information about all the certificates starting with the issuer of certificate c1 is displayed. It is also specified that the certificates are not linked.

```
1 show ssl certchain c1
2
3 Certificate chain details of certificate name c1 are:
4 1) Certificate Name: c2 not linked; not a root
 certificate
5 2) Certificate Name: c3 not linked; root certificate
6 Done
7 <!--NeedCopy-->
```

**Scenario 4:**

Certificate c2 is linked to c1.

Certificate c3 is not present on the appliance.

If you run the following command, information about the certificate linked to c1 is displayed. You are prompted to add a certificate with the subject name specified in c2. In this case, the user is asked to add the root CA certificate c3.

```
1 show ssl certchain c1
2
3 Certificate chain details of certificate name c1 are:
4 1) Certificate Name: c2 linked; not a root
 certificate
5 2) Certificate Name: /C=IN/ST=ka/O=netScaler/CN=test
6 Action: Add a certificate with this subject name.
7 Done
8 <!--NeedCopy-->
```

### Scenario 5:

A certificate is not linked to certificate c1 and the issuer certificate of c1 is not present on the appliance.

If you run the following command, you are prompted to add a certificate with the subject name in certificate c1.

```
1 sh ssl certchain c1
2
3 Certificate chain details of certificate name c1 are:
4 1) Certificate Name: /ST=KA/C=IN
5 Action: Add a certificate with this subject name.
6 <!--NeedCopy-->
```

## Generate a server test certificate

May 2, 2023

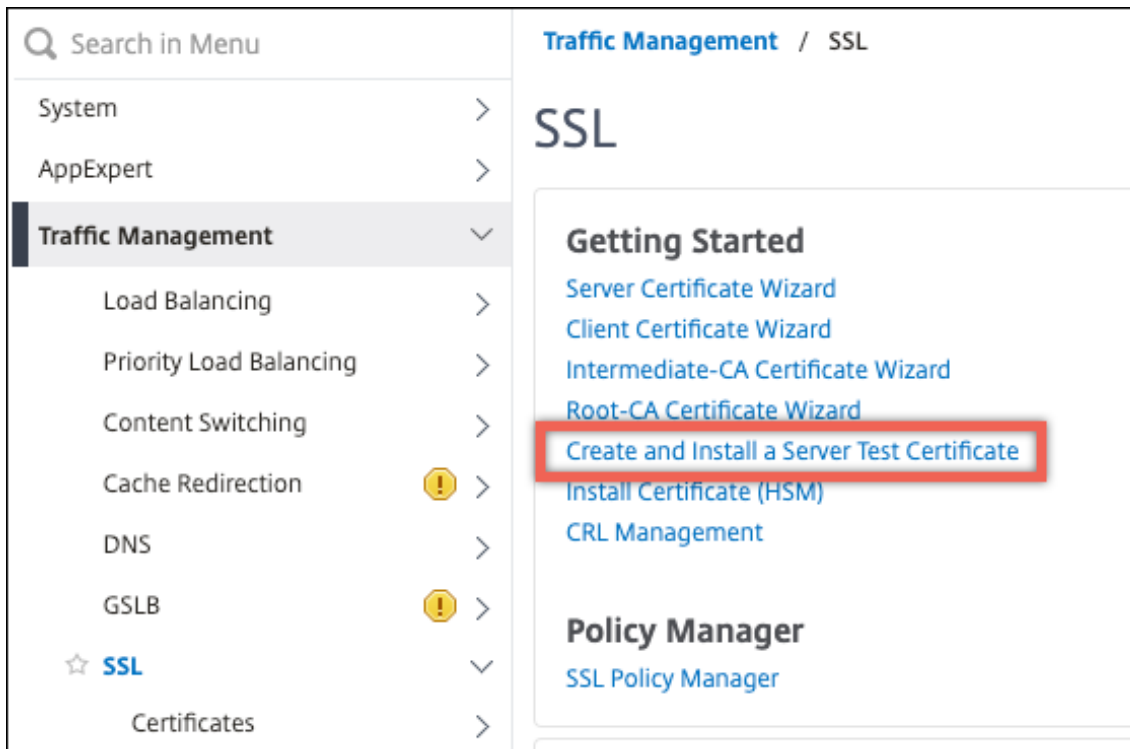

The NetScaler appliance allows you to create a test certificate for server authentication by using a GUI wizard in the configuration utility. A server certificate is used to authenticate and identify a server in an SSL handshake. Typically, a trusted CA issues a server certificate. The server sends the certificate to a client who uses it to authenticate the server.

For issuing a server test certificate, the appliance operates as a certificate authority. This certificate can be bound to an SSL virtual server for authentication in an SSL handshake with a client. This certificate is for testing purposes only. Do not use in a production environment.

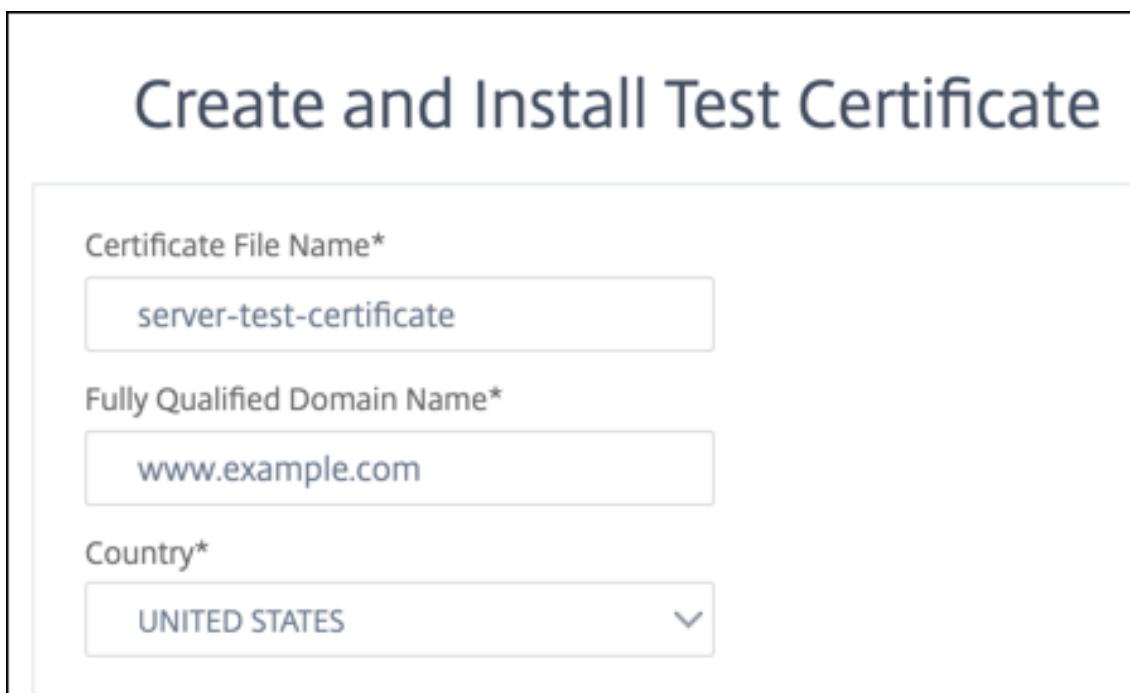

You can install the server test certificate on any virtual server that uses the SSL or the SSL\_TCP protocol.

### Generate a server test certificate by using the GUI

1. Navigate to **Traffic Management > SSL** and, in the **SSL Certificates group**, select **Create and Install a Server Test Certificate**.

2. Enter details for the parameters and click **Create**.

## Import and convert SSL files

April 12, 2024

You can now import SSL resources, such as certificates, private keys, CRLs, and DH keys, from remote hosts even if FTP access to these hosts is not available. This feature is especially helpful in environments where shell access to the remote host is restricted. Default folders are created in `/nsconfig/ssl` as follows:

- For certificate files: `/nsconfig/ssl/certfile`
- For private keys: the `/nsconfig/ssl/keyfile`
